ENGINEERING COST ANALYSIS FOR FLOOR I AND BTF OPTIONS I - 4

C.1 BACKGROUND

MACT stack gas emissions standards for a variety of hazardous air pollutants (HAPs) (including PM, LVM, SVM, Hg, HCI, Cl2, PCDD/PCDF, CO, and THC) have been proposed for specific existing hazardous waste burner facilities. These facilities include cement kilns, light weight aggregate kilns (LWAKS) and incinerators. For an individual HAP, proposed MACT standards include both those limiting the emissions of that HAP to a level designated as Floor I and to a level designated as Beyond the Floor (BTF). Appendix C-A lists both the proposed Floor and BTF emission limits for each HAP as specified for this analysis. As part of the rule making process, EPA is interested in the cost to industry such standards may impose. As part of this, of interest is the cost incurred by a facility to simultaneously meet specified standards for each HAP of concern. One cost is that incurred by a facility to meet Floor I standards for each HAP simultaneously. By definition, BTF levels are those which are more stringent than the originally designated Floor levels. Therefore, there is a different cost incurred by a facility to meet the BTF standards for each HAP simultaneously. Additionally, a facility may be required to meet BTF levels for only certain HAP, while for others the facility may only be required to meet the originally specified floor levels. To this end, different scenarios of Floor and BTF levels for each HAP were grouped into various BTF Options. To meet either the proposed MACT Floor standards for all HAPs simultaneous or to meet a specified BTF option, certain facilities may be required to upgrade or retrofit their existing air pollution control system (APCS). To estimate the cost of these upgrades and retrofits, the analysis as described in the following section was used.

C.2 OBJECTIVE AND APPROACH

The objective of this analysis was to estimate the APCD cost associated with proposed specified MACT standards for a variety of HAPs (listed above). The approach is described in

detail in the following sections. The outline of the procedure used is a follows:

- Identification of the emission levels of each HAP for each facility for which data was collected.
- Determination of the amount of emissions reduction required to meet the specified MACT standard for each HAP.
- Selection of a control strategy to achieve the required emissions reduction to meet the specified MACT standard for each HAP simultaneously.

- Group facilities into Model Plant Groups based on like selected control strategies.

- Determine the APCD retrofit and/or upgrade cost to each Model Plant Group using available cost models and based on the characteristics of the facilities assigned within the Model Plant Group.

This procedure is iterated, initially using no feed rate control and then using 25% hazardous waste feed control. This iteration is used to incorporate the use of feed control as a possible method of reducing HAP emissions. The impact of feed rate control is shown in the first step of the procedure in that the emission level for each HAP is adjusted to account for feed rate control. This is described further in a following section. The above procedure is also individually performed for the Floor or each BTF option of interest. For example, the above procedure is iterated twice to determine the cost of meeting BTF Option IA while using either 0% or 25% hazardous waste feed rate control. BTF Option IA is where each HAP is controlled to its specified Floor emission standard level and additionally, dioxin/furans are controlled to .5 ng/dscm.

C.2.1 Identification of HAP Emission Levels

The reported stack gas emissions rate (RSERi) for each HAP was compiled for all facilities for which trial bum test data was collected. A single emission rate value is used for each HAP for each facility by taking the arithmetic mean over all test condition runs of the median emission rate. In Section C.3, in Tables C-1 and C-2, RSERs are given for each facility and each HAP. It was recognized that feed rate control is one way in which facilities may control their emissions. To account for this, the RSERs are adjusted based on the impact a decrease in hazardous waste feed rate would have on the reported emissions. Specifically, Table C-1 shows adjusted stack gas emission rates (ASERi) for each HAP for each facility when no feed rate control is employed. Table C-2 shows the adjusted stack gas emission rates for each

HAP for each facility when utilizing 25% control of the hazardous waste feed rate. In addition, for many facilities, a complete set of stack gas emission rate data is not available (e.g., a facility may have PCDD/PCDF, HCI, PM, and CO and THC stack gas emission data, but does not have Hg, SVM, LVM, or C]2 data). Where data is not available, a "nr" notation is included.

C.2.2 Determination of the Required Emissions Reduction to Meet the Specified HAP Levels

For each hazardous waste burning facility and for each HAP, the amount of emissions reduction required to reach either MACT floor or BTF levels was determined. The amount of reduction required for each HAP was determined as:

%RRi (ASERi - Limiti) / ASERi 100

where: %RRi = % reduction required for individual HAPi to meet the MACT level ASERi adjusted stack gas emissions rate for HAPi

Limiti = MACT floor or BTF level for an individual HAPi

Required reductions (%RRs) are shown in Section C.3 in Tables C- Ia, C-2a, and Section C.4 in Tables C-3a, C-4a, C-5a, C-6a, C-7a, C-8a, C-9a, C- 1Oa, C-11 a, C-12a, C- 13a, C- 14a, C15a and C- 1 6a. The specific table pertains to the amount of emissions reduction required to meet the Floor or BTF option in question while using either 0% or 25% hazardous waste feed control. Two %RRs values are show for each HAP. In the first column, the %RR based on the

feed adjusted ASER is given; in the second column, negative ASERs are set at 0, and substituted %RRs are inserted in the place of "nr" (those ASERs where data is unavailable). In such cases where substitution is need, a %RR is randomly assigned (either as 0, 25, 50 or 75%) based on the %RR distribution of facilities in the same source category for which data for the specific

red Emissions Reduction

The %RRs are used to determine on a facility-by-facility basis which HAPs require additional control. Control strategies are assigned to each facility based on the existing APCS and the HAP types and %RR levels that are required as:

None: If the %RR is = 0, no additional retrofit or upgrade control is required for that specific HAP. If the %RR for all HAPs is 0, then no additional facility upgrading is required to meet the specified limits for all HAPs simultaneously.

Retrofit[Upgrade: If the %RR is > 0, additional control, either through retrofit/upgrade

HAP that is missing has been collected.

C.2.3 Selection of the Control Strategy to Achieve the Requi

of the existing APCS or add-on of a new air pollution control system/device, is required for that specific HAP. Determination of the appropriate control action is based on both the type of existing equipment and the %RR level, and is categorized into either Design, Operation, and/or Maintenance (D/O/M) of existing equipment, or installation on new equipment by:

0 Design/Operation/Maintenance (D/O/M) modifications of existing equipment:

If an existing device/system is capable of providing active control of the HAP of interest, then D/O/M practices may be able to meet the specified level. D/O/Ms are generalized into two categories ("small" or "moderate"), depending upon the %RR:

"Small" D/O/M: if %RR < 25%, a "small" DOM on existing equipment that is capable of controlling the HAP of interest is required.

"Moderate" D/O/M: If 25 < %RR < 75%, a "moderate" DOM on existing equipment consisting of a major redesign or modification of existing equipment that is capable of controlling the HAP of interest is required.

A new device for control of the specific HAP

No existing device is capable of controlling the HAP of interest and the %RR > 0.

The %RR is > 75%. If the %RR is > 75%, a new piece of control equipment is required, even if an existing one which

is capable of controlling the HAP is currently in place (e.g., if a facility with an existing FF needs > 75% reduction in its PM level, it is assumed that the facility would need a new FF to achieve the specified MACT level).

Selected control strategies are shown in Section C.3 in Tables C-Ib, C-2b, and Section C.4 in Tables C-3b, C-4b, C-5b, C-6b, C-7b, C-8b, C-9b, C- 1Ob, C-11b, C- 12b, C-13b, C-14b, C-1 5b and C-16b. The specific table pertains to the selected control strategy for each facility to meet the Floor or BTF option in question while using either 0% or 25% hazardous waste feed control.

Installation of New Equipment:
is required if either:

ESP Small

Moderate

FF Small

C.2.3.1 D/O/M Selection

The ability of a facility to use DOM to control a specific HAP is selected only when the required amount of reduction is small (<25%) or moderate (25-75%) and the facility already has the existing APCD for which the DOM is specified. The following DOM designation are used when determining specific DOM strategies for each of the different HAPs.

A small DOM to an existing ESP can be represented by the addition of humidification to the ESP. Note that improved electrical control has a similar impact.

A moderate DOM to an ESP can be accomplished by the installation of an additional field (A 133 ft' of additional SCA was assumed based on an average required to increase collection efficiency from 99 to 99.8%).

A small DOM to a FF can be achieved by either optimization of the cleaning cycles or test and maintenance procedures to eliminate leak paths (i.e. florescence smoke test to check for leaks).

It is assumed that a moderate DOM to a FF would be achieved by the use of more hardware oriented changes, specifically, the installation of improved bags (w/ PTFE membrane).

It is assumed that high energy wet scrubbers can be represented by a venturi scrubber since this is the primary type of WSHE In use. Other types include reverse jet scrubber and hydrosonic scrubber. High energy wet scrubbers can be used to control PM and to some extent acid gas. A small DOM to a venturi scrubber can be accomplished by an increase in differential pressure, an increase in L/G ratio, or enhanced maintenance.

A moderate DOM to a venturi scrubber can be represented by an increase in differential pressure to increase efficiency for collection of fine PM.

It is assumed that low energy wet scrubbers can be represented by a packed bed since this is a typical type in use. Other type of WSLE is a spray tower. A small DOM to a WSLE can be accomplished by an increase in the L/G ratio, enhanced pH control, or refurbish.

Moderate

WSHE Small

Moderate

WSLE Small

Moderate A moderate DOM of a low energy wet scrubber can be achieved by the

installation of structured or smaller packing or an increase in the amount of sorbent to improve collection efficiency.

Comb. A DOM on a combustor was assumed to be a modification of the burner/combustion zone to improve HC/CO burnout. Such a DOM was assumed to only be applicable to incinerators since the condition of the combustor is inaetly tied to product quality for cement kilns and LWAKs.

C.2.3.2 New Device Selection

The following guidelines are used to determine specific control strategies for each of the different HAPs when a new device is required.

C.2.3.2.1 *PM, LVM, and SVM Control:* An FF is added in all cases where a new device is required for PM, LVM, and SVM control due to economics over an ESP. An **IWS,**

ESP, and high energy wet scrubbers **(WSHE)** are also capable of control of these HAPs. It is assumed that a FF can be placed in series directly behind any existing PM control device within a "dry" system. It is assumed that a FF can be retrofitted directly into an existing "wet" system, upstream of the wet scrubbing system. Depending on site-specific factors such as flue gas temperature leaving the combustor and the existing flue gas cooling system, equipment, and physical layout, additional flue gas cooling equipment (e.g., water quench or air dilution) may be required in order to integrate the new fabric filter upstream of the existing wet scrubber system. Also, for existing wet systems that required additional LVM, SVM, and PM control, a wet ESP or IWS may be easier to incorporate since it can be added directly onto the back end of the existing wet scrubbing system. The difference between the current analysis would then be the cost differential between a fabric filter plus the appropriate cooling device and a wet ESP or IWS. For the analysis, it was assumed that this cost differential is small.

C.2.3.2.2 *Acid Gas Control:* Acid gas control pertains to the control of both HCI and C'2- The degree of control by a device of these two HAPs can vary. The following guidelines were used in the selection of a new acid gas device:

> HCI: Either wet (low energy such as PT or IWS) or dry scrubbing is possible when a new device is required for HCI control. Wet scrubbing is usually selected due to economics.
>
> Cl2 Wet scrubbing with alkaline pH reagent required.

In addition, for LWAKs a spray tower (ST) was usually selected over the use of a packed tower (FIT) since these facility types typically had a much higher level (ppm) of acid gas than the others. Due to econimic reasons the ST is advantageous for LWAKS. Specifically with the use of a spray tower, lime may be used instead of the more expensive NaOH. Normally, lime is not used in packed towers since it may cause problems with the packing (i.e., plugging).

C.2.3.2.3 *Hg Control:* Carbon injection or carbon bed is added whenever

Hg control is required. Although many wet scrubbers have demonstrated high (> 90%) control, many others have not shown any (O%) control. Additionally, the capture of Hg in wet scrubber may not be desirable, since it would complicate the treatment and disposal of scrubber blowdown (transferring Hg flue gas emissions to soluble blowdown). For effective carbon injection applications, the flue gas temperature must be below 400˚F. If it is above 400˚F, an addition of a water quench is required to achieve this. Additionally:

> Incinerators and Boilers: dry PM control device (FF or ESP) is required (either existing or the addition of a new one if not existing).
>
> CKs: Based on industry comments, a new dry PM control device is required (assumed to be FF), dedicated to capturing carbon. Cement kiln dust recycle is thus not affected.
>
> LWAKS: Like CKs, a new dry PM control device is required (assumed to be FF), dedicated to capturing carbon. LWAK aggregate product is thus not affected.

Carbon injection is usually chosen compared with carbon beds due to economics. Carbon beds are only economical on small sources. Additionally, it is assumed that carbon injection can not be performed immediately upstream of a wet PM control system (i.e., the carbon must be captured in

a dry PM control device), and that the application of carbon injection or carbon beds downstream of a wet system requires flue gas reheat to a temperature above the dew point.

C.2.3.2.4 *PCDDIPCDF:* For PCDD/PCDF control, two techniques can be used,

Temperature control of existing "dry" PM control device: CETRED and technology transfer from MWCs and MWIs has demonstrated that a reduction in operating temperature of a dry PM control device can reduce the PCDD/PCDF emissions level. Figure C-1 shows the PCDD/PCDF control % as a function of the temperature reduction; this is based on the assumption of a factor of 10 reduction in PCDD/PCDF for every 150˚F reduction in

separately or in combination, if required:

temperature, and is assumed to be valid in the temperature range of 350-750˚F.

- Carbon injection or carbon beds: To get additional PCDD/PCDF control, the use of either carbon injection or carbon beds is required. The same carbon injection and carbon bed limitations that were discussed above for Hg control are applicable to the application for PCDD/PCDF control.

C.2.3.2.5 *THCICO Control:* An afterburner (50% of primary heat input using natural

gas) is selected for THC/CO control technology for boilers and incinerators when a > 75% reduction is required. For boilers and incinerators where < 75% reduction is required, existing burner design, operation, and maintenance (DOM) is assumed ("DOM combustor"). For CK and LWAKS, it is assumed that all facilities are currently meeting the floor, since the floor is at the existing standard. To achieve "Beyond-the-floor" levels, an afterburner is required. When an afterburner is selected, a water quench system must also be added to cool the afterburner gases prior to entry into additional air pollution control equipment or release to the atmosphere.

C.2.3.3 Multiple HAP Control

Some DOM and/or new devices are capable of controlling two or more HAPs simultaneously. Many facilities may require the control of two or more different HAPs such as PM and Cl2 when attempting to meet standards for each HAP simultaneously. In these cases, engineering judgement is used to select the most cost effective option (i.e., the use of one device as opposed to the use of two devices to control two different HAPs) when the control of multiple HAPs is required. For example:

- When both PM and HCI control is required, an IWS or wet ESP, which has capabilities to control both of these HAPs simultaneously, is selected.
- Carbon injection or beds can control both Hg and PCDD/PCDF.
- A fabric filter which may be required as part of a carbon injection system will also increase the capture performance of PM, SVM, and LVM.

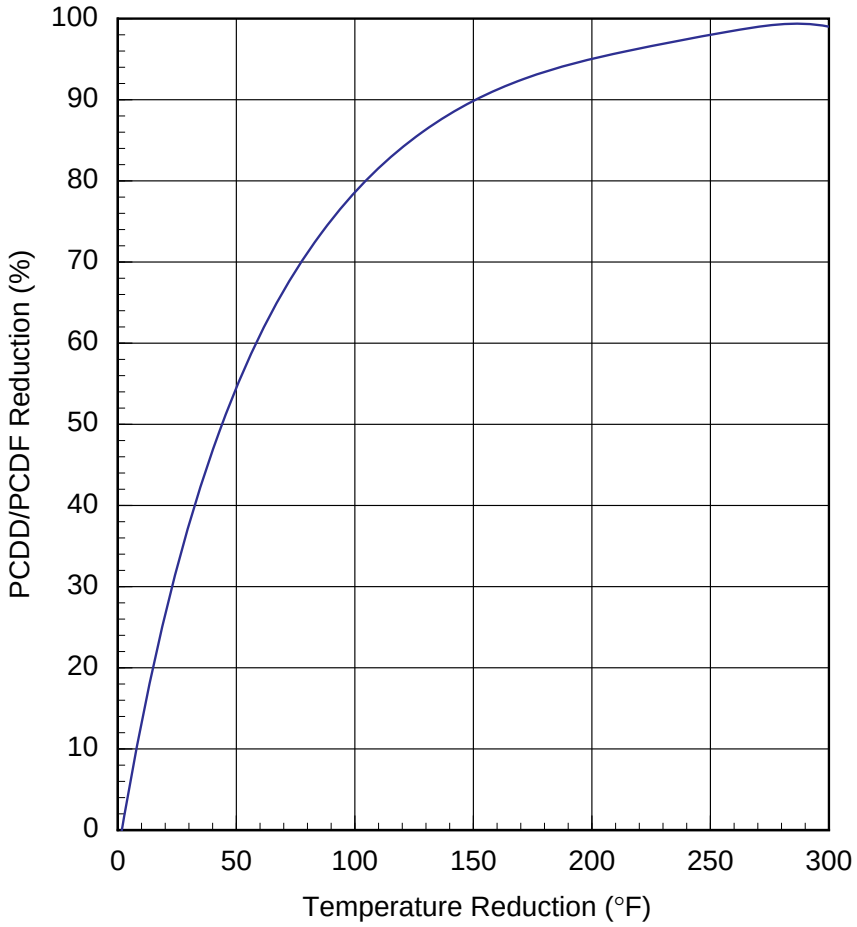

Figure 2-1. Acheivable PCDD/PCDF control as a function of PM air pollution control device temperature reduction (valid in a temperature range of 350-750°F).

- A wet scrubber may control both HCI and Cl2.

C.2.3.4 Upgrade/Retrofit APCS Requirements

Using the above discussed procedures, the most cost effective retrofit solution to simultaneously meet all HAP standard levels for the floor or BTF Option in question is determined for each hazardous waste burning facility. The selection is shown in the last column of Table C-Ib. As stated earlier, if the %RR for all HAPs is 0, then no additional facility upgrading is required to meet the specified limits for all HAPs simultaneously. For many facilities one or a combination of DOMs and new devices will be required to control one or more HAPs for which the facility does not currently meet the proposed levels.

C.2.4 Define Model Plants

Each of the facilities in Table Ic are grouped into categories based on common retrofit/upgrade requirements (i.e., None, Add FF, Moderate DOM on existing ESP, etc.). Each of these defines a "Model Plant Group". Model Plant Groups and the facilities associated with that group are shown in Section C.3 in Tables C-1c, C-2c, and Section C.4 in Tables C-3c, C-4c, C-5c, C-6c, C-7c, C-8c, C-9c, C-1Oc, C-11c, C-12c, C-13c, C-14c, C-15c and C-16c.. The specific table pertains to the Model Plant Groups as needed to meet the Floor or BTF option in question while using either 0% or 25% hazardous waste feed control. The definition of Model Plants Groups are not common across source categories. Appendix C-C defines each Model Plant Groups for each source category.

Each facility within a source group has been assigned into a size classification with a representative flue gas flowrate (in acfm). Cement kilns were divided into two size classifications (S and L) with average flue gas flowrates of 147,000 and 370,000 acfm, respectively. Incinerators were divided into three size classifications (S, M and L) with average flue gas flowrates of 3,900, 22,100 and 60,800 acfm, respectively. All light weight aggregate kilns were similar in size and were assigned to a single size classification (M) with an average flue gas flowrate of 40,500 acfm. The attached Figures C-2, C-3 and C-4 show the distribution of flue gas flowrates within each size classification for each source category, respectively. The size classifications were carried through to the Model Plant Groups in that the Groups are subdivided into subgroups based on facility size in acfm (i.e, S M or L).

Cl.2.5 Determine Model Plant Costs

For each of the Model Plant Groups defined in Table C-1c, the cost of the engineering retrofit/upgrade associated with that group are determined. The annualized operating costs are based on capital, installation, operation and maintenance costs, and capital recovery. The total cost to the national population of hazardous waste burners in each model

plant category is determined by multiplying each of the three individual sub-category model plant costs by the number of facilities in each of the size ranges, and adding the three subcategories. Costs are shown in Section C.3 in Tables C-Id, C-2d, and Section C.4 in Tables C-3d, C-4d, C-5d, C-6d, C-7d, C-8d, C-9d, C-1Od, *C-11*d, C-12d, C-13d, C-14d, C-15d and C-16d.. The

specific table pertains to the costs to meet the Floor or BTF Option in question while using either 0% or 25% hazardous waste feed control..

C.2.6 Feed Rate Reduction

As described throughout the preceding sections, the entire analysis process is done for two scenarios: facilities operating as-is with current waste feed rates, and facilities operating with a 25% reduction in waste metals and chlorine content (resulting in a 25% reduction in the feedrate of these constituents into the system). Feedrate adjusted stack gas emissions levels are estimated by the use of "partitioning factors" which are an estimation of the reduction in stack gas emissions levels corresponding to a reduction in hazardous waste feed rate inputs into the system (there is not always a direct one-to-one reduction is feed rate and stack gas emissions rates).

Partitioning factors were determined by estimating the impact of waste feed changes on the stack emissions of the various HAPs of concern. It was assumed that emissions are linearly dependent on feed rates and that the major factor which influences stack emissions is the ratio of the concentration of the HAP in the waste feed to the concentration of the HAP in the other feed streams (i.e., raw materials, fuels, and spike streams). For example, if mercury were fed to the combustion system in the waste only, a reduction of 25% in the waste feed rate will correspond to a reduction of 25% in stack emissions of mercury; however, if mercury were introduced into the system entirely in the other feed streams, a reduction of 25% in the waste feed rate will not reduce stack emissions of mercury. Appendix C-B summarizes the results of the impact of waste feed reduction on emissions for chlorine, LVM, SVM, and mercury from boilers, cement kilns, incinerators, and light weight aggregate kilns. These results were calculated from data belonging to many facilities within each combustion category and the median maximum and minimum values are shown in Appendix C-B.

C.3 COST ESTIMATES FOR EXISTING FACILITIES TO MEET PROPOSED FLOOR STANDARDS

Given in this section are the following tables which estimate the cost of an APCD upgrade and/or retrofit to facilities in order to comply with the proposed floor levels while using 0% or 25% feed rate control.

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribtion of reported values from other facilities

** Reported Ratio is equal to the no. of total units located at a site / the no. of units for which information was reported. Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered representative of the other nonreported units

nr = not reported

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribtion of reported values from other facilities

** Reported Ratio is equal to the no. of total units located at a site / the no. of units for which information was reported. Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units

nr = not reported

C.4 COST ESTIMATES FOR EXISTING FACILITIES TO MEET PROPOSED BEYOND THE FLOOR STANDARDS

This section contains all tables showing the cost to meet the various specified BTF options. The BTF Option as specified by EPA are listed in Appendix C-A. The tables given for each option are equivalent to Tables C-la, C-Ib, C-Ic and C-Id for the Floor with no feed rate control. An equivalent to Table C-I (and Table C-2 for the use of 25% feed rate control) is not included since the emissions values (both reported and feed adjusted) for each facility do not change across options.

Specifically, given in this section are the following tables which estimate the cost of an APCD upgrade and/or retrofit to facilities in order to comply with the desired BTF Option while using 0% and 25% hazardous waste feed rate control:

BTF Option	Tables
IA	C-3a to C-4d
IB	C-5a to C-6d
IC	C-7a to C-8d
2A	C-9a to C-10d
2B	C-11a to C-12d
3	C-13a to C-14d
4	C-15a to C-16d

C.5 NATIONAL EMISSIONS ESTIMATE AND ENGINEERING COST PER HAP

Table C-17 gives the national emissions estimate for Floor I and the BTF options. A discussion of the national emissions estimate is provided in Section 3.1 in the main body of the report. Table C-18 summarizes the engineering cost breakdown per HAP. A discussion of the apportionment of costs of each control device to the HAPs controlled by the device is contained in Section 3.4.

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribution of reported values from other facilities.

** Reported Ratio is equal to the number of total units located at a site divided by the number of units for which information was reported.

Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units.

nr = not reported

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribution of reported values from other facilities.

** Reported Ratio is equal to the number of total units located at a site divided by the number of units for which information was reported.
Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units.

nr = not reported

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribution of reported values from other facilities.

** Reported Ratio is equal to the number of total units located at a site divided by the number of units for which information was reported.

Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units.

nr = not reported

TABLE C-6c. CHARACTERIZATION OF MODEL PLANTS, OPTION 1B, 25% FEED CONTROL

Source Group	Model Plant Number	Required Equipment	Reported Ratio**	Site ID	Size Category	Facility Name	Existing APCD	Flue gas Flowrate (acfm)	Assigned Flue Gas Flowrate	Equivalent HCl Conc (ppm)

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribution of reported values from other facilities.

** Reported Ratio is equal to the number of total units located at a site divided by the number of units for which information was reported.

Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units.

nr = not reported

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribution of reported values from other facilities.

** Reported Ratio is equal to the number of total units located at a site divided by the number of units for which information was reported.

Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units.

nr = not reported

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribution of reported values from other facilities.

** Reported Ratio is equal to the number of total units located at a site divided by the number of units for which information was reported.
Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units.

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribution of reported values from other facilities.
** Reported Ratio is equal to the number of total units located at a site divided by the number of units for which information was reported.
Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units.
nr = not reported

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribution of reported values from other facilities.

** Reported Ratio is equal to the number of total units located at a site divided by the number of units for which information was reported.

Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units.

nr = not reported

TABLE C-11c. CHARACTERIZATION OF ATF MODEL PLANTS, OPTION 2B, 0%FEED CONTROL

Source Group	Model Plant Number	Required Equipment	Reported Ratio**	Site ID	Size Category	Facility Name	Existing APCD	Flue gas Flowrate (acfm)	Assigned Flue Gas Flowrate	Equivalent HCl Conc (ppm)
	Group 56	Moderate DOM on combustor & WS + Add RH + CI + FF	1	330 *	M	General Electric	QT/WS/DM	10,345	22,100	

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribution of reported values from other facilities.
** Reported Ratio is equal to the number of total units located at a site divided by the number of units for which information was reported.
Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units.
nr = not reported

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribution of reported values from other facilities.
** Reported Ratio is equal to the number of total units located at a site divided by the number of units for which information was reported.
Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units.
nr = not reported

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribution of reported values from other facilities

** Reported Ratio is equal to the number of total units located at a site divided by the number of units for which information was reported.

Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units.

nr = not reported

...cility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribution of reported values from other facilities.
...ported Ratio is equal to the number of total units located at a site divided by the number of units for which information was reported.
...ften a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units.
...ot reported

* Facility has been assigned to model group based on assumed emission level. Facility did not report the necessary emission value, therefore one was assigned based on the distribution of reported values from other facilities.

** Reported Ratio is equal to the number of total units located at a site divided by the number of units for which information was reported.

Often a facility will report data for only one unit even when the facility has two or three units at the particular site, since the single reported unit can be considered as representative of the other nonreported units.

nr = not reported
