Under Alternatives A, B and D, westslope cutthroat trout would not be protected in the Muskrat and Nursery Creek drainages by a 180 acre mineral withdrawal in riparian areas. Muskrat Creek has importance to westslope cutthroat trout restoration beyond the local level because after a ten year, \$50,000 restoration effort,

its population is now used as a donor source to re-establish westslope cutthroat trout populations in a number of different locations throughout Montana. Without the withdrawal, the genetically pure westslope cutthroat trout population in Muskrat Creek could be threatened by the loss of riparian vegetation, streambed and bank destabilization, erosion and sedimentation, loss of floodplain vegetation, alteration of floodplain morphology, and alteration of stream channel morphology that could occur in association with locatable minerals activities, particularly placer mining. Another key impact that placer mining could have on westslope cutthroat trout is excavation, crushing, or disturbance of streambed gravels during the critical period of 6/1 to 8/31 when westslope cutthroat trout are spawning and eggs are incubating/hatching in redds in the streambed. If extensive mining impacts occurred in Muskrat Creek, it would likely not be possible to reclaim the stream adequately to re-establish the current population level of westslope cutthroat trout.

MFWP, BLM, USFS, and other entities are currently making efforts to restore westslope cutthroat trout (a sensitive species) populations in a portion of their historic, but currently unoccupied habitat in the Upper Missouri River basin. One goal of these efforts is to prevent a federal listing of this species under the Endangered Species Act. The Muskrat Creek westslope cutthroat trout population is used by MFWP as a donor source of fish to re-establish populations in other streams within and beyond the Planning Area boundaries. In this sense, the Muskrat Creek population is disproportionately important to westslope cutthroat trout restoration throughout the Upper Missouri River basin. If mining operations cause a decline in this population, the population may no longer be able to function as a donor source and efforts to restore other populations and prevent a federal listing of this species may be impeded.

### **Plants**

Assuming that the low end of the range of proposed weed treatments is implemented under any alternative, under Alternative D the second lowest amount of noxious weed spread is forecast of all alternatives (47,000 acres), therefore the threat of special status plant habitat loss to noxious weed invasion could be less than the other action alternatives. The protections afforded by SMZs for the forested riparian species Idaho sedge and small yellow lady's slipper would be less than the buffers proposed by Alternatives B and C. Dry forest, shrub and grass treatments (44,050 acres per decade) to maintain or restore habitat of Lemhi penstemon, sapphire rockcress and lesser rushy milkvetch would be the highest under this alternative.

Oil and gas leasing NSO restrictions of known plant populations would protect the population but would provide limited protection of habitat with no set disturbance buffer.

## WILDLAND FIRE MANAGEMENT

### Effects Common to All Alternatives

Proposed management of the following resources, resource uses, and programs would have no or negligible anticipated impacts on fire management: Recreation (except Travel Management), Wilderness Study Areas, Energy and Minerals, Social and Economics, Farmlands, Environmental Justice, and Tribal Treaty Rights.

Treating forests and woodlands to reduce pest and disease risk would generally lead to a reduction in fuels and possibly a change in fire regime condition class (FRCC) by moving condition class toward Class 1 or 2. Reducing fuels would improve suppression effectiveness and firefighter safety. These treatments would be particularly important in the wildland urban interface (WUI). Removing forest products following wildland fire would have the same effect.

Treatments that mimic pre-fire suppression conditions would change FRCC at the stand level, by moving conditions class toward Class 1 or 2 in dry forest types, and consequently reduce fire intensity and improve wildland firefighter safety. All treatments specified (timber harvesting, small-diameter thinning, prescribed burning) would reduce understory fuels and reduce the incidence of stand-replacing fires. Treatments in the WUI would have the same effect, improving wildland fire suppression effectiveness and making it safer for firefighters to suppress wildland fires.

Treatments to reduce stem densities would change FRCC at the stand level, by moving condition class toward Class 1 or 2 and would reduce fuels in the cool moist forest types.

Conifer encroachment would be reduced through treatments, which would move toward changing the condition class in grasslands and shrublands to historic conditions.

Promoting the development of late successional riparian vegetation and reducing conifer encroachment would improve FRCC because conditions would become more like historic conditions in these areas.

Prescribed burning and livestock grazing (including Land Health Standards) would reduce fine fuels, which increase fire spread; and reduce ladder fuels, which facilitate stand replacing fires. Leasing currently unleased allotments or vacant available lands could reduce fine fuels, but could contribute to an increase in FRCC if conifer encroachment also occurs.

Noxious weed treatments would reduce noxious weed infestations, which could change FRCC in areas where cheatgrass or knapweed are contributing to the departure from historic fire regimes.

Reducing the invasion and establishment of undesirable or invasive vegetation species would change FRCC or

maintain it at current levels. In some instances, such as with cheatgrass, extreme fire behavior would be reduced, which would reduce fuels and the risk to firefighters.

Fuels management treatments would reduce fuel loadings which would reduce the intensity and severity of wildland and prescribed fires. Reductions in severity of wildland fire would help prevent adverse affects on soil integrity and stability, root systems, and recovery of post-fire vegetation.

Maintaining or moving toward historic fire regimes and Condition Classes would reduce or maintain FRCC. In the dry conifer type, this would improve firefighter safety and reduce the hazard associated with wildland fire risk in the WUI. Prescribed fire, timber harvest and other mechanical methods, used to create a mosaic of successional stages for the benefit of special status species, would change Condition Class and reduce fuels and fire behavior which would improve firefighter safety. Where these treatments occur in the WUI, the risk to the WUI would benefit from the change in FRCC in grassland and dry conifer sites. Treatments in the WUI would be designed to reduce risks and hazards of wildland fire, and would not necessarily be designed to reduce FRCC (particularly in shrubland and cool, moist conifer types), or provide other resource benefits, although changes in FRCC and resource benefits could be a by-product.

Mitigations to protect some species could reduce the extent of treatment or result in methods used that are not as effective in fuel reduction or restoration. For example, even-aged management might be the most effective way to restore FRCC, but the presence of a special status species could require the size of the treatment to be reduced, patches to be left undisturbed or require more cover, which would reduce the effectiveness of the treatment.

Managing areas as Wilderness Areas or Wilderness Study Areas limits activities which would modify FRCC or fuels, however, access would be limited which could reduce the number of human-caused fires, as well as the spread of noxious weeds, which could increase FRCC. Fire suppression would be minimal in these areas.

Mitigating short-term impacts on visual resources could reduce the extent or effectiveness of treatments to reduce FRCC or fuels by limiting areas treated and types of treatment in order to meet visual goals.

Use of prescribed natural fire in ACECs could change FRCC and fuel loadings, as would controlling noxious weeds.

Restrictions applied to wildland fire management actions or wildland fire suppression for air quality protection or to minimize air quality degradation could reduce the effectiveness of treatments or suppression by eliminating some types of treatments (prescribed burning, logging).

For soil resources, mitigation or seasonal restrictions applied to wildland fire management actions or wildland fire suppression in areas already compacted or eroding could reduce the effectiveness of treatments or suppression by eliminating some types of treatments (prescribed burning, logging).

Using Land Health Standards to ensure water quality could also promote changes in FRCC and fuels. However, mitigation to avoid impacts on water quality could influence the location and extent of some fuel reduction treatments or wildland fire suppression, which could result in less effective treatments or direct suppression by reducing the acres treated or switching to a less effective suppression tactic.

Designing wildland fire management projects, including suppression and fuel reduction to avoid disturbance of historic properties could reduce their effectiveness in some instances.

Granting right-of-way, road use agreements, permits, and leases on public lands could increase access or use by the public, which could result in more human-caused fire ignitions.

Disposal of lands which are difficult or uneconomical to manage would promote efficiency in BLM's fire management program, including reduction of FRCC and fire suppression. Overall fire suppression access would be improved if these lands were disposed of. These tracts are often within the WUI, so disposal would reduce the BLM's responsibility for WUI lands.

Access management for lands and realty would promote gaining additional access, including acquiring additional lands. Additional access would provide better access for fire suppression, but also may improve public access, which could lead to additional human caused fires. Acquiring additional acres could increase the acres of WUI, or lead to additional acres with a higher FRCC.

## Effects of Alternative A

Vegetation management actions (including salvage, timber harvesting, prescribed burning, small-diameter thinning, and thinning) would reduce densities of seedlings, saplings, and pole-sized trees and remove ladder fuels and other fuels to reduce the intensity of fires and to prevent wildland fires from spreading to the crowns of larger trees.

Fire suppression strategies under this alternative would allow for some flexibility to manage wildland fires, but a large percentage of fires could be controlled while still small in size.

Most BLM land in the Butte Field Office (258,200 acres, 85 percent) would be managed as Fire Management Category C. Fire and non-fire fuels treatments may be utilized to ensure constraints are met and to reduce undesirable effects of unplanned fires. Fuels reduction actions, including mechanical treatments and prescribed

fire, would result in reduced wildland fire intensity and less potential for unwanted fires.

Alternative A would treat up to 12,780 acres per decade to reduce fire intensity and behavior, improve wildland fire fighter safety, and change FRCC. Compared to the rest of the alternatives, only Alternative C treats fewer acres.

In Alternative A Recreation Opportunity Spectrum (ROS) would be determined on a case by case basis. This would provide for the most flexibility for designing and planning fuels projects.

Alternative A has the second fewest acres designated in VRM Class I and II. This would provide for more flexibility for designing, planning, and implementation of fuels projects as compared to Alternatives B and C.

Sleeping Giant ACEC (11,679) management to protect naturalness and primitive recreation, along with no fire-wood removal of down dead and down material would affect fire management, particularly mechanical fuel reduction. Prescribed burning however could be used to reduce fuels and FRCC.

There are no seasonal timing restrictions for prescribed fire or mechanical treatments in this alternative. This would provide for the most flexibility for implementation of fuels treatments.

## Effects Common to Action Alternatives

Wildland urban interface would be the top priority for hazardous fuels treatments. Those areas outside of WUI would be prioritized for treatment based on the historical fire regime and current condition classes. Funding for treatments within WUI and other fire dependent ecosystems would remain constant, and project level collaboration and coordination would continue with other agencies.

Fuels reduction in the WUI would result in removal of trees and shrubs to reduce the hazards associated with high intensity and severity wildland fires. Fuels reduction would decrease the density of trees and ground fuels and would result in reduced fire intensity and resistance to control.

Management to maintain fire-dependent ecosystems with fire regimes consistent with pre-suppression conditions would help maintain lower fuel levels and a reduced potential for high-severity fires.

Prescribed burning, mechanical treatments, and other appropriate methods would move toward restoring FRCC in grassland communities to historic conditions.

Meeting Land Health Standards equates to reducing or maintaining FRCC levels.

Emphasizing old forest structure (snag/down wood components and large diameter trees) could reduce the effectiveness of fire management actions, particularly in

the WUI where goals to retain old forest structure and fuel reduction goals may be in conflict.

Using FRCC to determine levels of fuel treatment outside the WUI would ensure that treatments maintain or move toward changing FRCC levels. In dry conifer and grassland types this would result in less intensive fire behavior. In cool, moist forest and riparian types, they could reduce fire behavior, but not necessarily.

Seasonal timing restrictions for big game winter and spring range, big game calving and grizzly spring and summer range could complicate the spring and early summer prescribed burning season and require additional mitigation.

## Effects of Alternative B

Effects of fire management activities in Alternative B would be the similar to those described under Alternative A. However, no Fire Management Units (FMUs) would have any Category A designated lands, so prescribed fire could be used throughout the Decision Area (given other resource constraints).

Fire suppression under this alternative would be similar to Alternative A except it would allow for more flexibility to manage fires with no FMU Category A designations.

Relative to the rest of the alternatives, Alternative B would treat the second most acres (up to 34,650 acres per decade) to reduce fire intensity and behavior, improve wildland fire fighter safety, and maintain or move toward historic FRCC levels.

In Alternative B Recreation Opportunity Spectrum (ROS) would place 36,800 acres in Semi-primitive non-motorized. This could limit the flexibility for designing and planning fuels projects and implementing fire suppression. This may limit the opportunities and effectiveness of to reduce fire intensity and behavior, improve wildland firefighter safety, and change FRCC.

Alternative B would have the 75,100 designated in VRM Class I and II. This could limit the effectiveness and flexibility for designing, planning, and implementation fuels projects on those acres. This may limit the opportunities and effectiveness to reduce fire intensity and behavior, improve wildland fire fighter safety, and change FRCC, especially in areas of wildland urban interface.

There are seasonal timing restrictions for prescribed fire in this alternative. This may cause delays, increase costs, and possibly decrease effectiveness in reducing fire intensity and behavior, improving wildland fire fighter safety, and changing FRCC.

## Effects of Alternative C

Alternative C would treat the fewest acres (up to 8,200 acres per decade) relative to the rest of the alternatives and therefore would do the least to reduce fire intensity

and behavior, improve wildland fire fighter safety, and change FRCC.

Based on the acres of anticipated treatment and the percentage of the FMUs in Category A, it is estimated that a maximum of 100 acres per decade of treatments using fire could be eliminated in the Central Missouri FMU. The majority of these treatments would have occurred in dry forest and grassland types. The Missouri FMU includes approximately 37,000 acres of the 147,000-acre Missouri watershed. In Alternative C a maximum of 4,425 acres of treatment would occur in this watershed, indicating there would be no impact on the overall treatment planned because all fire treatments could occur in the remainder of the watershed designated as Category B or C. The Blackfoot (1,000 acres) and Gallatin (2,000 acres) FMUs are also designated as Category A, but in Alternative C, no treatments would occur in these watersheds.

Most BLM land in the Butte Field Office (approximately 243,000 acres, 79 percent) would be managed as Fire Management Category C. These areas would receive lower suppression priority in multiple wildland fire situations. Fire and non-fire fuels treatments may be utilized to ensure constraints are met and to reduce hazardous effects of unplanned fires. Fuels reduction actions, including mechanical treatments and prescribed fire, would result in more open forests, dominated by larger trees, with less potential for unwanted ignitions of intense wildland fires.

In Category A and B areas, fire suppression is a high priority to prevent unacceptable resource damage or to prevent losses of life or property.

Fire suppression strategies under this alternative would allow for the least amount of flexibility to manage fires, but more fires could be controlled at smaller sizes.

The flexibility of fire management strategies in Wilderness Study Areas under Alternative C would allow opportunities to manage larger fires for resource benefits.

In Alternative C Recreation Opportunity Spectrum (ROS) would place 63,700 acres in Semi-primitive non-motorized; the most acres of all the alternatives. This could limit the flexibility for designing and planning fuels projects and implementing fire suppression. This may limit the opportunities and effectiveness to reduce fire intensity and behavior, improve wildland fire fighter safety, and change FRCC.

Alternative C has the most VRM Class II lands (62,300 acres) of any alternative, which may affect the extent of some fire management actions and fuel treatments.

This may limit the opportunities and effectiveness to reduce fire intensity and behavior, improve wildland fire fighter safety, and change FRCC especially in areas of wildland urban interface.

This alternative has the greatest level of seasonal timing restrictions for prescribed fire and mechanical treatments. This may cause delays, increase costs, and possibly decrease effectiveness in reducing fire intensity and behavior, improving wildland fire fighter safety, and changing FRCC.

## Effects of Alternative D

Alternative D would treat the most acres (up to 50,850 acres per decade) relative to the rest of the alternatives and therefore would do the most to reduce fire intensity and behavior, improve wildland fire fighter safety, and move toward historic FRCC levels.

Most BLM land in the Butte Field Office (approximately 265,000 acres, 86 percent) would be managed as Fire Management Category C or D, which are areas where fire is desired to manage ecosystems. These areas would receive lower suppression priority in multiple wildland fire situations. Fire and non-fire fuels treatments may be utilized to ensure constraints are met and to reduce hazardous effects of unplanned fires.

Fire suppression strategies under this alternative would allow for the most flexibility to manage fires with a smaller percentage of fires controlled at smaller sizes.

Flexibility in fire management strategies in Wilderness Study Areas would allow opportunities to manage larger fires for resource benefits.

Alternative D has the least VRM Class II lands (13,000 acres) of any alternative, which may affect the extent of some fire management actions and fuel treatments.

In Alternative D Recreation Opportunity Spectrum (ROS) would place 30,000 acres in Semi-primitive non-motorized. This could limit the flexibility for designing and planning fuels projects and implementing fire suppression. This may limit the opportunities and effectiveness of efforts to reduce fire intensity and behavior, improve wildland fire fighter safety, and change FRCC.

There are no seasonal timing restrictions for prescribed fire or mechanical treatments in this alternative. This would provide the most flexibility for implementation of fuels treatments.

## CULTURAL AND PALEONTOLOGICAL RESOURCES

### Effects Common to All Alternatives

Since most resource uses/programs are discretionary, management measures under all alternatives include inventories to identify cultural and paleontological resources to allow for avoidance or mitigation of impacts. The greatest risk of damage or destruction of cultural resources across all alternatives results from non-discretionary development, casual, unauthorized activities (such as dispersed recreational activity, OHV use, and vandalism) and natural processes (natural decay,

deterioration, or erosion). Under all alternatives, unquantified indirect impacts would occur. Cultural resources would continue to deteriorate through natural agents, unauthorized public use, and vandalism.

Achieving the Desired Future Condition for vegetation in riparian/wetland areas would be positive for cultural resources. Protection of cultural resources that occur in these fragile environments increases proportionately with the increase in the percent improvement towards DFC of riparian/wetland habitats.

Archeological sites in the same locations as livestock congregation areas are vulnerable to trampling. Historic buildings and sometimes rock art sites are vulnerable to livestock entry and rubbing. Grazing management which meets established Standards for Rangeland Health and Guidelines for Livestock Grazing should reduce the amount and extent of impacts or damage to cultural resources resulting from grazing on public lands.

All classes of cultural resources are vulnerable to impacts from timber harvest activity due to ground disturbance. The Butte Field Office has more sites recorded in the dry forest class than any other vegetation type. Sites located in cool forest types, grasslands and riparian areas are less vulnerable because of fewer proposed management actions. Activity in sagebrush areas fall in between the dry forest regimes and other vegetation classes. Inventories performed at the activity planning level would insure avoidance of known sites and localities from timber harvest and fuel management activities.

Threats to all classes of cultural resources from prescribed fires can be reduced with the proper use of protective measures. Sites vulnerable to fire damage will receive an evaluation prior to lighting, and if determined eligible, will receive protective measures as described in the burn plan for each project. In order to maximize the potential for locating vulnerable sites, BLM will focus on-the-ground inventory in both low and high-potential areas and also in areas where cabins and campsites are more frequently found. Survey will additionally be directed toward areas that contain historic mining properties. Based on the information recovered from these inventories, appropriate protective measures will be employed to reduce the potential risk from prescribed fire to vulnerable sites.

In some instances, cultural or historic sites would be damaged or destroyed by wildfire suppression efforts critical to protect human life or property. Under standard protocols, impacts to known cultural resources would be considered and mitigated. Rehabilitation efforts would generally increase the protection of cultural deposits that may have remained unaffected from wildland fire by preventing or reducing erosion and encouraging rapid revegetation of denuded surfaces. Potential impacts from rehabilitation activities (such as mechanical reseeding) would be mitigated under standard procedures.

The issuance of rights-of-way, leases and permits that result in ground disturbing activities have the potential to directly or indirectly impact cultural resources but impacts would be mitigated under standard avoidance or recovery procedures.

Acquisition of new land parcels would have a mixed effect on cultural and paleontological resources. On the one hand, more sites under the protection of federal preservation laws may be acquired. However, increasing access to public lands could have an indirect effect of exposing cultural resources to increased damage from illegal collection of artifacts and vandalism.

Impacts from dispersed recreational activity (camping, hiking, horseback riding, mountain biking, OHV use, rock climbing, etc.) are difficult to assess, particularly as such activities may impact cultural resources that have yet to be identified and recorded. Increased visitation and recreational use can lead to the illegal collection of artifacts and vandalism. Providing recreational or public interpretation of cultural and historic resources, such as those on the Lewis and Clark National Historic Trail, may enhance appreciation and understanding of the fragile and finite nature of cultural resources. Similarly, promoting the adaptive reuse of historic buildings and structures for recreational purposes would help preserve and protect significant historic properties, helping fulfill the requirements of Section 110 of the NHPA.

Under all alternatives, wheeled, motorized travel would be restricted to designated roads and trails throughout the majority of the Decision Area, thus reducing the potential for impacts caused by unregulated off-road travel. The potential for impacts to cultural resources is proportional to the number of miles open for travel in the Decision Area. Unimproved two-track roads and trails designated for use cut through sites, scattering and breaking artifacts and causing erosion problems. The noise level and presence of people can impact the use of traditional cultural properties by Native Americans in some instances.

Cultural resources would benefit directly from BMPs for visual resource management. Limiting visual intrusions preserves the setting of sites, which is especially important for cultural properties of religious importance to Indian tribes. SRMAs also provide intangible protection for sites with religious importance by providing enhanced visibility and solitude, as well as quieter environments.

Developing new, or upgrading existing, transportation facilities could result in the permanent mitigated loss of cultural resources. Again, increased accessibility to resources could lead to vandalism and unauthorized collection of artifacts, but conversely, could also facilitate the use of traditional locations by Native Americans.

The number of roads open or closed presents a mixed impact to cultural or paleontological resources. The maintenance and upgrades of those roads do present the

potential for adverse effects to the sites and localities located in the area of disturbance; however less use on closed roads would halt current damage, and reduce the threat of future damage to sites.

Construction of new travel routes, or diking/ripping of decommissioned routes, threaten buried cultural deposits. However, regardless of the alternative, the first priority of planning is to preserve known sites by avoidance; therefore all proposed new travel routes, or routes that need to be diked or ripped for any reason, would be inspected first. This would enable travel plans to incorporate design alternatives and avoid disturbance to cultural resources.

Abandoned Mine Lands (AML) reclamation and remediation would have a direct impact to historic mining features and properties that may be mitigated by a number of methods. Remediation of open mines for safety purposes could have less impact using light construction that leaves most of the feature intact. In more comprehensive project areas, construction may be more intensive and require additional, more intensive data recovery.

Permitting for locatable minerals is non-discretionary and can result in total loss of cultural resources in the Area of Potential Effect. Inventory and planning can help save some properties, but remaining eligible properties would require some form of data recovery, depending on the use category assigned to the site.

Surface disturbing activities associated with leasable mineral sales and energy exploration and development could result in mitigated impacts to cultural resources. In addition, the potential for indirect and inadvertent impacts would increase proportionally to the amount of land available for mineral leasing and development.

No Surface Occupancy stipulations for oil and gas leasing and field development would help protect eligible cultural resources, traditional cultural properties and paleontological localities in the area.

Land use authorizations and land exchanges place resources at risk from development and also from loss of federal protections when those properties leave federal ownership.

### ***Paleontological Resources***

Management measures common to all alternatives would preserve and protect paleontological resources for present and future generations. The protective measures outlined for cultural resources would also be applied to any paleontological localities located during planning inventories, as per BLM Manual (8720). Unavoidable adverse effects would be mitigated through specimen recovery and analysis by permitted paleontologists in keeping with the significance of the locality.

## Effects of Alternative A

Vegetation treatments under Alternative A would have a moderate impact on cultural resources, because this alternative would not reflect the high-end acreages proposed for vegetation treatments. Sites known to be in project areas, and those recorded in project areas during inventories, would be avoided during implementation.

The number of acres under VRM Class I would remain the same throughout all alternatives, but the number of acres in Class II in Alternative A would be much lower than Alternatives B and C. Since Classes III and IV would be managed on a case-by-case basis, it is not possible to determine if this alternative is more protective of visual resources than the others. Many more traditional cultural properties may or may not be adversely affected by this alternative, since the restrictions cannot be anticipated.

Alternative A would have the highest number of open roads and the lowest number of closed roads. More resources, both cultural and paleontological, would be impacted from increased access by motorized vehicles than with the other alternatives.

## Effects Common to Action Alternatives

Increasing the number of acres of forest treatments would place more cultural resource sites and paleontological localities at risk.

The effects of designating varying fire use polygons cannot be directly measured, since suppression efforts can both help and harm cultural resources. Variable fire use polygons would have mixed effects on cultural resources. For example, traditional fire suppression efforts may damage buried cultural deposits in the process of protecting historic buildings with dozer lines. Since suppression efforts would be eliminated in Category D polygons, proactive inventories would help limit the potential for adverse effects on historic properties during wildfire events by altering suppression plans. Buried sites are less vulnerable than sites exposed on the ground surface, but high fire temperatures may still cause various physical alterations to artifacts and natural remains.

Development of recreation sites may have an adverse effect on cultural and paleontological resources. Those adverse effects would be mitigated by avoidance through redesigning the project, or data recovery if the site or locality could not be avoided.

Road closures would have a beneficial effect on cultural and paleontological resources from reduced compaction, reducing exposure of resource deposits from the unrestricted development of two-track roads, and reduced chances of vandalism from access to remote areas with vehicles.

Designating the Humbug Spires, Sleeping Giant, Sheep Creek, and Elkhorns Tack-on WSAs as ACECs under all action alternatives would protect cultural and paleonto-

logical resources in these areas, due to greater restrictions placed on ground-disturbing activity.

Since the value of many traditional cultural properties is based on a high level of air quality and a natural appearance to the landscape, dropping the Black Sage and Yellowstone Island VRM Classes from I to II (in the event Congress eliminates them from wilderness consideration) would present an adverse effect to traditional cultural properties in the viewsheds of these two areas. Increasing the amount of Class IV acreages would be detrimental to traditional cultural properties in those viewsheds.

Public education is enhanced from interpretive efforts planning for the Elkhorns ACEC.

Disposal of the approximately 8,901 acres identified for disposal under all action alternatives could place approximately 24 cultural resources at risk, as per the site dispersal average for the Decision Area. Inventory and evaluation on a case-by-case basis would alleviate that risk.

The two energy corridors that would be designated under all action alternatives received considerable mitigation measures prior to construction. Adding utilities to these corridors would not impact cultural or paleontological resources.

Oil and gas leasing and resource development does not differ significantly enough between alternatives. This activity would put both cultural and paleontological resources at risk and would require site-specific mitigation. This would be done through project redesign and avoidance where possible, and if the resources cannot be avoided, data recovery would be used. Stipulations attached at the time of leasing, and again prior to development as part of the overall NEPA process, would protect prehistoric sites, traditional cultural properties, and paleontological localities.

## Effects of Alternative B

Increasing the amount of decadal vegetation treatments in both the dry forest and shrubland types may affect a proportional number of sites. However, inventories performed ahead of project implementation would mitigate the impacts to cultural resources. Increasing the number of acres managed at VRM Class II would improve the visual quality of traditional cultural properties in those viewsheds.

Protecting soils would protect valuable deposits of both paleontological and cultural resources. More cultural and paleontological resources would be threatened under Alternative B than under Alternative C from higher levels of ground disturbing activities. This would also be the case for travel management under Alternative B where decommissioned roads that may require ripping or additional blade work.

## Effects of Alternative C

Under Alternative C, upper-end acreages of proposed dry forest treatment acres would put fewer cultural and paleontological resources at risk than in any other alternative due to the significantly lower amount of ground disturbance from treatment activity. Visual resource management in this alternative would be the most beneficial to traditional cultural properties where the viewshed is an integral component of the value of the site. While Alternative C would not increase the acreage managed under VRM Class I, it would provide for the greatest increase in acres managed under Class II and Class III, and the fewest acres managed under Class IV; and as such, would allow the fewest intrusions into the natural viewsheds remaining in the Decision Area.

Traditional cultural properties would benefit most from the lowered development/disturbance scenario in Alternative C. Less activity would result in less noise and visual impacts, as well as disturbance from other public land users. Alternative C would also result in the fewest consultations with Native American tribal governments. Alternative C would create the least risk overall to cultural and paleontological resources due to its lowest proposed amount of development and soil disturbance.

## Effects of Alternative D

Under Alternative D, upper-end increases in proposed forest treatment acres would put more cultural and paleontological resources at risk than under the other three alternatives.

Visual resources managed under Alternative D would undergo more impacts than under either Alternative B or C, especially from a substantial drop in VRM Class II lands. The acres managed as VRM Class IV under Alternative D would be much higher than this acreage under Alternative C, but not much higher than under Alternative B. The Alternative D pattern of visual resource classes would have a more negative impact on traditional cultural properties that depend on the quality of the viewshed compared to Alternatives B and C.

Cultural and paleontological resources would be most vulnerable under Alternative D because of the increased risk of disturbing subsurface deposits. However, since avoidance of known sites is BLM policy, it does not necessarily follow that development would result in an increased amount of damage to cultural resources, paleontological localities, and traditional cultural properties. Because both resources are at greatest risk under alternative D than any other alternatives, more project-level planning and/or mitigation would be required with this alternative than with any of the other alternatives.

## VISUAL RESOURCES

### Effects Common to All Alternatives

Timber cutting and thinning could reduce the visual quality temporarily with regard to apparent modifications in color, line, and texture especially in sensitive viewing areas; however, projects would be designed to meet VRM classification objectives. Management in dry forest types would present the most potential for impacts on VRM objectives, as treatment acres would be the most extensive for this type.

Management in cool moist forests would generally be aimed at maintaining a diversity of age-classes (uneven-aged management). Generally, visual resource values could be maintained while selective cutting treatments are accomplished. An exception is lodgepole pine stands, which would require more even-aged management or clearcuts and therefore a higher potential for noticeability. Treatments that have long-term impacts on visual quality would be designed or mitigated to meet VRM objectives. Some treatments may be precluded if they are proposed in VRM Class I and II areas.

There may be some short or mid-term reductions in overall visual quality due to vegetation management actions in VRM III and IV areas. Because VRM would be considered during project planning, the overall VRM would be met over the long-term, but some activities (cutting or burning) may be visible during the short-term.

Protection and enhancement of riparian conditions would generally improve visual resources over the mid to long-term due to greater color and texture diversities and overall healthier appearances.

Limiting the spread of noxious weeds would be beneficial as the natural appearance of landscapes would be enhanced.

Wildland fire suppression and management actions for fire (wildland fire use, prescribed fire, and fuel reduction) may result in a short-term reduction in visual quality, however, these actions would promote long-term benefits as fewer acres would burn in an uncharacteristically large or severe manner. In addition to reducing the potential for severe wildland fires, these actions could also benefit visual resources by creating open vistas and more diverse landscapes with park openings and interspersed shrubs and trees. Due to fire suppression priorities and vegetative treatments, areas outside of the Wildland Urban Interface (WUI) would see more visual effects from wildland fire than those within the WUI.

Protection of Wilderness Study Areas, eligible Wild and Scenic River segments, ACECs, and National Trails would maintain visual resources and meet VRM objectives barring large-scale wildland fire events, substantial outbreaks of insect/disease occurrences to trees, or other natural alterations.

Following BLM Handbook H-8341-1 and mitigating short- and long-term visual impacts would help protect visual quality.

VRM I and II classifications would do the most to protect visual quality in the Decision Area and reduce the risk of visual quality impacts compared to other VRM classes. Alternatives with the most acres in VRM I and II would be the most protective of visual quality. VRM III and IV classifications would have the most potential to put visual resources at risk.

Minimizing or preventing air quality degradation would benefit visual quality by reducing the risk of degraded air quality (smoke obstructing viewpoints, etc.).

Depending on where land exchanges, ownership adjustment, or disposal occur, visual quality could be improved or negatively impacted. Negative impacts could occur where open, undeveloped tracts of land are disposed of and later developed.

Although VRM would be considered in land use authorization and access decisions, there is the potential for rights-of-way allocations to impact visual quality due to related disturbances with road building, vegetative removal, and new improvements.

Project proposals for mineral and energy exploration and development would be managed to prevent unnecessary and undue degradation; however, these activities could affect visual resources within the Planning Area. Mineral development outside special management areas could result in undesirable visual effects. These effects may be long-term. However, reclamation plans would consider visual restoration, so effects may not be permanent.

Restoring abandoned mines would improve visual quality in the areas where these disturbed sites are reclaimed and vegetated.

## Effects of Alternative A

Approximately 5,250 acres per decade of vegetation treatment activities in grasslands and shrublands would continue to pose potential impacts to visual resources due to modifications in color, texture, and form. Some vegetation management actions could cause short-term negative impacts while long-term effects would be enhanced due to improved vegetation conditions and reduced wildfire risks.

Timber harvesting and salvage would be designed to meet established VRM objectives, so there would be minimal effects on visual resources except in limited situations where such actions were noticeable.

Although prescribed fire would be designed to meet VRM objectives, there would be potential for short to mid-term impacts on visual quality. These actions would ultimately lower the long-term risk for large-scale wildland fires. Wildland fire is considered a natural event (not human-caused fires) but it also changes the current

condition of the visible landscape; therefore, wildland fire in VRM Class I and II areas could adversely impact visual resources to the greatest extent.

Discouraging timber cutting immediately adjacent to clearcuts, as required in elk management guidelines, would discourage the softening of edges that could be used to mitigate visual impacts created by clearcuts in noticeable areas. Conversely, this stipulation would benefit visuals in that additional adjoining clearcuts with large-scale modifications to the landscape would be prevented.

Continued management of six WSAs under Interim Management Guidelines would result in approximately 31,500 acres managed as VRM Class I.

Protective management on the Missouri River and Moose Creek eligible Wild and Scenic River segments would provide long-term visual resource protection and is important given that one of their outstanding remarkable values is Scenic. Current management of the major river corridors including the four eligible WSR segments would result in about 25,400 acres protected as VRM Class II. This classification would ensure that these sensitive viewsheds and their visual values would be retained. Since the Headwaters RMP did not distinguish between VRM Class III and IV areas, project-specific distinction would create increased workloads for visual management during project level planning.

Because Recreation Opportunity Spectrum (ROS) class has a component of VRM, not classifying ROS under Alternative A puts maintaining VRM to meet public preferences at a higher risk in the undesignated Class III and IV areas.

Management classes assigned to specific areas determine the amount of mitigation necessary to protect visual resources, which would allow at least partial modification of the landscape in nearly 81 percent of the BLM surface acres (VRM Class III and IV areas).

Areas withdrawn from mineral entry (6,300 acres) would continue to protect visual resources from locatable mineral actions. Impacts from salable mineral actions could potentially impact visual resources over the short and mid-term until reclaimed due to vegetative removal and excavation contrasts. The Controlled Surface Use oil and gas leasing stipulation for mapped VRM Class II, III, and IV areas would minimize visual impacts on 248,849 acres under Alternative B. However, of these 248,849 acres, approximately 66,962 acres would be even more protected from visual impacts due to being overlapped by other NSO stipulations or No Lease areas.

## Effects Common to Action Alternatives

There may be some short or mid-term reductions in overall visual quality due to grassland and shrubland treatments in VRM Class II and III areas. Because VRM objectives would be considered during project planning,

the overall VRM class objectives would be met, but some activities may be visible.

Maintaining residual stands that survive large-scale disturbance events would maintain visual quality.

Prevention of noxious weed invasion would maintain visual quality along roads, trails, urban interface areas, and recreation sites.

Thinning adjacent to clearcuts would not be discouraged, leaving open the opportunity to mitigate existing and future “hard edges” created by clearcuts if needed to improve visual quality and meet VRM objectives.

Meeting Land Health Standards on existing or future developed recreation sites would improve visual quality.

Continuing to manage the Sleeping Giant area as an ACEC would result in 11,679 acres of VRM Class II protection.

WSAs removed from wilderness consideration by Congress and not designated as ACECs (Black Sage and Yellowstone River Island) would see a reduced level of protection for visual quality. These lands are currently in VRM Class I, and in the future would be managed as VRM Class II.

Reseeding disturbed areas would maintain or improve visual quality.

## Effects of Alternative B

Effects from the management of dry forests described above under “Effects Common to All Alternatives” would occur on up to 14,750 acres per decade in this alternative.

Treatment of up to 15,450 acres per decade of grassland and shrubland habitat could create short to mid-term impacts to visual quality due to changes in color and texture. Short to mid-term impacts would promote long-term visual benefits due to the reduced potential for large-scale wildland fires resulting from these treatments.

Designating approximately one third of the Decision Area lands as ROS semi-primitive non-motorized, and semi-primitive motorized would provide additional management direction for protection of visual resources since new developments would not be compatible with these settings and a management emphasis would be made to retain the natural character of these areas.

Effects from potential mining activity on visual resources would be similar to those described for Alternative A. Actions lowering potential impacts under Alternative B compared to Alternative A, are that open road mileage would be reduced, 198 additional acres would be recommended for withdrawal from locatable mineral entry, and 13,968 fewer acres would be open to oil and gas leasing subject only to standard lease terms. However, Alternative B would still have 18,404 more acres

open to oil and gas leasing than Alternative A. The Controlled Surface Use oil and gas leasing stipulation for mapped VRM Class II, III, and IV areas would minimize visual impacts on 248,849 acres under Alternative B. However, of these 248,849 acres, approximately 87,765 acres (20,803 more acres than under Alternative A) would be even more protected from visual impacts due to being overlapped by other NSO stipulations or No Lease areas. This would be more protective than Alternatives A and D (where standard lease terms would apply), but less protective than Alternative C.

An additional 23,500 acres would be classified as VRM Class II (compared to Alternative A) due to adjustments made for sensitive visual areas primarily along major rivers. This classification would prevent basic element changes to the landscapes that are evident. Acres by VRM Class are displayed in **Table 4-14**.

VRM Class	Alternative A	Alternative B
I	31,500	31,500
II	25,400	48,900
III	250,400*	125,200
IV	N/A	101,700

\* VRM III and IV are combined in Alternative A

## Effects of Alternative C

Effects from management of dry forests would be the same as described under “Effects Common to All Alternatives” on up to 4,800 acres per decade, the least of any alternative.

Effects from management of cool, moist forests would be the same as described under “Effects Common to All Alternatives” on up to 550 acres per decade, the least of the alternatives.

Up to approximately 2,750 acres of grassland and shrubland vegetation treatment would be proposed in Alternative C. Effects on visual quality would be the same as described under Alternatives A and B although to a lesser extent. Alternative C would provide for the lowest number of grassland and shrubland treatment acres of any alternative.

The quantity of forest products removed and new roads constructed to support management for forest products would be the lowest of any alternative and therefore visual resources would be least impacted by these activities of any alternative.

Alternative C would provide for the highest acreages (125,300) to be managed as semi-primitive non-motorized and motorized ROS classes and therefore would provide greater protection for visual resources than any other alternative.

Effects from WSA and ACEC management would be similar to those of Alternative B. However the recommendation that all four eligible Wild and Scenic River segments be found suitable in Alternative C would potentially provide the greatest protection of visual resources of all alternatives in these areas since visual disturbances would be minimized.

Under Alternative C, adverse effects of energy and mineral exploration and development on visual resources would be the least of all alternatives. Supporting roads could not be constructed within riparian areas. Approximately 580,382 acres (approximately 89 percent of Decision Area total) would not be open to oil and gas leasing. The Controlled Surface Use oil and gas leasing stipulation for mapped VRM Class II, III, and IV areas would apply to 246,118 acres. However, of these acres, approximately 224,294 acres would be even more protected from visual impacts due to being overlapped by other NSO stipulations or No Lease areas. This would be the most protective of all alternatives. Salable mineral uses would be limited to existing community pits unless needed by the state or counties. Approximately 378 acres would be recommended for locatable mineral withdrawal.

Overall Alternative C provides the most protection to visual quality (Table 4-15) of all the alternatives.

VRM Class	Alternative A	Alternative C
I	31,500	31,500
II	25,400	67,600
III	250,400*	151,800
IV	N/A	56,500

\* VRM III and IV are combined in Alternative A

### Effects of Alternative D

This alternative would entail the greatest amount of vegetative treatments and therefore would have the greatest potential impacts to visual resources due to short and mid-term changes in colorations and texture. Effects of dry forest management would be the same as described under “Effects Common to All Alternatives” on up to 18,200 acres per decade, the most of any alternative.

Effects of cool, moist forest management would be the same as described under “Effects Common to All Alternatives” on up to 5,050 acres per decade, also the most of any alternative.

Alternative D would provide for up to 25,900 acres of vegetative treatment in grasslands and shrublands that could impact visual quality, the most of any alternative. Types of effects would be the same as described under Alternative A.

Potential effects from forest products removal, including timber salvage would be the highest under this alternative given the increases in projected potential timber harvest.

Black Sage and Yellowstone River Island WSAs would be subject to increased visual impacts from mineral activities if Congress releases these areas from wilderness consideration.

This alternative would have the fewest acres designated in the relatively protective VRM Class II lands than the other alternatives and therefore visual resources would be subject to more impacts than in the other alternatives.

No Wild and Scenic River segments would be recommended as suitable and no interim protective measures would be imposed for Wild and Scenic Rivers. As a result, visual resources within these segments would be prone to more impacts than with any alternative.

Alternative D would open the highest acreage (54,079 acres) to oil and gas leasing subject to standard lease terms and would not include the Controlled Surface Use stipulation on VRM Class II, III, and IV lands. Therefore Alternative D would present the highest potential for impacts to visual resources due to oil and gas development of any alternative. Effects from other energy and minerals activities would be similar to those described for Alternative A.

Alternative D would provide the least protection for preserving visual quality (Table 4-16). Alternative D has the fewest acres in ROS classes of semi-primitive non-motorized and semi-primitive motorized of any action alternative and therefore would have the highest risk that visual quality would not be protected. However, because Alternative A does not establish ROS, this alternative would have more protection for visual quality than Alternative A.

VRM Class	Alternative A	Alternative D
I	31,500	31,500
II	25,400	6,600
III	250,400*	142,900
IV	N/A	126,300

\* VRM III and IV are combined in Alternative A.

## EFFECTS ON RESOURCE USES

### FORESTRY AND WOODLAND PRODUCTS

#### Effects Common to All Alternatives

There would be no effects to forestry and woodland products from proposed management associated with livestock grazing, noxious weeds, cultural resources,

paleontological resources, energy and minerals, abandoned mine lands, hazardous materials management, farm lands, environmental justice, or tribal treaty rights.

Under all alternatives, management of any forest type that involves forest product removal would result in a contribution to the achievement of the PSQ. Types of products, size, and acres treated vary across the alternatives. Management actions would partially meet the public demand for wood products by providing sawtimber, posts and poles, and biomass, while improving forest health.

Vegetation treatments in grasslands, shrublands and riparian areas to remove conifer encroachment would provide some forest products, including posts, poles, biomass, and a limited amount of sawtimber. There are approximately 147,715 acres of land in the Decision Area (over 10 percent canopy closure and not in VRM Class I or WSA) from which commercial forest products and biomass could be produced through mechanical treatments. Prescribed burning could possibly remove some potential forest products, although effects would be limited as most of the material burned would be non-merchantable. In the long-term, prescribed burning and mechanical treatments could increase the value of forest products by increasing their quality (better growth form) and size (due to increased availability of nutrients and water).

Treating areas to reduce the risk of developing epidemic levels of forest insect or disease would provide forest products as a by-product of the treatment. However, preventing mortality from these sources could reduce the amount of salvage volume available in the future. In many cases however, treatments would reduce the severity of wildland fire, which could, in the long-term lead to increased quantities of forest products being available in the future.

Maintaining adequate access for forest/woodland management programs would help to maintain the economic feasibility of some treatments. The necessity to build roads (even temporary roads) can be cost-prohibitive particularly with smaller projects.

Management actions are expected to include design and BMP provisions for the protection of forest health, natural resources, water quality, and soils, which can limit the size and location of treatments and the removal of forest products. Streamside management zones would affect the methods used and outcome of forest products in those portions of riparian areas that are regulated under state law.

Providing small sale opportunities would help to meet local public demand for vegetative resources, including house logs, posts and poles, vegetative cuttings, conifer boughs, wildlings and ornamentals, grape stakes and juniper products, specialty cuttings, and wildflowers.

Limiting tractor logging to slopes averaging less than 40 percent would require that alternative methods of logging would be used. These alternative methods are generally more expensive than traditional ground based logging however; this is a common practice that the market is adapting to.

Slash disposal, site preparation and natural or artificial revegetation would promote re-establishment of the forest following treatment, which would lead to additional forest products in the future.

Enhancing riparian and wetland resources could result in some removal of forest products, because of the conifer removal component present in many prescriptions for these areas.

In the short term, fire suppression under all alternatives would maintain the availability of live forest products, and reduce the amount of salvage products. In the long-term however, fire suppression is likely to result in more uncharacteristically large and severe wildland fires that exceed suppression capabilities and result in an overall loss of forest products through fire consumption. An additional long-term effect could be future timber salvage opportunities if wildland fire size increases, along with vegetative type conversion from forest to grass or shrublands in severely affected areas that eliminate local sources of conifer seed.

Wildland fire use (allowing wildland fires to burn) and restoration of historic fire regimes would improve forest health in the long-term. Wildland fire use could produce salvage opportunities in the short term.

Fuels treatments to reduce wildland fire hazards would produce forest products in cases where by-products can be removed and used.

Management measures to protect special status species and priority species would affect the timing, location, or extent of most forest products removal projects. These effects would vary from minor to prohibitive. Management measures could also affect the economic viability of projects by limiting the intensity of management, the amount and type of products removed, the tools used, and the timing of activities. Timber removal may also be used as a tool to improve/restore special status species habitat, so activities to improve habitat for these species could, in some cases, produce forest products.

Forest product removal would be allowed under any of the Recreation Opportunity Spectrum classes established in the Planning Area. However, the more restrictive classes make management for overall forest products more difficult or expensive by restricting the level of disturbance or access to the management areas. Economically, this combination can be prohibitive, particularly where treatment prescriptions restrict removal of high value materials, specialized equipment is required, access is in need of considerable development, or the landing sites are inaccessible from the treatment site. In

particular, areas classified as Semi-primitive non-motorized would require inconspicuous treatments. Semi-primitive motorized areas could also be considered restrictive on a case-by-case basis.

Wilderness Study Areas would not have any forest product removal.

For all alternatives, the effects of Wild and Scenic River designations would be related to the subsequent river management plans and associated VRM and ROS classes.

VRM Class I areas are already set aside as Wilderness Study Areas, so there would be no additional effect beyond those described for WSAs. For VRM Class II areas, large-scale removal of sawtimber would be prohibited in most cases, which would restrict silvicultural management of those areas for forest products. Many activities that produce forest products could occur. However, economic efficiency would often be reduced due to less intensive activities, the need to leave more trees, and the need for non-intrusive road access. Most activities that produce forest products would be compatible with VRM Class III. VRM Class IV areas would have no effect on forest product activities.

Management of the Sleeping Giant ACEC (11,679 acres) to protect naturalness and primitive recreation, along with not allowing firewood removal of dead and down material, would minimize forest product removal from this area, although it would remain in the commercial forest category.

Requirements to comply with local, state, and federal requirements and mitigations for air quality may restrict slash disposal using prescribed burning related to some forest products removal actions, but this would not be expected to affect the overall achievement of PSQ, economic value, or meeting demand.

Implementing BMPs and mitigations for soil may affect logging and slash disposal related to the practices and timing used for some forest products removal actions,

but would not be expected to affect the overall achievement of PSQ or meeting public demand. Measures to protect steep slopes, water quality or limit soil erosion could increase the cost of forest products removal by limiting operating periods, access, equipment types, or requiring aerial logging methods.

Implementing BMPs and mitigations for water quality may affect logging and slash disposal related to some forest products removal actions, but would not be expected to affect the overall achievement of PSQ or meeting public demand. Measures to comply with the Montana Streamside Management Zone (SMZ) Law and state water quality rules could reduce the amount of timber that could be removed and increase the cost of forest products removal by limiting operating periods and access or requiring aerial logging methods. Forest management costs may also increase as state consultation and approval is required if alternate practices are needed to complete a timber removal project within an SMZ.

Providing rights-of-way, road use agreements, permits and leases could improve access for forest products management activities, which could increase economic viability.

Land tenure adjustments would result in more efficient management of forest products, which would improve economic viability and could improve BLM's ability to meet forest product demand.

Acquiring permanent access easements where needed would improve forest product removal efficiency and help meet public demand for forest products. Improved efficiency would result in better economic viability by providing assured access for later treatments and smaller scale activities and sales.

## Effects of Alternative A

**Table 4-17** displays the predicted output of forest products for Alternative A, given the resource protections detailed in the alternative description.

<b>Product</b>	<b>Amount</b>
Dry Forest	3,600 acres of timber and 1,000 acres of small-diameter thin
Cool Moist Forest	2,350 acres of timber and 50 acres of small-diameter thin
New Permanent Road Construction	55 miles
PSQ	12 to 27 MMBF
	40,000 to 97,000 CCF
Estimated Number of Permits Issued for Forest Products	350 Permits
Christmas Trees	4,500 Trees
Cords of Firewood	750 Cords
Small Timber Sales (Included in with PSQ)	1,650 MBF Sawtimber
Post, poles, Biomass, other woody materials	55 CCF
Timber Salvage	No Limit

Under Alternative A, mechanical treatment of vegetation in riparian areas could produce a few forest products from 30 acres per decade.

Compliance with SMZ Law would allow for forest product removal in SMZ areas solely for the economic purposes without meeting any riparian or other resource management objectives discussed in Alternatives B and C. Alternatives A and D also allow for a more aggressive approach to forest product removal in the riparian areas outside of the SMZs than the other alternatives.

Fire suppression within the first burning period of wildland fires would limit the loss of forest products to fire. Wildland fire use and prescribed burning could cause a loss of forest products, but could also create salvage opportunities in the short run while increasing the amount of products available in the future through improvement of forest health.

Alternative A has 240,000 acres in fire management Category C, which creates the potential for salvage opportunities on most of the DA.

In addition to the effects from special status and priority species management described under “Management Common to All Alternatives”, guidelines in the Montana Cooperative Elk Logging Study would limit the extent and timing of some forest products removal projects.

Under Alternative A, the recreational (ROS) and visual values (VRM) and opportunities could be considered on a case by case basis and may affect product removal dependant on individual analysis of impacts for each project. This is not expected to affect overall product removal levels nor support of the PSQ under Alternative A.

In addition to the effects described under “Effects Common to All Alternatives” for the Sleeping Giant ACEC, vegetation management in the Humbug Spires ACEC could result in limited forest products, although

trying to meet primitive recreation goals would preclude removal of sawtimber or construction of roads for access, adversely affecting the economic viability of forest products projects.

## Effects of Alternative B

**Table 4-18** displays the predicted output of forest products for Alternative B, given the resource protections detailed in the alternative description.

Timber salvage would produce sawlogs and other timber products, although Alternative B limits salvage compared to Alternative A.

Riparian treatments could produce a limited number of forest products, as riparian management objectives would dictate treatment type and level of forest change needed to meet objectives in the Riparian Management Zones (RMZs). Assuming a site-potential tree height of 80 feet, RMZs would limit the location and access to forest product removal projects in corridors defined as 160 feet on either side of fish-bearing streams and amounting to 38 acres per mile of stream, 80 feet on either side of non-fish bearing streams and amounting to 19 acres per mile of stream, and 50 feet on either side of intermittent streams which amounts to 12 acres per mile of stream. In these areas under Alternative B, treatment method, heavy equipment use, and vehicular access would be restricted to meet riparian objectives or prevent riparian impacts, thus reducing product removal efficiency and increasing cost. Under Alternative B, product removal would be allowed, while it would be prohibited under Alternative C. Alternatives A and D would allow for greater flexibility of product removal, because SMZ widths would be narrower than the RMZ widths.

Fire suppression within the first burning period (first day of a wildland fire) would limit the loss of forest products to fire. Wildland fire use and prescribed burning could

**Table 4-18**  
**Alternative B – Decadal Forest Products Output**

Product	Amount
Dry Forest	4,150 to 14,750 acres of timber and 300 to 1,000 acres of small-diameter thin
Cool Moist Forest	450 to 3,750 acres of timber and 100 to 400 acres of small-diameter thin
New Permanent Road Construction	Kept to a minimum, closed to public
PSQ	9 to 25 MMBF
	33,000 to 91,000 CCF
Estimated Number of Permits Issued for Forest Products	450 Permits
Christmas Trees	5,500 Trees
Cords of Firewood	1,000 Cords
Small Timber Sales (Included in with PSQ)	2,100 MBF
Post, Poles, Biomass, other woody materials	77 CCF
Timber Salvage	Variable, selective prescriptions considering the event size and associated wildlife values.

cause a loss of forest products, but could also create salvage opportunities. Alternative B is similar to Alternative A with 262,000 acres in fire management Category C, slightly higher than Alternative A at 258,200 acres. Management actions to reduce fuels in the Wildland Urban Interface and restore historic fire regimes in forested types could also produce forest products.

Timing restrictions for migratory birds prohibiting management-ignited prescribed fire from May 1<sup>st</sup> through August 30<sup>th</sup> would not reduce the availability of forest products for consumption. Disposal of slash and site preparation activities by burning may be restricted in higher elevation and north slope timber sale sites in the spring after May 1<sup>st</sup>, thereby increasing the cost and reducing the effectiveness of such activities.

Allowing no net increase in permanent roads in big game winter/calving range and grizzly bear distribution zone areas with low road density (defined as 1 mi/mi<sup>2</sup> or less in Alternative B) would reduce product removal efficiency in active forest management areas. Construction of more temporary roads would be necessary with most projects implemented. This also would limit the public's ability to use forest product permits in those areas.

Forest and woodland stands designated as ROS Semi-primitive non-motorized (18,554 acres), and Semi-primitive motorized (26,283 acres) under Alternative B amount to 41 percent of the forest and woodland available for product removal in the Decision Area. Forest product removal treatments and access development in these areas would be required to have relatively inconspicuous impacts on landscape character. This requirement could lead to increased costs due to a need for: more careful project design, more restrictions to protect recreation settings, and specialized equipment for implementation. Quantities of forest products removed may also decrease. Some commercial projects that would be feasible under Alternative A would not be feasible under Alternative B in these areas. Public use of the non-motorized designated areas for forest products, such as firewood and Christmas trees, would fall to very low

levels, as the harvested materials would have to be hand carried to vehicles and would probably only occur on the periphery of these non-motorized areas.

Forest and woodland stands designated as VRM Class II under Alternative B (16,902 acres) amount to 15 percent of the forest and woodland available for product removal in the Decision Area and are stands mainly found in areas designated as ROS Semi-primitive non-motorized. Forest product removal treatments would be restricted because treatments could not attract the attention of the casual observer in these areas. This would substantially reduce the level of product removal compared to Alternative A in VRM Class II areas.

In addition to the effects described under "Effects Common to All Alternatives" for the Sleeping Giant ACEC, vegetation management in the Humbug Spires ACEC could result in limited forest products removal, although trying to meet primitive recreation goals would preclude removal of sawtimber or construction of roads for access, adversely affecting the economic viability of forest products projects.

The Ringing Rock ACEC (160 acres) could produce forest products as long as VRM II could be met. Vegetation management in the Elkhorns ACEC (50,431 acres) would produce forest products and contribute to meeting public demand, except for the 3,575 acres of the Elkhorn Tack-on Wilderness Study Area, where forest products removal would be prohibited.

Timber salvage would be unlikely in any ACEC and would be prohibited in the Elkhorns ACEC, except when needed to provide for public safety.

### Effects of Alternative C

**Table 4-19** displays the predicted output of forest products for Alternative C, given the resource protections detailed in the alternative description.

Maintaining and promoting old forest structure and condition may produce a limited amount of small forest products.

<b>Product</b>	<b>Amount</b>
Dry Forest	2,050 to 4,800 acres of timber and 55 to 250 acres of small-diameter thin
Cool Moist Forest	50 to 550 of timber and up to 50 acres of small-diameter thin
New Permanent Road Construction	No new permanent roads
PSQ	5 to 12 MMBF 19,000 to 41,000 CCF
Estimated Number of Permits Issued for Forest Products	150 Permits
Christmas Trees	4,500
Cords of Firewood	50 Cords
Small Timber Sales (Included in with PSQ)	500 MBF
Post, Poles, Biomass, other woody materials	55 CCF
Timber Salvage	50 percent of affected area must be retained.

Timber salvage would produce sawlogs and other timber products; however Alternative C limits salvage more than the other alternatives. Salvage projects under Alternative C would be smaller and occur less often than the other alternatives due to higher large tree retention requirements and the areas where timber salvage would be prohibited (50 percent of contiguous areas of 1,000 acres or larger).

Requiring firewood to be live trees would eliminate the current agreement with the Forest Service for firewood permits and increase administration and enforcement cost. Green tree removal could result in fewer firewood permits overall because green trees are not desirable for firewood. Alternative C would not contribute to meeting public demand as well as the other alternatives would. No commercial forest products would be removed from RMZs under Alternative C, making Alternative C the most impactful alternative to commercial forest products from a riparian management standpoint. Under Alternative C Riparian Management Zones would be defined as 300 feet on either side of fish bearing streams and amounting to 73 acres per mile of stream; 150 feet on either side of non-fish bearing streams and amounting to 36 acres per mile of stream; and 50 feet on either side of intermittent streams which amounts to 12 acres per mile of stream.

Fire suppression within the first burning period (first day of a wildland fire) would limit the loss of forest products to fire. Wildland fire use and prescribed burning could cause a loss of forest products, but could also create salvage opportunities. The potential opportunity for timber salvage after fire events under Alternative C is similar to Alternative A, with 240,000 acres in fire management Category C compared to 258,200 acres in Alternative A. Management actions to reduce fuels in the Wildland Urban Interface and restore historic fire regimes in forested types could also produce forest products.

Under Alternative C, timing restrictions to protect migratory birds would prohibit vegetation treatments from May 1<sup>st</sup> through August 30<sup>th</sup> (unless breeding bird surveys document low potential for impact). This restriction would tend to push mechanical vegetation treatment, product removal, slash disposal and site preparation activities into the fall and winter under Alternative C. As this restriction is geared toward widespread disturbance of vegetation and potential nesting sites, it is not expected to affect the timing of more focused treatment support activities such as road maintenance or temporary construction which could be conducted during the restriction period. This should not reduce the availability of forest products for consumption, but this may increase the cost due to work being conducted during adverse winter conditions and when snow plowing may be required for anticipated heavy truck traffic to landings.

Under Alternative C, effects from special status and priority species management would generally be similar to Alternative B. However, allowing no net increase in permanent roads in big game winter/calving range and grizzly bear distribution zone areas with low road density (defined as 1.5 mi/mi<sup>2</sup> or less in Alternative C) would affect more areas, the most of any alternative. Additionally, maintaining blocks of at least 500 acres as unroaded or having closed roads during the hunting season may limit public access for forest products permits and access for management actions.

Forest and woodland stands designated as ROS Semi-primitive non-motorized (23,895 acres), and Semi-primitive motorized (31,583 acres) under Alternative C amount to 50 percent of the forest and woodland available for product removal in the Decision Area. Effects from area designations of ROS Semi-primitive classes would be similar to those described for Alternative B.

Forest and woodland stands designated as VRM Class II under Alternative C (27,259 acres) amount to 25 percent of the forest and woodland available for product removal in the decision area. Effects from area designations of VRM Class II would be similar to those described for Alternative B.

Effects from ACEC management would be the same as under Alternative B.

## Effects of Alternative D

**Table 4-20** (page 446) displays the predicted output of forest products for Alternative D, given the resource protections detailed in the alternative description.

Maintaining and promoting old forest structure and condition may produce a limited amount of small forest products.

Timber salvage would produce sawlogs and other timber products, although Alternative D limits salvage compared to Alternative A. Salvage projects under Alternative D would probably be larger and occur more often than under Alternatives B and C.

Alternative D would be most effective at meeting public demand for small sale products of all alternatives.

Fire suppression within the first burning period (first day of a wildland fire) would limit the loss of forest products to fire. Wildland fire use and prescribed burning could cause a loss of forest products, but could also create salvage opportunities. Because Alternative D has the most acres in Category D (180,000 acres compared to none in the other alternatives), it has the greatest potential to result in salvage opportunities, although it is only slightly higher than the 262,000 acres in Category C in Alternative B. Management actions to reduce fuels in the Wildland urban interface and restore historic fire regimes in forested types could also produce forest products.

Product	Amount
Dry Forest	7,300 to 18,200 acres of timber and 1,000 to 3,000 acres of small-diameter thin.
Cool Moist Forest	1,000 to 5,000 acres of timber and 400 to 1,200 acres of small-diameter thin.
New Permanent Road Construction	Kept to a minimum, some left open to public.
PSQ	10 to 30 MMBF 36,000 to 107,000 CCF
Estimated Number of Permits Issued for Forest Products	600 Permits
Christmas Trees	9,000 Trees
Cords of Firewood	1,500 Cords
Small Timber Sales (Included with PSQ)	5,200 MBF
Post, Poles, Biomass, other woody materials	105 CCF
Timber Salvage	30 percent of affected area must be retained.

Effects from special status and priority species would generally be similar to Alternative B, except allowing no net increase in permanent roads in big game winter/calving range areas with low road density (defined as 0.5 mi/mi<sup>2</sup> or less in Alternative D) would affect fewer areas. Effects associated with limiting net increases in permanent roads in the grizzly bear distribution zone would be the same as under Alternative B.

Forest and woodland stands designated as ROS Semi-primitive non-motorized (18,029 acres) and Semi-primitive motorized (13,823 acres) under Alternative D amounts to 29 percent of the forest and woodland available for product removal in the Decision Area. Effects from area designations of ROS Semi-primitive classes would be similar to those described for Alternative B.

Very few forest and woodland stands were designated as VRM Class II under Alternative D (173 acres). This amounts to one tenth of one percent of the forest and woodland available for product removal in the Decision Area. There would be little, if any, effect on forest products and support of PSQ from area designations of VRM Class II, similar to effects under Alternative A.

In addition to the effects described under “Effects Common to All Alternatives” for the Sleeping Giant ACEC, vegetation management in the Humbug Spires ACEC (8,374 acres) could result in limited forest products although trying to meet primitive recreation goals would preclude removal of sawtimber or construction or roads for access, adversely affecting the economic viability of forest products projects. Vegetation management in the Elkhorns ACEC (3,575 acres) would not produce forest products due to the Wilderness Study Area designation.

Effects from ACEC management would be the same as under Alternative B.

## LIVESTOCK GRAZING

### Effects Common to All Alternatives

There would be no effect from management of Lands and Realty-Land Use Authorizations, Energy and Minerals, Abandoned Mine Lands, Hazardous Materials Management, Environmental Justice or Tribal Treaty Rights.

Management actions to restore and improve riparian areas may require adjustments in grazing management such as adjusting numbers, rest, deferment, or maintaining existing livestock enclosures along streams, wetlands, and riparian areas in order to meet Proper Functioning Condition goals and the Western Montana Standards for Rangeland Health.

Maintaining or restoring the health and integrity of grasslands, sagebrush and shrublands, could change the amount of livestock grazing, or alter timing and utilization.

Wildland fire management activities (including prescribed fire and chemical and mechanical vegetation treatments) aimed at meeting or moving toward Land Health Standards would provide long-term benefits for vegetation and livestock by improving the forage base and availability.

Management actions to maintain cultural and paleontological resources may require adjustments in grazing management such as adjusting numbers, rest, deferment, or exclusion.

### Effects of Alternative A

Treatment of grasslands to remove conifer encroachment would improve long-term forage quality and quantity. Some short-term but negligible effects would occur where deferment and temporary removal of livestock is required before and after vegetation treatments. Alterna-

tive A differs from the action alternatives in that the action alternatives would result in improved forage quantity and quality on shrublands in addition to grasslands.

Livestock grazing would be allowed on three percent more acres than Alternatives B and C and the same as Alternative D. (See **Table 4-21** for a summary of acres and AUMs by alternative.)

Alternative A would limit the tools available for improving land health in the Medicine Rock (Northeast Helena) riparian area by excluding prescription livestock grazing from availability in that area. Specifically, grazing of sheep or goats could not be used as a tool to treat weeds.

Management of noxious weeds would control and contain the proliferation of invasive weed species and would reduce established populations to acceptable levels, thereby maintaining long-term forage production, diversity, and vigor in the treatment areas. Livestock management flexibility would be reduced over the long-term in untreated areas because of the presence of invasive weeds and the reduction of usable forage. Alternative A would impact the amount of forage available the least, because noxious weed spread would be the least—43,000 acres (assuming implementation of the low end of the range of proposed weed treatment acres under the action alternatives).

Management actions such as designating open access to vehicles would increase recreational use, public awareness of livestock grazing, and access (that is, roads and gates). These travel management actions often result in conflicts with the livestock grazing program. Alternative A would leave more acres open to wheeled vehicles (4,367 acres or one percent of the Decision Area) and snowmobiles (144,750 acres or 49 percent of the Decision Area) than the action alternatives, which would designate 283 acres (0.1 percent of the Decision Area) open to wheeled vehicles and 140,033 acres (48 percent of the Decision Area) as open to snowmobiles. Therefore, compared to the other alternatives, management actions for travel management and actions under Alternative A would have the greatest potential for conflicts with livestock grazing.

### Effects Common to Action Alternatives

In contrast to Alternative A, resource objectives on allotments without site-specific management objectives

would be met, in part, by imposing grazing utilization level limits. On such allotments, the utilization level as measured at the end of the grazing season would not exceed 55 percent on non-native seedlings and 45 percent on native herbaceous forage plants, on a pasture average basis, except where lower use levels may be necessary to prevent detrimental effects on vegetation and other resources. Higher utilization objectives may be acceptable when set through an interdisciplinary planning or NEPA process to achieve resource objectives.

Compared to Alternative A, forage conditions on small allotments would be improved or maintained by prohibiting livestock conversions from sheep or cattle to horses on existing allotments smaller than 160 acres and horse permits or leases on available vacant parcels on all areas less than 160 acres. These restrictions would minimize overgrazing by horses on small allotments.

Prescription livestock grazing would be allowed as a management technique to maintain or improve habitat conditions for special status plant species and animal species.

Management of crucial and important wildlife habitat, especially on winter range, may require adjustments to livestock grazing.

Under the action alternatives, fewer acres of open access for vehicles would be designated than under Alternative A and conflicts with livestock grazing from these actions would be reduced. Alternative A would leave more acres open to wheeled vehicles (4,367 acres or 1 percent of the Decision Area) and snowmobiles (144,750 acres or 49 percent of the Decision Area) than the action alternatives, which would designate 283 acres (0.1 percent of the Decision Area) open to wheeled vehicles and 140,033 acres (48 percent of the Decision Area) as open to snowmobiles.

### Effects of Alternative B

Treatment of grasslands and shrublands to improve desired ecological conditions would improve long-term livestock forage quality and quantity. Areas identified for prescribed burning would be rested from livestock grazing up to one year prior to treatment and treatment areas would be rested at a minimum of two full years following treatment resulting in short-term impacts on livestock grazing. Alternative B would treat three percent more acres of grasslands and shrublands (of Decision Area total) than Alternative C, one percent more

**Table 4-21**  
**Summary of Acres Available for Grazing by Alternative**

	Alternatives			
	A	B	C	D
Acres available for grazing	278,000	270,000	262,000	278,000
Acres not available for grazing	29,000	37,000	45,000	29,000
Permitted AUMs	25,677	24,710	24,710	25,677
Forage reserve, temporary non-renewable AUMs	0	1,312	936	0

than Alternative A and two percent fewer than Alternative D.

Livestock grazing would be allowed on three percent fewer public land acres than Alternatives A and D, and one percent more than Alternative C. (See **Table 4-21** for a summary of acres and AUMS by alternative.)

More acres would be managed as forage reserve than under any of the other alternatives. Forage reserve allotments (1,312 AUMs) would be managed to meet, or move toward meeting, Land Health Standards. Forage reserve allotments would provide opportunities for qualified applicants to rest allotments when required and would facilitate management actions or relieve resource problems. Management as forage reserve, as opposed to normally permitted allotments, is more costly to administer. Thus, the cost of administering forage reserves would increase the most when compared to the other alternatives. However, the number of AUMs managed as forage reserve is small (five percent) relative to the total number of AUMs under Alternative B, so the impact would be minor.

Alternative B would allow for greater flexibility, compared to Alternatives A and C, in the tools available for improving land health in the Centennial Gulch (Ward Ranch) allotment and the Medicine Rock (Northeast Helena) riparian area by allowing prescription livestock grazing in those areas.

The impacts from management of noxious weeds would be similar to those discussed under Alternative A; however the amount of noxious weed spread could be higher under this alternative—48,000 acres—than under Alternative A, thus reducing the amount of forage available (assuming implementation of the low end of the range of proposed weed treatment acres for Alternative B).

Fence modification costs to remove or reconstruct fences identified as wildlife barriers would be less than Alternative C, but more than D because the alternative B prescription has some flexibility.

### Effects of Alternative C

Compared to the other alternatives, management action in grasslands and shrublands in Alternative C would improve long-term livestock forage quality and quantity the least. Alternative C would treat two percent fewer acres than Alternative A (at Decision Area scale), three percent fewer than Alternative B and five percent fewer than Alternative D.

Six percent fewer public land acres would be available for livestock grazing than Alternatives A and D and three percent fewer than Alternative B (See **Table 4-21** for a summary of acres and AUMS by alternative.) Managing the McMaster Hills and Spokane Hills allotments as forage reserve allotments, as described under Alternative B, would increase the costs to administer those lands.

Alternative C would limit the tools available for improving land health in the Centennial Gulch (Ward Ranch) allotment and Medicine Rock (Northeast Helena) riparian area by excluding prescription livestock grazing from availability in those areas.

The impacts from management of noxious weeds would be similar to those previously discussed except the impacts to the livestock forage base could be highest because the amount of noxious weed spread would be highest under this alternative (assuming implementation of the low end of the range of proposed weed treatment acres for Alternative C).

Fence reconstruction costs to remove and replace fences identified as barriers to wildlife movement would be highest under this alternative because of the stringent management mandate.

### Effects of Alternative D

Compared to the other alternatives, management of grasslands and shrublands in Alternative D would result in the greatest improvement in long-term livestock forage quality and quantity from vegetation treatments on grasslands and shrublands. Alternative D would treat two percent more acres than Alternative B (at the Decision Area scale), three percent more than Alternative A, and five percent more than Alternative C.

Livestock grazing on public land would be allowed on the same amount of acres as Alternative A, two percent more than Alternative B, and three percent greater than Alternative C. (See **Table 4-21** for a summary of acres and AUMS by alternative.)

Compared to the other alternatives, noxious weed management in Alternative D could result in 47,000 acres of spread (assuming implementation of the low end of the range of proposed weed treatment acres for the action alternatives). Consequently more livestock forage could be maintained than under Alternatives B and C, but less than under Alternative A.

As with Alternative A, under Alternative D, the existing Instruction Memorandum 98-140 (1998) would be followed which would impose restrictions on new goat and sheep allotments as well as those allotments with conversions from cattle to sheep and goats in order to minimize physical contact between domestic and wild sheep.

Fences identified as barriers to wildlife movement would be considered for removal or reconstruction on a case by case basis, to follow BLM fence specifications for wildlife.

Designation of two new ACECs totaling 11,949 acres would require management activities to protect or enhance ACEC values. Management activities may include restrictions on livestock grazing, requirements to maintain/build boundary fences and cattle guards, and closely monitor livestock trailing.

## ENERGY AND MINERALS

### Effects Common to All Alternatives

#### *Energy and Minerals*

Approximately 6,300 acres would remain withdrawn or not available for mineral entry (leasable, locatable, and salable). Approximately 6,000 acres along the Missouri River Chain of Lakes would continue to be withdrawn in Power Site Reserve and Power Project withdrawals. The effect on mineral leasing would be negligible as the area represented is small and in scattered small parcels when compared with the overall area available to leasing in the Planning Area.

#### *Leasable Solid Minerals*

There are no known potentially economic deposits of leasable solid minerals such as sodium, potash, sulphur, oil shale, native asphalt, and solid and semi-solid bituminous rock in the Planning Area. If any were discovered on lands administered by the federal government, the decision to lease them would be made by the BLM on a case-by-case basis.

#### *Leasable Geothermal Resources*

Geothermal resource leasing activity is not anticipated, so there would be no effects.

#### *Leasable Fluid Minerals*

Stipulations applied to various areas with respect to occupancy, timing limitation, and control of surface use would have the greatest effects on oil and gas exploration and development. Some areas would be deemed unavailable for oil and gas leasing as a result of existing non-discretionary closures for Wilderness Study Areas. Others may be determined unavailable as a result of the discretionary decisions of this RMP. These lease stipulations and the availability of the federal mineral estate for fluid mineral leasing varies by alternative.

No Surface Occupancy stipulations may decrease some lease values, increase operating costs, and to a lesser extent (given the RFD) require relocation of well sites and modification of field development. Leases issued with moderate constraints (Timing Limitation and Controlled Surface Use stipulations) may result in similar impacts, and delays in operations and uncertainty on the part of operators regarding restrictions.

#### *Locatable Minerals*

Because the Planning Area is considered to be highly prospective for base and precious metal deposits, it is likely that there would be multiple applicants for exploration and that one or more mining companies would submit a proposed Plan of Operations to develop a new large scale metal mine at some point in the next 20 years.

Mineral exploration activities would include construction of exploration drill roads, drilling pads, and equipment staging areas. Activities would be conducted under a notice or an approved Plan of Operations and require bonding for reclamation and closure.

Large-scale mines, mine expansions, and small-scale mining operations are likely to result in disturbances from access road construction, increased traffic, surface disturbance (i.e. underground portals; mine pits; waste rock dumps; ore processing, tailing facilities, administration and maintenance facilities; and storm water run-off control ponds and diversions structures). Virtually all mineral activity also requires state permits.

Placer operations would affect streambeds or terrace deposits adjacent to streams, by excavating and processing sand and gravel deposits for the recovery of gold. These operations would have mitigation measures in place to protect riparian areas and other natural resources. Site reclamation work would be bonded by the BLM and the state to insure completion of reclamation following mining.

BLM anticipates that there would be four to ten placer mining operations per year on Decision Area lands, with the actual number depending on the price of gold.

BLM would develop and implement measures to prevent unnecessary or undue degradation from exploration, mining, and reclamation activities. In some areas, such as ACECs, these requirements could result in additional expenditures to protect resources and prevent unnecessary or undue degradation.

BLM or other agency authorization of rights-of-way for facilities such as roads, highways, and power lines could provide access and infrastructure for exploration of locatable minerals and mining operations. Alternatively, denial of rights-of-way could result in negative impacts on operations.

Land ownership changes could result in acquisition or disposal of lands with mineral value, and either increase or decrease opportunities for mineral development. Acquisition of legal access across private or other lands could result in increased opportunities to explore and develop areas not accessible by another route.

The following 31,349 acres of land in the Decision Area are currently WSAs:

- Sleeping Giant (6,666 acres),
- Sheep Creek (3,801 acres),
- Elkhorn's Tack-on (3,575 acres),
- Black Sage (5,917 acres),
- Humbug Spires (11,320 acres), and
- Yellowstone Island (69 acres)

These lands are managed under the Interim Management Policy (H-8550-1) and mineral development activities

are thus restricted. Once a final Congressional determination is made on wilderness consideration, these lands would either become wilderness areas or be released and managed according to this plan.

An approved Plan of Operations is required in designated ACECs for all surface disturbing activities exceeding the casual use level. Activities which could normally proceed after the filing of a Notice would require an approved Plan of Operations in an ACEC. The increased environmental review, mandatory public comment period, and application of management prescriptions needed to protect ACEC-values, would result in timing delays or increased costs for mineral operators.

Fire management activities could temporarily result in restricted access to a mining project during implementation of prescribed burning, or during wildland fire suppression.

Rehabilitation and closure of abandoned mine land sites and associated features would result in the removal or obscuring of information contained in waste dumps, excavations, adits, and shafts used by exploration companies to sample and map mineral deposits.

**Salable Minerals**

Extraction of salable material by excavation or mining would result in a mine or quarried pit. Effects from access roads and pit construction would be minor or moderate depending on the scale of the quarrying operations (size and ability to reclaim the ultimate pit). Existing requirements for topsoil salvage and reclamation would minimize impacts from mining.

Stipulated requirements and BMPs designed to avoid or minimize adverse effects on riparian zones from structures, support facilities, and roads could result in additional expenditures and a longer approval time for the developer. BLM’s discretionary sale approval policy could avoid sale of materials from riparian areas.

Mitigation measures to eliminate or reduce impacts resulting from exploration or mining operations could also result in additional expenditures and a longer permitting timeframe for the developer.

BLM or other agency authorization of rights-of-way for facilities such as roads, highways, and power lines could provide access and infrastructure. Alternatively, denial of rights-of-way could negatively affect operations.

**Effects of Alternative A**

**Energy and Minerals**

Approximately 287,457 acres of BLM lands would be available for locatable mineral entry and consideration for other mineral disposals. Energy and minerals permits would allow for development of the mineral resources to provide for the resource needs of society.

**Leasable Fluid Minerals**

Continuation of current management would result in the availability of approximately 597,384 acres for fluid mineral leasing across the entire Planning Area. Approximately eight percent (54,810 acres) of BLM subsurface ownership would be unavailable (Table 4-22), including Sleeping Giant, Sheep Creek, Elkhorn’s Tack-on, Black Sage, Humbug Spires, and Yellowstone Island WSAs.

Other areas unavailable for oil and gas leasing would include core areas of state wildlife management areas and lands recently acquired with LWCF funds. The remainder of federal mineral estate lands would be available for leasing, subject to the stipulations specified in Chapter 2 or under Standard Lease Terms.

Table 4-23 displays areas affected by no surface occupancy, timing limitations, and controlled surface use oil and gas stipulations.

The RFD scenario prepared for this RMP identified five areas in the Planning Area where it was the most reasonable to forecast conventional oil and gas or coal bed methane exploration and development based on existing information. These areas are described and defined in both Chapter 3 and Appendix M. The total Federal mineral estate in these five areas is approximately 116,295 acres.

<b>Classification</b>	<b>Acres</b>
No Surface Occupancy <sup>1</sup>	251,779
Timing Limitations <sup>1</sup>	285,993
Controlled Surface Use <sup>1</sup>	27,701
Standard Lease Terms <sup>1</sup>	31,911
<b>Acres Available for Oil and Gas Leasing</b>	<b>597,384</b>
Non-discretionary (unavailable)	28,774
Discretionary (unavailable)	26,036
<b>Acres Unavailable for Oil and Gas Leasing</b>	<b>54,810</b>

<sup>1</sup>Acres by stipulation subcategory were calculated such that the subcategories add up to the total available acres for leasing based on the following general concepts where multiple stipulations overlapped: No Surface Occupancy stipulations override and are more restrictive than Timing Limitations, Controlled Surface Use, and Standard Lease Terms. Timing Limitation stipulations override and are more restrictive than Controlled Surface Use and Standard Lease Terms. Controlled Surface Use stipulations override and are more restrictive than Standard Lease Terms. Non-overlapping individual stipulation-specific acreages are displayed by alternative in Tables 4-23, 4-27, 4-30, and 4-33.

<b>Table 4-23 Alternative A Acres Affected by Oil and Gas Stipulations</b>					
Type of Stipulation	Stipulation	Development Potential			Total Acres Stipulated <sup>1</sup>
		Moderate	Low	Very Low	
<b>No Surface Occupancy</b>					
Arctic Grayling Habitat	NSO ¼	202	10,459	2,694	13,355

VRM Class II, III and IV Areas	CSU	65,962	77,938	104,949	248,849

<sup>1</sup>Total acres affected by each stipulation are based on individual, independent, stipulation-specific GIS mapping and have not been overlapped with any other stipulations. Figures are provided here to display which stipulations for which resources are relatively dominant in the Decision Area.

<sup>2</sup>Total values of “0” indicate that there are currently no known sites or acres associated with this particular resource. Stipulation would apply to any newly detected sites or acres in the future.

An analysis was completed for each alternative to review the impact of constraints in the form of oil and gas lease stipulations imposed on oil and gas exploration and development within the boundaries of these five areas based on the belief that this would further quantify the effects of management under the various alternatives as these are the areas that the BLM believes have the most potential (low to moderate potential overall) for exploration and development (see **Table 4-24**).

<b>Classification</b>	<b>Acres</b>
No Lease	<b>9,849</b>
No Surface Occupancy	43,136
Timing Limitation	53,649
Controlled Surface Use	1,638
Standard Lease Terms	8,024
<b>Total Available for Oil and Gas Leasing</b>	<b>106,447</b>

Under Alternative A the analysis shows that approximately 8.5 percent of these five areas would not be available for oil and gas leasing. Approximately 37 percent of the areas would be subject to leasing subject to major constraints (no surface occupancy). Approximately 48 percent would be leased subject to moderate constraints. Approximately seven percent would be leased subject to standard terms and conditions. Alternative A is similar in its level of constraints to Alternative B. Both subject approximately 35 to 37 percent of the federal minerals to major constraints and approximately 48 to 55 percent to moderate constraints. Due to the level of major constraints, Alternatives A and B are somewhat more restrictive than Alternative D but much less restrictive than Alternative C.

**Locatable Minerals**

Locatable minerals activities would be regulated to prevent unnecessary or undue degradation as required by regulations (43 CFR 3809). Under Alternative A, 239,138 acres would remain open to mineral entry and consideration for salable mineral disposals without restrictions, 48,319 would be open to mineral entry with restrictions and 17,522 acres would be closed (**Table 4-25**).

**Salable Minerals**

Access roads and mine development for salable minerals would usually be located near municipalities or small rural communities. Impacts on natural resources and local residents would be avoided where possible or mitigated.

<b>Mineral Potential</b>	<b>Restricted Acres</b>	<b>Closed Acres</b>	<b>Open Acres</b>	<b>Totals</b>
<b>Alternative A</b>				
High	11,344	3,675	103,541	118,560
Medium	6,495	3,952	24,505	34,952
Low-None	30,479	9,894	111,092	151,466
<b>Totals</b>	<b>48,319</b>	<b>17,522</b>	<b>239,138</b>	<b>304,978</b>
<b>Alternative B</b>				
High	37,495	3,675	77,390	118,560
Medium	9,586	3,952	21,414	34,952

<b>Totals</b>	<b>88,728</b>	<b>17,547</b>	<b>198,704</b>	<b>304,978</b>
<b>Alternative C</b>				
High	43,456	3,746	71,359	118,560
Medium	13,527	3,952	17,473	34,952
Low-None	54,248	10,022	87,196	151,466
<b>Totals</b>	<b>111,230</b>	<b>17,720</b>	<b>176,028</b>	<b>304,978</b>
<b>Alternative D</b>				
High	11,344	3,675	103,541	118,560
Medium	6,495	3,952	24,505	34,952
Low-None	29,768	9,849	111,804	151,466
<b>Totals</b>	<b>47,607</b>	<b>17,522</b>	<b>239,850</b>	<b>304,978</b>

Acres analyzed excludes approximately 2,300 acres not covered by the MBMG Mineral Potential reviews and about 347,000 acres of federal subsurface minerals.

Restricted Areas include WSAs, ACECs, WSRs, and T&E habitat (grizzly bear, bald eagle, and bull trout).

Closed areas include Withdrawals, proposed withdrawals, and LWCF Lands (11,246 acres), Lands in Public Water Reserves, Power site Reserves, Protective withdrawals and WCF lands are static and do not change from one alternative to another).

Open areas are all other areas.

Travel Plan road designations not included in analysis.

**Effects of Alternative B**

**Energy and Minerals**

Approximately 287,456 acres of BLM lands would be available for locatable mineral entry and consideration or other mineral disposals. Energy and minerals permits would allow for development of the mineral resources to provide for the resource needs of society. Additional lands would be available from core areas of state wildlife management areas for oil and gas leasing compared to Alternative A.

Approximately 623,420 acres would be available for fluid mineral leasing under Alternative B. Four percent (approximately 28,774 acres) of BLM-administered federal mineral estate lands would not be available for oil and gas leasing (Table 4-26) including WSAs. The remainder of federal mineral estate lands in the Planning Area would be available for leasing, subject to the stipulations specified in Chapter 2 or to Standard Lease Terms.

Table 4-27 displays acres affected by no surface occupancy, timing limitations, and controlled surface use oil and gas stipulations. Additional lands would be available from core areas of state wildlife management areas (about 20,200 acres) for oil and gas leasing compared to Alternative A. The effects would be similar to Alternative A with respect to overall percent of acres available for leasing, 92 percent for Alternative A, and 94 percent for Alternative B.

Classification	Acres
No Surface Occupancy <sup>1</sup>	280,312
Timing Limitations <sup>1</sup>	286,800
Controlled Surface Use <sup>1</sup>	38,365
Standard Lease Terms <sup>1</sup>	17,943
<b>Acres Available for Oil and Gas Leasing</b>	<b>623,420</b>
Non-discretionary (unavailable)	28,774
Discretionary (unavailable)	0
<b>Acres Unavailable for Oil and Gas Leasing</b>	<b>28,774</b>

<sup>1</sup> Acres by stipulation subcategory were calculated such that the subcategories add up to the total available acres for leasing based on the following general concepts where multiple stipulations overlapped: No Surface Occupancy stipulations override and are more restrictive than Timing Limitations, Controlled Surface Use, and Standard Lease Terms. Timing Limitation stipulations override and are more restrictive than Controlled Surface Use and Standard Lease Terms. Controlled Surface Use stipulations override and are more restrictive than Standard Lease Terms. Non-overlapping individual stipulation-specific acreages are displayed by alternative in Tables 4-23, 4-27, 4-30, and 4-33.

Type of Stipulation	Stipulation	Development Potential			Total Acres Stipulated <sup>1</sup>
		Moderate	Low	Very Low	
<b>No Surface Occupancy</b>					
Bald Eagle Nest Sites	NSO ½	1,089	1,068	419	2,576
Bighorn Sheep Core Areas	NSO	24,012	13,781	32,822	70,615

<b>Controlled Surface Use</b>					
<i>Controlled Surface Use stipulations for TES Species, Cultural and Paleontological Resource Inventory, and Special Status Plant Habitats would apply across the entire Decision Area so acreages were not calculated separately.</i>					
Soils are either areas of mass wasting, unstable land areas; Non-Boulder Batholith with Slopes >30%; or Boulder Batholith with slopes >20%	CSU	40,927	78,990	129,220	249,137
Special Recreation Management Areas	CSU	15,965	47,439	34,657	98,061
VRM Class II, III & IV Areas	CSU	65,962	77,938	104,949	248,849

<sup>1</sup>Total acres affected by each stipulation are based on individual, independent, stipulation-specific GIS mapping and have not been overlapped with any other stipulations. Figures are provided here to display which stipulations for which resources are relatively dominant in the Decision Area.

<sup>2</sup>Total values of “0” indicate that there are currently no known sites or acres associated with this particular resource. Stipulation would apply to any newly detected sites or acres in the future.

### ***Leasable Minerals***

The timing limitation stipulation for sage grouse breeding habitats would be applied to 2,751 acres of the Decision Area, with limitations on surface access restricted seasonally for geophysical, drilling, and field develop-

ment activities from March 1 to June 30 added to the total acres affected by Alternative B compared to Alternative A.

An analysis of the five areas in the Planning Area considered to be the most prospective for oil and gas explora-

tion and development was completed for Alternative B. Under this alternative, approximately six percent of these areas would not be available for oil and gas leasing. Approximately 35 percent of the areas would be subject to leasing, subject to major constraints (no surface occupancy). Approximately 55 percent could be leased, subject to moderate constraints. Approximately 1.4 percent could be leased, subject to standard terms and conditions. Alternative B is similar in its level of constraints to Alternative A (Table 4-28).

Classification	Acres
No Lease	9,821
No Surface Occupancy	41,115
Timing Limitation	59,498
Controlled Surface Use	4,182
Standard Lease Terms	1,678
<b>Total Available for Oil and Gas Leasing</b>	<b>106,474</b>

**Locatable Minerals**

Approximately 198 acres would be recommended for withdrawal from mineral entry in developed recreation sites. These acres would not be open to future mineral entry.

Under Alternative B, 287,431 acres of federal surface/minerals would remain open to mineral entry and consideration for salable mineral disposals. A total of 47,081 acres of moderate and high potential would be restricted (Table 4-25). Alternative B would have more impact on access to mineralized areas than Alternatives A and D, but less than Alternative C. Impacts to areas with low mineral potential would not be substantial to mineral production.

**Effects of Alternative C**

**Energy and Minerals**

Like in Alternative B, approximately 287,258 acres of BLM lands would be available for locatable mineral entry and consideration for other mineral disposals under Alternative C. Approximately 56,982 acres of high and medium potential would be restricted under this alternative (Table 4-25).

Alternative C could result in additional expenditures for the mineral developer and, in some cases, could affect the ability to proceed with a project should access to water or the streambed be a critical part of the proposed operations. Existing roads and facilities would be closed and the landscape and rehabilitated when no longer required for mineral or land management activities.

**Leasable Minerals**

Under Alternative C, 89 percent (580,382 acres) of the Decision Area would not be available for oil and gas leasing (Table 4-29).

Classification	Acres
No Surface Occupancy <sup>1</sup>	23,903
Timing Limitations <sup>1</sup>	0
Controlled Surface Use <sup>1</sup>	30,893
Standard Lease Terms <sup>1</sup>	17,016
<b>Acres Available for Oil and Gas Leasing</b>	<b>71,812</b>
Non-discretionary (unavailable)	28,774
Discretionary (unavailable)	551,608
<b>Acres Unavailable for Oil and Gas Leasing</b>	<b>580,382</b>

<sup>1</sup>Acres by stipulation subcategory were calculated such that the subcategories add up to the total available acres for leasing based on the following general concepts where multiple stipulations overlapped: No Surface Occupancy stipulations override and are more restrictive than Timing Limitations, Controlled Surface Use, and Standard Lease Terms. Timing Limitation stipulations override and are more restrictive than Controlled Surface Use and Standard Lease Terms. Controlled Surface Use stipulations override and are more restrictive than Standard Lease Terms. Non-overlapping individual stipulation-specific acreages are displayed by alternative in Tables 4-23, 4-27, 4-30, and 4-33.

This includes the Wilderness Study Areas identified in Alternative B, plus lands in these additional locations:

- Prairie Dog Towns
- Sage Grouse Winter/Spring Range
- Lands within 0.5 miles of Sage Grouse Strutting Grounds (leks)
- State Wildlife Management Areas
- Big Game Winter/Spring Range Elk Calving/Big Game Birthing Areas
- Bighorn Sheep Yearlong habitat
- Lands within 1 mile of Bald Eagle Nesting/Breeding areas
- Lands within 0.5 mile of Raptor Breeding Areas
- Lands within 1 mile of peregrine falcon breeding territories
- Lands within 0.5 mile of Raptor Breeding Areas
- Lands within 1 mile of peregrine falcon breeding territories
- Lands within 0.5 mile of ferruginous hawk breeding territories

- Lands within 1 mile of 99 to 100 percent pure west-slope cutthroat trout habitats
- Yellowstone Cutthroat Habitat
- Municipal Watersheds
- Lands recently acquired with LWCF funds.

The remainder of mineral estate in the Planning Area (71,812 acres) would be available for leasing, subject to the stipulations specified in Chapter 2 or to Standard Lease Terms.

**Table 4-30** displays acres affected by no surface occupancy, timing limitations, and controlled surface use oil and gas stipulations. Alternative C would eliminate most of the Decision Area for oil and gas leasing activity, deny access for oil and gas exploration on most Decision Area lands, and greatly reduce the area available for the potential discovery and development of new oil and gas resources.

Type of Stipulation	Stipulation	Development Potential			Total Acres Stipulated <sup>1</sup>
		Moderate	Low	Very Low	
<b>No Surface Occupancy</b>					
Bull Trout Habitat	NSO 1	414	3,641	5,121	9,175

<b>Timing Limitations</b>					
Ferruginous Hawk Breeding Territories <sup>2</sup>	NL ½ + TL 3/1-8/31 1	0	0	0	0
<b>Controlled Surface Use</b>					
<i>Controlled Surface Use stipulations for TES Species, Cultural and Paleontological Resource Inventory, and Special Status Plant Habitats would apply across the entire Decision Area so acreages were not calculated separately.</i>					
Soils are either areas of mass wasting, unstable land areas; Non-Boulder Batholith with Slopes >30%; or Boulder Batholith with slopes >20%	CSU	40,927	78,990	129,220	249,137
VRM Class II, III & IV Areas	CSU	63,231	77,938	104,949	246,118

<sup>1</sup>Total acres affected by each stipulation are based on individual, independent, stipulation-specific GIS mapping and have not been overlapped with any other stipulations. Figures are provided here to display which stipulations for which resources are relatively dominant in the Decision Area.

<sup>2</sup>Total values of “0” indicate that there are currently no known sites or acres associated with this particular resource. Stipulation would apply to any newly detected sites or acres.

An analysis of the five areas in the Planning Area considered to be the most prospective for oil and gas exploration and development was completed for Alternative C. Under this alternative approximately 93 percent of these areas would not be available oil and gas leasing (**Table 4-31**).

<b>Classification</b>	<b>Acres</b>
No Lease	<b>108,784</b>
No Surface Occupancy	<b>2,185</b>
Timing Limitation	<b>0</b>
Controlled Surface Use	<b>3,898</b>
Standard Lease Terms	<b>1,428</b>
<b>Total Available for Oil and Gas Leasing</b>	<b>7,511</b>

Approximately two percent of the areas would be leasable, subject to major constraints (no surface occupancy). Approximately three percent would be leased subject to moderate constraints. Approximately two percent would be leased subject to standard terms and conditions. Based on this level of constraints it can be assumed that it is not reasonable to foresee any federal oil and gas development under this alternative.

### ***Locatable Minerals***

Effects to area availability for locatable mineral operations would be slightly greater than under Alternative B, with an additional 9,901 acres of high and medium potential lands being restricted. Impacts to areas with low mineral potential would not be substantial to mineral production.

### ***Salable Minerals***

The BLM would not allow the purchase of salable minerals (common varieties of sand, stone, gravel, pumice, cinders, clay and petrified wood), unless desired by the state or counties, or within existing community pits.

Alternative C would have the same effects on mining as Alternative A; however, Alternative C would eliminate private citizens and municipal applications for new sites because county and state governments would be the agencies that have to initiate the request. Private citizens and municipalities would have to purchase their mineral materials from commercial sources and pay higher costs for transportation.

## **Effects of Alternative D**

### ***Energy and Minerals***

Like in Alternative A, approximately 287,456 acres of BLM lands would be available for locatable mineral entry and consideration for other mineral disposals (**Table 4-25**).

Roads could be built in riparian areas, however, avoidance, mitigations, and BMPs would result in effects being the same as Alternatives A and B. Roads and facilities no longer required for mineral, or land management activities would be reclaimed to the extent possible.

### ***Leasable Minerals***

Under Alternative D approximately 615,788 acres would be available for fluid mineral leasing. Six percent (36,406 acres) of federal mineral estate lands would not be available for oil and gas leasing, including the Wilderness Study Areas and lands recently acquired with LWCF funds (**Table 4-32**).

<b>Classification</b>	<b>Acres</b>
No Surface Occupancy <sup>1</sup>	93,288
Timing Limitations <sup>1</sup>	436,410
Controlled Surface Use <sup>1</sup>	32,011
Standard Lease Terms <sup>1</sup>	54,079
Acres Available for Oil and Gas Leasing	615,788
Non-discretionary (unavailable)	28,774
Discretionary (unavailable)	7,632
<b>Acres Unavailable for Oil and Gas Leasing</b>	<b>36,406</b>

<sup>1</sup>Acres by stipulation subcategory were calculated such that the subcategories add up to the total available acres for leasing based on the following general concepts where multiple stipulations overlapped: No Surface Occupancy stipulations override and are more restrictive than Timing Limitations, Controlled Surface Use, and Standard Lease Terms. Timing Limitation stipulations override and are more restrictive than Controlled Surface Use and Standard Lease Terms. Controlled Surface Use stipulations override and are more restrictive than Standard Lease Terms. Non-overlapping individual stipulation-specific acreages are displayed by alternative in Tables 4-23, 4-27, 4-30, and 4-33.

The remainder of mineral estate in the Decision Area would be available for leasing, subject to the stipulations specified in Chapter 2 or to Standard Lease Terms.

Effects would be similar to Alternative B with respect to overall acres of BLM administered land available for leasing and not available for leasing (compare **Table 4-26** and **Table 4-33**). However, Alternative D would apply the same stipulations to different acres. For example, there are fewer acres of land under No Surface Occupancy and Controlled Surface Use stipulations and a much larger number of acres under Timing Limitations and Standard Lease Terms stipulations under Alternative D, than Alternative A (**Table 4-22** and **Table 4-33**). As a result Alternative D would be less stringent in the application of stipulations for leasing of essentially the same amount of land as Alternative A. The amount of

actual land disturbance from these less stringent leasing stipulations should be relatively minor because the amount of drilling would be driven by exploration potential, which is generally low throughout federal mineral estate lands.

**Table 4-33** displays acres affected by no surface occupancy, timing limitations, and controlled surface use oil and gas stipulations under Alternative D.

Type of Stipulation	Stipulation	Development Potential			Total Acres Stipulated <sup>1</sup>
		Moderate	Low	Very Low	
<b>No Surface Occupancy</b>					
Bald Eagle Nest Sites	NSO ½	1,089	1,068	419	2,576

Grizzly Bear – Denning Habitat (Distribution Zone)	CSU	34	29,008	24,905	53,947
Grizzly Bear – Recovery Zone	CSU	0	1,651	5,731	7,382
Fluvial/Adfluvial Arctic Grayling Habitat	CSU ½	390	20,944	6,068	27,401
Municipal Watersheds	CSU	13,083	86,169	47,224	146,477
Westslope Cutthroat Trout Habitat (90-99% pure)	CSU ½	0	255	1,939	2,194
Yellowstone Cutthroat Trout Habitat	CSU ½	599	5,050	1,462	7,111

<sup>1</sup>Total acres affected by each stipulation are based on individual, independent, stipulation-specific GIS mapping and have not been overlapped with any other stipulations. Figures are provided here to display which stipulations for which resources are relatively dominant in the Decision Area.

<sup>2</sup>Total values of “0” indicate that there are currently no known sites or acres associated with this particular resource. Stipulation would apply to any newly detected sites or acres.

An analysis of the five areas in the Planning Area considered to be the most prospective for oil and gas exploration and development was completed for Alternative D. Under this alternative approximately eight percent of federal mineral estate in these areas would not be available for oil and gas leasing. Approximately seven percent of the areas would be subject to leasing subject to major constraints (no surface occupancy). Approximately 87 percent would be leased subject to moderate constraints. Approximately five percent would be leased subject to standard terms and conditions. Based on this analysis Alternative D would be the least restrictive of the four alternatives for oil and gas development (Table 4-34).

<b>Classification</b>	<b>Acres</b>
No Lease	9,821
No Surface Occupancy	7,981
Timing Limitation	86,286
Controlled Surface Use	6,235
Standard Lease Terms	5,972
<b>Total Available for Oil and Gas Leasing</b>	<b>106,474</b>

### ***Locatable Minerals***

Effects on lands available for locatable mineral entry would be largely the same as Alternatives B and C. Alternative D has less of an impact than Alternatives B and C and more of an impact on access to mineralized areas than Alternative A (Table 4-25).

### ***Salable Minerals***

Effects from mining would be the same as Alternative A. Although mitigations for natural resources are not specifically stated in Alternative D, the BLM would apply mitigations, BMPs, and other restrictions on quarrying operations and plans for ultimate reclamation and closure to minimize the impacts on natural resources.

## **RECREATION**

### **Effects Common to All Alternatives**

Vegetative treatments would potentially affect Recreation Opportunity Spectrum (ROS) classes, natural settings, and user experience levels due to changes in apparent naturalness, screening quality and user distribution patterns, and social conflicts.

Prescribed burning could occur more frequently in the Special Recreation Management Areas (SRMAs) outside of the urban interface, which could negatively alter the recreation experiences due to smoke and poor air quality. These impacts would be temporary and could be

mitigated or minimized with respect to timing, location, and methods used. Reducing the potential for future large-scale wildland fires would benefit recreation opportunities and experience levels over the long-term.

Managing riparian areas to restore and improve natural functioning conditions would benefit recreation users seeking opportunities for scenic viewing, fishing, bird-watching, hunting, and hiking. Development of new recreation sites and expansion of existing recreation facilities would need to minimize adverse impacts to riparian areas, which could limit site development opportunities and access concentration points to dispersed recreation use areas.

Allowing no new grazing permits on river islands would result in an improvement in water-based recreation experiences for boaters, anglers, nature observers, picnickers, and tent campers in these areas. Managing livestock numbers and practices in a manner that is responsive to all resource needs, combined with interdisciplinary reviews will maintain or enhance recreation experiences over the long-term.

Habitat improvement projects for special status and priority species would have an impact on recreation uses, especially those seeking opportunities for wildlife viewing and hunting. Creating blocks of hiding and security for elk could improve the number of elk and other big game for viewing and hunting.

Minimizing human activities that disrupt habitat during sensitive seasons (breeding periods or during winter) would limit the time and type of recreation uses and travel within these sensitive areas.

Recreation restrictions for aquatic habitat protection may impact water-based recreation and shoreline uses during months of breeding or migrating. Management to enhance or rehabilitate aquatic and riparian habitat would positively impact the angling recreation use in areas where there are nationally recognized sport fishing opportunities, such as the Madison, Big Hole, Jefferson, Missouri, and Yellowstone Rivers.

Developing comprehensive and collaborative travel management plans throughout the Decision Area that are responsive to environmental values and social needs would have varying effects on motorized and non-motorized recreation users. Although the limited travel designation restricts all motorized public travel to designated routes, variances for appropriate uses would be considered and the 300-foot rule exception for dispersed camping, firewood gathering, and game retrieval varies among the 13 Travel Planning Areas in the Decision Area. The 300-foot rule allows dispersed camping in the nine areas where travel plans have not been completed and as per indicated in previously completed site-specific travel plans. Although this rule limits opportunities for recreational firewood gathering and impacts game retrieval, it would enhance ROS classes, travel management, and non-motorized experiences. The 300-

foot rule exception for dispersed camping would allow greater opportunities for motorized camping in primarily rural or motorized semi-primitive recreation settings. The transportation system would continue to provide access to a variety of recreation opportunities and experiences. Conducting scheduled recreation site and route condition assessments and maintaining these facilities in accordance with BLM standards would promote public safety, and enhance recreation opportunities and visitor expectations.

All existing recreation sites would continue to be managed for public use and enjoyment. The more developed fee sites where visitation is highest would be given priority for funding to ensure that user expectations are met.

Limiting camping stays to 7 days at recreation sites in areas regularly exceeding capacities during fee-use seasons would allow more equitable opportunities for visitors to obtain and enjoy a camping site.

Management of special recreation use permits for commercial, competitive, and special events would continue to be considered on a case-by-case basis with priority given to existing permittees as new permits would not be issued that conflict with existing permit uses.

The recreational management emphases would be prioritized within designated Special Recreation Management Areas to ensure quality recreation opportunities and experiences are provided. Intensive management in these priority areas would be dedicated to providing quality settings and experiences for recreation opportunities in response to identified market demands.

Management of the six WSAs would continue to provide primitive and unconfined recreation opportunities and solitude experiences in a natural setting. If Congress releases a WSA from further consideration, then the resource protection under the IMP guidelines would not continue and these areas would be managed as specified under each alternative. The Sleeping Giant WSA and the Sheep Creek WSA would be protected as ACECs under each alternative.

BLM would continue to manage recreational resources in a cooperative manner with other agencies, which would promote comprehensive management for a wide diversity of both water and land based opportunities in the Decision Area.

Proposed VRM management would continue to provide for mitigating visual disturbances. This would have a positive impact on recreation resources and experiences by creating a landscape compatible with the recreation settings and SRMA management.

The Sleeping Giant ACEC is the only area that would be managed as an ACEC under all alternatives. Management actions would continue to preserve a natural setting for recreation uses within Sleeping Giant. This management would benefit solitude experiences and opportuni-

ties for non-motorized and unconfined forms of recreation.

Motorized recreation uses could be temporarily, seasonally, or permanently restricted in areas with significant soil erosion or soil compaction. This could reduce motorized recreation opportunities to a minor degree on a case-by-case basis.

Management actions to enhance access to BLM lands would positively affect recreation users, because the public would have additional opportunities to enjoy recreation activities on public land.

Solid and fluid mineral actions (road building, exploration, excavation/extraction, and removal) could impact recreation uses due to associated noise, smoke and visible human disturbances. Project-level environmental analyses would consider and mitigate these impacts on recreation use before authorizations are granted.

## Effects of Alternative A

Vegetative treatments for grasslands (up to 5,250 acres/decade), forest types (up 7,500 acres/decade) and forest product sales (up to 27 MMBF/decade) would create the second lowest potential of all alternatives for impacts on recreation settings and dispersed recreation uses due to associated disturbances.

Riparian actions would impact dispersed recreation experiences the most and developed site management the least, given that riparian management measures would be less restrictive than with Alternatives B and C.

Assuming implementation of the high end of the proposed ranges of noxious weed treatment acres under the action alternatives, proposed noxious weed treatments under Alternative A (up to 20,000 acres/decade) would be the lowest of all alternatives and therefore impacts on recreationists seeking natural settings could be affected by this alternative the most.

Road management would generally allow existing roads to remain open for public use. This would benefit motorized vehicle users and potentially impact non-motorized recreationists to the greatest degree.

Recreationists seeking organized, motorized events would be affected the least under this alternative since 10 of the 13 Travel Planning Areas would remain available for consideration. Snowmobilers would continue to have the greatest opportunities under this alternative since fewer restrictions would be imposed as 143,206 acres would remain open to cross-country use, and 137,038 acres would be available but limited to established routes.

Motorized opportunities for wheeled vehicle travel would also be the greatest under this alternative as 4,367 acres would be open to cross-country travel and approximately 684 miles of routes (roads and trails) would be available (yearlong or seasonally). Conversely, oppor-

tunities for non-motorized recreationists to enjoy areas free of the sights and sounds of motorized activities would be affected the most.

No outfitter and guide fees would be charged for the commercial fishing and floating use of BLM river and lake access sites. Extensions to the 14-day camping limit would continue to be considered for hunters and other users subject to stipulations. Outfitter and guide permit issuance would continue to be considered for both day-use and overnight camping.

This alternative does not allocate ROS classifications. As a result, no ROS allocation system would be established to help recreation managers communicate and provide appropriate settings for a diverse range of opportunities and experiences. Recreation use could be negatively affected as recreation opportunities would continue to be managed in a manner that is reactive rather than proactive. Planning efforts, recreation opportunities, and management would continue to be prioritized primarily within the five SRMAs. The SRMAs represent over 66,000 acres with recreation management focus, which is more than in Alternative D, but less than in Alternatives B and C (Table 4-35).

Motorized and non-motorized recreational uses would continue to be allowed 24 hours a day in the Scratchgravel Hills area. With no change in management, the impacts of this action would be continued violations of

travel management restrictions, social conflicts, human caused fires, and illegal activities.

All six WSAs would continue to be managed as WSAs, which would result in no change to the availability of primitive recreation opportunities and experiences provided in WSAs.

Although the Wild and Scenic River suitability study for the four eligible rivers would not be completed, the recreation values associated with these segments would be protected under WSR interim management.

Approximately 56,900 acres would be managed as VRM Class I and II areas and therefore recreation settings governed by these classes would remain primarily natural in character. This alternative would protect the second lowest acreage under these classes compared to other alternatives and includes WSAs and major river frontage lands.

Recreation sites would not be recommended for withdrawal from mineral entry and therefore these sites and the visitor experiences associated with them could be affected by mineral related activities.

This alternative imposes the second lowest amount of restrictive stipulations on solid and fluid mineral activities and therefore related impacts would have a relatively high probability for affecting recreation settings and visitor experiences.

Name	SRMAs Included in the Alternative = X			
	A	B	C	D
Hauser Lake		X	X	X
Lower Holter Lake/Missouri River		X	X	X
Holter Lake/Sleeping Giant <sup>1</sup>	X			
Humbug Spires	X	X	X

Sheep Mountain		X	X	X
Sleeping Giant/Missouri River		X	X	
Uppermost Missouri River		X	X	X
Upper Big Hole River	X	X	X	X

Source: BLM Butte Field Office, RMP Alternatives Description, 2005.

<sup>1</sup> The action alternatives split this SRMA into Holter Lake/ Missouri River and Sleeping Giant SRMA.

## Effects Common to Action Alternatives

All action alternatives would establish ROS classifications (**Appendix H, Table 4-36**) which would facilitate management of desired recreation opportunities, experience levels, facility developments, and other resource uses.

The majority of the potential SRMAs would target the Community Recreation Tourism Market (RTM). This emphasis would impact recreation management in that a marketing focus would be adopted. This emphasis would be to attract and provide opportunities/services for visitors from nearby communities or from communities dependant on recreation-based tourism.

Upper Big Hole River SRMA would be managed as a Destination RTM and would attract national or regional recreation-tourism visitors and others who value public lands as recreation-tourism destinations.

SRMAs managed for Undeveloped RTM would be Sleeping Giant/Missouri River and Humbug Spires. This management emphasis would attract national, regional, or local visitors who value public lands for the distinctive kinds of dispersed recreation produced by the vast size and largely open, undeveloped character of the recreation setting.

Providing forested, security cover (250-acre, minimum blocks) for big-game would benefit non-motorized recreation uses compared to Alternative A.

Monitoring roads during hunting season could reduce the number of violations and misdeeds, and therefore provide a more enjoyable recreation experience for visitors.

Semi-primitive non-motorized would be the primary ROS classification on BLM lands in the Sleeping Giant/Missouri River (ACEC and eligible WSR portions), Humbug Spires, and Sheep Mountain (northern portion) potential SRMAs. The semi-primitive motorized ROS class would be emphasized in the Sleeping Giant (outside the ACEC). The remaining potential SRMAs would emphasize either the roaded natural or rural ROS class, where human influences are noticeable and interaction with others is typical.

Establishing specific guidance for managing designated boat-in camp sites along the shoreline of Holter Lake and Hauser Lake shoreline (if needed) would address the relationship between resource impact concerns and boat-in dispersed camping opportunities.

Issuing fees through recreation permits to commercial fishing and floating outfitters using developed sites to access state waterways could increase client fees and possibly deter some outfitters from providing fishing and floating experiences to visitors on some water segments.

Additional mitigations on new special recreation permits would potentially affect new permittees more than in Alternative A.

Extending commercial outfitting permits from 5 to 10 years for permittees that demonstrate satisfactory performance standards would improve management efficiency and potentially act as an incentive that could improve outfitter performance standards.

BLM would coordinate with MFWP to manage appropriate uses at BLM launch sites as necessary to ensure quality recreation opportunities and reduce social conflicts on streams and lakes.

Given budgetary constraints, new sites that have partnership support would be given first priority for development. This policy would minimize funding shortfalls at existing sites where investments and traditional uses are established.

Subjecting recreation sites to Land Health Standards could increase mitigation costs at existing sites and potentially limit opportunities for new sites. Conversely, this stipulation would enhance the natural setting of recreation sites as well as associated visitor experiences.

Implementing management guidance for SRMAs and Recreation Management Zones would enhance targeted opportunities, visitor experiences, appropriate facility levels, and settings. Implementing land management consistent with surrounding lands and prescriptions would protect WSA values if released from further consideration as wilderness.

Sleeping Giant, Sheep Creek, Humbug Spires, and Elkhorns Tack-on WSAs would be managed as ACECs

ROS Class	Alt A	Alt B		Alt C		Alt D	
		Acres	% of DA	Acres	% of DA	Acres	% of DA
Semi-primitive Non-motorized	NA	36,800	12%	63,700	21%	30,000	10%
Semi-primitive Motorized	NA	71,800	23%	66,900	22%	37,600	12%
Roaded Natural	NA	171,100	56%	158,100	51%	186,100	61%
Roaded Modified	NA	16,600	5%	15,900	5%	19,600	6%
Rural	NA	11,000	4%	2,700	1%	34,000	11%

Source: BLM Butte Field Office, GIS data, 2005.

which would promote administrative protection of the existing recreation values and opportunities. These areas would continue to offer natural settings and user experiences subject to fewer restrictions governing mineral activities if Congress should remove them from further wilderness consideration.

The action alternatives would require that the two National Trails be managed to consider the adopted ROS classification, VRM classes, travel plans, and oil and gas stipulations. Re-routing the Continental Divide Trail would increase the recreation opportunities for the non-motorized user because the trail segment would traverse through more natural settings and less privately owned property. Recreation experiences for the non-motorized users would improve because the re-route would be closed to motorized uses, which would reduce user conflicts.

ACEC designations for Sleeping Giant (11,679 acres), Humbug Spires (8,400 acres), and the Elkhorns Tack-on (3,575 acres) would continue to be managed for semi-primitive, non-motorized recreation opportunities.

Retaining 298,408 acres in BLM ownership and establishing a high priority for land acquisitions to enhance special management designations and recreation sites would benefit long-term recreation opportunities especially, for non-motorized users.

Managing mineral activities to meet Land Health Standards would benefit natural settings and associated recreation experiences. Providing accessibility to mineralized areas for exploration and development would impact the naturalness of ROS classes and the recreation experiences associated with them. The restoration of abandoned mine lands and hazardous material areas would enhance public safety, ROS classes, and the quality of opportunities across BLM lands.

## Effects of Alternative B

Proposed vegetative treatments for grasslands (up to 11,800 acres/decade), shrublands (up to 3,650 acres/decade), forest types (up 18,500 acres/decade) and forest product sales (up to 25 MMBF/decade), although mitigated, would create the second highest potential for impacts on dispersed recreation uses due to associated disturbances. The construction of new permanent roads, although minimized due to resource and travel planning constraints, could impact ROS classes while enhancing motorized travel and access opportunities.

Actions to restore riparian areas would improve dispersed recreation experiences and could affect developed site management the second most of all alternatives, given that Riparian Management Zones would be larger than in either Alternative A or D.

Proposed noxious weed treatments (up to 50,000 acres/decade) would be the second highest and therefore recreationists seeking natural setting experiences could

be benefited to the second greatest extent of all alternatives.

Restrictions on prescribed burning would coincide with the peak recreation use season. Although these actions would create some short and mid-term impacts on ROS, long-term benefits should be realized due to a lower likelihood for large scale fire events.

Under Alternative B, where road densities exceed 1 mi/mi<sup>2</sup> in big game winter range and calving areas, there would be no net increase in permanent roads. This prescription would affect motorized users the second most of the action alternatives (more than Alternative D but less than Alternative C), primarily in the four pending travel plan areas for which site-specific travel planning would be done after finalization of this RMP (Missouri Foothills, Broadwater, Jefferson and Park/Gallatin).

Recreationists seeking organized, motorized events would be affected the second most under this alternative as only the Pipestone area would be considered for competitive as well as non-competitive events.

Snowmobile riding opportunities would be reduced to the second greatest extent of the alternatives as 112,682 acres would be open to cross-country use and on 139,921 acres use would be limited to established routes.

Implementing a flat annual Special Recreation Use Permit fee with the long-term goal of developing a coordinated, interagency fee system with MFWP and other agencies would promote fair value revenues from outfitters using waterway access sites for commercial fishing and floating. This alternative would be more efficient than Alternative C for both the customer as well as BLM since there would be less required paperwork and the annual fee would cover all access sites. Preference for granting extensions to the 14-day camping limit during the hunting season would focus on developed recreation campgrounds after the high use fee season. This prescription would better protect resource values while camping opportunities (primarily for hunters) beyond 14 days would be reduced. Restricting special recreation permit camping authorizations during the hunting season to hardened campgrounds and not allowing such uses in developed recreation sites from Memorial to Labor Day weekends would reduce conflicts with public hunters and campers. Impacts to hunting outfitters would be minimal given that no camping permits exist and demands are negligible.

The effects of closing the Scratchgravel Hills area to motorized vehicle uses would reduce use violations, risks of human caused fires, conflicts with proximity residents and law enforcement incidents.

Limiting all BLM boat-in camping opportunities along Holter and Hauser Lake shorelines to designated sites would reduce the number of dispersed recreation sites available along the shoreline.

This alternative would allocate ROS classifications as follows: SPNM-36,800, SPM-71,800, RN-171,100, RM-16,600, and R-11,000. These designations represent a more evenly balanced approach for managing recreation settings, opportunities and experiences for a more diversified representation of settings and experiences as compared to Alternatives C and D. Opportunities for both motorized and non-motorized opportunities within the range of varying settings would be provided most evenly. Approximately 56 percent of the Decision Area would be in the roaded natural ROS (Table 4-36).

In addition to the Sleeping Giant area, a large portion of the Elkhorns, Humbug Spires, and Ringing Rocks would be designated as ACECs. ACEC designation would provide long-term protection of each area's ROS values and recreation opportunities. Alternative B provides the second greatest amount of protection associated with proposed ACEC designations of any of the alternatives.

Nine SRMAs totaling 78,700 acres would be designated for priority recreation management, four more than in Alternatives A and D (Table 4-35). These SRMAs include areas along major waterways (rivers and lakes), highly natural areas, and OHV riding areas where management demands are the greatest. Pipestone and Sheep Mountain would be newly managed as SRMAs. The majority of these areas would be managed as ROS-Roaded Natural (46 percent) and ROS-Semi-primitive Non-motorized (31 percent).

Recommending Muskrat Creek (2.6 miles) as suitable, and the Upper Missouri River (3.1 miles) as preliminarily suitable as National Wild and Scenic Rivers could provide long-term protection for the associated recreation values (natural viewing, hiking, fishing, and hunting) if designated by Congress. Conversely, no additional protection would be established for the recreation values associated with the Upper Big Hole River and Moose Creek segments since they would not be recommended in this alternative.

Across the Field Office, approximately 80,400 acres would be managed as VRM Class I and II areas and therefore recreation settings governed by these classes would be managed for natural character retention. The remaining 226,900 acres would be managed as VRM Class III and IV which would allow more landscape alterations such as roads which would increase motorized access and travel opportunities. This alternative would have the second highest acreage under Classes I and II and the second lowest acreage under Classes III and IV of all the alternatives.

Under Alternative B, 198 acres in eight recreation sites would be recommended for withdrawal from mineral entry. This would protect these recreation facility investments as well as site opportunities and experiences better than in Alternatives A and D, which propose no new withdrawals for developed recreation sites.

This alternative imposes the second highest amount of restrictive stipulations of all alternatives on solid and fluid mineral activities and therefore related impacts would have a lower probability for impacting recreation settings and visitor experiences than in Alternatives A and D.

## Effects of Alternative C

Proposed vegetative treatments for grasslands (up to 2,000 acres/decade), shrublands (up to 750 acres/decade), forest types (up to 8,500 acres per decade), and forest product sales (up to 12 MMBF/decade) would create the lowest potential for impacts on recreation settings and dispersed uses due to associated disturbances from these actions.

Unlike the other alternatives, Alternative C would prohibit new permanent roads associated with forest harvests and timber sales. This prescription would benefit natural recreation settings and limit additional access for motorized-based recreation activities.

Actions to restore riparian areas would improve dispersed recreation experiences and affect developed site management the most of any alternatives, given that Riparian Management Zones would be the most extensive of any alternative.

Impacts from the timing of prescribed fires would be the same as described for Alternative B.

Proposed noxious weed treatments (up to 38,000 acres/decade) would be the second lowest of any alternative and therefore recreationists seeking natural setting experiences would be potentially affected to the second greatest extent due to a relatively small amount of proposed treatments.

Under Alternative C, where road densities exceed 0.5 mi/mi<sup>2</sup> in big game winter range and calving areas, there would be no net increase in permanent roads. This prescription would impact motorized riders the most of all alternatives, primarily in the four pending travel plan areas for which site-specific travel plans would be developed after finalization of this RMP (Missouri Foothills, Broadwater, Jefferson, and Park/Gallatin).

Recreationists seeking organized, motorized events would be affected the most under this alternative since none of these activities would be authorized within the Decision Area. Under this alternative, conflicts with other motorized and non-motorized users would be reduced and groups seeking such events would need to find other non-BLM areas.

Snowmobile riding opportunities would be reduced to the greatest extent of all the alternatives. Designated open areas (to cross-country use) would be reduced to 26,148 acres; closed areas would be increased to 65,270 acres; and limited areas would be increased to 215,891 acres.

Implementing Special Recreation Use Permits and established fees would increase costs to outfitters using BLM sites to access state waterways the most of any of the alternatives. This prescription would displace some outfitter fishing and floating use to non-BLM site segments and it would not be as customer friendly as Alternative B or D due to the need for additional permits and actual use statements. In addition, BLM would incur higher management demands than from any other alternatives due to the large number of permits and required process procedures.

The effects of eliminating variances to the 14-day camping limit would best protect recreation settings while camping opportunities (primarily for hunters) beyond 14 days would be reduced the most compared to the other alternatives. Impacts of restricting commercial camping uses would be similar to Alternative B.

Although closing the entire Scratchgravel Hills area to both motorized and non-motorized recreational uses after dark (dusk to dawn) yearlong would best protect the area from violations, management and law enforcement demands would increase compared to Alternatives A, B, and D. Impacts on legitimate public users would be negligible as their use of the area after dark is minimal.

Closing the entire BLM shoreline on Holter and Hauser Lake to boat-in camping except at developed sites would eliminate opportunities for dispersed camping and best protect the natural conditions within these recreation settings.

This alternative maximizes the acreage designated under ROS as semi-primitive non-motorized at 63,700 acres which is about twice that of Alternatives B and D (Table 4-36). The effects of this increase would enhance opportunities for hiking, walk-in hunting, mountain biking, horseback riding and other forms of non-motorized uses. Conversely, motorized uses would be eliminated within these areas.

Alternative C would designate the same nine SRMAs as Alternative B (Table 4-35); however, most of the SRMAs would be within the semi-primitive, non-motorized ROS, 46 percent, with the roaded natural ROS encompassing approximately 31 percent (Table 4-36).

Recommending all four river segments (12 miles) as suitable National Wild and Scenic Rivers would provide the greatest long-term protection of any of the alternatives for the associated values if designated by Congress.

Alternative C would manage the most areas and acres under ACECs. Impacts on recreation from the Sleeping Giant and Humbug Spires ACECs would be the same as that described in "Effects Common to Action Alternatives". Impacts on recreation from the Ringing Rocks ACEC would be the same as that described for Alternative B.

Management of the Elkhorn ACEC and the addition of Spokane Creek (14 acres) would have similar impacts on recreation uses as described for Alternative B, except Alternative C would emphasize more opportunities for non-motorized recreation.

At the Field Office scale, this alternative would designate 99,100 acres under VRM Class I and II areas. The natural character of the recreation settings within these classes would be best protected from disturbances than in any other alternative. The remaining 208,200 acres would be managed as VRM Class III and IV which would allow more landscape alterations such as roads and would increase motorized access and travel opportunities. This alternative has the highest acreage under Classes I and II and the lowest acreage under Classes III and IV of all alternatives.

As with Alternative B, recommending 198 acres in eight recreation sites for withdrawal from mineral entry would protect these recreation facility investments as well as site opportunities and experiences better than in Alternatives A and D that do not propose these withdrawals.

This alternative would impose the highest amount of restrictive stipulations on solid and fluid mineral activities of all alternatives and therefore related activities would have a lower probability for impacting recreation settings and visitor experiences than with any other alternative.

## Effects of Alternative D

Proposed vegetative treatments for grasslands (up to 3,500 acres/decade), shrublands (up to 6,800 acres/decade), forest types (up to 23,250 acres/decade) and forest product sales (up to 30 MMBF/decade) would create the highest potential of any alternative for impacts on recreation settings and dispersed uses due to associated disturbances from these actions.

Effects of riparian, forest product roads and re-issuance of grazing permit actions would be similar to Alternative A.

Proposed noxious weed treatments (up to 61,000 acres/decade) would be the highest of any alternative and therefore impacts on recreationists seeking natural setting with fewer invasive weeds could be benefited by this alternative the most.

Under Alternative D, where road densities exceed 1.5 mi/mi<sup>2</sup> in big game winter range and calving areas, there would be no net increase in permanent roads. This prescription would have the second lowest impacts on motorized riders in the four pending travel plan areas for which site-specific travel plans would be developed after finalization of this RMP (Missouri Foothills, Broadwater, Jefferson, and Park/Gallatin) since road densities would be more restrictive under Alternatives B and C.

Groups seeking organized motorized activities would be affected less than under Alternative C as the Pipestone

Area would remain available for **competitive and** non-competitive, motorized events. Areas open to snowmobiles and effects on users would be similar to Alternative B.

Special recreation use permits would not be required for commercial fishing and floating outfitters that use BLM river and lake access sites, until a multi-agency state-wide fee system is established. Of all alternatives, Alternative D would be the most customer-friendly and management-efficient method of obtaining fair value returns from commercial users should the state and other agencies decide to participate.

The effects of managing variances to the 14-day camping limit; access within the Scratchgravel Hills; commercial camping permits; and boat-in camping along Hauser and Holter Lakes would be the same as with Alternative A as no changes in current management would occur in Alternative D.

With regard to ROS designations, Alternative D would be similar to Alternative A in that about 90 percent of the total Decision Area would be managed under ROS designations that allow motorized activity (**Table 4-36**).

Planning efforts, recreation opportunities, and management would continue to be prioritized within five SRMAs, as in Alternative A (**Table 4-35**). These SRMAs represent the highest visitor use areas where facility infrastructure and improvements are the greatest.

None of the four eligible river segments would be recommended as suitable for National Wild and Scenic River designation by Congress. Consequently, the ROS and primitive forms of recreation would be subjected to additional resource uses and associated impacts.

Impacts on recreation from management of the Humbug Spires and Sleeping Giant ACECs would be the same as described in Alternative B. The Elkhorns ACEC would be limited to the existing WSA boundary, about 3,575 acres. This designation would ensure that semi-primitive non-motorized recreation opportunities would continue to be provided and emphasized, if the WSA were to be removed from Congressional wilderness consideration. Not designating Spokane Creek and Ringing Rocks could potentially subject these natural settings to increased impacts associated with other resource uses.

This alternative would be the least protective of recreational opportunities and experiences that are dependent on high quality visual resources since the lowest acreage (**38,100** acres) would be managed as VRM Classes I and II.

Mineral entry withdrawal recommendations and their effects would be the same as Alternative A.

This alternative imposes the lowest amount of restrictive stipulations on solid and fluid mineral activities of the action alternatives and therefore related impacts would

have a higher probability for affecting recreation settings and visitor experiences than Alternative B or C.

## TRAVEL MANAGEMENT AND ACCESS

### Effects Common to All Alternatives

#### *Travel Management – Field Office Level*

Restrictions on surface-disturbing activities associated with recreation management, special designations, vegetation management, water quality, watershed and soils management, and wildlife and fisheries management could modify the locations and routes of proposed roads and road realignments.

Access developed for mineral extraction and timber harvesting could enhance travel and access opportunities. Restrictions on road development in areas with important resource values could limit the degree of increased access and travel opportunities.

Vegetation management could affect transportation by providing more roads that could be considered for designation under the travel management system. Additionally, during an active vegetation project, temporary closure of existing roads could be required for safety reasons. The potential for, and degree of these impacts would depend largely on the acres treated and miles affected.

Enhancing and protecting riparian and wetland vegetation could directly affect travel management through the temporary or permanent closure of roads and trails. Effects would be short or long-term, depending on temporary or permanent restrictions. Closures for resource protection could result in an overall net decrease of available routes in the Decision Area. Activities within riparian areas to maintain and restore riparian habitat could lead to roads and trails being relocated outside of riparian areas.

Route restrictions and closures could occur during wildland fire management activities, directly affecting travel management. Short-term effects could include an increase of fire management equipment traffic on BLM-administered routes, and an increase of motorized vehicle traffic on routes that remain accessible until fire management activities stop. Managing invasive species and noxious weeds could potentially cause short-term impacts on travel by temporarily displacing users from closed or restricted treatment areas.

Implementing recovery programs, mitigation activities, or projects to avoid impacts or to enhance riparian and wetland resources or listed plants could affect travel management if travel routes need to be relocated or closed. Effects would be short or long-term depending on the timeframe (temporary or permanent) of the restriction.

Travel management prescriptions and activities in all alternatives would designate areas as either “Open”,

“Closed” or “Limited”, and routes as Open Yearlong, Open with Restrictions, Closed Yearlong, Decommissioned, and Game Retrieval. Four existing travel management plans designate areas as Limited, with a few exceptions in Elkhorn Mountains and Whitetail-Pipestone. There is a direct correlation between area/route management decisions and the level (and quality) of recreational opportunities available to either motorized or non-motorized users. For motorized users, a reduction in the availability of motorized areas and designated routes means relatively fewer motorized opportunities. Simply stated, there would be fewer areas and miles of designated roads or motorized trail available for full sized or OHV vehicles to travel upon, either for recreational driving, or for access. Conversely, for non-motorized users, fewer motorized areas and designated routes means more area and miles of closed roads or trails available for quiet, non-motorized (hiking, biking, horseback riding) recreation use.

Likewise, there is a direct correlation between travel management decisions and the level of conflict between motorized and non-motorized users. Travel management decisions that create separate use areas reduce conflict between motorized and non-motorized recreation users. Conversely, travel management designations that mix motorized and non-motorized recreation use lead to increased conflict.

Additionally, dispersing use activity within areas primarily managed for either motorized or non-motorized use would provide a higher quality of recreational experience. Simply stated, regardless of the type of recreation activity (motorized, non-motorized, etc.) dispersing users over a larger area would result in fewer encounters, improving road/trail safety and providing a higher quality of recreational experience.

Conversion of temporary area closures to permanent area closures would reduce motorized access. New easement agreements with private landowners could increase accessibility for motorized and non-motorized travel into BLM lands. Agreements for interagency travel management could lead to improved trail accessibility, which could increase route connectivity.

Establishing and maintaining information kiosks would enhance user compliance, public safety, and enjoyment.

Under the existing Sleeping Giant travel management plan, motorized wheeled vehicle access would remain restricted to designated routes only. No snowmobile use would be allowed, including travel on designated routes. The Sleeping Giant area would not be available for organized, motorized events.

Any expansion to the Lewis and Clark National Trail system would be related to the day-use activities or lake access for water-based recreation opportunities.

Road and trail access in the Scratchgravel Hills area could increase with expanded hiking, mountain biking, horseback riding, hunting, and other recreation activities.

Under the existing Clancy-Unionville travel management plan, motorized wheeled vehicle access in the Sheep Mountain area would remain restricted to designated routes only. Cross-country snowmobile travel would continue to be permitted south of the Jackson Creek county road during the season of use (December 2-May 15), snow conditions permitting. Under the existing Whitetail-Pipestone travel management plan, motorized wheeled vehicle access would remain restricted to designated routes only. Cross-country snowmobile travel would continue to be permitted (on designated routes as well) during the season of use (12/2-5/15), snow conditions permitting. Travel management would continue to be exclusively non-motorized in the Wilderness Study Areas and would be maintained at current levels. No transportation or access impacts would be expected.

VRM classifications would limit the type, location, and density of roads in the Decision Area. Visually sensitive areas would be more restrictive on transportation system expansion.

Management within ACECs could affect transportation and travel management. Routes determined to be affecting values for which the designations were established could be relocated, reconstructed, or decommissioned.

Under the existing Sleeping Giant travel management plan, the non-WSA portion of the Sleeping Giant ACEC would continue to be managed as primarily non-motorized, with no impact.

Management of soil-disturbing activities could decrease the number of roads and trails available for motorized use for all or part of a year. Management actions would target highly traveled recreation areas for sediment reduction, which would limit access to certain recreation places.

Activities and projects to protect or maintain watersheds could result in seasonal route restrictions or permanent road closures, reducing motorized travel opportunities. Protective measures for cultural resources could affect travel management at specific sites. Restrictions on roads could result in an overall reduction in available routes.

Land acquisitions and easements could improve public access, expanding both motorized and non-motorized opportunities. Lands identified for disposal could decrease public access

Minerals management, including heavy equipment and truck traffic could affect public access, although, most effects would be short term and would only occur during development activities. New permanent routes established for mineral development could increase public access.

Minerals activities in areas with special-status or priority species would be designed to mitigate impacts, which could prohibit or restrict public access to roads.

Activities related to cleanup, remediation, and closure of contaminated or abandoned mine sites could result in the closure of system roads as well as trails to prohibit public access to these hazardous sites.

Remediation of hazardous materials to protect public health and safety could cause temporary or permanent closure, decommissioning, or restriction of some access roads to motorized and non-motorized travel.

**Effects of Alternative A**

***Travel Management – Field Office Level***

This alternative would continue to allow all existing travel plans, including sub-planning and emergency area closures, to be brought forward and remain in effect.

New route construction (up to 5.5 miles per year) could occur during forest product management activities. This could increase road density for both motorized and non-motorized users. New road construction allowed under Alternative A would be more than the action alternatives.

In the Elkhorn Wildlife Management Area, new road construction would be kept to a minimum and all new roads would be closed to the public.

Wheeled travel management would continue in accordance with the 2003 Statewide OHV ROD and Plan Amendment. The ROD did not address snowmobile management. Under Alternative A, existing snowmobile management would be brought forward along with alternative proposals for the five activity level travel plans being developed with this RMP revision, and area designations for four travel plan areas for which activity level plans will be developed in the future. Availability of areas for snowmobiling would be greater than under any other alternative.

Under Alternative A, BLM would continue to allow recreational activities including motorized vehicle uses within the Scratchgravel Hills 24 hours a day. This would lead to continued illegal activities (underage drinking, vandalism, dumping) as described under the Activity Level Plans for the Helena TPA.

**Effects Common to Action Alternatives**

***Travel Management – Field Office Level***

Seasonal wildlife closures would create short term impacts on travel and access to these areas. Maintaining core blocks of 250 acres of unroaded or closed roads during hunting season for big game protection under the action alternatives would affect existing routes by concentrating use on fewer roads than under Alternative A.

Relocating/aligning roads to reduce sedimentation, identifying and removing unnatural barriers, eliminating fish passage barriers, and restoring or maintaining riparian vegetation would have no effect on the transportation system as long as routes are not restricted or closed. Under all action alternatives, the effects of management for fish on transportation and travel management would be greater than under Alternative A.

Closure, decommissioning, or re-routing segments of the existing transportation system could result from the route-by-route evaluations within each Travel Planning Area. Social and environmental considerations would be made when evaluating individual TPAs.

All action alternatives would allocate the same acres of Open, Limited, and Closed Area Designations for wheeled motorized use (Table 4-37). The alternatives differ in their selection of Open Yearlong, Open with Restrictions, and Closed route designations.

<b>Indicator</b>	<b>Alt A</b>	<b>Alt B</b>	<b>Alt C</b>	<b>Alt D</b>
<b>Wheeled Vehicles</b>				
Open	4,367	283	283	283
Limited	271,442	275,526	275,526	275,526
Closed	31,500	31,500	31,500	31,500
Total	307,309	307,309	307,309	307,309
<b>Snowmobiles</b>				
Open	143,206	112,682	26,148	139,138
Limited	137,038	139,921	215,891	136,889
Closed	27,065	54,706	65,270	31,282

Source: BLM Butte Field Office transportation GIS database, 2005.

Under the action alternatives, motorized wheeled cross-country travel would be allowed during any military, fire, search and rescue, or law enforcement emergency.

The 2003 OHV ROD did not address snowmobile management. Under the action alternatives, existing snowmobile management would be brought forward along with alternative proposals for the five activity level travel plans being developed with this RMP revision, and area designations for four travel plan areas for which activity level plans will be developed in the future. Alternatives B and C would provide for less snowmobile use (both area and designated route availability) than Alternatives A and D. Alternatives B and C would help reduce conflicts between non-motorized users (cross-country skiers, snowshoers) and snowmobilers, providing separate areas of use. Alternative C would provide

the highest level of opportunities for non-motorized winter recreationists, and the lowest level of conflicts between motorized and non-motorized winter recreationists of all alternatives.

A feasibility study would be conducted to determine if a motorized section of the Continental Divide National Trail could be re-routed to enhance the non-motorized experience and reduce user conflicts. This action would be done in cooperation and coordination with the Forest Service.

The Humbug Spires potential ACEC would be closed yearlong to all motorized travel in order to protect natural and scenic values. No new roads or motorized trails would be authorized.

## Effects of Alternative B

### *Travel Management – Field Office Level*

Under Alternative B, road density levels in big game winter and calving ranges (1 mi/mi<sup>2</sup>) would result in a net decrease of available motorized routes. This effect would be less than under Alternative C, but more than under Alternatives A and D.

Prohibiting competitive motorized events would result in long-term effects on users who prefer these activities.

Placing restrictions on cross-county snowmobile travel in some areas would create long-term effects on users who prefer to recreate in this manner.

Acquiring easements to access popular travel routes could result in an increase in the overall route network and expand both motorized and non-motorized opportunities.

The signing and long-term monitoring required under Alternative B would result in an increase in BLM travel management costs compared to Alternatives A and D.

With the exception of a few routes needed for residential access, public access would be restricted to non-motorized trailheads. As a result, illegal activities (underage drinking, vandalism, dumping) in the Scratchgravel Hills would be substantially reduced. Travel management costs would increase for signage and user compliance monitoring under Alternative B. See Activity Level Planning for Helena TPA.

Managing special designations in a way that would restrict certain motorized and non-motorized activities from jeopardizing resource values special to the area would potentially alter the transportation network or by restricting access.

Route closures and prohibitions on new construction in the Spokane Creek and Elkhorns potential ACECs could directly affect visitors by restricting access to some sites and would result in an overall reduction in routes available to motorized users. Non-motorized opportunities in this area would increase.

Motorized route closures would be maintained in accordance with the Pipestone Travel Plan for the Ringing Rocks Potential ACEC.

## Effects of Alternative C

### *Field Office Travel Management*

Impacts to travel management from forest treatments would be greater under Alternative C than the other alternatives. Forest treatments would occur in areas already accessible by the current transportation system under Alternative C. No new permanent roads would be constructed and temporary road construction would be kept to a minimum. Temporary roads would be decommissioned within one year of project completion.

Impacts from the management of special status and priority species would be similar to Alternative B, except this alternative would have more strict resource protection.

Disallowing competitive and organized motorized events under Alternative C would result in long-term effects on users who engage in these types of activities.

Restrictions placed on snowmobile travel would create long-term effects on users who prefer cross-country snowmobile use.

Seeking public access easements for all locations where BLM routes are accessed either from or cross private property could increase the overall route network and expand both motorized and non-motorized opportunities.

Closing the entire Scratchgravel Hills area to motorized and non-motorized recreational uses after dark yearlong would decrease illegal activities but would increase travel management costs for signage and user compliance monitoring. See Activity Level Planning for Helena TPA.

Managing special designations to restrict certain motorized and non-motorized activities that may jeopardize resource values would result in route restrictions. This could directly affect visitors by limiting accessibility to some sites and could result in an overall reduction in routes available to access public lands. Alternative C is more restrictive than the other action alternatives.

Managing recreation settings and opportunities in accordance with Alternative C ROS classifications would result in the greatest amount of non-motorized recreation and least motorized recreation under Alternative C compared to the other alternatives.

Route closures and prohibitions on new construction in the Spokane Creek and Elkhorns potential ACECs could directly affect visitors by restricting access to some sites and would result in an overall reduction in routes available to motorized users. Non-motorized opportunities in this area would increase.

Unlike Alternatives B and D, this alternative would not allow new or existing mineral operations to construct access roads within Riparian Management Zones for mineral development.

## Effects of Alternative D

### *Field Office Travel Management*

Effects of forest management would be similar to those identified under Alternative A. Under Alternative D, some new roads may be built for long-term management of areas where multiple entries would be necessary to meet objectives but new and temporary road construction would be kept to a minimum. Some new permanent roads could be “Open Yearlong” to the public if travel plan objectives for the area are met. The degree of new road construction under Alternative D would be less than Alternative A, but more than would be allowed under Alternative B.

Alternative D is less restrictive on management actions that affect travel management than the other action alternatives and could result in more routes in the transportation system.

Allowing no net increase in permanent open road mileage in areas where open road densities are 0.5 mi/mi<sup>2</sup> or less in big game winter and calving ranges and reducing open road densities in big game winter and calving ranges where they currently exceed 1.5 mi/mi<sup>2</sup> would result in an overall net decrease of available motorized routes but to a lesser extent than under Alternatives B and C. Opportunities for walk-in hunters and other non-motorized enthusiasts would also be less than the other action alternatives.

With some exceptions (see activity level plan alternatives), cross-country snowmobile use would be allowed, as well as travel on all existing routes during the season of use (12/2-5/15), snow conditions permitting. Conflicts between non-motorized users (cross-country skiers, snowshoers) and snowmobilers would be expected to continue or increase as a result.

Evaluating competitive and non-competitive motorized events on a case by case basis for the Pipestone area could result in more opportunities for these types of events than under the other action alternatives.

Seeking public access easements for all locations where BLM routes are accessed either from or cross private property would result in an increase in the overall route network, expand both motorized and non-motorized opportunities, and enhance connectivity.

There would be a moderate increase in travel management costs due to initial implementation efforts (signing), and long-term monitoring (trail ranger patrols). This effect would be similar to Alternative B, but less than Alternative C.

Allowing motorized and non-motorized recreational uses 24 hours per day in the Scratchgravel Hills would lead to continued illegal activities, similar to current conditions. See Activity Level Planning for Helena TPA.

Managing special designations in a way that would restrict certain motorized and non-motorized activities that could jeopardize resource values special to the area could result in direct effects on the transportation management system.

Managing recreation settings and opportunities in accordance with Alternative D ROS classifications would result in the greatest amount of motorized recreation and the least amount of non-motorized recreation than any of the alternatives.

## TRANSPORTATION FACILITIES

Effects associated with RMP management are discussed below. Effects associated with the five site-specific travel plans at the scale of each TPA as well as at the Field Office scale are discussed in the “Environmental Consequences of Five Site-Specific Travel Plans” section.

### Effects Common to All Alternatives

Future vegetative regimens and activities have the potential to affect transportation facilities by providing more roads that could require periodic stabilization, sign maintenance, and bridge and culvert maintenance.

Temporary routes would be constructed where other routes are not available under approved travel management plans. BLM would construct such routes to minimal standards and implement BMPs that supplement basic guidelines for road planning, construction, drainage, and maintenance.

Route location could be affected by forest product activities, directly affecting transportation facility management. Under all alternatives route locations would be determined on the basis of topography, drainage, soil type, and other natural features to minimize erosion. Skid roads would be rehabilitated by seeding and/or scarification. Short-term effects could increase maintenance costs to comply.

Maintenance of BLM roads and facilities would create safer conditions for the public and provide for administrative uses. Certain resources could be affected directly by surface-disturbing maintenance activities or indirectly as a result of increased use or traffic generated by improved travel routes.

### Effects of Alternative A

Effects associated with Alternative A are described under “Effects Common to All Alternatives”. Estimated costs for annual maintenance and periodic stabilization would be about 30 percent more than under the action

alternatives (see the “Environmental Consequences of Five Site-Specific Travel Plans” section).

### **Effects Common to Action Alternatives**

Subjecting road maintenance to seasonal timing restrictions to mitigate impacts of human activities on important seasonal wildlife habitat could have short-term effects on facilities management by increasing the planning effort and reducing the economic efficiency of maintenance activities, depending on whether routes in these areas are among those maintained by BLM.

Reducing open road density in big game winter and calving ranges and grizzly bear distribution areas could have indirect effects on facilities management. By condensing current use on fewer roads there could be increased maintenance required and possibly a decrease in public safety due to increased traffic. However, reducing open road miles in these areas would reduce the number of road miles that would need maintenance, thereby contributing to reduced maintenance costs.

Designing roads to reduce the effects of fisheries resources could have short-term economic effects on facility management depending on whether the specifications for these protective features increase project costs or whether additional maintenance would be necessary to ensure their effectiveness.

Installing gates or other barriers at roads and trails closed to the public would have a direct affect on facility management. Increased personnel would be needed to install and maintain these fixtures and therefore, facility management costs would increase.

Under all action alternatives, there would be a moderate increase in facility management costs due to initial travel plan implementation efforts (signing, trailhead development) and sign maintenance. Route maintenance costs would be lower than current levels, due to the overall reduction in available routes.

Designing and maintaining roads in a manner that provides for water quality protection would result in an increase in facility management costs. Controlling placement of fill material, keeping drainage facilities open, following BLM culvert design standards, and repairing ruts and failures to reduce erosion and sedimentation of aquatic habitats would involve additional planning efforts and could result in additional personnel time during maintenance activities.

### **Effects of Alternative B**

Under Alternative B, replacing barbed wire gates with cattle guards and easily operated metal gates (wherever problems are known to occur) would result in a short-term increase in transportation facilities costs. However, due to the overall reduction in available routes under

Alternative B, transportation facility costs would be lower than current levels (see the “Environmental Consequences of Five Site-Specific Travel Plans” section).

Higher design standards under Alternative B, such as outsloping roadway surfaces where possible, minimizing disruption of natural hydrologic flow paths, and minimizing road and landing locations in RMZs may result in a short-term increase in transportation facility costs due to increased engineering efforts during route design and a long-term increase from culvert maintenance compared to Alternative A. Similar effects would be realized from Alternative D.

### **Effects of Alternative C**

Under Alternative C, installing cattle guards and gates on newly constructed roads and trails, as needed, would result in a short-term increase to transportation facility costs. However, due to the overall reduction in available routes under Alternative C, transportation facility costs would be lower than current levels (see the “Environmental Consequences of Five Site-Specific Travel Plans” section).

Higher design standards under Alternative C, such as maintaining stream crossings that would withstand a 100-year flood event, may result in a short-term increase in transportation facility costs due to increased engineering efforts during route design. Less maintenance would be required under Alternative C than under the other action alternatives due to higher capacity drainage fixtures.

### **Effects of Alternative D**

Under Alternative D, replacing barbed wire gates with cattle guards and easily operated metal gates (wherever they currently exist) would result in a short-term increase in cost for transportation facility management. However, due to the overall reduction in available routes under Alternative D, transportation facility costs would be lower than current levels (see the “Environmental Consequences of Five Site-Specific Travel Plans” section).

Increased levels of reconstruction and new route construction to restore deteriorated routes and provide additional loop routes would result in a short-term increase in transportation facility costs for the signage, culverts, and bridges that may be required and a long-term increase for route maintenance.

Higher design standards under Alternative D, such as outsloping roadway surfaces where possible and minimizing road and landing locations in SMZs may result in a short-term increase in transportation facility costs due to increased engineering efforts during route design and a long-term increase from culvert maintenance compared to Alternative A. Similar effects would be realized from Alternative B.

## LANDS AND REALTY

This section includes discussion of effects on land tenure adjustments, land use authorizations, utility corridors, and communication sites.

### Effects Common to All Alternatives

Effects analysis indicated that vegetation, travel management, and abandoned mine lands would not have impacts on lands and realty.

While management actions for livestock grazing vary among the alternatives, the impacts to the Lands and Realty Program are essentially the same. In areas where livestock grazing occurs, land use authorizations such as rights-of-way and BLM access easements could be required to include conditions and or mitigation measures that limit livestock grazing during the construction and rehabilitation phases of the project, and facilitate livestock movement and public travel (e.g., fencing and cattle guards) throughout the effective period of the authorization. Percentage of the Decision Area (DA) available for livestock grazing would be 93 percent under Alternatives A and D, and 90 percent under Alternatives B and C.

In general, wildland fire management actions would help protect facilities on public lands authorized through the Lands and Realty Program by reducing fuel loads and suppressing fires. However, there is always a slight possibility of losing control of prescribed fire and damaging the above-ground facilities.

Management actions to identify, protect, and conserve special status plant and animal species would impact land use authorizations, land ownership adjustments, and acquisition of legal and physical access to public lands. Facilities proposed to be constructed under various land use authorizations or access easements in areas where these types of vegetation and animal species are present may need to be mitigated, constructed in alternate locations, or in extreme cases, dropped from consideration. The need to protect these resources could also result in the restructuring or elimination of a land ownership adjustment proposal such as an exchange or sale.

Recreation management actions, including designation of Special Recreation Management Areas, could result in land ownership adjustments or easement acquisitions in order to improve access to public lands for recreation opportunities.

Under all alternatives, the six existing Wilderness Study Areas would continue to be managed under the Interim Management Policy and Guidelines for Lands under Wilderness Review (BLM Handbook H-8550-1, dated 1995) until such time as Congress either designates them as wilderness or releases them from further consideration as wilderness. Such management would impose restrictions on the use of these areas for land use authorizations and land disposals.

Managing the national trails located within the DA to protect the values for which they were designated could impact land use authorizations such as rights-of-way as well as BLM actions to obtain legal and physical access to public lands. Proposed facilities such as power lines may need to be mitigated (e.g. burial of the line) or re-routed in order to protect trail values. Land ownership adjustments such as sales or exchanges may need to be restructured or eliminated from consideration in order to avoid disposing of public lands containing important trail segments.

Visual Resource Management under all alternatives would affect land use authorizations such as rights-of-way, leases, and permits. Facilities would need to meet objectives for the particular VRM class in which a project was proposed. This could include mitigation, relocation, or elimination of certain facilities resulting in additional time and costs in project development.

Management actions to protect soil, air, and water quality could affect land use authorizations such as rights-of-way, leases, and permits, as well as BLM actions to obtain legal and physical access to public lands. Proposals for facilities and actions that would degrade these resources would have to be mitigated, sited in acceptable alternative locations, or in more extreme cases, denied altogether. Applicants for such proposals could encounter time delays and greater costs in terms of project development.

Management of cultural resources could affect several aspects of the Lands and Realty Program including land use authorizations, land ownership adjustments, and the acquisition of legal and physical access to public lands. These lands and realty actions are considered federal undertakings and must avoid inadvertent damage to federal and non-federal cultural resources through compliance with Section 106 of the National Historic Preservation Act. Cultural inventories would need to be completed prior to these federal undertakings and impacts to important cultural sites would need to be avoided by project redesign, project abandonment, and/or mitigation of adverse impacts through data recovery. This could result in actions such as re-routing a proposed right-of-way or road easement, or restructuring or abandoning a proposed land ownership adjustment such as a land exchange or sale. Such actions can increase processing costs and processing time for both the federal and non-federal parties.

Impacts from the management of paleontological resources would be similar to those of cultural resources. Lands and realty projects occurring in known fossiliferous areas would require that adequate time and resources be allocated to conduct resource inventory. The discovery of scientifically important paleontological resources could result in the rerouting or redesign of proposed land use authorizations and easement facilities. The presence of these resources could also lead to the restructuring or abandoning of land ownership adjustments such as land

exchanges or sales. Such actions can increase processing costs and time for both the federal and non-federal parties.

Locating new right-of-way facilities within or adjacent to existing rights-of-way would minimize the number of acres designated for new right-of-way development. Implementation of *Suggested Practices for Raptor Protection on Power Lines* (APLIC 1996) and Best Management Practices (BMPs) established in the Programmatic Wind Energy EIS and ROD (December 2005) would require mitigation for wildlife impacts on new rights-of-way development.

The Interagency West-wide Energy Corridor Programmatic EIS currently being prepared will identify energy corridors on BLM and other federal lands. The Final PEIS will provide plan amendment decisions that will address energy corridor related issues, including the utilization of existing corridors, identification of new corridors, supply and demand considerations, and compatibility with other corridor and project planning efforts. Identification of corridors in the PEIS may affect the BFO, and the approved PEIS would subsequently amend the Butte RMP.

Reviewing existing withdrawals and classifications and revoking or terminating those that are no longer serving their intended purpose would ensure that public lands are not unnecessarily encumbered and are open to the widest possible array of public land uses consistent with other portions of the plan. Such reviews would also ensure that withdrawals and classifications still serving their intended purpose would remain in place. Withdrawal proposals under all alternatives would be in conformance with current withdrawal and energy policies and would ensure that such actions encumbered the minimum area necessary to achieve the intended purpose.

New withdrawal proposals would be limited to the minimum area required for the intended use, would require strong justification, and would be initiated only where applicable alternative prescriptions, such as the use of rights-of-way, leases, permits, or cooperative agreements, are inadequate to protect the resource values.

Recommendations developed by the BLM/Secretary of the Interior and Department of Army/Department of Defense on the proposed withdrawal at Limestone Hills will be submitted to Congress. Congress and the President will then determine whether the withdrawal should be enacted, and the amount of public land to be withdrawn. Up to approximately 20,000 acres of public land could potentially be transferred to the administration of the Department of the Army, or managed cooperatively with the BLM. The EIS for this withdrawal would subsequently amend the Butte RMP.

Consideration of land ownership adjustments on a case-by-case basis would allow for flexibility in managing public lands to achieve improved management efficien-

cy or enhance other programs. BLM-administered land within disposal areas would be made available for disposal through sales or exchanges or both. BLM lands to be sold would meet the disposal criteria from the Federal Land Policy and Management Act of 1976.

Actions such as exchanges, sales, and purchases would adjust the relatively fragmented public land pattern to better manage public lands over the long-term. Consolidation of public land holdings could facilitate access to public lands and reduce the number of access easements needed. Consolidation could also lead to a reduction in encroachment problems on public lands from adjacent property owners as a result of fewer private inholdings within the DA.

Lands that meet Recreation and Public Purposes Act (R&PP) classification criteria for public purposes would be made available for state and local governments and other organizations. This would assist those entities in meeting the need for reasonably priced land to serve a broad array of public needs.

Access to public lands would be improved by the pursuit of land exchanges, easement acquisitions, and land donations.

The management of leasable, salable, and locatable minerals under all alternatives would likely result in requests for land use authorizations such as rights-of-way and permits for utilities and access.

Any renewable energy developments proposed for public lands managed by the BFO within the DA lands could result in requests for land use authorizations such as rights-of-way and permits. There are two areas where wind energy developments are anticipated to occur: one near Whitehall in the vicinity of Golden Sunlight Mine and one near Livingston.

In terms of health and safety, land use authorizations for uses which would involve the disposal or storage of material which could contaminate the land would not be issued. Lands proposed for acquisition or disposal would need to be inventoried for the presence of hazardous materials. The presence of contaminants may lead to actions such as the modification or abandonment of a land ownership adjustment proposal, or remediation in the form of cleanup and removal of the contaminants.

Management to protect prime or unique farm lands would require that actions be reviewed to evaluate their impacts on these resources. Although no prime or unique farm lands have been identified in the Decision Area, adjustments to land use authorizations and land ownership may be required to minimize or eliminate these impacts if prime farm lands are identified on a case by case basis.

Tribal treaty rights on public lands within the DA could impact land ownership adjustments such as exchanges and sales. It is possible that potential actions such as these would need to be restructured or eliminated from

consideration if it were determined that they adversely affected tribal treaty rights.

## Effects of Alternative A

BLM forest product sales and stewardship projects may also require road easement acquisitions to cross private lands to secure access to the federal sale or project area. In comparison to the other alternatives, Alternative A would likely have a greater need for access to forested areas than Alternative C but a lesser need than Alternatives B and D.

Management of the four National Wild and Scenic River-eligible river segments to protect wild and scenic river eligibility and tentative classification would result in restrictions or denial of land use authorizations for new facilities such as electric transmission lines, roads, etc.

Management actions to protect relevant and important resource values on ACECs would restrict land use authorizations, land ownership adjustments, and access to public lands within the DA. Under Alternative A, the pre-existing Sleeping Giant ACEC (11,679 acres) would continue to be managed as an ACEC. Under the original management plan no new ACECs would be established. Compared to the other alternatives, Alternative A would have the least impact on the Lands and Realty Program from ACEC management.

Alternative A would provide the greatest flexibility in locating facilities such as transmission lines, pipelines, and communication sites since there would be no designated right-of-way corridors or use areas, 74,489 acres of avoidance areas, and no exclusion areas. The lack of designated corridors could lead to a proliferation of separate rights-of-way which would need to undergo NEPA evaluation. Not designating corridors and use areas for the above-mentioned facility types could result in a greater likelihood that other land uses would preclude the location of these types of right-of-way uses. Not concentrating major right-of-way facilities in certain areas could make them, along with the public which relies on them, less vulnerable to potential natural disasters.

Alternative A (along with Alternative D) would allow for the greatest flexibility in authorizing mineral entry activities by considering withdrawals from mineral entry on a case-by-case basis.

Planning guidance with respect to land ownership adjustment would be the same as that provided by the 1984 Headwaters RMP and the 1979 Dillon Management Framework Plan. Further and more specific guidance would be provided by the "Land Pattern and Land Adjustment, Supplement to the State Director Guidance for Resource Management Planning in Montana and the Dakotas, 1984" (BLM 1984b). This guidance was later amended by the 1989 State Director's guidance pertaining to access. This direction established land exchange

as the predominant method of land ownership adjustment. It also established retention, disposal, and acquisition criteria to be used in categorizing public land. Criteria in the supplement were used to identify retention and disposal zones within the DA. These zones would be applied in this alternative.

Under Alternative A, management actions for access would progress toward BLM management goals by following guidance provided by the Headwaters RMP/EIS as supplemented by guidance prepared by the Montana State Office on access (BLM 1989). Alternative A would likely provide the most flexibility than the other alternatives in terms of how and where access could be obtained.

Designation of approximately nine percent of federal mineral estate lands in the DA (54,810 acres) as closed to oil and gas leasing would eliminate effects on land use authorizations, withdrawals, or access from oil and gas leasing in these areas. Under Alternative A, fewer acres would be closed to oil and gas leasing activities than under Alternative C, but more than under Alternatives B and D.

## Effects Common to Action Alternatives

Designation of approximately 283 acres (0.10 percent of lands in the DA) as open to wheeled vehicles under the action alternatives would require less road easement acquisitions than Alternative A.

Managing the two National Trails (Continental Divide National Scenic Trail and Lewis and Clark National Historic Trail) in accordance with the Recreation Opportunity Spectrum settings, Visual Resource Management classes, travel plan direction, and oil and gas stipulations established under the action alternatives would further restrict land use authorizations and land ownership adjustments on public lands containing important trail segments. Land ownership adjustments would be required to re-route the Continental Divide Trail segment in coordination with the Forest Service to enhance non-motorized opportunities; reduce current needs for use easements/acquisitions through private lands; and remove user conflicts associated with the motorized road.

Limiting new communication facilities to the seven designated communication sites would concentrate these uses and diminish the proliferation of separate rights-of-way and their associated impacts when compared to Alternative A. Designation of these use areas would put the public on notice that these are the preferred areas for certain types of right-of-way facilities. Designation and management of right-of-way corridors and use areas would make it more likely that these types of right-of-way uses would not be precluded by other land uses. However, having these types of right-of-way facilities in close proximity to one another could make them, and the public that relies on them, more vulnerable to potential natural disasters.

Designating avoidance (75,626 acres) and exclusion (27,361 acres) areas would limit or exclude potential rights-of-way development in those areas. Issuance of any new land use authorizations in or near riparian areas would include special stipulations to protect riparian values.

New leases, permits, rights-of-way, and easements would be permitted in a manner consistent with meeting Land Health Standards and applicable BMPs, and the guidelines set forth in BLM's Wind Energy Development Programmatic EIS, June 2005.

Compared to Alternative A, implementation of any of the action alternatives would improve land ownership adjustment management and provide better guidance in achieving BLM land ownership goals by prioritizing actions which are associated with chronic management problems and protecting public resource values. High priority areas for retention and potential land acquisition would be associated with ACECs, Wild and Scenic Rivers, Wilderness Study Areas, National Trail Corridors, Special Recreation Management Areas, recreation sites, and habitat for priority and special status species. Under all action alternatives, specific land ownership adjustment criteria developed for retention, disposal and acquisition would be followed. These criteria are described in **Appendix L – Lands and Realty**.

Under all action alternatives, management actions would progress toward BLM access management goals by following guidance provided by the specific access criteria outlined in **Appendix L – Lands and Realty** for obtaining new access and managing existing access to BLM-administered lands. Implementation of the action alternatives would provide better guidance than Alternative A in terms of how and when access should be obtained.

Under all action alternatives, up to 8,901 acres of BLM land identified for disposal could potentially pass to private ownership and would no longer be subject to federal land management laws and policies.

### Effects of Alternative B

Building and using new roads for long-term use for forest products would result in the need for BLM to obtain road access to forested areas through easement acquisition. Compared to the other alternatives, Alternative B would have a greater need for additional access for management of forest products than Alternative C, but likely less than Alternatives A and D.

Under this alternative, impacts to the Lands and Realty Program from the management of suitable Wild and Scenic Rivers segments (5.7 miles) to protect outstandingly remarkable values would be less than under Alternatives A and C, but greater than Alternative D.

Designation of four new ACECs and management actions to protect relevant and important resource values would restrict land use authorizations, land ownership

adjustments, and access to public lands within the DA on approximately 70,644 acres. Compared to the other alternatives, ACEC management in Alternative B would have a greater impact on the Lands and Realty Program than with Alternatives A and D, but a lesser impact than Alternative C.

Alternative B would set the priority for new withdrawal proposals or other protective actions to developed recreation sites followed by new acquisitions, and ACECs to protect resources and values as needed.

In alternative B, approximately 198 acres at various developed recreation sites, would be recommended for withdrawal from mineral location. Designation of approximately 36,406 acres as closed to oil and gas leasing would eliminate the need for land use authorizations, withdrawals, or access for the purpose of oil and gas leasing on approximately 6 percent of BLM-managed federal mineral estate lands in the DA. With fewer acres closed to oil and gas leasing activities than under the other alternatives (except for Alternative D, which would close the same number of acres), Alternatives B and D would have the greatest potential need for land use authorizations, withdrawals, or access from oil and gas leasing in these areas.

### Effects of Alternative C

By not building new roads for long-term use, the need for road access through easement acquisitions would be minimized. Compared to the other alternatives, Alternative C would have the least need for additional access for management of forest products.

Alternative C would allow for a similar number of withdrawn acres as Alternative B by setting the priority for new withdrawals to developed recreation sites followed by all new acquisitions through exchange or purchase, and in ACECs.

Under this alternative, impacts to the Lands and Realty Program from the management of suitable Wild and Scenic Rivers segments (12 miles) to protect outstandingly remarkable values would be the same as under Alternative A.

Designation of four new ACECs and management actions to protect relevant and important resource values on ACECs would restrict land use authorizations, land ownership adjustments, and access to public lands on approximately 87,892 acres of the DA. Compared to the other alternatives, ACEC management under Alternative C would potentially have the greatest impact on the Lands and Realty Program of all the alternatives.

Approximately 180 acres of land in riparian areas of the Muskrat Creek drainage, as well as approximately 198 acres at various developed recreation sites, would be recommended for withdrawal from mineral location in Alternative C.

Alternative C would designate 580,382 acres as closed to oil and gas leasing, more than any other alternative. This would eliminate the need for land use authorizations, withdrawals, or access for the purpose of oil and gas leasing on the greatest amount of acreage of any of the alternatives.

### Effects of Alternative D

Allowing new roads for long-term use for forest products would result in the need for road access to forested areas in the form of road rights-of-way and road use agreements. Compared to the other action alternatives, Alternative D would have the greatest need for additional acres for access for management of forest products.

Like Alternative A, withdrawals from mineral entry would be pursued on a case-by-case basis.

Under this alternative no river segments would be recommended as suitable for inclusion in the National Wild and Scenic River System, and therefore would not be subject to restrictions on lands and realty actions for eligible river segments.

Designation of two new ACECs and management actions to protect relevant and important resource values on ACECs would restrict land use authorizations, land ownership adjustments, and access to public lands on approximately 23,695 acres of the DA. Compared to the other alternatives, Alternative D would potentially have a greater impact on the Lands and Realty Program than Alternative A, but a lesser impact than Alternatives B and C.

The greatest potential need for land use authorizations, withdrawals, or access from oil and gas leasing would be the same as in Alternative B.

## SPECIAL DESIGNATIONS

### Effects Common to All Alternatives

No impacts to special designation areas are anticipated from proposed management associated with special status and priority plants, air quality, soils, water quality, cultural resources and traditional cultural properties, paleontological resources, abandoned mine lands, hazardous materials, social and economic, prime farm lands, environmental justice, or Tribal treaty rights.

Actions emphasize monitoring the impact grazing has on meeting resource value standards, particularly for vegetation and water quality. This action would benefit the values of special designation areas since problems and corrective measures would be identified and potentially corrected in a timely manner.

Wildlife actions to improve habitat to stabilize or increase wildlife populations would indirectly enhance wildlife and vegetation resource values within established special designation areas.

Special designation areas with outstanding values associated with wildlife habitat or species diversity would be protected. Habitat management plans, conservation strategies and coordinating with other agencies to improve habitat within special designation areas would directly help retain or enhance vegetation, wildlife species, solitude, naturalness, and scenic values.

All existing special designation areas would be managed to prevent unnecessary and undue degradation to existing values and resource characteristics.

### Effects Common to Action Alternatives

Vegetative treatment actions would focus on restoring the desired ecological conditions of special management areas and would occur to protect or enhance important resource values. Wildland fire management would concentrate on the enhancement and/or protection of special area values except in instances where private lands and structures are threatened. Active public outreach to educate visitors about noxious weeds and control efforts would have a positive effect on the vegetation and habitat values in ACECs, National Trail corridors, WSRs and WSAs.

The action alternatives would implement a variety of management actions designed to enhance the habitat conditions for special status and priority plant and animal species in the Decision Area, which would directly enhance the wildlife and habitat values of all special designation areas.

The protection and enhancement of riparian areas, native fisheries, and aquatic resources would have a positive impact on special designation areas and visitor experiences.

Travel management and access within the special designation areas would be limited to designated routes or closed to protect unique resource values and enhance primitive and unconfined recreation opportunities.

All lands within special management areas would be classified for future retention and acquisitions that enhance important values and their management would be given priority.

## AREAS OF CRITICAL ENVIRONMENTAL CONCERN

### Effects Common to All Alternatives

**Table 4-38** displays the acres of ACEC proposed by Alternative. ACECs located close to or within urban interface areas could be directly affected by wildland fire prevention and suppression activities designed to control the ignition and spread of wildland fires. Activities, such as mechanical or hand thinning, could damage the special characteristics of an ACEC. Fuels reduction treatments in the ACECs outside of the urban interface areas would emphasize prescribed burning; however,

these treatments would be designed to minimize or mitigate effects to values associated with special designation areas.

Activities to improve and maintain wildlife habitat would enhance wildlife and vegetation resource values in the ACECs.

Management would focus on conserving special status and priority species and implementing habitat improvement projects or recovery plans, which would benefit all ACECs by alternative.

The non-WSA portion of the Sleeping Giant ACEC would be managed as “Limited” to motorized use, which would continue to benefit the ACECs outstanding values while allowing vehicle access to walk-in trailheads.

Existing management would protect the relevant and important values of the Sleeping Giant ACEC.

Many ACECs would be managed as Class II areas and proposed projects would be subject to visual contrast ratings to ensure visual resource disturbances are not evident.

The Sleeping Giant and Humbug Spires and portions of the Elkhorn areas would be designated and managed as ACECs under all action alternatives.

### Effects of Alternative A

The existing Sleeping Giant ACEC (11,679 acres) would continue to be managed under the current ACEC management plan (Table 4-38). No additional ACECs would be designated and therefore this alternative would pro-

vide the least protection of relevant and important resource values.

### Effects of Alternative B

All potential ACECs would be managed as ACECs except Spokane Creek under Alternative B. This alternative would establish the second highest acreage of lands (70,644 acres) under ACEC designation and protection (Table 4-38). This alternative proposes one less ACEC area than Alternative C, and a smaller portion of the Elkhorns area would be designated under Alternative B.

### Effects of Alternative C

Alternative C would designate all five potential areas and the most acres (approximately 87,893 acres) as ACECs of all alternatives (Table 4-38). This alternative would designate all of the land within the Elkhorns Wildlife Management Unit MOU in the Elkhorns ACEC and Spokane Creek. This alternative would provide the greatest protection for the identified relevant and important values associated with the ACEC review process.

### Effects of Alternative D

Of all the action alternatives, Alternative D would manage the least amount of acreage as ACECs (23,695 acres) (Table 4-38). Three potential ACECs would be designated including Sleeping Giant, Elkhorns, and Humbug Spires. The Elkhorns ACEC boundary would be the same as the Elkhorns Tack-on WSA boundary, which is the lowest acreage managed in the Elkhorns ACEC compared to the other action alternatives.

**Table 4-38**  
**Acres of Potential ACECs and WSAs Designated in Each Alternative**

Name	Total Acres			
	Alt A	Alt B	Alt C	Alt D
<b>ACEC</b>				
Sleeping Giant	11,679	11,679	11,679	11,679
Humbug Spires	-	8,374	8,374	8,374
Spokane Creek	-	-	14	-
Ringing Rocks	-	160	160	-
Elkhorns	-	50,431	67,665	3,575

## NATIONAL TRAILS

### Effects Common to All Alternatives

National Trail segments located close to or within urban interface areas could be directly affected by wildland fire prevention and suppression activities designed to control the ignition and spread of wildland fires.

### Effects of Alternative A

No ROS or VRM designations or management plans would be created for the Continental Divide National Scenic Trail. The Lewis and Clark National Historic Trail would be managed in accordance with the Missouri River Comprehensive Recreation Management Plan. Most lands along this river would be managed as VRM Class II and no ROS designations would be allocated.

Lowest protection provided for the two National Trail corridors given that ROS, VRM, Travel and oil and gas restrictions would be lowest.

### Effects of Alternative B

Alternative B offers the second highest protection for the National Trails as resource use restrictions would be greater than under Alternatives A and D.

### Effects of Alternative C

This alternative offers the greatest protection of the existing National Trails and associated user experiences since all resource uses such as timber harvesting, motorized travel, rights-of-way, minerals, and oil and gas would be restricted the most through ROS, VRM, and travel management.

### Effects of Alternative D

This alternative offers the second lowest protection for National Trails as potential impacts from other resource uses would be higher than Alternatives B and C.

## WILD AND SCENIC RIVERS

### Effects Common to All Alternatives

Management would focus on conserving special status and priority species and implementing habitat improvement projects or recovery plans, which would benefit the Upper Big Hole River, Missouri River and Muskrat Creek WSRs where recommended as suitable by alternative.

### Effects of Alternative A

The outstandingly remarkable values of all eligible Wild and Scenic river segments would be protected and would be negligibly-to-minimally impacted by management.

### Effects of Alternative B

Under this alternative Muskrat Creek would be recommended suitable for inclusion in the National Wild and Scenic Rivers System. The Missouri River segment would be found preliminarily suitable pending Forest Service concurrence. The management of these two segments would not change from the existing management, as described under Alternative A. The Upper Big Hole River and Moose Creek would be identified as non-suitable for the National Wild and Scenic Rivers System, and protective management actions, regarding important resource values, would not continue. The Moose Creek segment would fall back to WSA and ACEC management as it is part of the Humbug Spires WSA (and potential ACEC) while the Upper Big Hole River would be managed as a Special Recreation Management Area under the Upper Big Hole River Management Plan.

### Effects of Alternative C

All four of the Wild and Scenic River segments would be recommended as suitable for consideration in the National Wild and Scenic Rivers System; however, the interim management of these segments would be the same as in Alternative A to manage for their outstandingly remarkable values.

### Effects of Alternative D

All four eligible Wild and Scenic River segments would be identified as non-suitable for inclusion into the National Wild and Scenic Rivers System. Management actions governing these river segments would not specifically protect outstandingly remarkable values so they would be subject to greater impacts than in the other alternatives.

## WILDERNESS STUDY AREAS

### Effects Common to All Alternatives

**Table 4-38** displays the acres of Wilderness Study Area proposed by alternative. There are no additional lands with wilderness characteristics in the Decision Area.

All six WSAs would be managed as they are currently, under the Interim Management Policy and Guidelines for Lands under Wilderness Review. This status may change if Congress designates the WSAs as wilderness or if they are removed from consideration. If a WSA becomes a wilderness area, a wilderness management plan would be created. If a WSA is removed from consideration, the area would no longer have legislative protection for the outstanding values. The Sleeping Giant and Sheep Creek WSAs would have fall back administrative protection since these areas would be designated and managed as ACECs under all alternatives.

Fire management activities would be conducted to avoid unnecessary impairment of each area's suitability for preservation as wilderness. Retardant, motorized equipment and earth disturbances would be restricted to the minimum necessary to protect human life and property. Priority would be given to locate large fire camps outside WSAs and to utilize fire crews to rehabilitate impacts prior to being released. These actions would benefit the preservation of the wilderness characteristics within the WSAs.

Pre-FLPMA grazing uses would be allowed to continue subject to unnecessary and undue degradation concerns while new livestock uses and developments would be restricted to actions that enhance wilderness values and satisfy the nonimpairment criteria. Prohibiting the removal of forest fiber products and vegetation conversions/manipulations; allowing noxious weed to be controlled; and limiting vegetative rehabilitation efforts to native species would prevent impacts to naturalness qualities and reduce impacts to visitors seeking wilderness related experiences.

Activities to improve and maintain wildlife habitat for native, priority, and special status species would be conducted subject to IMP guidelines. These efforts would enhance supplemental wildlife values and natural characteristics in the WSAs.

All WSAs would be closed to motorized travel except Black Sage and the southern portion of Humbug Spires which is limited to established routes. These restrictions enhance fisheries, wildlife, water quality, native vegetation, apparent naturalness, solitude, and primitive recreation values.

Opportunities for solitude and a variety of primitive and unconfined recreation experiences within WSAs would continue to be promoted. Recreational activities that do not meet nonimpairment criteria would generally be prohibited with the exception of motorized uses on established vehicle ways.

WSAs would be managed to achieve VRM Class I, which would directly preserve the naturalness and scenic qualities in each WSA.

All land use authorizations within WSAs would follow interim management policies and guidelines. Given that all new actions are subject to the nonimpairment standard, no wilderness character impacts are foreseeable. Land use authorizations relating to grandfathered and valid existing rights may disrupt natural processes and may cause negative impacts on outstanding values.

Oil and gas leasing and development would be prohibited in all WSAs subject to the rights of owners of non-BLM mineral estate. There are no known leases within the WSAs that have valid existing rights or grandfathered uses associated with them. Geothermal leasing would also be prohibited in all WSAs as no valid or grandfathered leases exist.

Locatable mineral activities would be subject to IMP protection within WSAs. Mineral activities within WSAs studied under Section 603 of FLPMA (Sleeping Giant, Humbug Spires, Black Sage, and the Yellowstone River Island) will be regulated to nonimpairment standards while Section 202 WSAs (Sheep Creek and the Elkhorns Tack-on) will be managed to prevent unnecessary and undue degradation. As a result valid mining claim activities pose greater potential risks for impacting the wilderness characteristics of these 202 WSAs.

## Effects of Alternative A

All WSAs would continue to be managed under the Interim Management Policy and Guidelines and therefore wilderness values would continue to be protected, under the assumption that no Congressional action would occur.

## Effects Common to Action Alternatives

All WSAs (Sleeping Giant, Sheep Creek, Humbug Spires, and Elkhorns Tack-on) except Black Sage and the Yellowstone River Island would be managed as ACECs under all action alternatives. These designations would provide long-term resource value protection should Congress remove these WSAs from further wilderness consideration or in the case of the Elkhorns Tack-on, should the adjoining Forest Service lands be dropped from wilderness consideration.

Black Sage and the Yellowstone River Island, if dropped from wilderness consideration, would be managed under varying fall back managing strategies under Alternatives B, C and D. Management prescriptions for these WSAs would address recreation, motorized travel, visual, minerals, and land ownership, which would aid in protecting their outstanding values (solitude, naturalness and primitive and unconfined recreation opportunities).

The Elkhorn Tack-on WSA would be dropped from further wilderness review, should the adjoining FS lands be released from wilderness consideration, as this small WSA is not capable of providing outstanding opportunities for solitude or primitive and unconfined recreation on its own. This action would not impose major impacts to the existing values of the area given the fall back ACEC designation.

## Effects of Alternative B

Under this alternative fall back management for the Black Sage and the Yellowstone River Island would be less protective than under the IMP guidelines. Major changes in the management of Black Sage would be that existing roads could be re-routed; VRM would be managed as Class II; new Rights-of-Ways could be authorized; locatable minerals would be open subject to unnecessary and undue degradation; oil and gas entry would be allowed subject to big-game timing limitations from 12/1 to 6/30; all saleable and other leasable minerals would remain unavailable; and vegetative treatments

could be conducted provided they were done in a manner that restored or maintained natural processes. The effects of these management changes could impact natural qualities, solitude and primitive and unconfined recreation opportunities and supplemental value characteristics of this 5,917-acre area due to surface disturbances, visual modifications, increased vehicular travel, and noise intrusions.

Fall back management changes for the Yellowstone River Island would be less impacting since most resources and uses would be managed similar to IMP protection guidelines. The major differences would be that the VRM Class would change from I to II, locatable mineral entry would be open subject to unnecessary and undue degradation; and leasable minerals would be subject to No Surface Occupancy. Although the island would be open to locatable minerals, the probability for impacts to the island's wilderness characteristics would be minimal given its difficult accessibility issues, natural river barriers, and low desirability for mineral activity given the high operating and reclamation costs.

### Effects of Alternative C

Fall back management for Black Sage and the Yellowstone River Island would be similar to Alternative B if dismissed from further wilderness consideration by Congress, with the exception of oil and gas. Oil and gas stipulations would be most restrictive of all alternatives in that no new leases would be issued. Impacts on wilderness characteristics would be less than Alternative B given the added restrictions on oil and gas activities.

### Effects of Alternative D

For most land management activities in the Black Sage and Yellowstone River Island WSAs, management would be similar to Alternative B in the event that these areas were dismissed from further wilderness consideration by Congress. The major difference would be that the Black Sage WSA would be open to all salable and leasable minerals and oil and gas leases would have timing limitations from 12/1 to 5/15 for big game winter/spring range protection. These management changes would subject the area's wilderness characteristics to greater potential impact from mineral related activities. Impacts to the Yellowstone River Island could be slightly greater since the island would be available for land adjustment as well as salable and all leasable minerals under this alternative.

## EFFECTS ON SOCIAL AND ECONOMIC CONDITIONS

### ECONOMIC

#### Effects Common to All Alternatives

The economic analysis assesses the economic effects of the direct use of resources in terms of jobs and income.

This type of analysis does not include other types of economic value that may be associated with unique natural resources and protected areas. These types of values, often referred to as non-market values, include natural amenities and quality of life, non-use values, bequest values, and ecosystem services.

#### *Non-Market Values*

Natural amenities and quality of life have been increasingly recognized as important factors in the economic prospects of many rural communities in the American West and elsewhere (Rudzitis and Johnson 2000). While natural amenities and life quality do not directly generate income in the same sense as, for example, a sawmill or a tourist lodge, they do act to attract and keep residents, and may attract new businesses. Open spaces, scenery, and protected lands are important to residents of Montana and throughout the Rocky Mountain west and may contribute to healthy economies and lifestyles (Sonoran Institute 2003). This relationship is, however, difficult to quantify as is assessing the effects of different management actions on the economic activities that these amenities are believed to indirectly generate. In this case, the impacts of the action alternatives relative to Alternative A are not expected to result in measurable changes in this type of indirect economic activity.

#### *Non-Use Values*

Non-use values, as the name might suggest, represent the value that individuals assign to a resource independent of the use of that resource. These types of values, which include existence, option, and bequest values, are usually measured via surveys that ask people how much they would be willing to pay to have a particular area preserved or designated as wilderness. These values represent the value that individuals obtain from knowing that a resource exists, knowing that it would be available to use in the future, and knowing that it would be left for future generations. Wilderness has been the subject of numerous non-use studies, usually conducted for specific natural areas, and willingness-to-pay estimates for protection or designation have identified a wide range of values (Krieger 2001; Loomis and Richardson 2001).

No attempt has been made to quantify potential non-use values associated with the RMP alternatives because none of the alternatives propose new wilderness that would significantly restrict current uses.

Based strictly on the number of acres that would be in an ACEC, Alternative C would likely have the highest wilderness and protected land-related non-use values. Alternative A would have the lowest values, followed by Alternative D.

#### *Ecosystem Services*

Ecosystem services may be defined as those natural processes that provide long-term life support benefits to society as a whole. Examples of these types of benefits include watershed processes, soil stabilization and ero-

sion control, improved air quality, climate regulation and carbon sequestration, and biological diversity (Krieger 2001).

No attempt has been made to assign monetary values to the ecosystem services that would be provided because these values are difficult to quantify at this analysis level. In addition to the difficulties involved in developing accurate estimates of these values, the impacts of project alternatives are rarely quantified in the type of units that would allow these values to be assigned. However, the fact that no monetary value is assigned to ecosystem services in this document does not lessen their importance in the decision making process.

The potentially affected local economy is characterized for the Planning Area counties in the Affected Environment portion of this document (Chapter 3). None of the alternatives would be expected to affect economic diversity (the number of economic sectors) or economic dependency, which occurs when the local economy is dominated by a limited number of industries. While the proposed alternatives have the potential to affect local businesses and individuals, as discussed in the following sections, the relative contribution of Butte Field Office-related activities to the local economy and the relative differences between the alternatives would not be large enough to have any measurable effect on economic diversity or dependency. This is also the case with respect to economic stability, which is typically assessed in terms of seasonal unemployment, sporadic population changes, and fluctuating income growth rates. Butte

Field Office-related activities include logging and recreation, which are typically characterized by seasonal employment, but none of the alternatives would be expected to affect existing trends in these or other industries.

Wildland fuel treatment costs are included for the purposes of this analysis in the total BLM expenditures identified by alternative (**Table 4-39**). Projected fuel treatment costs range from approximately \$400,000 under Alternative C to approximately \$1.26 million under Alternative D. Other potential wildland fire-related costs (such as property loss, lost revenues, and increased suppression costs) are difficult to project and are unknown. It is commonly accepted that fire suppression costs and risk to life and property should be less on wildland fires that occur where hazardous fuels have not been reduced. For example, fires generally burn hotter, flame length is higher, and fires in tree canopies are more likely in non-treated areas. A comparison of fire suppression costs in Western Montana and Eastern Montana help illustrate the differences in suppression costs.

Fire suppression costs incurred on the Beaverhead-Deerlodge, Gallatin, and Helena National Forests from 2000 through 2003 are summarized in (**Table 4-40**). These costs, presented as average suppression costs per acre, are provided to illustrate potential wildland fire suppression costs. The alternatives involve different approaches to, and levels of, vegetation treatment, as well as different approaches to wildland fire manage-

**Table 4-39**  
**Estimated Outputs by Alternative**

<b>Output</b>	<b>Current<sup>1</sup></b>	<b>A</b>	<b>B</b>	<b>C</b>	<b>D</b>
Actual Use Cattle (head month) <sup>2</sup>	31,200	31,200	28,300	28,800	31,200
Actual Use Sheep (head month) <sup>2</sup>	6,430	6,400	6,400	6,400	6,400
Estimated Timber Output (CCF) (PSQ) <sup>3</sup>	9,800	9,800	9,200	4,100	10,800
Dimension Stone (short tons)	N/A	400	400	400	400
Construction Sand and Gravel (short tons)	20,000	20,000	20,000	20,000	20,000
Limestone (short tons)	330,000	330,000	330,000	330,000	330,000
Natural Gas (M Cubic Feet)	0	980,000	980,000	0	980,000
General Recreation (1000 visits)	897	897	889	882	894
Fish and Wildlife Recreation (1000 visits)	437	437	426	417	434
BLM Expenditures (\$000,000s)	3.7	3.7	4.2	3.5	5.0

<sup>1</sup> Estimates include actual use levels (recreation visits in 2004) and authorized amounts (grazing and timber). Data are not available for minerals.

<sup>2</sup> Data, including the current estimate, are based on head months available for activation. Actual use has averaged about 70 percent of the total over the past seven years. 1 head month of cattle and horses = approximately 0.78 AUMs for cattle and horses; 1 head month for sheep and goats = approximately 0.2 AUMs for sheep and goats.

<sup>3</sup> Sawtimber data, including the current estimate, are based on the Probable Sale Quantity (PSQ). Actual sawtimber harvest was approximately 21 percent of the PSQ in 2003.

ment. This would tend to reduce the threat to life and property. Across all fire size class categories, the fire suppression costs per acre for the Custer NF were about one-fourth the average of the cost over the other three forests. It is not, however, possible to project the level of non-prescribed wildland fire that would occur under any of the alternatives. Based on the level of hazardous fuels treatments for each alternative, total wildland fire suppression costs for fires in the Butte Field Office would be highest for Alternative C and lowest for Alternative D.

This section discusses impacts to potentially affected groups that are unlikely to vary substantially by alternative.

**Timber and Forest Product Production**

The local primary forest product industry described by the Bureau of Business and Economic Research (BBER, 2001) is a long standing and basic industry that all of the alternatives would continue to supply with traditional materials shown in the PSQ estimates. The alternatives provide for changes that are anticipated through industrial research and development, and through entry of new businesses in the field, offering a different assortment of products such as biomass, that would use non-traditional and currently low value forest materials that were utilized inefficiently or were often considered to be waste in the past. While the harvest amounts being proposed under all of the alternatives would not have a significant effect on the total amount of material available from all ownerships in the area, they are still important, as the current timber harvest levels in Montana are considered to be insufficient to sustain the current industry for the next decade (BBER, 2004).

The commercial treatments proposed would tend to reduce the intensity of wildfire events and the tree conditions that favor development of epidemic levels of forest insect or disease. These treatments are expected to reduce the severe levels of tree mortality and site damage that are experienced during such large scale, stand replacement events, and would reduce the amount of salvage volume available from such events in the future. The intended reductions in the severity from such events would also tend to insure a steady and continuing supply of future forest products, helping to sustain economic conditions and improving local acceptance of active forest management and forest product removals.

Each of the alternatives also would sustain current local government revenues from the product sales within the eight-county area, as four percent of non-stewardship timber receipts are returned through the state to the counties where they are generated.

**Ranching**

Livestock grazing on BLM-managed land in the eight-county Planning Area would continue to involve approximately the same number of operators. Less than seven percent of the farms and ranches in the Planning Area would hold BLM grazing permits. The amount of livestock grazing would change less than 10 percent among the alternatives and BLM would continue to provide less than one percent of the total forage needed to feed livestock in the Planning Area (AMS, Appendix P (USDI-BLM 2006c)). The economic dependency of livestock producers on BLM forage would remain unchanged. However, often BLM forage would continue to provide a critical element of some livestock producers' complement of grazing, forage, and hay production. Farm income would continue to account for approximately one percent of total income in the eight-county study area.

<b>National Forest</b>	<b>Fire Size Class<sup>1,2</sup></b>						
	<b>A</b>	<b>B</b>	<b>C</b>	<b>D</b>	<b>E</b>	<b>F</b>	<b>G</b>
Beaverhead-Deerlodge	14,667	5,913	2,387	1,435	519	808	340
Custer	8,938	1,156	305	206	264	462	39
Gallatin	15,033	8,136	4,264	4,150	2,881	1,245	411
Helena	8,668	2,500	2,049	N/A	N/A	N/A	120
Average	12,789	5,516	2,900	2,793	1,700	1,027	290

<sup>1</sup>Fire size class is defined as follows:

- |   |                              |   |                                  |
|---|------------------------------|---|----------------------------------|
| A | 0.01 acres to 0.25 acres     | E | 300.00 acres to 999.90 acres     |
| B | 0.26 acres to 9.90 acres     | F | 1,000.00 acres to 4,999.90 acres |
| C | 10.00 acres to 99.90 acres   | G | 5,000.00 acres and larger        |
| D | 100.00 acres to 299.90 acres |   |                                  |

<sup>2</sup>Data are from the Forest Service which manages fire suppression in the Planning Area.

Source: Region 1 (FS) Fire Suppression Average Acre Cost by Unit. Derived from individual S100-2 reports 2000-2003.

### ***Recreation Use, Permitted Outfitters and Guides***

None of the proposed alternatives would be expected to affect current outfitter and guide use. The action alternatives do vary in terms of fee collections for commercial fishing and floating outfitters who use developed BLM river access sites. Payment of these fees would have different administrative impacts, but the actual costs would likely be passed on to the clients. Outfitters and guides would continue to have the same opportunities under all alternatives as they currently do, with the exception of potential hunting outfitter and guides who would not be able to camp at developed fee sites during hunting season under Alternatives B and C. There are currently no commercial outfitter and guides using developed fee sites during hunting season.

Revenues from recreation use permits, campground receipts, and outfitter and guide receipts would be similar (approximately \$123,000 per year) for all alternatives.

### ***Lands and Realty***

Use authorizations, e.g., rights-of-way, permits, and lease rentals would continue to generate an estimated \$110,000 of revenue annually for the federal government. Payments in Lieu of Taxes (PILT) from the federal government to the eight counties would continue to be approximately \$5.1 million with all the alternatives.

### ***Other Impacts***

Under all alternatives, economic diversity indicated by the number of economic sectors would remain relatively unchanged, though shifts in emphasis could occur. Estimated costs to local governments would also remain unchanged, i.e. demand for services and infrastructure would not change.

### ***Environmental Justice***

Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, requires each federal agency to make the achievement of environmental justice part of its mission by identifying and addressing disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority and low income populations. The Order further stipulates that agencies conduct their programs and activities in a manner that does not have the effect of excluding persons from participation in, denying persons the benefits of, or subjecting persons to discrimination because of their race, color, or national origin.

None of the proposed alternatives would be expected to have disproportionately high and adverse human health or environmental effects on minority and low income populations. All four alternatives are expected to result in increases in employment and labor income over the next decade, with alternatives resulting in a very small

share of total employment within the eight counties that comprise the Planning Area.

Public involvement efforts for this project have been inclusive and the agency has considered input from persons or groups regardless of race, color, national origin, income, or other social and economic characteristics.

### ***Public Health and Safety***

Under all alternatives, the hazardous materials management program focuses on immediate and urgent threats to human health and the environment from spills, releases, dumping, and discovery of hazardous waste sites. In terms of health and safety, land use authorizations for uses which would involve the disposal or storage of materials which could contaminate the land would not be issued. Lands proposed for acquisition or disposal would need to be inventoried for the presence of hazardous materials. The presence of contaminants may lead to actions such as the modification or abandonment of a land ownership adjustment proposal, or remediation in the form of cleanup and removal of the contaminants. Standard operating procedures required under the National Oil and Hazardous Substances Pollution Contingency Plan would be implemented during cleanup.

There would be no effects to public health and safety from proposed management associated with vegetation communities, special status and priority plant and animal species, recreation, ACECs, air quality, soils, water, paleontological resources, energy and minerals, environmental justice or tribal treaty rights.

Under all alternatives, abandoned mines that pose a significant risk to human health and the environment would be remediated.

Abandoned mine land (AML) reclamation prioritization would enable BLM to address immediate problem sites that pose a threat to public health and safety.

Reclamation activities conducted in accordance with Land Health Standards would contribute to achievement of the resource use vision statement.

Monitoring AML sites after reclamation would reduce risk to public safety by clarifying where risk to public health and safety has been reduced as well as where risks still exist.

## **Effects of Alternative A**

### ***Economic Environment***

Estimates of the levels of employment and labor income that would be supported by Alternative A are based on projected resource outputs and projected BLM expenditure levels (**Table 4-39**). Estimated average annual employment and labor income are summarized by resource area in **Table 4-42** and **Table 4-41**, respectively.

Resource	Current	A	B	C	D
Recreation	510	510	506	502	508
Wildlife and Fish	292	292	285	278	290

D = Data withheld to avoid disclosing confidential data of individual firms. Source: FEAST2007

Alternative A would allow an average annual harvest of approximately 9,800 CCF of timber (Table 4-39). The majority of this estimate (9,700 CCF) is based on the sawtimber PSQ and reflects the annual volume that would be available rather than actual harvest projections. Actual sawtimber harvest was approximately 21 percent of the PSQ in 2003. The remainder of the harvest estimate consists of fuel wood (61CCF) and post and poles (5.5 CCF). This harvest, if it were to occur, would support approximately 110 jobs and \$3.0 million in labor income (Table 4-42 and Table 4-41) within the local or regional economy.

Alternative A would continue current levels of forest product offerings and provide no adjustment in current economic condition.

Alternative A would authorize average annual grazing of approximately 31,200 cattle head months (HMs) and 6,400 sheep HMs (Table 4-39) and support about 10 jobs and \$200,000 in labor income (Table 4-42 and Table 4-41). Annual revenues from grazing permits would amount to approximately \$35,000 (25,677 AUMs x \$1.35/AUM= \$34,664). Approximately 64 percent of the AUMs sold within the Butte Field Office are section 3 permits of which 12.5 percent of revenues are distributed to the state and local counties; 36 percent of the

AUMs are section 15 permits of which 50 percent of revenues are distributed to state and local counties. Total consumer surplus associated with 25,677 BLM AUMs would continue to be approximately \$376,000. Annual federal revenues from livestock grazing would be about \$35,000, of which about \$8,400 would be distributed to the state and counties.

Recreation is the largest program managed by the Butte Field Office. It is estimated that recreation, including fish and wildlife-related recreation activities, would account for about 60 percent of all the jobs and about 50 percent of all the labor income that would be supported by Butte Field Office activities (Table 4-42 and Table 4-41). Motorized access and motorized recreation opportunities would not change from the current condition. An annual average of approximately 900,000 general recreation visits and 440,000 fish and wildlife-related recreation visits are projected under Alternative A (Table 4-39). Alternative A would support approximately 800 jobs and \$21 million in labor income (Table 4-42 and Table 4-41). Annual federal revenues from recreation management (including user fees and partnership donations for site maintenance and improvements) would be about \$123,000.

Currently, no oil and gas operations occur on federal lands/minerals. About 36,200 acres of federal minerals are currently leased within the planning area. Although acres available for oil and gas leasing would vary among alternatives, for this analysis the number of acres that would be leased under Alternative A, B, and D is projected to be about 37,700 acres. (37,731 acres are currently suspended with nominations. These would be available for lease upon completion of the RMP under alternatives A, B, and D.) Federal revenues from oil and gas leasing would include one-time lease bids (minimum of \$2.00/acre), and annual rental fees on leases (\$1.50 per acre/year for the first five years and \$2.00 per acre/year each year thereafter). Currently, 36,243 acres are leased and generate about \$72,000 in rental revenues. If all the new acres with suspended nominations were leased in one year the one-time lease bid would be at least \$75,000. Annual lease rentals for the first five years of these new leases would be about \$56,000. After the first five years, annual lease rentals (current and new) would be about \$148,000. Total State lease revenue would be 50 percent of Federal lease revenues. This would amount to about \$74,000 annually. At the scale of development projected, employment and income impacts on local residents would be limited and temporary. For analysis purposes, it is assumed that not more than one exploratory well would be drilled per year. Drilling would employ 15-20 workers per well for periods of up to 300 days. Average income per job in the mining sector would be about \$49,000 per year (average for the State of Montana, 2000, Northwest Economic Association). However, since drilling would likely be undertaken by outside firms, much of the employment and income effects would not show up in the local economy. Gas production would contribute to state and local government revenues through oil and gas tax revenues. For analysis purposes it is assumed that 980,000 MCF of natural gas would be produced annually. This would generate an estimated \$813,000 in Federal royalties (based on a six month average price of natural gas at wellhead of \$6.64/MCF, Energy Information Adminis-

tration, 10/11/07); one half (approximately \$407,000) would be distributed to the State of Montana; and 12.5 percent of the state portion (about \$102,000) would be distributed to the county or counties of production.

Alternative A would result in the estimated average annual production of 980,000 MCF of natural gas, 330,000 short tons of limestone, 400 short tons of dimension stone and 20,000 short tons of construction sand and gravel from public lands and federal minerals (Table 4-39). It is estimated that minerals exploration, development, and production on public lands/federal minerals would support about 90-100 local jobs and an estimated \$4.6 million in local labor income. (Table 4-42 and Table 4-41)

Annual average level of activities associated with ecosystem restoration would include fuels treatments and pre-commercial thinning (1,275 acres), weed spraying (2,000 acres), and road closures (172 miles). These activities would support about 10 jobs and \$340,000 in labor income. BLM expenditures include both expenditures for employee salaries and other non-salary expenditures related to Butte Field Office operations. Non-salary expenditures are purchases made in support of resource programs and operations and include items such as contracts, gasoline, diesel, ammunition and explosives, animal feed, computer equipment, and so on. Budget expenditures by program would remain constant under Alternative A and would continue to support approximately 90 jobs and \$2.9 million in labor income (Table 4-42 and Table 4-41).

In conclusion, the estimated total (direct, indirect, and induced) number of local jobs and associated local labor income contributed by BLM land and resource management would be about 1,270 jobs and \$38 million, respectively. Total employment and labor income generated by BLM resource management would increase by about 6 percent and 11 percent, respectively, compared to current management. These BLM-related contributions, i.e. jobs and labor income, would continue to be less than one percent of total within the local economy. The largest employment and labor income effects would occur in the accommodations and food services, government, and retail trade industry sectors (FEAST, 2007). All program revenues to the federal government would be about \$1.1 million per year. Annual payments to the State of Montana and to counties would be approximately \$5.5 million, most of which would be PILT payments. The dependency of the local economy on livestock industry, timber production, mining, oil and gas exploration, and recreation activities would not be affected by BLM resource management. The influence of resource management on BLM-administered lands would not change local economic diversity (as indicated by the number of economic sectors), dependency (i.e. where one or a few industries dominate the economy), or stability (as indicated by seasonal unemployment, sporadic population changes, and fluctuating income rates).

## ***Social Environment***

The following social analysis assesses the potential effects of different management actions on potentially affected social groups. These groups were identified based on past studies in and around the Planning Area and the results of public scoping conducted for the Butte RMP. The analysis addresses the potential impacts of the alternatives based on the issues and concerns raised by these groups during the public scoping process.

Timber employment is concentrated in only a few areas in the analysis area and lands managed by the Butte Field Office account for a very small portion of total harvest in this area. There would be no change in available timber harvest opportunities under this alternative. Public access and the availability of firewood and other forest resources would also remain unchanged. As a result, this alternative would be unlikely to affect current social conditions with respect to forest products. Timber-related issues, raised during public scoping for this project included concerns regarding noxious weeds, fuel hazard reduction, and dead tree salvage. The action alternatives, with the possible exception of Alternative C, would treat larger areas of weeds and based on this issue, Alternative A is likely to be less favored among those concerned about noxious weed treatments.

Fire suppression within the first burning period would limit the loss of forest products to fire. Wildland fire use and prescribed burning could cause a loss of forest products, but could also create salvage opportunities. Heavily stocked tree conditions contribute to epidemic levels of forest insect or disease and increase the intensity of wildfire events. Commercial treatments would reduce heavily stocked conditions and corresponding severe levels of tree mortality and site damage. Local acceptance of active forest management and forest product removals would likely be improved as the threat of intensive wildfire and the threat of forest mortality from disease and insects is reduced.

Lands managed by the Butte Field Office accounted for less than one percent of the total AUMs in the Planning Area in 2003, ranging from 0.02 percent of total AUMs in Broadwater County to 2.7 percent of the total in Jefferson County. These lands do, however, account for more than one-third of total AUMs for approximately 20 of the 174 existing ranchers who use Butte Field Office lands. In addition, these lands may be important to operators because of their relatively low grazing fees, which are \$1.35 per AUM for 2007.

There would be no change in the authorized AUMs under Alternative A (Table 4-39). Conflicts between livestock grazing and wheeled vehicles would continue under this alternative. A wide range of recreation opportunities are available within the Planning Area. These activities involve diverse groups of people and changes in recreation management can affect people who engage in particular recreation activities very differently. Con-

cerns were expressed during the public scoping process that demand for motorized recreational access has increased in recent years, while motorized access has decreased, largely as a result of federal land management action and policies that favor non-motorized users. Some commenting felt that public lands should be available to all users, both motorized and non-motorized, but some areas and trails should have limited types of use (hiking use only or OHV use only) where different types of use tend to be incompatible. Others felt that non-motorized uses are presently favored over motorized uses and felt that this balance should be changed, with motorized users allowed equal access (USDI-BLM 2005a).

Alternative A would not allocate ROS classes and recreation opportunities on Decision Area lands would continue to be managed under site-specific plans only. Management would continue to be challenging around developed recreation sites during peak recreation use seasons, particularly near shorelines and water-based recreation opportunities. Motorized access and motorized recreational opportunities (including organized motorized events) would continue unchanged under this alternative. As a result, this alternative would not address concerns about conflicts between motorized and non-motorized use or, between motorized use and livestock grazing. It would also not address concerns that the Butte Field Office should provide additional motorized recreation opportunities.

Permit requests by outfitter/guide hunters would be considered on a case-by-case basis throughout the decision area subject to environmental, social, and public health and safety concerns. No fees would be charged for commercial fishing and floating outfitters using developed BLM river access sites. This alternative would likely be favored by outfitter/guides over Alternatives B and C, which would impose constraints on potential outfitter/guide activities.

A number of individuals and organizations commenting during scoping for this project expressed concern about resource protection issues, with particular emphasis placed on wildlife, fisheries, water, and special area designations. Comments included requests that habitat corridors for threatened, endangered, and sensitive species and the integrity and non-motorized character of all roadless areas be maintained. Some respondents identified areas for designation as special use areas, including ACECs, wild and scenic river areas, and recreational river areas (USDI-BLM 2005a).

The current levels, methods, and mix of multiple use management would continue on Decision Area lands under this alternative and activity-level wildlife habitat and riparian protection measures would be less restrictive under this alternative than they would be under Alternatives B and C. The four eligible Wild and Scenic River segments would continue to be managed to protect the values that make them eligible and the six existing

WSAs would continue to be managed under the Interim Management Policy and Guidelines. No new ACECs would be established under this alternative. Based on these criteria, individuals and groups who give high priority to resource protection would be less likely to support this alternative than they would Alternatives B and C.

A number of individuals and groups expressed concern about limitations being placed on the availability of public lands for commercial uses such as livestock grazing, mineral development, and timber harvest. These people believe that local communities depend on these industries, which are a primary source of high paying jobs to local economies. Comments received during scoping for this project requested that the RMP revision focus on beneficial economic and social use of public lands, not locking them up from development or public access.

The current levels, methods, and mix of multiple use management would continue on Decision Area lands under this alternative. Resource outputs and current levels of motorized access and motorized recreation opportunities would not change under this alternative. Individuals and groups concerned about resource use limitations would likely favor this alternative or Alternative D.

## Effects Common to Action Alternatives

### *Social Environment*

ROS classes would be established and used to manage for desired recreation opportunities, experience levels, facility developments, and other resource uses. Implementation plans for Special Recreation Management Areas delineated Recreation Management Zones would be developed where specific management, marketing, monitoring, and administrative guidance is needed. The greatest difference between the action alternatives is the variation between motorized and non-motorized access.

Alternatives B and C would have the overall effect of reducing opportunities available for motorized recreation when compared to Alternative A, but the quality of the experience may increase because separating uses would reduce conflicts between user groups. Allocating areas to non-motorized use lets both non-motorized and motorized users know which areas they would have access to in the future.

Localized impacts from changes in management direction would be most likely to occur in the Scratchgravel Hills area, which would be managed differently under the action alternatives.

### *Public Health and Safety*

In addition to impacts described under Effects Common to All Alternatives, Alternatives B, C and D would include the AML reclamation program requiring an abandoned mine shaft in the Ringing Rocks Potential ACEC

to be reclaimed. The physical safety hazard for this site would be reduced.

## Effects of Alternative B

### *Economic Environment*

Estimates of the levels of employment and labor income that would be supported by Alternative B are based on projected resource outputs and projected BLM expenditure levels (**Table 4-39**). Estimated average annual employment and labor income are summarized by resource area in (**Table 4-42** and **Table 4-41**), respectively. The projected outputs and estimated employment and labor income are discussed by resource in the following sections.

Alternative B would provide for an average annual harvest of approximately 9,200 CCF of timber (**Table 4-39**). The majority of this estimate (9,100 CCF) is based on the sawtimber PSQ and reflects the annual volume that would be available rather than actual harvest projections. Estimated sawtimber harvest (9,100 CCF) would be approximately 99 percent of the PSQ. The remainder of the harvest estimate would consist of fuel wood (82 CCF) and post and poles (7.7 CCF). This harvest, if it were to occur, would support approximately 100 jobs and \$2.8 million in labor income (**Table 4-42** and **Table 4-41**).

Alternative B would cause slightly smaller levels of forest product offerings with higher levels of acreage treatments. These changes would not have noticeable difference in economic conditions locally.

Alternative B would authorize average annual grazing of approximately 28,300 cattle HMs and 6,400 sheep HMs (**Table 4-39**) and support approximately 10 jobs and \$180,000 in labor income (**Table 4-42** and **Table 4-41**). Annual revenues from grazing permits would amount to less than \$32,000. (24,710 AUMs x \$1.35/AUM=\$31,587). Estimated total distribution to state and local counties would be about \$7,600. Total consumer surplus associated with 24,710 BLM AUMs would be about \$362,000. Annual federal revenues from livestock grazing would be about \$31,600 and the amount distributed to the state and counties would be about \$7,600. Alternative B emphasizes a balance of motorized and non-motorized recreation and access opportunities compared to the other action alternatives (Alternatives C and D). The number of recreation visits to Butte Field Office-managed areas is expected to increase at a rate of two percent per year over the next 10 years under all of the alternatives. The projected average annual visits summarized for Alternative B in **Table 4-39** were estimated based on this expected increase. The total number of visits projected under Alternative B is expected to be slightly lower than under Alternative A.

Management actions under Alternative B are projected to result in a relative reduction in the number of visits associated with motorized vehicle travel, hunt-

ing/archery, wildlife/natural viewing, and snowmobiling, and a relative increase in non-motorized recreation visits (e.g., foot travel, biking, and horseback riding) (**Table 4-39**). Annual federal revenues from recreation management would be about the same as with Alternative A (\$123,000).

An annual average of approximately 889,000 general recreation visits and 426,000 fish and wildlife-related recreation visits are projected under Alternative B (**Table 4-39**). These visits would support approximately 790 jobs and \$20.3 million in labor income (**Table 4-42** and **Table 4-41**).

The economic impacts associated with minerals management and operations would be similar to those described for Alternative A. (**Table 4-42** and **Table 4-41**). Indirectly, Alternative B would likely provide an environment that is more conducive to continuing long-term population growth and corresponding economic growth than Alternatives A and D because it offers more protection of public lands and resources through the management of ACECs, Wild and Scenic Rivers, travel management restrictions, and semi-primitive non-motorized recreation management. Studies indicate that “protected public lands, set aside for their wildland characteristics, can and do play an important role in stimulating economic growth...” (Prosperity in the 21st Century West, Rasker et al, 2004).

Estimated annual average level of activities associated with ecosystem restoration would include hazardous fuels treatments and pre-commercial thinning (2,560 acres), weed spraying (2,900 acres), road decommissioning (5 miles), and road closures (318 miles). These activities would support about 20 jobs and \$590,000 in labor income.

In conclusion, the economic effects of Alternative B would be very similar to those of Alternative A. The estimated total (direct, indirect, and induced) number of local jobs and associated local labor income contributed by BLM land and resource management described above in Alternative B would be about 1,260 jobs and \$38 million, respectively. Like Alternative A, total employment and labor income generated by BLM resource management under Alternative B would increase by about 6 percent and 11 percent, respectively, compared to current management. These BLM-related contributions, i.e. jobs and labor income, would continue to be less than one percent of total within the local economy. The largest employment and labor income effects would occur in the accommodations and food services, government, and retail trade industry sectors. All program revenues to the federal government would be about \$1.1 million per year. Annual payments to the State of Montana and to counties would be approximately \$5.53 million, most of which would be PILT payments. The dependency of the local economy on livestock industry, timber production, mining, oil and gas exploration, and recreation activities would not be affected by BLM

resource management. The influence of resource management on BLM-administered lands would not change local economic diversity (as indicated by the number of economic sectors), dependency (i.e. where one or a few industries dominate the economy), or stability (as indicated by seasonal unemployment, sporadic population changes, and fluctuating income rates).

### ***Social Environment***

Projected timber harvest levels under Alternative B are slightly lower than current levels. Access to firewood, Christmas trees and other forest resources would be reduced under this alternative due in part to a 34 percent reduction in the roads currently available for public use to remove such materials and a 17 percent reduction in the forest and woodland area available under Alternative A through Recreational Opportunity Spectrum designation as Semi-primitive non-motorized where in some cases currently open roads would be closed. Access reductions would be greater than under current conditions, but lower than they would be under Alternative C.

An estimated 21,000 to 50,000 acres of weeds would be treated each decade under Alternative B. This may be slightly more to over twice the estimated 20,000 acres that would be treated under Alternative A. As a result, Alternative B would likely be relatively favored by those primarily concerned with noxious weed issues. Fire management impacts would be similar to those projected under Alternative A. Timber salvage would produce sawlogs and other timber products, but salvage would be more limited under this alternative than it would be under Alternatives A and D.

The numbers of AUMs permitted for livestock would be slightly less than for Alternative A; this decrease is not expected to affect any ongoing operation.

The effects to ranching would be the same under this alternative as they would under Alternative A. Relinquished allotments would be evaluated for suburban/urban interface issues, critical wildlife habitat, riparian values, or recreational considerations before being re-offered for permit or lease. Fewer conflicts between livestock grazing and wheeled vehicles would occur under this alternative than under Alternative A.

Alternative B emphasizes a balance of motorized and non-motorized recreation and access opportunities compared to the other action alternatives (Alternatives C and D); with 34 percent of Decision Area lands allocated to semi-primitive ROS classes. Management actions under this alternative are expected to result in a relative reduction in the number of visits associated with motorized vehicle travel, hunting/archery, motorized wildlife/scenery viewing, and snowmobiling, and a relative increase in non-motorized recreation visits (e.g., foot travel, biking, and horseback riding) (**Table 4-39**). Organized motorized events would be limited to the Pipestone area unless being held in conjunction with adjacent public or private lands. With the exception of a few

routes needed for residential access, the entire Scratch-gravel Hills area would be closed to wheeled motorized vehicle use yearlong. This alternative would address concerns about conflicts between non-motorized and motorized use and between motorized use and livestock grazing. It would not address concerns that the Butte Field Office should provide additional motorized recreation activities.

Annual day-use fees (to be established in accordance with FLREA) per commercial guided boat would be charged for commercial fishing and floating outfitters using developed BLM river access sites. Payment would be collected at the time of use. Commercial camping permits within developed fee sites would not be allowed during the fee season (Memorial Day to Labor Day). Special Recreation Use Permits during the hunting season would be limited to day-use activities with the exception that camping uses would be considered within developed recreation sites during the non-fee season. Based on these constraints, commercial outfitter/guides would be less likely to favor this alternative than they would Alternatives A or D.

This alternative emphasizes moderate levels of resource protection, use, and restoration, with project-level wildlife habitat and riparian protection measures greater than under Alternatives A and D, but less than under Alternative C. Individuals and groups who give high priority to resource protection would be more likely to favor this alternative than Alternatives A and D.

This alternative emphasizes moderate levels of resource protection, use, and restoration. Estimated average annual timber harvest would be higher under this alternative than under Alternative C, approximately the same as under Alternative A, but less than under Alternative D (Table 4-39). Oil and gas leasing constraints would be more restrictive than under Alternatives A and D, but less restrictive than under Alternative C. Based on these criteria, individuals and groups who give high priority to resource use would be more likely to favor this alternative than Alternative C and possibly Alternative A, depending on the specific priorities of the group or individuals concerned.

## Effects of Alternative C

### *Economic Environment*

Estimates of the levels of employment and labor income that would be supported by Alternative C are based on projected resource outputs and projected BLM expenditure levels (Table 4-39). Estimated average annual employment and labor income are summarized by resource area in Table 4-42 and Table 4-41, respectively. The projected outputs and estimated employment and labor income are discussed by resource in the following sections.

Alternative C would provide for an average annual harvest of approximately 4,100 CCF of timber (Table 4-39).

This is lower than under current conditions and lower than the other alternatives. The majority of this estimate is based on the sawtimber PSQ and reflects the annual volume that would be available rather than actual harvest projections. This harvest, if it were to occur, would support approximately 50 jobs and \$1.3 million in labor income (Table 4-42 and Table 4-41). The local employment and labor income supported by timber harvest on BLM lands would be less than half of current levels.

This alternative would authorize average annual grazing of approximately 28,800 cattle HMs and 6,400 sheep HMs (Table 4-39) and support approximately 10 jobs and \$183,000 in labor income (Table 4-42 and Table 4-41). Economic effects of and permittee responses to grazing management would be similar to those described for Alternatives A and B. Annual revenues from grazing permits would be similar to Alternative B (about \$32,100), (24,710 AUMs x \$1.35/AUM=\$32,095). Estimated total distribution to state and local counties would be about \$7,700. Total producer surplus would be about \$362,000. The total number of visits projected under Alternative C is the lowest of the four alternatives. Management actions under Alternative C are projected to result in a relative reduction in the number of visits associated with motorized vehicle travel, hunting/archery, wildlife/natural viewing, and snowmobiling. Projected reductions in these areas would be twice as large as those under Alternative B but still relatively minor when measured in terms of regional economic impacts. Alternative C is also expected to result in a relative increase in non-motorized recreation visits (e.g., foot travel, biking, horseback riding, and non-motorized boating).

An annual average of approximately 882,000 general recreation visits and 417,000 fish and wildlife-related recreation visits are projected under Alternative C (Table 4-39). This increase over the current (2004) level of visitation is due to the baseline increase in recreation visits (two percent per year) that is projected under all of the alternatives. Alternative C would support approximately 780 jobs and \$20.1 million in labor income (Table 4-42 and Table 4-41). Annual federal revenues from recreation management would be about the same as with Alternative A because the increase in recreation use would occur largely in dispersed recreation use where BLM does not collect fees. Alternative C would result in the estimated average annual production of 330,000 short tons of limestone, 400 short tons of dimension stone, and 20,000 short tons of construction sand and gravel from public lands (Table 4-39). It is estimated that minerals exploration, development, and production on public lands/federal minerals would support about the same level of employment and labor income as current management. However, there would likely be no contribution from oil and gas leasing from BLM mineral estate lands due to the high degree of leasing restrictions under this alternative.

Estimated annual average level of activities associated with ecosystem restoration would include hazardous fuels treatments and pre-commercial thinning (450 acres), weed spraying (2,200 acres), road decommissioning (5 miles), and road closures (375 miles). These activities would support less than 10 jobs and about \$250,000 in labor income.

BLM budget expenditures would be lower under Alternative C than under any other alternative, including Alternative A, No Action (**Table 4-39**). Alternative C would have lower expenditures than Alternative A in the range, fuels, and weed treatment programs, with the largest reduction occurring under the fuels program. BLM expenditures under this alternative would support approximately 90 jobs and \$2.7 million in labor income (**Table 4-42** and **Table 4-41**).

Indirectly, Alternative C would provide an environment that would be more likely to sustain long-term population growth and corresponding economic growth than the other alternatives because it offers the most protection of public lands and resources through the management of ACECs, Wild and Scenic Rivers, travel management restrictions, semi-primitive non-motorized recreation management, and less mineral development. Studies indicate that “protected public lands, set aside for their wildland characteristics, can and do play an important role in stimulating economic growth...” (Prosperity in the 21st Century West, Rasker et al, 2004).

In conclusion, Alternative C is the only alternative analyzed in detail that would result in a short-term loss of local employment and labor income. The estimated total (direct, indirect, and induced) number of local jobs and associated local labor income contributed by BLM land and resource management described above in Alternative C would be about 1,100 jobs and about \$31.3 million, respectively. Total employment and labor income generated by BLM resource management under Alternative C would decrease by about 8 percent compared to current management. These BLM-related contributions, i.e. jobs and labor income, would continue to be less than one percent of total within the local economy. The largest employment and labor income effects would occur in the accommodations and food services, government, and retail trade industry sectors. All program revenues to the federal government would be about \$0.2 million per year. Annual payments to the State of Montana and to counties would be approximately \$5.1 million, most of which would be PILT payments. The dependency of the local economy on livestock industry, timber production, mining, oil and gas exploration, and recreation activities would not be affected by BLM resource management. The influence of resource management on BLM-administered lands would not change local economic diversity (as indicated by the number of economic sectors), dependency (i.e. where one or a few industries dominate the economy), or stability (as indi-

cated by seasonal unemployment, sporadic population changes, and fluctuating income rates).

### ***Social Environment***

Projected timber harvest levels are much lower under Alternative C than under the other alternatives. This alternative would likely be less favored than the other alternatives by those primarily concerned about timber employment. Access to firewood, Christmas trees and other forest resources would be limited under this alternative due in part to a 41 percent reduction in the roads currently available for public use to remove such materials and a 29 percent reduction in the forest and woodland area available under Alternative A through Recreational Opportunity Spectrum designation as Semi-primitive non-motorized where in some cases currently open roads would be closed.

Projected ground disturbance would be lower under this alternative than it would under the other action alternatives and, as a result, less aggressive weed treatment would be required. An estimated 16,000 to 38,000 acres of weeds would be treated per decade under this alternative.

Timber salvage would be limited under this alternative and, as a result, is less likely to be favored by those primarily concerned with salvage opportunities. Similarly, this alternative would require that firewood be live trees and could, as a result, substantially reduce the number of firewood permits.

The effects to ranchers would be similar to Alternative B. The existing Indian Creek allotment (2,215 acres and 376 AUMs), as well as any lands acquired from the Iron Mask acquisition, would be unavailable for grazing lease or permit under this alternative.

Alternative C would emphasize non-motorized recreation opportunities more than the other alternatives, with 41 percent of the Decision Area lands allocated to semi-primitive ROS classes. Based on this relative distribution, Alternative C is likely to be preferred by recreationists who favor non-motorized recreation opportunities. Management actions under this alternative are expected to result in a relative reduction in the number of visits associated with motorized vehicle travel, hunting/archery, motorized wildlife/scenery viewing, and snowmobiling. Opportunities for organized motorized events would be eliminated and the entire Scratchgravel Hills area would be closed to motorized vehicle use after dark (dusk to dawn) yearlong. This alternative would address concerns about conflicts between motorized and non-motorized use and between motorized use and livestock grazing. It would not address concerns that the Butte Field Office should provide additional motorized activities.

Annual day-use fees of \$90 per commercial guided boat would be charged for commercial fishing and floating outfitters using developed BLM river access sites. Out-

fitters would be billed in advance. Commercial camping permits within developed fee sites would not be allowed during the fee season (Memorial Day to Labor Day). Special Recreation Use Permits during the hunting season would be limited to day-use activities only. Based on these constraints, commercial outfitter/guides would be less likely to favor this alternative than they would the other alternatives.

This alternative emphasizes a lesser degree of vegetative restoration than the other action alternatives (Alternatives B and D), but project-level wildlife habitat and riparian protection measures would be greater than under the other three alternatives. All four eligible Wild and Scenic River segments would be recommended as suitable for the National Wild and Scenic Rivers System and four new ACECs, including a total of approximately 76,000 acres, would be established. Based on these criteria, individuals and groups who give high priority to resource protection would likely favor this alternative.

Estimated average annual timber harvest would be lower under this alternative than under any other alternative (Table 4-39). Oil and gas leasing constraints would be the most restrictive of any alternative. Groups and individuals who are concerned about restrictions on resource use would likely prefer all other alternatives over Alternative C.

## Effects of Alternative D

### *Economic Environment*

Estimates of the levels of employment and labor income that would be supported by Alternative D are based on projected resource outputs and projected BLM expenditure levels (Table 4-39). Estimated average annual employment and labor income are summarized by resource area in Table 4-42 and Table 4-41, respectively. The projected outputs and estimated employment and labor income are discussed by resource in the following sections.

Alternative D would provide for an average annual harvest of approximately 10,800 CCF of timber (Table 4-39). This is higher than the volumes projected for the other action alternatives. The majority of this estimate (10,700 CCF) is based on the sawtimber PSQ and reflects the annual volume that would be available rather than actual harvest projections. This harvest, if it were to occur, would support approximately 120 jobs and \$3.3 million in labor income (Table 4-42 and Table 4-41).

Alternative D would offer higher levels of forest product offerings with higher levels of acreage treatments; however these changes would not be large enough to cause substantial differences in local economic conditions.

Economic impacts associated with grazing management would be similar to current management (Alternative A). This alternative would authorize average annual grazing of approximately 31,200 cattle HMs and 6,400 sheep

HMs (Table 4-39) and support approximately 10 jobs and \$198,000 in labor income (Table 4-42 and Table 4-41). Annual revenues from grazing permits would amount to about \$35,000 (25,677 AUMs x \$1.35/AUM = \$34,664). Estimated total distribution to state and local counties would be about \$8,400. Consumer surplus would be about \$376,000. Annual federal revenues from livestock grazing and the amount distributed to the state and counties would be about the same as with Alternative A.

Alternative D emphasizes motorized access and recreation opportunities more than the other action alternatives. The total number of visits projected under Alternative D is the highest of the four alternatives. Management actions under Alternative D are projected to result in a relative increase in the number of visits associated with motorized vehicle travel, hunting and archery, wildlife and natural viewing, and snowmobiling, with the projected visits for other activities expected to remain as projected under Alternative A.

Management actions under Alternative D, coupled with an annual two percent increase in the number of visits, are expected to result in an annual average of approximately 894,000 general recreation visits and 433,000 fish and wildlife-related recreation visits (Table 4-39) and support approximately 800 jobs and \$20.5 million in labor income (Table 4-3 and Table 4-4). Annual federal revenues from recreation management would be about the same as with Alternative A (\$580,000).

Alternative D would result in the estimated average annual production of 980,000 MCF of natural gas, 330,000 tons of limestone, 400 short tons of dimension stone and 20,000 short tons of construction sand and gravel from public lands (Table 4-39) and support 90-100 jobs and \$4.6 million in labor income (Table 4-42 and Table 4-41). The economic impacts associated with minerals management would be similar to those described for Alternative A.

Estimated annual average level of activities associated with ecosystem restoration would include hazardous fuels treatments and pre-commercial thinning (3,345 acres), weed spraying (3,600 acres), road decommissioning (4 miles), and road closures (266 miles). These activities would support about 20 jobs and \$750,000 in labor income.

Budget expenditures would be higher under Alternative D than under any other alternative, with the majority of the relative increase associated with expenditures in the fuels and fish and wildlife management programs. BLM expenditures under this alternative would support approximately 100 jobs and \$3.9 million in labor income (Table 4-42 and Table 4-41).

In conclusion, the estimated total (direct, indirect, and induced) number of local jobs and associated local labor income contributed by BLM land and resource management described above in Alternative D would be about

1,300 jobs and almost \$39.3 million, respectively. Total employment and labor income generated by BLM resource management under Alternative D would increase by about 9 percent and 16 percent, respectively, compared to current management. These BLM-related contributions, i.e. jobs and labor income, would continue to be less than one percent of total within the local economy. The largest employment and labor income effects would occur in the accommodations and food services, government, and retail trade industry sectors. All program revenues to the federal government would be about \$1.1 million per year. Annual payments to the State of Montana and to counties would be approximately \$5.5 million, most of which would be PILT payments. The dependency of the local economy on livestock industry, timber production, mining, oil and gas exploration, and recreation activities would not be affected by BLM resource management. The influence of resource management on BLM-administered lands would not change local economic diversity (as indicated by the number of economic sectors), dependency (i.e. where one or a few industries dominate the economy), or stability (as indicated by seasonal unemployment, sporadic population changes, and fluctuating income rates).

### ***Social Environment***

Alternative D would have the highest projected timber harvest levels and would support approximately 70 jobs (Table 4-42 and Table 4-41). This alternative would likely be relatively favored by the timber industry and workers concerned about employment. These potential employment opportunities represent a very small share of total employment within the Planning Area, but may be important to those concerned and may have small, but positive, impacts in one or more local communities. Access to firewood, Christmas trees and other forest resources would be reduced under this alternative due in part to a 24 percent reduction in the roads currently available for public use to remove such materials and a 16 percent reduction in the forest and woodland area available under Alternative A through Recreational Opportunity Spectrum designation as Semi-primitive non-motorized where in some cases currently open roads would be closed. Access reductions would be greater than under current conditions, but lower than Alternatives B and C.

Projected ground disturbance would be higher under this alternative than it would under the other action alternatives and, as a result, more aggressive weed treatment would be required. An estimated 25,000 to 61,000 acres of weeds would be treated per decade. Timber salvage would be limited under this alternative compared to Alternative A. Fire created salvage opportunities would be higher under this alternative than under the other action alternatives. The effects on ranching would be the same under this alternative as Alternative A. Unlike the other action alternatives (Alternatives B and C), relinquished allotments would remain available for livestock

grazing leases or permits without evaluation for suburban/urban interface issues, crucial wildlife habitat, riparian values, or recreational considerations before re-offering. Fewer conflicts between ranchers and off-highway motorized vehicle users would occur than under Alternative A.

Alternative D emphasizes motorized access and recreation opportunities more than the other alternatives, with just 21 percent of Decision Area lands allocated to semi-primitive ROS classes. Based on this relative distribution, Alternative D is likely to be preferred by recreationists who favor motorized recreation opportunities, including hunters who prefer motorized hunting opportunities and groups and individuals that engage in snowmobiling. Two areas would remain open for organized motorized events and motorized and non-motorized recreational uses would be allowed 24 hours per day in the Scratchgravel Hills area in accordance with the travel management plan. This alternative would address some of the concerns about conflicts between motorized and non-motorized use. It would not address concerns that the Butte Field Office should provide additional motorized recreation activities.

BLM would postpone fees for commercial fishing and floating outfitters using developed BLM river and lake sites accessing state waterways until a multi-agency statewide fee system is established. Authorization of commercial camping activity and permit requests by outfitter and guide hunters would be considered throughout the Field Office on a case-by-case basis subject to resource constraints, management capabilities, social conflicts and public health and safety concerns. This alternative would impose fewer constraints on commercial outfitter and guides than the other two action alternatives (Alternatives B and C) and would, as a result, be more likely to be favored by those groups.

This alternative emphasizes a greater degree of vegetative restoration than the other action alternatives (Alternatives B and C), but project-level wildlife habitat and riparian protection measures would be less restrictive under this alternative than they would be under the other three alternatives. None of the four eligible Wild and Scenic River segments would be recommended as suitable for the National Wild and Scenic Rivers System. This alternative would establish two new ACECs, including a total of approximately 12,000 acres, less than half the new ACEC acres proposed under the other action alternatives (Alternatives B and C). Based on these criteria, individuals and groups who give high priority to resource protection would be less likely to favor this alternative than the other action alternatives.

Estimated average annual timber harvest would be higher under this alternative than under any of the other alternatives (Table 4-39). Oil and gas leasing constraints would be less restrictive than Alternatives A and B, and much less restrictive than Alternative C. Alternative D emphasizes motorized recreation opportunities more

than the other alternatives. Based on these criteria, individuals and groups who give high priority to resource use would likely favor this alternative.

## TRIBAL TREATY RIGHTS

### Effects Common to All Alternatives

BLM will manage vegetation to fall within the historic range of variability, with diverse plant communities that contain healthy populations of a variety of native species. Enhancement of wildlife habitat and native plant communities provides increases in opportunity for tribal members to exercise tribal treaty rights such as hunting, fishing, and gathering on public lands. New road construction would not occur in association with travel plan alternatives with the exception of a small number of short routes to provide loop opportunities under Alternative D.

## CUMULATIVE EFFECTS

This section is divided into two main parts. The first part describes the past, present, and reasonably foreseeable future actions on lands within the Planning Area, organized by management activities associated with the most pertinent particular resources or resource uses. Activities described under one resource or resource use heading could affect other resources or resource uses in the Planning Area. The second part of this section describes cumulative effects on resources and resource uses.

The cumulative effects analysis area for this RMP consists of the approximately 7.2 million acre Planning Area. BLM lands are generally widely scattered throughout the Planning Area and therefore tend to have a relatively small contribution to cumulative effects of all activities taking place within the Planning Area. Major approximate land ownership acreages within the Planning Area consist of the following: 3.5 million acres of private lands; 2.8 million acres of National Forest (USFS) lands; 320,000 acres of state-owned land; 307,309 acres of BLM lands (Decision Area lands); 150,000 acres of National Park Service lands; 15,000 acres of local government lands; and 11,000 acres of Bureau of Reclamation lands. BLM lands make up approximately four percent of all lands in the Planning Area. The wide distribution of BLM lands within the Planning Area make it necessary to establish such a large analysis area in order to encompass Decision Area lands addressed in this document.

## PAST, PRESENT AND REASONABLY FORESEEABLE ACTIONS

The following discussion characterizes past, present and reasonably foreseeable future actions considered in the cumulative effects analysis. More detail on these activities can be found in the administrative record.

Activities outside of BLM jurisdiction considered in the cumulative effects analysis are included. Some activities identified under a particular resource or resource use heading may affect more than one resource. For example, activities listed under Soil Resources may affect water quality. Effects are discussed in the second main part of this section. It should be noted that acreage figures are approximate based on GIS layers from multiple sources that are subject to varying degrees of error.

## Soil Resources

Approximately 8,000 acres of land near Helena (Fort Harrison) in the Planning Area are managed by the National Guard. Some activities include military maneuvers, non-live fire training, and off-road use of military vehicles. Some soil compaction will likely occur with these activities.

Acquisition of the Iron Mask property would place approximately 5,565 acres of range and mountainous land under more stringent resource protection standards through the implementation of Land Health Standards than are currently in place on these private lands. In addition, the acquisition would protect the area from future development.

Expansion of the Indian Creek Mine could increase the disturbance area within the Limestone Hills Training Area from the present size of about 300 acres.

Construction and use of a 75-acre area for a new qualifying training range proposed for the Limestone Hills Training Area could result in short-term episodes of accelerated erosion during road construction and clearance for facilities. In addition, the range would be located within a grazing area and could occur on productive soils. This potential future action would result in the loss of some soil productivity and short term accelerated erosion.

The proposed Limestone Hills Training Area withdrawal of the Limestone Hills Training Area could result in a transfer of natural resource and resource use management from BLM to the Montana Army National Guard on approximately 20,000 acres of federal land. Because the Montana Army National Guard is required to manage land in accordance with requirements similar to those implemented by BLM, no different impact on soil resources is expected from this reasonably foreseeable action.

## Water Resources

Canyon Ferry Reservoir and Dam on the Missouri River would continue to be operated to provide flood control, power generation, irrigation, municipal water and to stabilize downstream flows.

PPL of Montana manages water flows through Hauser, and Holter Lake dams. Hauser and Holter Lakes are managed as full-pool, run-of-river reservoirs. Flows within and through these three reservoirs are managed to

optimize energy production; provide for water right uses; and maintain appropriate conditions for fisheries, wildlife and recreation.

Since 1997, the Butte Field Office has reclaimed the Alta Mine, Comet Mine/High Ore Creek, Redwing/Waldy Mines, Gregory Mine, Bertha Mine, Park Mine/Upper Indian Creek, Wicks Smelter, Wicks Manganese, and Lower Indian Creek Dredge Piles to address water quality.

Beginning in 1997, BLM began cleanup of abandoned mines under the Abandoned Mine Lands (AML) program. To date, 14 mines have been reclaimed covering approximately 81 acres, 7 repositories were constructed, and 5 mines are planned for reclamation in the next 5 to 10 years including the Belle Lode (Wickes Manganese), Indian Creek Dredge Piles, Great Divide, Iron Mask and Hard Cash.

Irrigation of privately owned lands will continue.

## Vegetation

The Vegetation Management EIS (Draft EIS, November 2005) covering 17 western states, including Montana, expanded herbicide use and allows for use of new herbicides to improve BLM's ability to control hazardous fuels and unwanted vegetation.

Vegetation disturbances likely occur from National Guard training activities. The Guard inventories, maps, and treats noxious weeds on their lands. In the past wildland fires have occasionally initiated there as a result of training exercises.

There are approximately 3.5 million acres of private lands within the Planning Area. Vegetation management will likely include loss of vegetation from road construction and residential development, effects of continued livestock grazing, forest fuels reduction in urban interface areas and timber harvest for commercial uses.

Vegetation management will continue on National Forest System lands (outside some special designation areas) including noxious weed treatment and control, livestock grazing, road construction/management, forest products removal, timber salvage, fuel reduction and wildland fire suppression. Effects would likely be most pronounced on 2.1 million acres, but less pronounced on the approximately 700,000 acres of wilderness on National Forest lands in the Planning Area.

## Wildlife

Past, present, and reasonably foreseeable actions focused on wildlife and wildlife habitat on BLM lands include: establishment of a multi-party vision for vegetation conditions in the Elkhorn Mountains Cooperative Management Area to benefit wildlife, primarily big game; reintroduction of bighorn sheep into historically occupied habitat in several locations including Crow Creek and Indian Creek areas in the Elkhorn Mountains, the

Sleeping Giant area, and the Camp Creek/Soap Gulch area in the Highland Mountains; restoration of approximately 1,000 acres of bighorn sheep habitat through vegetative treatments in the Shep's Ridge area (6 miles west of Townsend); and vegetative treatments to improve approximately 700 acres of habitat in the Toll Mountain area to provide a desirable mosaic of vegetative conditions for local wildlife species.

The Canyon Ferry reservoir supports white-tailed and mule deer, antelope, elk, moose, grouse, ducks, geese, pheasants, numerous song birds, beavers, mink, bald eagles, osprey and other raptors. Approximately 11,500 acres of Bureau of Reclamation lands surrounding Canyon Ferry will continue to be managed to enhance wildlife.

Approximately 170,000 acres in the Planning Area are managed by MFWP as wildlife management areas.

Approximately 2.1 million acres of National Forest lands are managed for multiple use including maintenance and improvement of wildlife habitat through projects such as noxious weed reduction, removal of conifer encroachment in grasslands and shrublands, conifer thinning, road closures, and aspen and riparian restoration. An additional approximately 700,000 acres of National Forest lands are in wilderness where wildlife remains relatively undisturbed by human activity.

An additional approximately 150,000 acres in the Planning Area are within the boundary of Yellowstone National Park and are managed for natural values including wildlife.

## Fish

Fish populations are subject to recreational fishing throughout the Planning Area. Rivers that provide high quality opportunities include the Big Hole River, Missouri, Jefferson, and Madison. Within the Decision Area, Hauser and Holter Lakes as well as Canyon Ferry provide sport fisheries. Most sport fisheries are for non-native fish species such as rainbow trout, brown trout, brook trout, walleye, and yellow perch.

Approximately 11,500 acres of Bureau of Reclamation lands surrounding Canyon Ferry will continue to be managed to enhance fish. The Canyon Ferry reservoir supports a wide variety of sport fish, including rainbow and brown trout, perch, and walleye.

There is one fish hatchery in the Planning Area, located in Anaconda and operated by Montana Department of Fish, Wildlife, and Parks. This hatchery focuses on propagating westslope cutthroat trout for stocking into local lakes, ponds, and waterways to provide sportfishing opportunities. This hatchery may also provide westslope cutthroat trout for restorative re-introduction projects.

## Special Status Species

Federal and state land management agencies will continue to protect habitat for listed species as required by law. Protection for sensitive species will continue on most federal and state lands. No specific requirements for the protection of sensitive species exist on privately owned lands. Some species listed as Threatened on the Endangered Species List could be removed from the list, and others may be added.

One of the most impactful human activities affecting special status fish populations has been the historic stocking of non-native fish. Throughout the Planning Area non-native fish have either outcompeted or hybridized with native fish such as westslope cutthroat trout, Yellowstone cutthroat trout, bull trout, and to some extent Arctic grayling. The result has been broad-scale displacement of native fish species from their historically occupied habitat.

Recent projects on BLM lands to improve habitat for special status fish species include the following: pool creation in LaMarche Creek, tributary to the Big Hole River, to benefit Arctic grayling; and watershed restoration including road decommissioning and instream wood placements in Nursery Creek, tributary to Muskrat Creek in the Elkhorn Mountains, to benefit westslope cutthroat trout.

BLM has continued to be a funding partner in re-establishing the genetically pure westslope cutthroat trout population in Muskrat Creek from approximately 1997 to the present. This project has entailed removal of non-native brook trout and establishment of a barrier to prevent brook trout immigration at the downstream end of approximately 5.3 miles of habitat now occupied solely by westslope cutthroat trout.

## Wildland Fire Management

### Treatments

Fuel reduction and fire management actions that have occurred recently include prescribed fire (472 acres) and mechanical treatments (141 acres) in the Big Hole Watershed since 1997.

Planned projects in the Big Hole watershed include prescribed fire on 3,159 to 4,159 acres with prescribed fire and approximately 3,087 to 7,087 acres of mechanical treatment.

BLM has treated approximately 2,332 acres of forest and non-forest ground with prescribed fire, and approximately 2,339 acres of the same using mechanical methods since 1997 in the Jefferson River watershed.

In the Missouri River watershed, BLM has treated approximately 4,965 acres with prescribed fire and 2,284 acres with mechanical methods since 1997. Currently three projects are planned with prescribed fire on a total of approximately 314 acres, and mechanical treatment is

planned on approximately 8,500 acres could occur in these areas over approximately the next decade.

In the Yellowstone River watershed, BLM has treated approximately 40 acres with prescribed fire and currently, no mechanical or prescribed fire treatments are planned.

Wildland fire suppression and management will continue on most lands within the Planning Area, including state, private, Bureau of Recreation, BLM, and National Forest Lands. Counties within the Planning Area have generally developed plans to identify where fuels treatments are needed to protect communities. Federally managed lands generally have a plan in place that allows some areas to burn where conditions would result in beneficial vegetation changes as a result of naturally occurring wildland fires.

Vegetation management on privately owned lands and National Forest System lands will likely include forest fuels reduction in urban interface areas.

### Wildland Fire

The Butte Field Office has record of approximately 200 wildland fire starts in the Planning Area from 1981 to 2004, 93 of which were lightning caused, and 107 of which were human-caused wildfires. The total acres were approximately 20,257.8 acres from human-caused wildland fire and 435.8 acres of lightning caused wildland fire. Wildland fire will continue to occur in the Planning Area. The numbers of recorded fire starts and acres affected may increase in rate in the future because past fire statistics underestimated past fire history and hazardous fuels buildup has made fires harder to control.

In the past wildland fires have occasionally initiated from National Guard training exercises.

Across the Planning Area, wildland fires will continue to be ignited from lightning and human activities (mostly accidental). In most cases, these fires will continue to be suppressed to protect health, safety, property, and natural resources. Some may be allowed to burn where a plan is in place and results would be beneficial.

## Forestry and Woodland Products

**Table 4-43** characterizes the forest products removed from BLM lands prior to and after 1996. For the same period of time, this amounts to less than 20 percent of the total product volume removed from BLM lands in Montana and less than 0.1 percent from all timber lands in Montana for the same period (USFS Region 1, 2005). Out of a total timber harvest of 6,994 MMBF in Montana during that period, private lands harvested approximately 70 percent, state lands under DNRC administration harvested 5 percent and the National Forests harvested 19 percent.

Removal of forest products will continue mainly from privately owned lands in the Planning Area as well as

from State Lands managed by DNRC and the non-wilderness National Forest System lands, including timber salvage.

### Livestock Grazing

In the past, livestock grazing has been permitted on approximately 90 percent of Butte Field Office lands, or 273,000 acres. On average, 70 to 75 percent of allowable AUMS (25,677 Active preference) have been activated each year—roughly 18,000 to 19,000 AUMS.

Livestock grazing and vegetation management to facilitate availability of livestock forage will continue on privately owned lands. The extent of livestock grazing on private lands will likely decrease over the next 20 years due to continuing subdivision and residential development of existing ranches.

Other past and future grazing related activities include development of livestock water wells, new spring developments, new fence construction, and fence removal.

Livestock grazing will continue on National Forest lands throughout the Planning Area. This will likely focus mostly on the 2.1 million acres available for multiple use. Some livestock grazing may occur in the 700,000 acres of wilderness areas on National Forest System lands but relatively little commodity production would occur here.

### Energy and Minerals

#### Leasable Minerals

There are currently 34 suspended lease nominations within the Planning Area covering approximately 41,611 acres. These parcels will be offered for lease when this RMP is finalized. In addition there are seven lease nominations covering approximately 4,892 acres under review by BLM staff as of July 2006. In June 2006, nine leases were issued by the BLM for lands within Broadwater and Gallatin counties for mineral estate under BLM jurisdiction. These leases cover approximately 7,583 acres. Activity is anticipated to take place from 2006 through 2016. If fluid minerals are discovered then activity would expand and occur over a much longer time period.

It is estimated that a total of 31 conventional oil and gas wells could be drilled, most likely within the five areas with the most potential over 15-20 years. Nineteen of these wells would be exploratory, with six of them being producers. The RFD assumes that there would be two additional step-out wells developed for each of the six producers, resulting in a total of 18 producing wells overall. The RFD also assumes that seven of these producing wells would be on federal mineral estate with the remainder being non-federal. As many as 40 wells might be drilled for coal bed natural gas, most likely near Bozeman Pass. None of this activity is forecast to take place on federal mineral estate. (A further description of the RFD scenario can be found in **Appendix M – Fluid Minerals**). Each well would consist of a well pad, mud pit, and staging complex, generally totaling less than 5 acres per site with associated access roads if needed.

In addition to BLM activity, there are currently 68 suspended oil and gas leases on the Gallatin National Forest that cannot be developed until the Forest Service, with assistance from the BLM, completes an EIS that examines the effects of leasing and development of these leases.

Canyon Ferry Reservoir and Dam on the Missouri River would continue to be operated to provide power generation. Water flow through Hauser and Holter Lake dams will continue to be managed to optimize energy production.

#### Locatable Minerals

Larger-scale mining operations are listed in **Table 4-44**.

The Butte Field Office routinely permits a number of small scale placer mining operations. These take place in various locations throughout the field office and collectively occupy up to 30 acres of BLM land at any one time. Small-scale placer mining has taken place since before the previous RMP was written and will continue into the foreseeable future.

At any given time there are a number of precious and/or base metal exploration projects taking place at various locations throughout the field office. These may occupy up to 30 acres of BLM land at any one time.

#### Salable Minerals

Forest Product	1984 – 1995	1996 – 2004
Sawtimber (MMBF)	2.951	6.444
Christmas Trees and Boughs (# of trees/lbs. of boughs)	6,633/500	4,013/1,500
Post and Pole Sales (CCF)	253	50
Public Use Products (# permits)	No data	352
Firewood (cords)	1,082	694
Trespass (MMBF)	0.4	0.4

**Table 4-44  
Present and Foreseeable Mining Activity**

Name	Description	Location	Approximate Size	Anticipated Operation Timeframe
	rock quarry railroad ballast and other durable crushed rock	T2N, R5W, Section 20	55-acre	1992 - 2010
<b>Golden Sunlight Mine</b>	gold and silver open pit mine	T2N, R3-4W,	2,500 acres with approximately 600 acres on BLM	1992 - 2010
<b>Montana Tunnels Mine</b>	lead and zinc with associated gold and silver from an open pit mine	T7N, R4W, various sections	1,500 acres with 130 acres on BLM.	1986 - 2008
<b>Graymont Western U.S.</b>	limestone to produce lime and hydrated lime	T7N, R1E, various sections	600 acres on BLM	1981 - 2060
<b>Bald Butte Mine</b>	molybdenum	T11N, R6W, section 10	Currently less than 5 acres, likely to expand to a total of 30 acres with 5 acres of BLM	2006 - 2015

The Butte Field Office routinely permits a number of mineral material sales, the majority of which are sand and gravel for county or state use. These take place in various locations throughout the field office and collectively occupy up to 30 acres of BLM land at any one time. These sales have been important sources for construction material in the past and will continue into the foreseeable future.

### ***Mineral Developments on Private Land***

On private land, Holcim currently mines limestone north of the town of Three Forks (T2N, R3E, various sections). This mine is approximately 300 acres, none of which occurs on BLM lands.

Ash Grove Cement company mines limestone west of Montana City (T9N, R3W, various sections) on approximately 100 acres. None of this occurs on BLM lands.

Activity began in 1980 and is anticipated to continue until approximately 2060.

The Butte Mine operated by Washington Group is currently mining molybdenum, copper and associated precious metal by-products from the open pit mine in Butte. This activity occurs in uptown Butte over an extensive area of several thousand acres. Mining activity has occurred here since 1870 and will likely continue well into the foreseeable future. None of this ongoing activity is on public land.

### **Recreation**

Past, present, and reasonably foreseeable actions include ROS designations; improvement of recreation sites at White Sandy, Holter Dam, Holter Lake day-use facilities, French Bar, and Spokane Bay; 15 to 20 special use permits annually for a variety of events; VRM classification; and continued management of 49 recreation sites on BLM lands.

Canyon Ferry will continue to be managed to enhance recreation. There are approximately 24 recreation sites

around the reservoir, 12 of which are managed for camping. In addition there are three boat marinas that are managed as private concessions.

Lands owned by local governments in the Planning Area would continue to be managed as parks to provide public recreation opportunities.

On National Forest Lands, Recreation Opportunity Spectrum classifications would continue to be used to manage for a variety of recreation opportunities, including road access and degree of development.

The BLM will continue to participate fully in the coordinated management of the Missouri River through the Missouri River Comprehensive Recreation Plan.

Motorized and non-motorized recreation and developed and undeveloped recreation will continue on state and federal lands.

### **Travel Management and Access**

Past, present and reasonably foreseeable future actions for Travel management and access are discussed in the "Environmental Consequences of Five Site-Specific Travel Plans" section.

### **Lands and Realty**

#### ***Land Use Authorizations***

The Butte Field Office administers approximately 554 rights-of-way, which encumber over 40,837 acres of BLM land including: water pipelines, communication sites, ditches, railroads, material sites, fiber optic lines and a Montana Army National Guard training site. Road rights-of-way are the most common type of grant, accounting for 53 percent, or over half of the total. Approximately 10 to 15 right-of-way actions are processed annually.

Twenty communication site rights-of-way on seven different locations are authorized within the Planning Area.

The Butte Field Office administers seven FLPMA Section 302 leases involving about 910 acres of BLM land (BLM 2004i): 904.91 acres to the Great Divide Ski Area and six occupancy leases for a total of 5.3 acres. There are no permits or easements under Section 302 of FLPMA or airport leases located within the DA. One R&PP lease has been issued under Section 212 of FLPMA to the Last Chance Handgunners involving 39.1 acres (USDI-BLM 2004i). R&PP patent transfers are discussed below under the section Land Ownership Adjustment.

Approximately 20,000 acres in the Limestone Hills west of Townsend, is under a right-of-way grant held by the Montana Army National Guard for military training purposes (BLM 1984c).

Wind Hunter LLC has submitted an application for a Wind Energy Site Testing and Monitoring Facility near Whitehall Montana.

**Land Ownership Adjustments**

Seven land acquisitions were completed using Land and Water Conservation Fund (LWCF) appropriations: one in the Devil’s Elbow area, two associated with Crimson Bluffs, portions of the Iron Mask Ranch, McMaster Ranch, and a small portion of the Ward Ranch. The Causeway Land Exchange is currently pending. Eight parcels of land were donated to the United States, through BLM: one in the Sleeping Giant area, two on Holter Lake, two on the Ward Ranch, two at Iron Mask, and one at White Sandy. Three land sales were completed, one southeast of Mount Helena, one near Montana City, and one east of Holter Lake.

The Butte Field Office completed five Recreation and Public Purposes (R&PP) patent transfers since approval of the Headwaters RMP. These are: 34.09 acres to the MFWP for a recreation site; 40 acres to Lewis and Clark County for a sewage treatment area; 71.62 acres to Jefferson County for a warehouse and storage area; 400 acres to Broadwater County for a shooting range; and 622.38 acres to MFWP for expansion of the Beartooth State Wildlife Management Area.

**Table 4-45** lists land ownership adjustment actions for the Planning Area since the approval of the Headwaters RMP in 1984. Note that acreage values are approximate.

**Access**

Since 1984, 40 permanent exclusive easements were acquired for legal access to BLM land. Six permanent non-exclusive easements were acquired. Eleven temporary easements, encroachment permits/easements or permanent easements for specific projects such as fences, livestock or water pipelines and troughs were acquired.

**Special Designations**

Nearly 700,000 acres of National Forest are designated wilderness lands managed to protect natural values and provide non-motorized recreation experiences.

The Forest Service is the lead managing agency for the Continental Divide National Scenic Trail and is currently in the process of reconstructing and upgrading numerous segments of this trail system. The National Park Service is the lead managing agency for the Lewis and Clark National Historic Trail.

**Social and Economic**

No cumulative impacts were identified for Environmental Justice.

**Social Conditions**

Under all the RMP alternatives, public access and recreational opportunities have the greatest potential to affect social conditions. As such, Alternative C, being the most restrictive on public access for firewood and other product gathering as well as motorized recreational access, would have the greatest cumulative effects. Other federal land management agencies in the Planning Area are following a trend of reducing motorized access. Alternatives B and D also reduce motorized access and would have some cumulative effects as described above, but not to the same degree. Alternative A maintains current access. Since BLM manages only 4.2 percent of the access in the Planning Area, the extent of cumulative

Type of Action	Number of Actions	Acres Disposed	Acres Acquired
Public Sales	3	10	-
Purchases	4	None	140
LWCF Purchases	9	None	8,987
Donations	7	None	2,352
R&PP Patent transfers	5	1,168	-
Land Exchanges	13	23,290	18,895
<b>Total Acres</b>		<b>24,468</b>	<b>30,374</b>

effects is not great. However, federal and state public lands are used more extensively than other lands for these purposes.

### ***Economic***

Outputs compared to the overall output in the Planning Area are relatively minor and cumulative impacts from BLM resource management would likely not be noticeable.

The differences in timber production between the alternatives would amount to less than five percent of the annual timber volume removed from the Planning Area.

Reduced AUMs in Alternatives B and C would place additional grazing pressure on private lands and/or increase the demand for hay or other forage alternatives. Expanding recreational demand across all alternatives could increase opportunities for private sector business growth.

While some BLM actions may affect individuals or businesses in a few communities, none of the alternatives would cause more than one percent change in local employment or labor income over the Planning Area.

### ***Public Health and Safety***

Under all alternatives, BLM actions to reclaim abandoned mine lands should contribute to a cumulative beneficial effect to public safety by reducing the numbers of hazardous mine openings and improving water quality in areas where projects occur.

### **Tribal Rights**

Cumulative impacts on cultural resources may occur through incremental resource degradation. Decreases in resource conditions such as water quality, riparian habitat, wildlife forage, native plant communities, or land

tenure and access could affect cultural, traditional, and other tribal treaty rights important to Native Americans. If resources were to become scarce on BLM lands or other adjacent federal lands, there could be increased competition between tribal members and non- members for these resources.

## **CUMULATIVE EFFECTS ON RESOURCES**

Cumulative effects discussions below are general due to the general lack of site-specificity of proposed management actions in RMP alternatives. At the activity plan or project level, site-specific NEPA analyses would be completed for proposed management actions. Finer scale cumulative effects analysis would occur within these finer scale NEPA documents and would more specifically analyze and describe cumulative effects to pertinent resources and resource uses.

Cumulative effects on resources or resource uses may result from any of the alternatives considered. For many resources (air, soil, special status species, cultural and paleontological resources, energy and minerals, transportation facilities, lands and realty, special designations), and tribal rights) management actions in each alternative are similar enough that the cumulative effects would be the same. Cumulative effects for those resources are discussed below, but not by alternative. For other resources (water, vegetation, wildlife, fish, wildland fire management, visual quality, forestry and woodland products, recreation, transportation, and access, and social and economic conditions) management actions would result in differing direct and indirect effects and therefore, their potential cumulative effects may vary. Cumulative effects on those resources are broken out by alternative.

<b>Watershed</b>	<b>Total Acres in Watershed</b>	<b>BLM Managed Acres In Watershed</b>	<b>Percent of Watershed Managed by BLM</b>
Blackfoot	126,749	932	0.7%
Big Hole	406,542	58,983	14.5%
Boulder	485,996	40,341	8.3%
Gallatin	1,023,095	872	0.1%
Jefferson	465,188	40,748	8.8%
Shields	514,509	223	0.0%
Upper Missouri	1,894,597	153,103	8.1%
Upper Clark Fork	520,950	649	0.1%
Upper Yellowstone	994,054	8,010	0.8%
Scattered*	760,669	3,449	0.5%
<b>Total</b>	<b>7,192,349</b>	<b>307,309</b>	<b>4.2%</b>

\*These acres occur within the counties that make up the Planning Area, but not in any of the major watersheds listed.

An important component of the cumulative effects analysis is the degree of influence that management actions taken by the BLM would have when added to actions taken by other land owners or management agencies. Because of the distribution of public lands managed by BLM in any particular watershed, BLM's actions would have limited impacts on the ecosystem and human environment. **Table 4-46** demonstrates the percent of each watershed managed by BLM. As shown, over the extent of the Planning Area, BLM manages slightly more than four percent of the land base.

## AIR QUALITY

Smoke from prescribed or wildland fires burning on state, federal, and private land could cause air quality to deteriorate in local airsheds. Large wildland fires or escaped prescribed fires could occur simultaneously, resulting in an increase in air quality degradation caused by separate events. Dust generation from unpaved federal, state, and county roads would add to the particulates contributed by smoke.

Additional adverse effects to air quality due to airborne dust and greenhouse gas (GHG) emissions would occur from a variety of activities in the Planning Area such as vehicle emissions, residential and industrial developments on non-BLM lands, agricultural uses, energy development, and energy consumption in day to day human life activities. Contributions of BLM activities to greenhouse gas emissions would be relatively low in the context of other activities on non-BLM lands due to the dominance of non-BLM lands and the presence of many human communities within the Planning Area. On BLM-administered lands, greenhouse gas emissions would originate from implementation of BLM projects, permitted public recreation and use of roads/trails, permitted livestock grazing, and potential oil and gas exploration and development.

While oil and gas development potential is low overall on BLM mineral estate lands, the RFD predicts up to 7 producing federal conventional gas wells. This represents a small proportion of the total of up to 18 producing conventional oil and gas wells, and up to 30 producing coalbed natural gas wells forecast in the RFD Planning Area-wide. The wells on federal mineral estate would constitute approximately 0.1 percent of projected state-wide oil and gas development. Greenhouse gas emissions from this activity would be minor at both the Planning Area-wide and state-wide scales. While there are potential emissions of GHGs from the RFD for oil and gas development in this RMP, these effects may not actually occur. The Butte Field Office would permit the development in the RFD, but this office has not received an Application for a Permit to Drill (APD) on any of its federal mineral estate lands in over 20 years.

While some BLM activities would emit GHGs, carbon sequestration would also occur on BLM lands as vegetation takes in and uses carbon dioxide. Vegetation treat-

ment activities may promote increased carbon sequestration in the long-term. It is unknown whether BLM lands and activities would be a net source or sink of GHGs under the various RMP alternatives.

## SOIL RESOURCES

All identified reasonably foreseeable activities across all land ownerships in the Planning Area would contribute to soil disturbance, erosion, and compaction. At the scale of the 7.2 million acre Planning Area, the extent of effects from BLM activities would be relatively minor.

Within the RMP alternatives, livestock grazing, vegetation treatments, roads management, and mining activities have the greatest potential to contribute to cumulative effects to soils on BLM lands. Alternatives A and D would likely contribute the greatest to cumulative effects to soils. Alternative B would contribute less than either Alternative A or D, but more than Alternative C.

## WATER RESOURCES

Under all alternatives, water quality on BLM managed lands should improve, over the long-term, through the management actions proposed in these alternatives. The most important actions are improving riparian conditions through the use of the Riparian Land Health Standard and vegetative restoration, road closures and reclamation, abandoned mine land reclamation, and reducing the risk of high severity fire.

While ground disturbing activities on adjacent ownerships would continue to affect BLM managed lands, there should not be substantial increases in adverse effects over the current levels. Part of the reason for this is that there are now several watershed groups in the area that have been formed to improve water quality at the watershed scale. This is a ground based effort that includes local landowners, conservation districts, environmental groups, local governments, state government, and other federal governments. The efforts of these groups should improve overall water quality throughout the Planning Area.

Another factor that should lead to improved water quality is the anticipated completion of several "Total Maximum Daily Loads" (TMDL). The Lake Helena TMDL has already been completed and water quality restoration work is already being planned (road rehabilitation). TMDLs for the rest of the Planning Area are scheduled for completion by 2012. The BLM would also work with Montana Department of Environmental Quality to ensure that contaminants affecting BLM resources are addressed, regardless of ownership (as noted in our 2002 Memorandum of Understanding).

Given the expected long-term improvements on both BLM and non-BLM managed lands, there should be an overall cumulative improvement of water quality under all alternatives. Potential impacts resulting from additional decreases in stream flow should be negligible

since most basins in the Planning Area are closed to additional appropriation.

Of the alternatives, B and C would tend to minimize cumulative effects to water quality associated with erosion and sedimentation because they provide for Riparian Management Zones that would be more protective of water resources than the standard Streamside Management Zones provided for under Alternatives B and D. These alternatives also have the greatest potential for water quality improvement due to road related restoration and reduced grazing impacts.

It is expected that coalbed natural gas would be developed in the Butte Field Office on non-federal lands. These wells would likely be injected with a combination of sand and chemicals to allow the gas to flow to the surface. The fluids can migrate along the coal seam and contaminate groundwater and streams (Pembina 2007). After completion, water produced during coalbed methane operations may have high levels of salinity that may seep into the groundwater or be directly discharged into stream channels (Davis et al. 2006). The production of water from coalbed methane developments can significantly drawdown aquifers and reduce important ground and surface water. This could reduce the flow in rivers and streams adjacent to the wells. In this case, based on projected well depths, it is assumed that produced water would be reinjected if technically possible and not disposed of on the surface which will mitigate potential impacts.

## VEGETATIVE COMMUNITIES

**Table 4-47** displays the extent of proposed vegetation treatments on communities on BLM lands within the Planning Area per decade.

### *Grasslands and Shrublands*

Management actions on grasslands and shrublands throughout the Planning Area (e.g., prescribed fire, weed treatments, livestock grazing, mechanical treatments, and reseeded) would affect vegetation composition and structure. Grasslands and shrublands would likely continue to be altered or lost on private lands where residential and urban development occurs. Although proposed vegetation treatments on Decision Area lands would vary by RMP alternative (**Table 4-47**), effects at the Planning Area scale would be minor for all alternatives.

### *Riparian*

Riparian vegetative communities would likely continue to be altered on private lands by residential/urban development, mining, livestock grazing, road construction, timber harvest, wildland fire, and other uses.

On public lands riparian vegetation would continue to be affected primarily by livestock grazing, wildland and prescribed fire, timber harvest, road construction/maintenance, and in some cases mining exploration and development.

Although proposed vegetation treatments to restore riparian vegetative communities on Decision Area lands would vary by RMP alternative (**Table 4-47**), effects at

			Acres and % of Planning Area Treated Per Decade on BLM Lands*			
Vegetation Zone	Acres in Planning Area	% of Acres in Planning Area	Alternative A	Alternative B	Alternative C	Alternative D
Grassland Zone	2,451,212	34	5,250	11,800	2,000	19,050
			0.2%	0.5%	0.1%	0.8%
Shrubland Zone	313,385	4	0	3,650	750	6,800
			0.0%	1.2%	0.2%	2.2%
Dry Forest	1,091,820	15	5,100	14,750	4,800	18,200
			0.5%	1.4%	0.4%	1.7%
Cool Moist Forest	800,387	11	2,400	3,750	550	5,050
			0.3%	0.5%	0.1%	0.6%
Subalpine Fir Zone	1,305,766	18	0	0	0	0
			0.0%	0.0%	0.0%	0.0%
Riparian	171,313	2	30	700	200	1,700
			0.0%	0.4%	0.1%	1.0%
BLM Treatment Totals/ Percent of PA Total Acres			12,780 0.2%	34,650 0.5%	8,300 0.1%	50,800 0.7%

\*Based on top range identified in Chapter 2.

the Planning Area scale would be minor for all alternatives.

On Decision Area lands, Alternatives B and C would lessen impacts to riparian vegetation associated with potentially harmful activities and promote vegetative recovery more than Alternatives A and D due to the provision of Riparian Management Zones in Alternatives B and C. This effect would be minor in the context of the Planning Area scale.

### ***Forests and Woodlands***

Timber harvest activities would continue on private, state, and federal land throughout the Planning Area. On private lands in urban interface areas there would likely be a focus on removing trees and snags to reduce fuel loading, especially where forest insects or disease have caused substantial tree mortality. Some forest and woodlands on private lands may be converted to residential or urban developments.

Roads built to access forest treatment units on BLM land may lead to timber harvest on adjacent land. Under all RMP alternatives, timber harvest and other vegetation management actions on BLM lands would be geared toward restoring forest health in most cases. This could reduce vegetation density and fuel loads and help prevent wildland fires that could affect non-BLM vegetation resources in the Planning Area.

Although proposed forest vegetation treatments on Decision Area lands would vary by RMP alternative (**Table 4-47**), effects at the Planning Area scale would be minor for all alternatives.

### ***Noxious Weeds***

The total acres of noxious weed and non-native invasive species infestations would increase in the Decision Area. Noxious weed infestations would increase on BLM land and on adjacent private, state land and other federal land through natural expansion and with management actions that disturb soils and vegetation and increase motorized traffic. Noxious weeds would also increase with severe wildland fire on BLM and adjacent land. Infestations of noxious weeds and non-native invasive species could displace desirable native plants and increase erosion.

## **WILDLIFE**

Vegetation management and travel management in the RMP alternatives have the most potential to affect wildlife. Many other activities would continue to occur within the Planning Area that can also affect wildlife including timber harvesting, livestock grazing, fire, road construction and use, mining, weed treatment, residential and commercial development, and recreational activities. Low density rural home development is the fastest growing form of land use in the United States since 1950 (Hansen et al. 2005). Many people are choosing to live away from town on small parcels of land or in rural subdivisions. This is currently occurring adjacent to

many communities in the Planning Area including but not limited to; Helena, Butte, Bozeman, Livingston, and Boulder. Land that was traditional used for ranching, forest products, or mining is now being converted to home sites. Although these lands had historic human uses, they also provided quality and/or functioning wildlife habitat. Historically, these areas provided a diversity of habitats that contributed to; big game winter range, travel corridors, habitat for resident and migrating wildlife, as well as foraging, breeding and hiding habitat. For many plant and animal communities, native species richness decreases as housing density increases. Non-native species, however, tend to increase with development (Hansen et al. 2005). Wildlife populations, including carnivores, may be reduced even at very low levels of residential development due to; loss of habitat, an increase in human access (from roads) in areas that previously had low levels of disturbance, and an increase in hunting pressure. Residential development can also lead to an increase in noxious weed infestations that can reduce the quality and quantity of wildlife habitat.

Pets can also have a negative impact to native wildlife. Cats hunt and kill birds and small mammals. Dogs that are allowed to roam can chase, injure, or kill wildlife. This can result in areas becoming unavailable to wildlife.

Other federal and state agencies are generally following a trend of reducing areas where motorized access is allowed in the Planning Area. As shown in Appendix P of the AMS (USDI-BLM 2006c), timber harvest has also declined across the Planning Area in the last 30 years, which reduces human disturbance of wildlife, including roads and road use.

Throughout the Planning Area, regardless of land ownership, roads can impact wildlife in a number of ways. Roads can increase harassment, poaching, collisions with vehicles, and displacement of terrestrial vertebrates, affecting a variety of large mammals such as caribou, bighorn sheep, mountain goat, pronghorn antelope, grizzly bear, and gray wolf. Direct mortality of large mammals on forest roads is usually low, except for those with a home range that straddles a road. Forest roads pose a greater hazard to slow-moving migratory amphibians than to mammals. Nearly all species of reptiles seek roads for cooling and heating. Vehicles may kill considerable numbers to a point of making well-used roads population sinks for some species. Roads can prevent wildlife movement, create disturbance, cause the spread of noxious weeds, and fragment habitats on the landscape. Open roads typically increase the level of recreation within areas adjacent to them. This can result in additional disturbance or displacement of wildlife species within the vicinities of more heavily used open roads.

Timber harvest has declined across the Planning Area over the last 30 years. This reduction in timber harvest activity has resulted in reduced alteration of habitat and

disturbance to wildlife associated with timber harvest operations including road construction and use.

Alternative C reduces the effects on wildlife associated with roads and in some cases disturbance due to other management actions more than the other RMP alternatives and therefore would contribute less to the cumulative effects. Alternative A would contribute the most, followed by Alternative D, then Alternative B. With any RMP alternative, the relative extent of effects at the Planning Area scale is limited by the area of BLM lands where effects could occur, less than five percent of the Planning Area.

Alternative D would, however, be the most active in restoring vegetation to more resemble its historic conditions, which would, in turn benefit most wildlife within the cumulative effects analysis area (Planning Area) in the long-term. Alternative B would have the second greatest long-term benefits to wildlife of all alternatives due to vegetation restoration, followed by Alternatives A and C. Again, the extent of the effects is limited by the acres BLM manages.

Livestock grazing in the Planning Area could reduce the amount of annual residual grass, forbs, and shrub vegetation, and potentially cause changes to productivity. In the Decision Area, the applied utilization and resource management standards would provide for maintenance or improvement of vegetative and soil resource conditions that are consistent with objectives. Deferred and rotational grazing systems used in allotments would vary the time of year each pasture is grazed so plants have the ability to reproduce and recover.

Throughout the Planning Area, continued development of mining operations can affect wildlife by reducing the quality and quantity of habitat available, creating disturbance to wildlife, and releasing contaminants. Effects to wildlife from mining vary by the size and nature of individual operations.

## FISH

BLM is responsible for managing lands containing about 239 miles of the 7,638 miles of stream within the Planning Area (3 percent). Consequently, the variation between effects from most activities within the RMP alternatives is likely to be immeasurable within the cumulative effects analysis area. Additionally, activities that occur on other ownerships have a much greater potential to have effects on fisheries at the Planning Area scale than the BLM's RMP alternatives.

The types of activities that can result in cumulative effects to fisheries include, but are not limited to, new proposals and ongoing actions involving:

- Livestock grazing;
- Placer and hard-rock mining;
- Highway construction;
- Construction or maintenance of power transmission corridors;
- Maintenance of irrigation diversions;
- Maintenance of existing communication lines;
- Crop production;
- Herbicide application for weed control;
- Road and highway maintenance;
- General travel management;
- Construction of new or improvement of existing developed recreational sites; or,
- Fisheries and watershed enhancement projects.

Many watersheds in the Decision Area are already in less than optimal condition due at least partly to negative cumulative effects that have occurred from past activities. In some cases, ongoing activities or conditions present from past activities continue to result in localized negative effects on fisheries and aquatic resources.

The effects of roads on aquatic habitat can be widespread. At the landscape scale, roads can influence the frequency, timing, and magnitude of disturbance to aquatic habitat. Increased fine-sediment composition in stream gravel has been linked to decreased fry emergence, decreased juvenile fish densities, loss of winter carrying capacity, and increased predation of fishes, and can reduce benthic organism populations and algal production. Roads can act as barriers to migration, lead to water temperature changes, and alter stream flow regimes. Improper culvert placement at road-stream crossings can limit or eliminate fish passage. Roads greatly increase the frequency of landslides, debris flow, and other mass movement. These effects are currently taking place to varying degrees across all land ownerships in the Planning Area. In some areas where increased residential or urban development occur on private lands, these effects would likely increase in severity.

Within Decision Area lands, Alternative C would have the least contribution to adverse cumulative effects to fisheries resources associated with roads and vegetation treatments combined. Alternative D would have the greatest contribution of all alternatives associated with roads and vegetation treatments combined. Alternative A would have the greatest contribution to cumulative effects associated with roads but a lesser contribution associated with vegetation treatments than Alternative D. Alternative B would have a greater contribution to cumulative effects to fisheries resources associated with roads and vegetation treatments than Alternative C but a lesser contribution than either Alternatives A or D. Although Alternative B proposes more ground-disturbing

vegetation treatments than Alternative A, it also establishes more protective Riparian Management Zones than the Streamside Management Zones provided in Alternatives A and D.

Mineral development has occurred across the region in the past and will continue into the future. The effects from mining in both the Planning and Decision Areas could be loss of habitat due to placer mining and mining in riparian habitat, the introduction of contaminants and effects due to associated development such as roads and facilities. Mining in the Planning Area could result in isolated populations of aquatic species or the decline in species.

Other effects of activities in the Planning Area could include loss of fish habitat or reduction in habitat quality associated with oil and gas related development, prescribed fire or wildland fire, or water diversion and reservoir drawdown.

## **SPECIAL STATUS SPECIES**

Activities on non-federal lands such as timber harvest, livestock grazing, residential development, mining, agriculture, and road construction would negatively influence special status species. Human developments are expected to expand in major valleys, resulting in barriers to movement and displacement or increased mortality of grizzly bear, wolf, and lynx.

Loss of riparian habitat associated with residential and industrial development and agriculture on non-federal land is expected to cause additional loss of habitat for bald eagle.

Roads can cause a wide variety of effects to terrestrial wildlife. Species, such as gray wolf and grizzly bear, are adversely affected by repeated encounters with people. Roads can increase harassment, poaching, collisions with vehicles and displacement of special status wildlife species.

In the context of special status fish species, historic stocking of non-native sport fishes has displaced native fishes (bull trout, westslope cutthroat trout, Yellowstone cutthroat trout, and Arctic grayling to some extent) from the majority of their historic habitat in the Planning Area.

Restoration and maintenance of the Muskrat Creek population of westslope cutthroat trout has beneficial cumulative effects in many places within the Upper Missouri River watershed. Westslope cutthroat trout from Muskrat Creek are currently being used by Montana Fish, Wildlife and Parks as brood stock for re-introduction of this species in several streams within and near the Planning Area. Muskrat Creek fish are also being collected and used in development of a westslope cutthroat trout broodstock that will be used throughout the Upper Missouri River watershed beyond the Planning Area boundaries. The proposed mineral withdrawal of 180 acres of

riparian areas in the Muskrat Creek watershed under Alternatives B and C would protect westslope cutthroat trout habitat in 2.4 miles of stream from direct effects of potential mining activities. This benefit would not take place with either Alternative A or D as these alternatives do not include the proposed withdrawal.

Cumulative effects to special status plant species across all land ownerships in the Planning Area would be habitat loss, destruction of individual plants, habitat conversion to less than marginal habitats, and loss of habitat connectivity and variability.

Noxious weed management may have the greatest potential to affect special status plant species and habitat conditions under all of the alternatives. Ineffective control of noxious weed spread would lead to habitat degradation and loss. Herbicides used to control noxious weeds could have a cumulative and detrimental effect on potential future special status plant species (i.e. species which are not considered imperiled or threatened now, but may be in the future.) Unauthorized herbicide treatments could potentially have detrimental effects on special status plants and habitat.

Activities implemented on non-public lands could detrimentally affect special status plant populations in a manner that contributes to federal listings of special status plants. Although the BLM could not change the way other land owners manage special status plant species, the development of conservation agreements and species management plans with other land managers/owners could potentially reduce these off-site effects to special status plant species. The BLM would consider these effects in the analysis of all proposed management activities that affect special status plant species and their habitats.

Because Alternative A would provide the least protection of special status species, it may contribute to adverse cumulative impacts resulting from activities on adjacent lands, particularly wildland fire, residential development and grazing. Alternatives B, C, and D would improve conditions to varying degrees, but due to the limited extent of BLM's influence on management across the Planning Area, these effects would not likely be measurable or distinguishable at the Planning Area scale, with the exception of the proposed Muskrat Creek mineral withdrawal in Alternatives B and C described above.

## **WILDLAND FIRE MANAGEMENT**

Residential development and population increases could create more Wildland Urban interface areas. Additional interface areas could increase potential ignition sources, the need for fire protection services, and the potential need for fuel treatments. Residential development and population growth could also result in an increase in the numbers of recreational users and create the potential for more human-caused ignitions on public lands. As a

result, an increase in these activities would also add risk to firefighter and public safety.

Compared to the present levels of fuels treatments, there could be an increase of treatment acres over the long-term across federal, state, and private lands. As a result more acres would move toward historic fire regimes and a reduction of fuel loading would occur. Where treatments have been implemented, future fire intensity and severity could be reduced. Urban interface areas would be the highest priority for treatment. This could increase conflicts with visual concerns, smoke emissions, and funding for these projects.

## CULTURAL RESOURCES

Cumulative impacts to cultural resources could occur through incremental degradation of the resource base from a variety of sources and all ownerships. Degradation which reduces the interpretive and informational potential of historic and prehistoric properties, or affects the traditional cultural values important to Native Americans impacts cultural resources. Potential impacts could stem from vegetation management, recreation, travel route closures and development, wildland fire, wildland fire suppression, mineral/oil and gas development, increases in human population and vandalism.

Other regional resource, land use and economic development planning could affect the types and intensity of uses on lands within the Planning Area and could potentially affect regional cultural resources, in addition development of lands not protected by federal or state cultural resource statutes and regulations could further decrease the resource base and limit cultural resource management opportunities in the Planning Area. Planning coordination at the regional level could help protect important cultural resource values.

## PALEONTOLOGICAL RESOURCES

Cumulative impacts to paleontological resources would be similar to those described in the *Cultural Resources* section.

## VISUAL RESOURCES

Activities such as timber harvest, mine development, subdivision and development, road construction or the occurrence of wild and prescribed fire on adjacent lands will continue to impact the visual features of form, line, color, and texture. These changes will influence development of similar projects on BLM lands where visual resource management objectives are a consideration.

Alternative C provides for the least amount of forest products removal, thereby resulting in the least cumulative impacts on visual resources. Alternative D could have the greatest impact on visual resources in the Planning Area due to its highest level of proposed vegetation treatments.

## CUMULATIVE EFFECTS ON RESOURCE USES

### FORESTRY AND WOODLAND PRODUCTS

Private and state forests and woodlands would tend to be managed for timber products and commodities while federal lands would tend to be managed for forest health and restoration with associated commodity outputs from restorative vegetation treatments.

Additional effects on forested vegetation would occur from stand replacing fires; continued fire suppression necessary as a result of increasing wildland urban interface; intermingled land ownership; and large-scale insect and disease outbreaks that are likely to continue throughout the planning period.

Fuel build-up on adjacent lands could influence the susceptibility of BLM stands to high severity fire events. Insects and diseases present in adjacent forest stand could impact BLM forest. Loss of forest resources due to insects and disease and wildfire events occurring under the current declining forest health and fuel conditions could result in long-term resource impacts and a general reduction in the future availability of forest products from the stands impacted by such events.

On BLM lands Alternative D would provide the most forest products and contribute the most to long-term forest health improvement due to restorative vegetation treatments. Alternative B would provide the next highest contribution to these effects, followed by Alternative A, then Alternative C.

### LIVESTOCK GRAZING

Potential cumulative impacts on livestock grazing would occur from a combination of activities and land uses occurring within the Planning Area. Such impacts would result primarily from surface-disturbing activities such as road construction, mining operations, and possibly some vegetation treatments, that reduce the quantity of available forage. These activities result in livestock displacement and direct removal and indirect degradation of forage, regardless of land ownership.

On BLM lands, mine reclamation efforts and some vegetation treatments would increase forage for livestock to a similar degree in all alternatives.

BLM lands would provide less than one percent of the AUMs available in the Planning Area under any of the RMP alternatives. The variability in livestock grazing by RMP alternative would have a negligible effect on livestock grazing at the Planning Area scale.

Sale, subdivision, and residential development of rangeland on private lands will likely increase in the future and reduce the amount of livestock grazing in the Planning Area.

## ENERGY AND MINERALS

### *Leasable Minerals*

Oil and gas resources would be removed by producing wells on leases.

Oil and gas development will have the potential to occur on BLM and other lands within the Planning Area. Alternative C would reduce the available mineral estate more than other alternatives for a total of 88 percent.

Alternatives A, B, and D are similar within the extent of the Planning Area and would maintain current development levels. However, under Alternatives B, C, and D the impact to federal leases would be a reduction in lease value resulting from stipulations and regulations. The impacts to lease developments would result from a reduction in wells drilled on leases encumbered with stipulations, an increase in wells drilled on leases with minimal constraints, and an increase in operating costs because of land use decisions, lease stipulations, and regulations.

Restrictions on federal leases could impact the leasing and development of adjacent non-federal leasable minerals. If an exploration company cannot put a block of leases together because of restriction on federal leasable minerals, the private or state minerals may not be leased or developed. Leasing of federal minerals on the other hand, could encourage the leasing of private or state minerals.

### **Locatable Minerals**

Within the Planning Area, all the RMP alternatives would generally have similar impacts on locatable mineral exploration and development. While there are differences in the levels of restrictions between the alternatives, the majority of the lands in all categories of mineral potential, high, moderate, and low, would be open to mineral location. There would be little discernible cumulative effects on locatable minerals associated with the RMP alternatives.

### **Salable Minerals**

The effects on salable minerals would be similar between RMP alternatives, and have a minor contribution to cumulative effects within the Planning Area.

## RECREATION

Demands for recreational opportunities and resources will continue to increase with increases in population. Development of private and other state and federal land will decrease the resource base available for recreation putting further pressure on BLM resources.

Potential impacts also include management directed activities such as prescribed fire, thinning, timber harvest, weed control, riparian restoration, wildlife habitat improvement, and other activities which would affect recreational experiences in the short term but provide long-term resource benefits.

Mineral and gas leasing on BLM or adjacent lands may limit recreational opportunities due to area closures, development of facilities, roads, and increased traffic.

Alternatives B and C would provide for greater solitude on BLM lands by reducing road access. However, they also concentrate motorized use which increases impacts on recreation values and facilities.

Recreation management and enhancements along the Missouri River would continue to be coordinated in a comprehensive manner by numerous agencies and the public through a multi-agency MOU and the Missouri River Comprehensive Recreation Management Plan.

## TRAVEL MANAGEMENT AND ACCESS

Cumulative effects to travel management and access are discussed in the Cumulative Effects portions of the "Environmental Consequences of Five Site-Specific Travel Plans" section.

## TRANSPORTATION FACILITIES

Continued growth in population and demands for recreation facilities is expected. Furthermore, impacts could occur as the result of population growth, changing recreation values and changes in accessibility on other federal state and private lands in the Planning Area. Changes in resource availability (funding) for continued compliance monitoring, weed control, signage and maintenance of roads and trails could affect transportation facilities. Regional coordination of recreation and travel planning could reduce potential impacts on facilities in the Planning Area.

Alternatives B and C provide the least miles of open road and could concentrate recreation and other forest uses; having the greatest effect on existing facilities.

## LANDS AND REALTY

Demand for communication facilities, road rights-of-way, and utility corridor rights-of-way and permits for communication sites will increase as population increases and if resources are developed in the area for mineral or power generation. In addition, development of adjacent federal, state, and private land will increase the need for utility and communication equipment and right-of-way development.

## CUMULATIVE EFFECTS ON SPECIAL DESIGNATIONS

### ACECs

No other agency in the Planning Area has ACECs so there would be no cumulative effects from ACEC designations. Impacts from activities implemented on adjacent land not managed by BLM could create additional cumulative impacts to relevant and important values in an indirect fashion. Lack of noxious weed abatement on adjacent land could impact relevant and important special status plant values, and exercise of water rights could result in impacts to water or wetland-based values. Upstream de-watering actions above Spokane Creek or Humbug Spires would degrade aquatic and riparian habitats as well as fish spawning activities. Adjacent land disturbances to soils and vegetation from development actions could create both short and long-term air quality, soil erosion and visual impacts within potential ACECs. Finally, trespass actions such as grazing, timber harvests, motorized travel, and created routes within the ACECs could cause serious impacts to relevant and important values.

### National Trails

Resource management decisions or actions on state, private, and other federal lands have the potential to affect designated National Trails in the Planning Area, particularly since segments of both National Trails are across other agency lands and potential cumulative impacts are difficult to estimate.

### Wild and Scenic Rivers

Potential impacts to outstandingly remarkable values from present or future projects or actions on lands within the Decision Area would be considered to be negligible to nonexistent because of the existing protections under current laws, regulations and policies. Water related projects on streams within the Decision Area have had an influence on natural stream flows, but not to the extent to alter their free-flowing nature. However, impacts from activities implemented on adjacent land not managed by BLM could create additional cumulative impacts to outstandingly remarkable values. Should upstream water users fully exercise their water rights during low flow periods, both the quantity and quality of water flows within BLM segments would be degraded. In addition, wetland plant species and fisheries would be impacted. The lack of weed control efforts on proximity lands could impact special status plant species and native vegetation. Poor livestock grazing practices upstream could alter water quality and adversely impact aquatic communities. Finally, additional residential developments or other soil disturbing activities could have detrimental impacts on Wild and Scenic Rivers as well.

## Wilderness Study Areas

There are several wilderness areas within the planning area on Forest Service lands. In addition the FS has other areas that are under wilderness review. There are no known legislative bills pending before Congress that affect these areas. The wilderness characteristics of the six existing WSAs will continue to be protected under the Interim Management Policy and Guidelines for Lands under Wilderness Review until Congress acts and therefore impacts to these values are unlikely.

## CUMULATIVE EFFECTS ON SOCIAL AND ECONOMIC CONDITIONS

### Social and Economic

No cumulative impacts were identified for Environmental Justice.

#### *Social Conditions*

Under all the RMP alternatives, public access and recreational opportunities have the greatest potential to affect social conditions. As such, Alternative C, being the most restrictive on public access for firewood and other product gathering as well as motorized recreational access, would have the greatest cumulative effects. Other federal land management agencies in the Planning Area are following a trend of reducing motorized access. Alternatives B and D also reduce motorized access and would have some cumulative effects as described above, but not to the same degree. Alternative A maintains current access.

#### *Economic*

BLM's contribution of outputs compared to the overall output in the Planning Area is relatively minor and cumulative impacts from BLM resource management would likely not be noticeable.

The differences in timber production between the alternatives would be less than five percent of the annual timber volume removed from the Planning Area.

Reduced AUMs in Alternatives B and C would place additional grazing pressure on private lands and/or increase the demand for hay or other forage alternatives. Expanding recreational demand across all alternatives could increase opportunities for private sector business growth.

While some BLM actions may affect individuals or businesses in a few communities, none of the alternatives would cause more than one percent change in local employment or labor income over the eight-county planning area.

#### *Public Health and Safety*

Under all alternatives, BLM actions to reclaim abandoned mine lands should contribute to a cumulative beneficial effect to public safety by reducing the num-

bers of hazardous mine openings and improving water quality in areas where projects occur.

## Tribal Treaty Rights

Cumulative impacts on cultural resources may occur through incremental resource degradation. Decreases in resource conditions such as water quality, riparian habitat, wildlife forage, native plant communities, or land tenure and access could affect cultural, traditional, and other tribal treaty rights important to Native Americans. If resources were to become scarce on BLM lands or other adjacent federal lands, there could be increased competition between tribal members and non- members for these resources.

Ongoing consultation would strengthen the government-to-government relationships between the Butte Field Office and tribal entities associated with the DA. These relationships would help preserve resource availability and access to those resources guaranteed by treaty.

## GLOBAL CLIMATE CHANGE (GCC)

The science of assessing “greenhouse gas” (GHG) emissions and their effect on global climate change is in its formative phase; therefore, it is not yet possible to predict with confidence impacts to climate from particular sources of GHG emissions. The lack of scientific tools designed to predict climate change on regional or local scales also limits the ability to quantify potential future impacts. This is due, in large part, to the lack of historical baseline data from which to form definitive conclusions (Easterling et al. 1999), so various predictive models have been formulated to explain GCC. Generally, these models lack the predictive ability to be of use at a site-specific scale to aid in land management practice decision making and can even offer contradictory predictions (Zhang 2003). Efforts are underway by other agencies and educational institutions to improve climatic monitoring with GCC in mind, which may in the future lead to better analytical tools for analyzing and quantifying the effects of land management activities on GCC as well as the effects and trends of GCC on natural resources. Because the tools and necessary level of information are not available to address net effects of climate change quantitatively, impacts in this section are described qualitatively and are “common to all alternatives.”

At the scale of the state of Montana, greenhouse gas (GHG) emissions associated with the Butte RMP would be minimal. Leading sectors emitting GHGs in Montana include electricity (26 percent), agriculture (26 percent), transportation (20 percent), and the fossil fuel industry (11 percent). Most activities associated with GHG emissions that may be authorized consistent with the Butte RMP would fall under transportation (public use of BLM roads), agriculture (livestock grazing), and the fossil fuel industry (fluid mineral leasing). At approx-

imately 307,300 acres, the Decision Area for surface management makes up 0.3 percent of total acres state-wide. The approximately 652,000 acres of federal mineral estate in the Decision Area make up 0.7 percent of state-wide acreage. There are no activities proposed with this RMP that would be disproportionate contributors to GHG emissions beyond other contributing activities in the state. Montana GHG emissions make up 0.6 percent of total gross emissions in the United States (Center for Climate Strategies 2007). However, most BLM acres in the Decision Area are vegetated where carbon sequestration occurs and where proposed vegetation treatments would emit GHGs during implementation, but would tend to foster improved carbon sequestration in the long-term. Net effects of all these activities are unknown.

It is important to note that many of the projected effects associated with global climate change described for specific resources or resource uses would occur at variable rates, mostly over the next several decades to a century. The monitoring approach described in **Appendix N** of this RMP is intended to provide for flexibility to alter management as needed based on site-specific conditions to respond to changes that may occur for particular resources or resource uses. A more specific monitoring plan will be described in the Approved RMP that will be released with the Record of Decision for this plan.

## IRRETRIEVABLE OR IRREVERSIBLE COMMITMENT OF RESOURCES

Irreversible and irretreivable resource commitments are related to the use of nonrenewable resources and the effects this use could have on future generations. Irreversible effects primarily result from the use or destruction of a specific resource (e.g., energy and minerals) that cannot be replaced within a reasonable time frame. Irretreivable resource commitments involve the loss in value of an affected resource that cannot be restored as a result of the action (e.g., loss of special status species habitat or the disturbance of a cultural resource).

Actions that alter a vegetation community sufficiently enough to change the site potential, or give other species competitive advantage over native species may represent irreversible commitment of resources. Mineral development would result in the loss of vegetation resources, habitat, and wildlife and livestock forage. While reclamation of disturbed areas would reduce the magnitude of these impacts, loss of wildlife habitat could result in altered migration patterns and displacement of local wildlife populations. Irretreivable losses to visual characteristics near mining sites would occur during development and operation. In addition, irretreivable loss of forested habitat could result from wildland fire, insects and disease, or harvesting. Most forest habitat loss, while long-term, would eventually regenerate and is therefore not irreversible. Without vegetation treatments,

noxious weeds or invasive species may not be reasonably controlled, potentially resulting in an irreversible change in ecosystem health.

Alternative A, having the most miles of open road, could contribute to irreversible impacts on passive or wilderness experiences if OHV use continues to grow. Cultural resources are by their nature irreplaceable, so the alteration or elimination of any such resource due to management under one of the alternatives, represents an irreversible and irretrievable commitment. There would be no irretrievable or irreversible impacts on recreational resources if management restrictions were implemented effectively. The exact nature and extent of any irreversible and irretrievable commitment of resources cannot be well defined due to uncertainties about location, scale, timing, and rate of implementation, as well as the relationship to other actions and the effectiveness of mitigation measures.

## **UNAVOIDABLE ADVERSE IMPACTS**

Unavoidable adverse impacts are impacts that remain following the implementation of mitigation measures, or impacts for which there are no mitigation measures.

Some unavoidable adverse impacts would occur as a result of proposed management under one or more of the alternatives.

Vegetative treatments including prescribed fire could cause displacement of wildlife, decreases in quantity and quality of forage, and loss of non-target ecosystem components. Changes in the amount of recreational visitation and patterns of use could result in increased conflicts between users, vandalism, and illegal collection of cultural resources.

Other unavoidable adverse impacts also result from public use within the Planning Area such as development of mineral resources which could create visual intrusions, soil erosion, compaction problems, or loss of vegetation cover. Accidental introduction of exotic plant or animal species could result in harm or loss of populations of native plants or animals. However, proposed restrictions on recreation, livestock operations, and other land use authorizations to protect sensitive resources and other values would lessen the ability of operators, permittees, individuals, and groups to use the public lands and could increase their operating costs. Potential unavoidable adverse impacts could range from short-term to long-term and are difficult to quantify.

## CHAPTER 4

### ENVIRONMENTAL CONSEQUENCES – CONTINUED

---

#### ENVIRONMENTAL CONSEQUENCES OF FIVE SITE- SPECIFIC TRAVEL PLANS

This section discusses effects of alternatives for five site-specific travel plans (implementation decisions). After a discussion of Analysis Assumptions, the section is organized by travel planning area such that all effects (including cumulative effects) are described for the various resources and resource uses contiguously for each specific travel planning area. Alternatives for the Helena, East Helena, Lewis and Clark County NW, Boulder/Jefferson City, and Upper Big Hole River Travel Planning Areas (TPAs) are discussed.

Adjustments made to the Preferred Alternative for travel management between the Draft RMP/EIS and the Proposed RMP/Final EIS were assessed to be so minor as to not cause any marked changes in analyses or conclusions based on road management. Therefore, while actual road mileage changes are reflected for each TPA where pertinent in the Proposed RMP/Final EIS, road-based analyses (such as road density calculations, road-based moving windows analyses, mileage distribution by soil erosion impact categories, economic analyses) were not re-done since the Draft RMP/EIS.

#### ANALYSIS ASSUMPTIONS

##### Travel Management and Access

- Designating roads as either “Open Yearlong,” “Open with Restrictions,” or “Closed Yearlong” would improve travel management and protection of natural resources.
- Comprehensive inventories of all existing routes would be used.
- Routes were considered non-motorized if they were existing trails, closed roads or decommissioned roads.
- Visitor-use and demand is likely to continue to increase for both motorized as well as non-motorized users.
- Demand for adequate public and agency access to public lands will remain high in the future.
- Changes in OHV and snowmobile design and technology will continue, enabling OHV users to travel into areas that were once thought of as inaccessible due to terrain and water or soil features.
- Analysis of the travel system only included routes documented during the inventory period.

##### Transportation Facilities

- Road maintenance will be conducted on routes designated as Open and Restricted.
- Annual road maintenance is estimated at \$400/mile for this analysis.
- Annual trail maintenance is estimated \$200/mile for this analysis and would only be performed on motorized trails.
- Periodic road stabilization is estimated at \$40/mile for this analysis.
- Periodic trail stabilization is estimated at \$20/mile for this analysis and would only be performed on motorized trails.
- Twenty percent of Open/Restricted routes will require annual maintenance.
- Eighty percent of Open/Restricted routes will require periodic maintenance.
- Monitoring/compliance costs are estimated at \$50/mile for this analysis.
- Weed control is estimated for this analysis at 2.5 acres of spraying/mile of road at \$15/mile.

##### Air Quality

- Visitor use and demand for recreational motorized use is expected to continue to increase, resulting in higher vehicle emissions (exhaust gasses, particulates) levels.
- Most BLM roads and motorized trails have dirt or granitic surfaces. Few have been paved or graveled. This situation is unlikely to change, due to budget restraints, and user preference. Motorized travel across these substrates creates airborne dust. Wind erosion of these substrates also creates airborne dust. In sufficient quantities, airborne dust could pose a safety hazard (visual obstruction), or act as a respiratory irritant.
- Drier climate conditions could make unimproved route surfaces (soil road base) more susceptible to motorized erosion, resulting in higher levels of airborne dust.

##### Soil Resources

- BLM roads will continue to be maintained, with priority placed on those most heavily used by the public.
- State and major county roads will continue to be maintained to current levels and generally, county roads will not be abandoned. BLM facilities, mainly

roads, will continue to be maintained, with priority placed on those most heavily used by the public.

- Natural process assumptions include: roads in the Butte Field Office will continue to erode from natural causes, increased vegetative cover would lead to reduced soil erosion, and removal of conifer encroachment could minimize accelerated soil erosion.

## Water Resources

- Natural process assumptions include: roads in the Butte Field Office will continue to erode from natural causes resulting in potential impacts on water quality in adjacent streams, increased vegetative cover will lead to reduced soil erosion and in certain instances reduced deposition of sediments into streams, and removal of conifer encroachment could result in an increased quantity of water.

## HELENA TPA

The Helena TPA area contains 10,162 acres of BLM lands within the 95,492-acre TPA. The majority of lands in the TPA are privately owned (56,499 acres) with USFS lands making up a substantial portion as well (23,911 acres). The approximately 52.2 miles of BLM roads make up about 7.5 percent of the approximate total of 694 road miles in the entire TPA. Most roads (528 miles) are on private lands.

## AIR QUALITY

### Effects Common to All Alternatives

Motorized recreation use is expected to continue to increase, resulting in higher levels of vehicle emissions.

Motorized travel across dry unpaved routes or trails would continue to produce airborne dust.

There could be areas with localized air pollution as a result of higher use numbers, and more concentrated use on fewer miles of available routes.

Drier climate conditions could make soils more susceptible to the effects of motorized travel, resulting in higher levels of airborne dust.

Impacts to air quality vary by alternative and travel plan area. In general, alternatives that reduce the level of motorized use (have fewer available miles) could have a positive impact on air quality; while alternatives that maintain or increase the level of motorized use, could lead to increased air quality impacts. This would not necessarily be a direct relationship, however, because reduction in available road miles for motorized use could redistribute use or focus more use on remaining open routes.

Under all alternatives, impacts from airborne dust could be reduced through mitigation such as hardening native surface roads with gravel or periodically spraying them with water trucks during the dry season. During BLM

project work, in addition to watering native surface roadbeds, speed limits could be reduced to further minimize dust emissions.

## Effects of the Alternatives

Under Alternative A (present management), adverse impacts to air quality would be expected to continue, and likely increase, concurrent with higher levels of motorized recreational use. Each of the action alternatives, however, would provide fewer available motorized routes. Alternatives B and C would provide 80 percent and 85 percent fewer motorized routes respectively than Alternative A, while Alternative D would provide 58 percent fewer routes than Alternative A. As a result, airborne dust and vehicle emissions would be taking place on fewer BLM routes and could be reduced.

It should be noted that even without motorized use, airborne dust, resulting from wind erosion of exposed native surface roads will continue. Therefore, travel plans with more miles of native surface roads would result in more airborne dust.

Under all alternatives, mitigation measures, such as graveling and /or watering native surface roads, could reduce dust emissions even further, and/or help offset the effects of increased or concentrated use on the remaining open routes.

## Cumulative Effects on Air Quality

Under all alternatives, the cumulative effects to air quality from travel management in the Helena TPA would arise from a number of past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands.

For perspective, BLM managed lands in the Helena Travel Plan area represent approximately 11 percent of the total travel planning area (95,492 total acres, 10,162 BLM acres). Under present management (Alternative A) BLM routes represent a small portion, approximately 7.5 percent, of the total routes available (693 total miles, 52.2 miles BLM roads/trails). Potential air quality impacts associated with activities on non-BLM lands and roads would be a greater contributor to cumulative effects to air quality than activities on BLM lands and roads.

In the past, prior to the 2003 Statewide OHV ROD, BLM management allowed unrestricted cross country travel by all forms of wheeled motorized use. Under present management, in the absence of other existing travel plan direction, all motorized wheeled travel is restricted to existing roads and trails. Under current management, all BLM routes in the Helena TPA are open yearlong. This mileage available for use would be reduced under the action alternatives as described above with associated potential differences in effects to air quality.

Under all alternatives, cumulative increases in human population, urbanization, recreation use, user conflicts; and concerns for wildlife, noxious weed spread, soil erosion, air/water quality, and illegal activities may lead to increased demands to restrict motorized travel.

## SOILS

### Effects Common to All Alternatives

Road construction, use, and maintenance affect soils in a number of ways. Soils are often compacted by these activities. Soil compaction can lessen the amount of precipitation that can infiltrate into soil and increase runoff, erosion, and sedimentation – in turn decreasing soil/site stability and hydrologic function, as well as soil productivity and plant vigor and diversity.

Ground disturbance associated with road construction, use, and maintenance can result in erosion. Erosion affects soil/site stability and hydrologic function. Erosion and sedimentation can destabilize the surface and sub-surface cohesion of the soil, resulting in soil loss from erosion sites. Loss of soil can impede or prevent establishment and development of vegetation communities.

Closing or decommissioning roads often leads to beneficial effects to soils through decreased site disturbance and re-establishment of vegetative cover on road surfaces. This tends to reduce soil erosion and stabilize soils. Decommissioning roads may in some cases entail ripping road surfaces to de-compact them, thus improving water infiltration, hydrologic function, and the ability of the treated area to revegetate more successfully.

Impacts to soils associated with site-specific travel plan alternatives were assessed based on the potential for soil erosion using the following erosion risk criteria:

- High – the area a route travels through has slopes greater than 30 percent gradient.
- Moderate – the area a route travels through has slopes ranging from 15 to 30 percent gradient; or, for granitic soils, slopes ranging from 0 to 30 percent gradient.
- Low – the area a route travels through has slopes ranging from zero to 15 percent gradient and soils are not granitic in origin.
- Unrated – road mapping not available at time of erosion impact rating.

### Effects of the Alternatives

The distribution of road miles by erosion impact category and by proposed road management category for all the alternatives is shown for the Helena TPA in **Table 4-48** Error! Reference source not found.. Roads in the “unrated” category were excluded from detailed consideration and are provided for the purpose of displaying the extent of lacking information.

Under current conditions (Alternative A) approximately 11.8 miles of open BLM roads are located in areas with high erosion risk, and 34.3 miles are in moderate erosion areas. Soil erosion would be reduced under Alternative B because this alternative would reduce those open road mileages in high and moderate erosion categories to 4.4 miles and 7.4 miles, respectively. Approximately 28.2 miles of road in the high and moderate classes would be closed under Alternative B with an additional 6.6 miles in these categories being decommissioned. Vegetative recovery should occur on closed and decommissioned roads, with a beneficial effect on soils of reducing erosion from these areas.

Soil erosion would be most reduced under Alternative C because the lowest mileage of roads in the high and

<b>Proposed Road Management</b>	<b>Erosion Risk Category</b>	<b>Alternative A</b>	<b>Alternative B</b>	<b>Alternative C</b>	<b>Alternative D</b>
<b>Open Road Miles (including Open w/restrictions)</b>	High	11.8	4.4	2.1	6.3
	Moderate	34.3	7.4	4.0	13.4
	Low	3.5	0.9	0.8	0.8
	Unrated	2.6	1.0	0.1	0.8
<b>Closed Road Miles</b>	High	0	4.5	8.1	5.4
	Moderate	0	23.7	27.7	17.7
	Low	0	2.2	2.3	2.3
	Unrated	0	1.7	2.6	2.2
<b>Decommissioned Road Miles</b>	High	0	3.0	1.7	0.2
	Moderate	0	3.2	2.6	2.6
	Low	0	0.4	0.4	0.4
	Unrated	0	0	0	0

Note: Open roads include seasonally open roads as well as roads open yearlong.

moderate erosion categories would be left open (6.1 miles combined), while the greatest mileage in these categories would be closed (35.8 miles combined) of all alternatives. An additional 4.3 miles in these categories would be decommissioned under Alternative C.

Soil erosion associated with roads would be reduced under Alternative D compared to Alternative A, but would still be higher than under either Alternative B or C. Approximately 19.7 miles of BLM road in the moderate and high erosion categories combined would remain open under Alternative D, while about 23.1 miles in these categories would be closed and 2.8 miles would be decommissioned under this alternative.

### Cumulative Effects on Soils

Under all alternatives, cumulative effects to soils in the Helena TPA would arise from a number of past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands. Within this 95,492-acre TPA, BLM lands comprise about 10,162 acres or 11 percent of total lands. The approximately 52 miles of BLM roads (under Alternative A) make up about 7.5 percent of the approximately 693 road miles in the TPA. Therefore road-related effects to soils described by alternative for BLM roads would affect about 7.5 percent of all roads in the TPA. The majority of lands and roads within the TPA boundary are private property. Non-BLM roads are managed by the county, Forest Service, state, and private landowners.

Approximately 8,000 acres of land in the Helena TPA are managed by the National Guard. In addition to having and using various barracks and classrooms present, the Guard conducts various military maneuvers and training on these lands including non-live fire training and off-road use of military vehicles. Some helicopter-based training also occurs here including landings to drop off soldiers. Some soil erosion and compaction as well as loss of vegetative ground cover further exacerbating soil effects occur here, but to an unknown degree.

Approximately 481 BLM acres are permitted for various rights-of-way and leases. About 359 of these acres are for specific road rights-of-way. The remaining 122 acres are associated with powerlines, waterlines, communication sites, oil and gas pipelines, and other utility facilities.

Impacts to soils range from compaction and occupation of ground with buildings, roadbeds, and other facilities, to revegetation and ground cover being re-established to stabilize soils.

Selective timber harvest has occurred on about 133 acres of BLM land in the TPA since 1995. Adverse effects on soils were minor with treated areas having undergone revegetation and soil stabilization since treatment. Timber harvest has also occurred on private and Forest Service lands, will likely continue, and will likely have localized impacts on soils for the foreseeable future.

From 1981 to 2004, wildland fire has burned across 65 acres in the Helena TPA, having a mosaic of soil effects with more severely burned areas experiencing localized erosion while many areas were relatively little affected.

There has been one fuels reduction treatment on BLM lands in the TPA in the last 10 years. Approximately 150 acres in the Scratchgravel Hills around the Wildland Urban Interface had hazardous fuels mechanically removed and ground up on site. Effects to soils from this project were negligible. Within the next several years, BLM anticipates additional fuels treatments on 1,500 to 2,500 acres of WUI areas in the Scratchgravel Hills. These treatments would consist of a combination of mechanical and prescribed fire treatments and would generally have minor effects on soils. Prescribed burning would occur under conditions where fire severity and intensity would be low, thereby minimizing potential damage to soil or desired vegetation. All treatments would minimize compaction so as to promote vegetative recovery. Fuels treatments conducted on private and Forest Service lands will also likely occur for the foreseeable future with variable effects to soils. Reducing fuels under the controlled conditions of deliberate treatments may benefit soils in the long-term by reducing the risk of high severity fires in treated areas.

Livestock grazing on BLM lands, other public and private lands throughout much of the TPA has created areas of localized soil erosion and compaction. This will continue to occur for the foreseeable future.

Increasing residential development will likely continue for the foreseeable future to variable degrees within the TPA. Erosion, compaction, and covering of soils would occur due to additional road construction, clearing/leveling for home sites, and establishment of utility infrastructure for residential developments.

Under Alternative A, the contribution to cumulative effects on soils from BLM road management would continue as it occurs today. Retaining approximately 52 miles of road open yearlong would allow for the same level of compaction and erosion impacts that currently exist.

From a BLM road management perspective, all action alternatives would benefit soil resources compared to Alternative A. Alternative B would benefit soils by providing for a reduced contribution to adverse cumulative effects than would Alternative A because about 73 percent of BLM roads would be closed or decommissioned under Alternative B (compared to all being open yearlong under Alternative A). Erosion should be reduced on these closed/decommissioned roads as disturbance is eliminated and revegetation occurs and stabilizes soils.

Alternative C would benefit soils the most and provide for the least contribution to adverse cumulative effects on soils of all alternatives. This alternative would provide for closure or decommissioning of about 86 percent

of BLM roads in the TPA, thus allowing these areas to vegetatively recover and stabilize soils.

Alternative D would provide for the greatest contribution to adverse cumulative effects on soils of the action alternatives, but would still provide for greater long-term benefits to soils than Alternative A. Alternative D would provide for closure or decommissioning (and therefore vegetative recovery and/or soil stabilization) of about 58 percent of BLM roads in the TPA, compared to 73 percent for Alternative B, and 86 percent for Alternative C.

Due to the scattered distribution and relatively small proportion of BLM lands (11 percent) and roads (7.5 percent) relative to the total quantities of lands and roads in the TPA, none of the BLM alternatives would substantially contribute to cumulative effects to soils at the scale of the entire Helena TPA.

## WATER RESOURCES

### Effects Common to All Alternatives

Hydrologic function is an interaction between soil, water, and vegetation, and reflects the capacity of a site to:

- Capture, store, and safely release water from rainfall, runoff, and snowmelt;
- Resist a reduction in this capacity; and
- Recover this capacity following degradation.

Interception of precipitation results when precipitation falls on vegetation. When vegetation is removed, precipitation falls directly on the soil. This can increase surface erosion and sedimentation, and decrease the amount of time between initial precipitation arrival and peak surface runoff – in turn decreasing soil/site stability and hydrologic function. Roads remove vegetation and therefore decrease interception of precipitation.

Infiltration is the process of precipitation entering and traveling through soil. Infiltration reduces the peak runoff during precipitation events by extending the period of runoff after a precipitation event. Infiltration also filters precipitation and reduces erosion and sedimentation. If infiltration is reduced, runoff and erosion will increase and hydrologic function will decrease. Generally, roads are compacted surfaces that have decreased infiltration, thus increasing runoff and potentially increasing erosion.

Runoff can affect the amount of erosion and sedimentation, as well as flooding – both onsite and offsite. If runoff is increased, all of these effects can increase with a result that water quality and hydrologic function will decrease.

Increased sediment entering water bodies increases turbidity; increases width-to-depth ratios, and consequently increases temperature and dissolved oxygen saturation levels; and creates adverse habitat for aquatic animals and plants.

Alteration of flow routing can also affect water resources. For example, roadcuts into areas with relatively shallow groundwater can intercept groundwater, bring it to the surface, and transport it some distance (i.e. in a roadside ditch) before delivering it to a stream. This can lead to erosion of road ditchlines and subsequent sedimentation of streams during runoff periods, or increased thermal loading of water before delivery to streams during summer periods.

Closure and decommissioning of roads tend to reduce erosion and sedimentation effects stemming from roads on water quality. On an equivalent road mile basis, decommissioning roads would benefit water quality to a greater degree than closing roads because the decommissioning process would often entail implementing measures to restore hydrologic function. During road decommissioning, items such as compaction, drainage, stream crossing culverts, and ground cover are often addressed in a manner that markedly improves hydrologic function. These features are not fully addressed on roads that are merely “closed”. However, because surface disturbance is reduced on newly closed roads, and because vegetation tends to re-establish ground cover on them, erosion and subsequent sedimentation effects to water quality are often reduced from closed roads.

### Effects of the Alternatives

Generally, road density is an indicator of overall watershed health and function. Watersheds with higher road densities tend to have lower water quality due to greater disruption of hydrologic function (described above), and potential for erosion and subsequent sedimentation. Road density also is related to the distribution and spread of noxious weeds. **Table 4-49** shows acres of BLM land in three road density categories by alternative for the Helena TPA. These data reflect differences between alternatives based on roads proposed for “decommissioning” by alternative. While many “closed” roads would gradually contribute to increased hydrologic function over time, decommissioned roads would more directly contribute to hydrologic function because restoring hydrologic function would likely be part of the treatment during decommissioning. Alternative A would have the greatest amount of BLM land with “high” road densities of greater than 2 mi/mi<sup>2</sup>. Alternative B would

TPA Alternative	Road Density Category		
	Low (<1 mi/mi <sup>2</sup> )	Moderate (1 to 2 mi/mi <sup>2</sup> )	High (> 2 mi/mi <sup>2</sup> )
<b>A</b>	461	1,446	8,294
<b>B</b>	461	1,623	8,117
<b>C</b>	461	1,539	8,200
<b>D</b>	461	1,484	8,258

have the lowest acreage in the high category with the greatest acreage in the moderate category of all alternatives. Alternative C would have the next lowest acreage in the high road density category while Alternative D would have more acres in the high category than either Alternative B or C, but less than Alternative A. Overall, all the action alternatives would improve hydrologic function but by this measure Alternative B would make the greatest contribution to improved hydrologic function of all the alternatives.

Motorized routes within 300 feet of streams generally have greater potential to directly impact water quality through erosion and sedimentation, increased water temperatures (due to loss of shading vegetation), and direct alteration of stream channel morphology than those farther away. **Table 4-50** shows the miles of open and closed roads on BLM lands within 300 feet of streams by alternative. Under Alternative A there are about 7 miles of open road within 300 feet of streams. All action alternatives would improve water quality by closing or decommissioning roads in close proximity to perennial streams. Alternatives B and C would create the most benefit as both would close or decommission 4.1 of the seven total miles of road within 300 feet of streams. Alternative D would have slightly less benefit by closing or decommissioning 2.5 of these 7 miles.

### Cumulative Effects on Water Resources

Cumulative effects to water resources in the East Helena TPA would arise from a number of past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands. Within this 95,492-acre TPA, BLM lands comprise about 10,162 acres or 11 percent of total lands. The approximately 52 miles of BLM roads (Alternative A) make up about 7.5 percent of the approximately 693 road miles in the TPA. Therefore road-related effects to water resources described by alternative for BLM roads would pertain to about 7.5 percent of all roads in the TPA. Within the entire TPA (all land ownerships) there are approximately 108 miles of perennial streams, including 37 miles of fish bearing streams. Of these, approximately 8 miles (including 2 miles of fish bearing) flow through BLM lands. The majority of lands and roads within the TPA boundary are private

property. Non-BLM roads are managed by the county, Forest Service, state, and private landowners.

Some of the main access roads (non-BLM) follow valley bottoms and parallel streams. Many of these roads are directly affecting stream channel and floodplain function by filling or impinging on active stream channels or floodplains, precluding the presence of riparian vegetation (including large woody material in forested locations), producing sedimentation in streams (from road surfaces, ditchlines, winter “road sanding” operations), and promoting thermal loading by lessening streamside shade.

Approximately 8,000 acres of land in the Helena TPA are managed by the National Guard. In addition to having and using various barracks and classrooms present, the Guard conducts various military maneuvers and training on these lands including non-live fire training and off-road use of military vehicles. Some helicopter-based training also occurs here including landings to drop off soldiers. Some soil erosion and compaction as well as loss of vegetative ground cover occur here. This is exacerbating potential erosion and sedimentation effects, but to an unknown degree. Sevenmile Creek, one of the streams listed as impaired by Montana Department of Environmental Quality on the 303(d) list flows through these lands.

Approximately 481 BLM acres are permitted for various rights-of-way and leases. About 359 of these acres are for specific road rights-of-way. The remaining 122 acres are associated with powerlines, waterlines, communication sites, oil and gas pipelines, and other utility facilities. Impacts to water resources are generally minor with some localized erosion and sedimentation emanating from areas of ground disturbance.

Selective timber harvest has occurred on about 133 acres of BLM land in the TPA since 1995. Adverse effects on water resources were minor with treated areas having undergone revegetation to minimize erosion. Timber harvest has also occurred on private and Forest Service lands and will likely continue. This activity will have localized sedimentation and possibly increased runoff effects associated with compaction for the foreseeable future.

**Table 4-50**  
**Miles of Open and Closed Roads on BLM Lands within 300 ft. of Fish-Bearing Streams and Perennial, Non-Fish-Bearing Streams by Alternative for the Helena TPA**

	Perennial Fish-Bearing Streams		Perennial Non-Fish-Bearing Streams	
	# Open Road Miles	# Closed Road Miles	# Open Road Miles	# Closed Road Miles
<b>Alt. A</b>	1.7	0	5.3	0
<b>Alt. B</b>	1.7	0	1.2	4.1
<b>Alt. C</b>	1.7	0	1.2	4.1
<b>Alt. D</b>	1.7	0	2.8	2.5

Note: Open roads include seasonally open roads as well as roads open yearlong. Closed roads include decommissioned roads.

From 1981 to 2004, wildland fire has burned across 65 acres in the Helena TPA, having minimal effects in streams.

There has been one fuels reduction treatment on BLM lands in the TPA in the last 10 years. Approximately 150 acres in the Scratchgravel Hills around the Wildland Urban Interface had hazardous fuels mechanically removed and ground up on site. Effects to water resources from this project were negligible as site-specific ground disturbance was minor and there are no streams in this portion of the TPA. Within the next several years, BLM anticipates additional fuels treatments on 1,500 to 2,500 acres of WUI areas in the Scratchgravel Hills. These treatments would consist of a combination of mechanical and prescribed fire treatments and would likely have minor effects on water resources. Prescribed burning would occur under conditions where fire severity and intensity would be low so as not to scorch soils and facilitate severe erosion. All treatments would minimize compaction so as to promote vegetative recovery and retain hydrologic function. There are no perennial streams in the area where this project is being planned so effects to water resources are expected to be minor to negligible.

Fuels treatments conducted on private and Forest Service lands will also likely occur for the foreseeable future with variable effects to water quality. Reducing fuels under the controlled conditions of deliberate treatments may benefit water quality in the long-term by reducing the risk of high severity fires in treated areas.

Livestock grazing on BLM land, other public and private lands throughout much of the TPA has created areas of localized streambank trampling, soil erosion and compaction, and nutrient inputs to streams. In severe cases stream channel morphology may be altered due to severe loss of riparian vegetation, loss of streambank integrity, channel widening and shallowing, and substantial sediment inputs. These effects to water quality will continue to occur for the foreseeable future. Agricultural water withdrawals occur on private lands in this TPA. These withdrawals reduce stream flows in the TPA, notably in Sevenmile Creek (listed as impaired water body by MDEQ on the 303(d) list).

Increasing residential development will likely continue for the foreseeable future to variable degrees within the TPA. Impairments to hydrologic function such as erosion, soil compaction, and runoff would likely increase due to additional road construction, clearing/leveling for home sites, and establishment of utility infrastructure for residential developments. Nutrient, chemical pollutant, and pathogen inputs to streams would also likely increase due to leaching from septic systems, urban runoff (fertilizer, chemicals, and petroleum pollutants), and waste from livestock.

Under Alternative A, the contribution to cumulative effects on water quality from BLM road management

would continue as it occurs today. Retaining approximately 52 miles of road open yearlong would allow for the same level of effects to water resources that currently exist.

From a BLM road management perspective, all action alternatives would benefit water resources compared to Alternative A. Alternative B would benefit water quality by providing for a reduced contribution to adverse cumulative effects from BLM roads compared to Alternative A because about 81 percent of BLM roads would be closed or decommissioned under Alternative B (compared to all being open yearlong under Alternative A). Alternative B would provide for decommissioning the greatest road mileage (6.5 miles) of all alternatives. Erosion and sedimentation should be reduced on these closed/decommissioned roads as disturbance is eliminated and vegetation becomes re-established on roadbeds. On an equivalent road mile basis, decommissioning roads would benefit water quality to a greater degree than closing roads because the decommissioning process would often entail implementing measures to restore hydrologic function.

Alternative C would reduce the contribution to adverse cumulative effects from BLM roads (and benefit water resources) to a similar degree as Alternative B although there are some differences between the two alternatives. Alternative C would provide for the most closed roads (40.7 miles compared to 36 under Alternative B) of all alternatives, but only the second most decommissioned roads (4.6 miles).

Alternative D would provide for the greatest continuing contribution to adverse cumulative effects on water resources of the action alternatives, but would still provide for greater long-term benefits to water resources than Alternative A. Alternative D would provide for closure (27.7 miles) or decommissioning (3.1 miles) of about 58 percent of BLM roads in the TPA, compared to 81 percent for Alternative B, and 86 percent for Alternative C.

Due to the scattered distribution and relatively small proportion of BLM lands (11 percent) and roads (7.5 percent) relative to the total quantities of lands and roads in the TPA, none of the BLM alternatives would substantially contribute to cumulative effects on water resources at the scale of the entire Helena TPA.

## **VEGETATIVE COMMUNITIES – FOREST RESOURCES AND FOREST AND WOODLAND PRODUCTS**

### **Effects of the Alternatives**

Under all alternatives, existing roads and roads built to access timber and forest product sales on BLM lands may encourage timber harvest and forest product sales on adjacent lands, particularly where landowners and other agencies are looking to improve economic effi-

ciency or opportunities in the management on their lands.

In general, vegetative treatment contractors tend to bid more readily on projects in areas with vehicle access or valuable forest products. BLM often prioritizes forest vegetation management activities such as forest products and forest protection activities (e.g. wildfire suppression and forest insect and disease control) in similar areas.

Rehabilitation of roads (decommissioning or in some cases road closure) would revegetate currently unvegetated roadbeds, which would increase vegetation biomass production on the landscape through colonization of sites with grasses, forbs, shrubs, and trees. Increases in revegetated area would occur at a rate of approximately 1.5 to 3 acres per mile of rehabilitated road. Eventually rehabilitated roads would support plant communities consistent with site potentials which would help resist weed invasions. However, road closures and removals (decommissioning) could make vegetation management treatments more difficult and costly, thereby inhibiting proposed treatments, reducing public access for forest product use and removal, and potentially slowing fire detection and suppression.

Under Alternatives A (52.2 open road miles) and D (21.9 open road miles) in the Helena TPA, the major vehicle access roads in the forest and woodland areas remain open, so there would be little increase in project analysis and implementation costs, and no change in the feasibility of vegetative and fuels reduction treatments. Under Alternatives B (9.8 open road miles) and C (7 open road miles), the access roads into the forest and woodland areas would be closed, so there could be a reduction in the feasibility of many projects. For projects that are feasible, there could also be increases in vegetative analysis, project planning, and treatment costs to the BLM.

In the context of gathering firewood and other forest products by the general public, mileage of open roads would represent the relative extent of public opportunities by alternative. For the Helena TPA, Alternative A would retain the most public opportunities for these activities, followed in sequence by Alternative D, Alternative B, then Alternative C.

## **Cumulative Effects on Forest and Woodland Resources and Products**

No BLM forest health/silvicultural treatments or resource product removal projects are currently imminent in this TPA within the next five years. Fuels reduction projects with forest health considerations have a high priority because of the high degree of residential development surrounding BLM lands. The major block of land that includes BLM forest and woodlands in this TPA is located in the Scratchgravel Hills, with some woodland stands in a block located northwest of Fort Harrison near Austin. One fuels reduction project (antic-

ipated at 1,500 to 2,000 acres) is currently being planned in the Scratchgravel Hills area. These stands are of low productivity and commercial value, so the forest products generated would provide little revenue in timber sale projects. In other vegetation manipulation projects, derived products would provide only small offsets to costs for stewardship (exchange of goods for services) projects.

Forested vegetation on BLM lands would also be affected by approximately 481 acres of rights-of-way and leases on BLM land. Forested vegetation located in these areas usually is harvested and/or removed to accommodate the necessary access or facilities. Forest vegetation removal would occur on new authorizations in the future and would occur as necessary to maintain sight distances and safety clearances associated with roads and facilities.

Urbanization is expected to continue on the 56,499 acres of private lands within this TPA. Forest products are commonly removed from these areas prior to permanent construction. Urbanization is likely to continue in the future and will affect forested vegetation at an unknown rate. As private construction increases, miles of road on private land will most likely increase from the current 528 miles.

Risk to forests from human-caused wildfires is commonly associated with miles of open roads because increased fire starts occur in these areas. Risk to forests from wildfire on BLM lands would be greatest under Alternative A with 52.2 miles of open road. Alternative B would have less risk of human-caused fire starts with 9.8 miles of open road. Alternative C would have the least risk to forests of all alternatives with only 7.0 miles of road open during summer months. Alternative D (21.9 miles) would have less risk than Alternative A but more risk than either Alternative B or C. Given that the majority of roads in the TPA (92 percent) are non-BLM roads, this contribution to reduced fire risk from BLM roads in the action alternatives is relatively small in the context of the entire TPA.

Since BLM roads constitute only 7.5 percent of all roads in this TPA, and BLM lands make up only 11 percent of all lands in the TPA, urbanization and activities on open non-BLM roads in the vicinity may have more cumulative effects on forested vegetation in the TPA than BLM decisions regarding miles of open and closed road.

## **VEGETATIVE COMMUNITIES – NOXIOUS WEEDS**

Under all alternatives, any snowmobile use would have negligible effects on noxious weed spread. Invasive noxious weeds and non-native species are degrading wildland health. These aggressive plants can outcompete many native plants, as they have few natural enemies to keep them from dominating an ecosystem. These plant species are spread by many means. However, any land

disturbing activity in the TPA has the most potential to introduce and spread weed species. Motorized vehicles are one vector for noxious weed spread as weed seed becomes attached to vehicles and their tires, and are transported from one area to another where seeds become detached and germinate to inhabit new areas.

### Effects of Alternative A

Under Alternative A, all existing routes in the Helena TPA would continue to be open yearlong (52.2 miles open yearlong, zero miles seasonally restricted and closed) to wheeled motorized users. Cross-country snowmobile travel would continue to be allowed as well as travel on all routes. Under Alternative A the open BLM roads would represent about 7.5 percent of all open roads in the Helena TPA.

Alternative A would have the most roads open and in turn would promote the greatest amount of weeds and other undesirable plant spread and production of all alternatives. More herbicide control would be needed to control weeds under Alternative A than under the other alternatives.

### Effects of Alternative B

Under Alternative B wheeled motorized travel (9.8 miles open yearlong) would be restricted in the Scratchgravel Hills to routes leading to five non-motorized trailheads; as well as several routes needed for residential access. Roads would be open yearlong. Cross-country snowmobile use would be allowed, as well as snowmobile travel on all existing routes during the season of use (12/2-5/15), conditions permitting. Under Alternative B, 42.5 miles of BLM road would be closed or decommissioned, leaving 9.8 miles open yearlong as compared to 52.2 miles of road open yearlong under Alternative A. This would prevent weed spread caused by motorized vehicles on these closed routes, but would increase spread on the open routes because of the more concentrated use of these routes. Overall Alternative B would reduce weed spread, but would increase weed treatment costs per road mile on the remaining open road miles compared to Alternative A. Under Alternative B, the 9.8 miles of open BLM road would constitute about 2 percent of all open roads in the Helena TPA.

### Effects of Alternative C

Alternative C would restrict wheeled motorized travel to five non-motorized trailheads in the Scratchgravel Hills. This alternative would provide the least number of wheeled motorized routes in the Helena TPA (7.0 miles open yearlong). Under this alternative, no snowmobile use would be allowed, including at the trailhead access routes. Under Alternative C, 40.7 miles of BLM road would be closed, leaving 7.0 miles open yearlong as compared to 52.2 miles of road open yearlong under Alternative A and 9.8 miles open under Alternative B. This would prevent weed spread caused by motorized

vehicles on these closed routes, but would increase spread on the open routes because of the more concentrated use of these routes. Overall Alternative C would reduce weed spread more than any other alternative, but would increase weed treatment costs per road mile on the remaining open road miles compared to Alternative A. Under Alternative C, the 7 miles of open BLM road would make up about 1 percent of all open roads in the Helena TPA.

### Effects of Alternative D

Under Alternative D, 21.9 miles of open routes would be available yearlong for wheeled motorized use. Of the action alternatives, Alternative D would provide the greatest opportunities for motorized users, and the least for non-motorized users. Cross-country snowmobile use would be allowed, as well as travel on all existing routes during the season of use (12/2-5/15), snow conditions permitting. This alternative would close 27.7 miles of road leaving 21.9 miles open yearlong as compared to 52.2 miles of road open yearlong for Alternative A. This would prevent weed spread caused by motorized vehicles on these closed routes, but would increase spread on the open routes because of the more concentrated use of these routes. Overall Alternative D would reduce weed spread more than Alternative A but less than Alternatives B and C, but would increase weed treatment costs per road mile on the remaining open road miles compared to Alternative A. Under Alternative D, the 21.9 miles of open BLM road would make up about 3 percent of all open roads in the Helena TPA.

### Cumulative Effects on Noxious Weeds

Under all alternatives, other past, present and reasonably foreseeable future BLM and non-BLM actions and outside influences affect noxious weeds.

Recreation use is well established in the TPA. Primary recreation activities include motorized OHV uses (ATV, motorcycle) and non-motorized uses (hiking, jogging, horseback riding, mountain biking, etc.). Motorized recreation uses are one of the leading causes of introduction and spread of noxious weeds and non native species. Weed seeds are transported by many recreational vectors (i.e. motorized vehicles including their tires), non-motorized vehicles including their tires, pack animals, and humans.

Urban development may lead to an increase in right-of-way permits on public lands to accommodate private property/development access. As a result, soil disturbing activities (i.e. roads, powerlines, telephone lines, etc.), will increase causing weeds to increase.

A variety of resource management projects, such as BLM initiated vegetation treatments, or fuels reduction projects, could affect weeds in the TPA. The Scratchgravel Hills Fuel Treatment Project is proposed in this TPA. It will consist of mechanical and/or prescribed fire treatments on from 1,500 to 2,500 acres focused on the

urban interface areas. There has been a fuels treatment project completed in the Scratchgravel Hills in the last 5 years which consisted of reducing fuels on a 150 acre area. Any project creating soil disturbance has the capability to increase weedy plant species. Prescribed burning projects give the ground surface a fertilization effect and eliminate some plant competition for weedy species giving them a niche for establishment and expansion in some areas. Ground disturbing equipment could also transport noxious weed seed to these project sites. BLM implements weed control measures in the aftermath of such ground-disturbing activity so as to minimize noxious weed spread.

Wildland fires create good seed beds and supply nutrients for weed species introduction and production. From 1981 to 2004 there have been 14 wildland fires that have burned about 65 acres. This TPA contains sufficient fuel to support a wildland fire in the foreseeable future.

Mining is a land disturbing activity and the activity itself and weed seed contaminated equipment that is used could promote weeds in the area. There are a number of active claims in the TPA but relatively little ground-disturbing activity associated with them is taking place at this time.

Noxious weeds and non-native invasive species are well established and spreading in the area. Weed control activities by BLM and other entities, while often effective at reducing or minimizing weed spread and weed populations, can also lead to some weed spread. Herbicide spray equipment is driven through weed infestations and weed seeds as well as other weed vegetative parts are spread to other lands during and following treatment. Herbicide and biological control treatments in recent years have been accomplished on approximately 30 to 40 acres in the Scratchgravel Hills area. These weed treatments have varying success in killing undesirable plants, depending on many environmental parameters. The weeds that have been treated are primarily in the urban interface area where heavy motorized use plays a large role in the distribution of noxious weeds.

Timber sales have built in stipulations for mitigating weed production and spread. However, with ground disturbance the potential exists for weed introduction to occur on these sites. Vehicular access for tree plantings could contribute to the spread of existing weeds on site. Since 1984, there has been 10 acres of forest planting. From 1995 to the present there has been 133 acres of timber harvest in the TPA. Herbicide treatment of existing weeds was coordinated with tree seedling planting locations and timing so as to minimize potential exacerbation of weed spread. Reclamation associated with abandoned mine lands has led to some spread of weeds. Herbicide control treatments have followed these reclamation actions to minimize or eliminate impacts.

Future travel management (for all agencies, nationwide) is likely to lead to fewer opportunities for motorized recreational use than under current management (particularly for OHV use). As a result, the Scratchgravel Hills could experience increased use from displaced users, and such use could cause a larger than anticipated introduction and spread of weeds. An increase in weeds would lead to an increase in needed treatment on BLM lands.

The National Guard manages approximately 8,000 acres of land (Fort Harrison) in the Helena area. These actions could potentially increase weed spread and production on (and off) BLM managed lands.

Portions of the TPA provide winter range for mule deer and elk. The Birdseye section is within a wildlife movement corridor that provides a connection between the Northern Continental Divide Ecosystem and the Greater Yellowstone Ecosystem, as well as local daily movements and seasonal movements between higher elevation summer ranges. Noxious weed seed are transported and spread by wildlife through their digestive systems and by attaching to the animals themselves and then being released at a later time.

Livestock grazing on and off BLM lands also contributes to weed spread either through seed being introduced by livestock themselves, or through vehicular uses needed to manage grazing operations.

Like much of the West, the Helena Valley has been experiencing steady human population growth. This trend is expected to continue, along with increased recreational use of this travel planning area. The increasing population in the Helena area will in turn lead to an increase in use of this TPA creating more opportunities for weed spread and production.

The majority of BLM managed routes for the Helena Travel Planning area are located in or adjacent to the Scratchgravel Hills and Birdseye area. Scratchgravel Hills is basically an island of undeveloped hills surrounded by residential development (there is some internal development as well). Residential development has tripled from 300 residential homes in 1984 to over 1,000 homes today. Additional development is ongoing. This development/increase in human population has led to an increase in use of the Scratchgravel Hills area by residents living adjacent to or within this area which in turn leads to an increase in weed spread and propagation.

Only 7.5 percent of all the travel routes in the Helena TPA are located on BLM managed lands (under Alternative A). Lands near roads and away from roads in the TPA are infested with weeds. The travel on all roads in the TPA is spreading weeds and weeds off these roads are being spread by the weed plants themselves and other natural means. Because the majority of roads (92 percent) and lands (89 percent) in the TPA are non-BLM, activities in these areas play a stronger role than activi-

ties on BLM lands in determining the status of weed spread and weed populations in the TPA overall.

## VEGETATIVE COMMUNITIES – RIPARIAN VEGETATION

### Effects Common to All Alternatives

This section focuses on effects to riparian vegetation. For additional discussion of effects to water quality and stream channels, see the Water Resources and Fish sections.

Roads in riparian areas constitute ground disturbance that can eliminate or preclude presence of native riparian vegetation. This ground disturbance and loss of riparian vegetation may facilitate erosion and sedimentation of streams. Roads may also interfere with natural stream channel functions by occupying floodplains or active stream channel margins (see Water Resources section for more discussion). Noxious weeds may dominate riparian vegetation communities after some type of disturbance (such as roads, livestock grazing, mining, etc.) has reduced native vegetation. Noxious weed seed can be spread into riparian areas by motor vehicles via open roads. Closure of roads and trails can improve or maintain riparian condition by reducing avenues of noxious weed spread, as well as allowing for bare area revegetation which filters sediment in addition to stabilizing banks in some areas. Road and trail restrictions have the same effects but to a lesser degree, because some traffic will inhibit vegetation growth and recovery.

### Effects of the Alternatives

As a means of comparing alternatives, **Table 4-51** depicts the miles of wheeled motorized routes that cross or are within 300 feet of streams on BLM lands for the Helena TPA.

Under Alternative A, 10.9 miles of roads and trails would remain open that cross or are within 300 feet of streams on BLM lands. The noxious weed spread, streambank, and sediment delivery effects would continue as described above.

Under Alternative B, 4.2 miles of BLM roads and trails that cross or are within 300 feet of streams would remain open, and 6.7 miles of roads and trails would be closed. The noxious weed spread, streambank, and sediment

delivery effects would be slightly reduced in comparison to Alternative A, however the roads along Sevenmile Creek and Skelly Gulch which impact riparian areas the most would remain open because they are non-BLM county roads and provide access to these respective areas.

Under Alternative C, 3.4 miles of BLM roads and trails that cross or are within 300 feet of streams would remain open, and 7.4 miles of roads and trails would be closed. The noxious weed spread, streambank, and sediment delivery effects would be slightly reduced in comparison to Alternatives A and B, however the roads along Sevenmile Creek and Skelly Gulch which impact riparian areas the most would remain open because they are non-BLM county roads and provide access to these respective areas. Alternative C would provide the most benefit of all alternatives to riparian vegetation on BLM lands.

Under Alternative D, 4.9 miles of BLM roads and trails that cross or are within 300 feet of streams would remain open, and 6.0 miles of roads and trails would be closed. The noxious weed spread, streambank, and sediment delivery effects would be slightly reduced in comparison to Alternatives A, but would be greater than under Alternatives B and C. The roads along Sevenmile Creek and Skelly Gulch which impact riparian areas the most would remain open because they are non-BLM county roads and provide access to these respective areas.

### Cumulative Effects on Riparian Vegetation

Noxious weed spread, mining, roads and trails, logging operations, and livestock grazing have affected riparian resource conditions in all TPAs, including the Helena TPA. Some of these factors continue to cause riparian area degradation primarily through direct disturbance or loss of riparian vegetation. Ground disturbance and loss of riparian vegetation facilitate erosion and sedimentation of streams. In the case of noxious weeds, they usually dominate riparian vegetation communities after some type of disturbance (such as roads, livestock grazing, mining, etc.) has reduced native vegetation.

Anticipated subdivision growth on private lands will lead to more road construction and maintenance. More roads and development will increase severity of runoff events which in turn will cause more sediment delivery to creeks and streams. The additional sediment is likely to affect the functioning condition of some riparian areas by causing streambeds to aggrade at unnatural rates. Streambanks may also be affected if road placements do not allow for natural stream movements or meanders.

Logging and forestry practices on public and private lands are subject to streamside management zone (SMZ) requirements designed to maintain water quality and riparian vegetation. The proposed Riparian Management Zones under Butte RMP Alternatives B and C would be wider than SMZs and activities in these areas would be

<b>Miles of Wheeled Motorized Routes</b>	<b>ALT A</b>	<b>ALT B</b>	<b>ALT C</b>	<b>ALT D</b>
Open	10.9	4.2	3.4	4.9
Restricted	0	0	0	0
Closed	0	6.7	7.4	6.0

designed to benefit riparian resources, thus providing more riparian protection and more targeted management of riparian vegetation in both forested and non-forested areas than under RMP Alternatives A and D. The disturbance associated with timber activities does have the potential to increase noxious weed spread which degrades riparian area function and health. On public lands noxious weed control is a standard feature of any ground disturbing activities whereas on private lands noxious weed control is variable.

Livestock grazing will continue in the area and has the potential to impact riparian resource conditions. On BLM lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain riparian vegetation health and vigor. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided. Riparian conditions may improve or degrade as management changes.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, riparian conditions would improve because of the streambank protection gained from shrubby root systems and filtering capability of native riparian sedge and rush species.

The BLM fuels reduction project currently being planning for the Scratchgravel Hills would not have any cumulative effects to riparian vegetation because no activities would be planned near riparian areas. There are very few riparian areas in the Scratchgravel Hills portion of the TPA.

Cumulatively the effects of Alternative B would be similar to Alternative A, but would be a slight improvement to riparian vegetation. The closure of a few roads may slightly offset some of the private land road construction and maintenance effects described above.

Cumulatively the effects of Alternative C would be similar to Alternatives A and B, though Alternative C would make the greatest contribution to riparian vegetation by closing the greatest mileage of riparian roads on BLM lands of all alternatives. In comparison to Alternative B, the closure of a few more roads than Alternative B may slightly offset more of the private land road construction and maintenance effects described above.

Cumulatively the effects of alternative D would be similar to alternatives A, B, and C. In comparison to Alternatives B and C, the closure of a few less roads than Alternatives B or C may slightly offset less of the private land road construction and maintenance effects described above.

Overall, because BLM roads make up only 7.5 percent of all roads in the TPA (under Alternative A), and BLM lands make up 11 percent of all lands in the TPA, the contributions to riparian vegetation benefits associated with closing riparian roads on BLM lands would be minor at the scale of the entire Helena TPA.

## WILDLIFE

### Effects of Alternative A

Under Alternative A, the Helena TPA would have substantially more open roads (52 miles) compared to the action alternatives and would have the highest actual road density on BLM lands, 1.9 mi/mi<sup>2</sup> (Table 4-52) compared to the action alternatives. Open roads typically increase the level of recreation adjacent to roads. This can result in additional disturbance and displacement of wildlife species. Roads can also encourage the public to recreate in areas that had formerly been secluded. Roads can cause direct mortality to wildlife through road kill, prevent wildlife movement, create disturbance to wildlife via vehicular use, cause the spread of noxious weeds, reduce or eliminate habitat and cause habitat fragmentation on the landscape (Joslin et al. 1999). Open road miles that exceed 1 mi/mi<sup>2</sup> have also been found to provide less than 60 percent of functional habitat for elk (Christensen et al. 1993). Permanent and temporary roads could negatively impact wildlife, including special status species, particularly if roads are open during critical periods such as during the winter or breeding seasons.

Under Alternative A, this TPA would have fewer acres of functional winter range (461 acres of low road density area) compared to the action alternatives (Table 4-52). The action alternatives would all provide a similar amount of functional winter range, approximately 1,200 acres. Due to the isolated nature of BLM parcels and the substantial amount of development in the TPA, winter range value for big game species is extremely low compared to other areas.

**Table 4-52**  
**Decision Area Road Densities (mi/mi<sup>2</sup>) within Elk Winter Range in the Helena Travel Planning Area**

	Actual Road Density	Acres of Low Road Density	Acres of Moderate Road Density	Acres of High Road Density
<b>Alternative A</b>	1.9	461	1,331	2,611
<b>Alternative B</b>	1.0	1,152	1,165	2,087
<b>Alternative C</b>	0.7	1,270	1,113	2,021
<b>Alternative D</b>	0.9	1,267	1,110	2,027

Low Density = 0-1 mi/mi<sup>2</sup>, Moderate Density = 1-2 mi/mi<sup>2</sup>, High Density = >2 mi/mi<sup>2</sup>

Although the Helena TPA is open for cross country snowmobile use under Alternatives A, B and D, BLM lands in this TPA do not often get favorable snow conditions for this use. Due to snow conditions, the use of snowmobiles would be limited and the effects to big game and other wildlife species would be expected to be minimal the majority of the time. However, when snow conditions do become favorable, snowmobile use of the TPA could have negative effects to big game and other wildlife species. The negative effects due to cross-country snowmobile use could include harassment of big game and other species during the high stress winter season (Joslin et al. 1999). This could cause individuals to leave an area (temporarily or permanently) and/or an increase in stress that could lead to mortality.

In evaluating impacts of travel planning on elk and other big game species, it is important to consider impacts on security habitat. Elk security is the inherent protection allowing elk to remain in an area despite increases in stress or disturbance associated with the hunting season or other human activities. Security habitat includes blocks of nonlinear forested habitats greater than 250 acres in size that are at least 0.5 mile from an open road (Hillis et al. 1991). Security habitat should also consist of larger trees (greater than 8 inches DBH) with vegetation dense enough to hide an adult elk (Thomas et al. 2002). Under Alternatives A and D, there would be no functional security habitat for big game species and Alternatives B and C would provide only a negligible amount of security habitat (257-404 acres) (Table 4-53). As with winter range, the isolated nature of BLM parcels along with development of private lands and open roads throughout the TPA prevents the area from having a large amount of functional security habitat.

	<b>A</b>	<b>B</b>	<b>C</b>	<b>D</b>
<b>Helena TPA</b>	0	257	404	0

Core areas are areas large enough for wildlife (especially animals with large home ranges such as carnivores and big game) to forage and reproduce. Subcore areas are areas that could act as stepping stones for wildlife as they move through the region (Craighead et al. 2002). For all lands in the Helena TPA, all alternatives would have the same amount of acres with low (5,942 acres with road density less than 1 mi/mi<sup>2</sup>), moderate (2,762 acres with road densities of 1-2 mi /mi<sup>2</sup>), and high (2,061 acres with road densities greater than 2 mi/mi<sup>2</sup>) road densities in core and subcore habitat.

On BLM lands, there are only 501 acres in core/subcore habitat. All alternatives would have the same acres in low (71 acres), moderate (216 acres) and high (114 acres) road densities for core and subcore habitat.

Wildlife corridors are areas of predicted movement within or between core and subcore areas. Within the Helena TPA there are no acres identified as “high quality” wildlife movement corridors under any land ownership. There are approximately 21,804 acres identified as moderate quality corridors for all land ownerships and 19,439 acres within low quality corridors. Under all alternatives, moderate quality movement corridors would have 6,455 acres with low road density, 4,803 acres with moderate road density but the majority of acres, 10,546, would be in high road density. On BLM lands in the TPA there are only 379 acres mapped as moderate quality movement corridors but there is more BLM land (2,660 acres) in areas considered to be low quality corridors.

Riparian areas provide crucial habitat and critical travel corridors for wildlife including special status species. Riparian areas also provide a refuge for native plants and animals in times of stress such as drought or fire. Roads in riparian areas can prevent use of these crucial areas by wildlife, limit use, or cause loss of habitat (Wisdom et al. 2000). Under Alternative A, there would be 10.9 miles of open roads in riparian areas, the most of any alternative.

### Effects of Alternative B

Under Alternative B, the Helena TPA would have substantially fewer open roads (9.8 miles) compared to Alternative A (52 miles). Alternative B would have more open road than Alternative C (7 miles) but less than Alternative D (22 miles). Alternative B would decrease harassment to wildlife during all seasons of use compared to Alternatives A and D. This alternative would also improve habitat and reduce fragmentation more than Alternatives A and D but less than Alternative C.

Under Alternative B, the actual road density in elk winter range in the Helena TPA would be at the 1 mi/mi<sup>2</sup> recommended as a maximum by FWP in big game winter range. This is lower than the road density under Alternative A, 1.9 mi/mi<sup>2</sup>, higher than Alternative C (0.7 mi/mi<sup>2</sup>) and higher, but similar, to Alternative D (0.9 mi/mi<sup>2</sup>) (Table 4-52). Open road miles that are 1 mi/mi<sup>2</sup> have also been found to provide roughly 60 percent of functional habitat for elk (Christensen et al. 1993).

Under Alternative B, this TPA would have more acres of functional winter range (1,152 acres) compared to Alternative A (461 acres), slightly less than Alternative C (1,270 acres) but also slightly less than Alternative D (1,267 acres) (Table 4-52). All action alternatives would improve the quality and quantity of winter range in the Helena TPA to a similar degree and all action alternatives would have more beneficial effects on winter range compared to Alternative A.

Like Alternatives A and D, the entire Helena TPA would be open for cross country snowmobile use with Alternative B. The effects would be the same as described under Alternative A.

The amount of big game security habitat would be low, but still more under Alternatives B and C (257 and 404 acres, respectively) compared to Alternatives A and D which would have no functional security habitat (**Table 4-53**).

Alternative B would protect and restore more riparian habitat than Alternative A by reducing the miles of open roads in riparian areas to 4.2 miles (from 10.9 miles under Alternative A). Alternative B would have more open roads in riparian areas than Alternative C (3.4 miles) but less than Alternative D (4.9 miles). Alternative B would allow for more breeding, foraging, and hiding habitat as well as improve more movement corridors for a wide variety of species than Alternatives A and D but less than Alternative C.

### Effects of Alternative C

Under Alternative C, the Helena TPA would have substantially fewer open roads (7.0 miles) compared to Alternative A (52 miles). Alternative C would also have fewer open roads than Alternative B (9.8 miles) and Alternative D (22 miles). Alternative C would decrease harassment to wildlife during all seasons of use compared to all other alternatives. This alternative would also improve habitat and reduce fragmentation more than all other alternatives.

Under Alternative C, the actual road density in elk winter range in the Helena TPA on BLM lands would be 0.7 mi/mi<sup>2</sup>, below the maximum of 1 mi/mi<sup>2</sup> recommended by FWP in big game winter range. This is lower than the road density under Alternative A (1.9 mi/mi<sup>2</sup>), lower than Alternative B (1.0 mi/mi<sup>2</sup>) and lower than Alternative D (0.9 mi/mi<sup>2</sup>) (**Table 4-52**). Christensen et al. (1993) found that reducing open road miles to 0.7 mi/mi<sup>2</sup> would increase the amount of effective habitat available to elk to roughly 65 percent.

Under Alternative C, this TPA would have more acres of functional winter range (1,270 acres) compared to Alternative A (461 acres), slightly more than Alternative B (1,152 acres) and nearly the same as Alternative D (1,267 acres) (**Table 4-52**). All action alternatives would improve the quality and quantity of winter range in the Helena TPA to a similar degree and all action alternatives would have more beneficial effects on winter range compared to Alternative A.

Under Alternative C, snowmobile use throughout the entire Helena TPA would be limited to open routes (2.8 miles). This would greatly reduce the negative effects associated with snowmobile use to big game and other wildlife species compared to all other alternatives.

The amount of big game security habitat under Alternative C would be low (404 acres), but would still be greater than under any other alternative (**Table 4-53**).

Alternative C would protect and restore more riparian habitat than Alternative A by reducing the miles of open roads in riparian areas to 3.4 miles (from 10.9 under

Alternative A). Alternative C would also have fewer open roads in riparian areas than Alternative B (4.2 miles) and Alternative D (4.9). Alternative C would allow for more breeding, foraging, and hiding habitat as well as improve more movement corridors for a wide variety of species more than all other alternatives.

### Effects of Alternative D

Under Alternative D, the Helena TPA would have considerably fewer open roads (22 miles) compared to Alternative A (52 miles). Alternative D, however, would have considerably more open roads than Alternative B (9.8 miles) and, especially, Alternative C (7 miles). Alternative D would allow considerably more harassment to wildlife during all seasons of use than Alternatives B and C but less than Alternative A. This alternative would also restore fewer acres of habitat and allow more fragmentation than Alternatives B and C but substantially less than Alternative A.

Under Alternative D, the actual road density in elk winter range in the Helena TPA would be below the maximum of 1 mi/mi<sup>2</sup> recommended by FWP in big game winter range at 0.9 mi/mi<sup>2</sup>. This is lower than the road density under Alternative A (1.9 mi/mi<sup>2</sup>), lower than Alternative B (1.0 mi/mi<sup>2</sup>) and higher than Alternative C (0.7 mi/mi<sup>2</sup>) (**Table 4-52**).

Under Alternative D, this TPA would have more acres of functional winter range (1,267 acres) compared to Alternative A (461 acres), slightly more than Alternative B (1,152 acres) and nearly the same as Alternative C (1,270 acres) (**Table 4-52**).

Like Alternatives A and B, the entire Helena TPA would be open for cross country snowmobile use with Alternative D. The effects would be the same as described under Alternative A.

There would be no functional big game security habitat under Alternatives D and A. Although low, there would be 257 acres of security habitat under Alternative B and 404 acres under Alternative C (**Table 4-53**).

Alternative D would protect and restore more riparian habitat than Alternative A by reducing the miles of open roads in riparian areas to 4.9 miles (from 10.9 under Alternative A). Alternative D would have more open roads in riparian area than Alternative B (4.2 miles) and Alternative C (3.4 miles). Alternative D would allow for more breeding, foraging and hiding habitat as well as improve more movement corridors for a wide variety of species than Alternative A but less than Alternatives B and C.

### Cumulative Effects on Wildlife

Wildlife habitat in the Helena TPA has been affected by roads, historic and current mining, timber harvest, weed infestations, urbanization and development, recreation, powerline corridor development and communication sites.

Like much of the West, the Helena Valley has been experiencing steady population growth. This trend is expected to continue, along with increased recreational use of this travel planning area. The majority of BLM managed routes for the Helena TPA are located in or adjacent to the Scratchgravel Hills and Birdseye area. The Scratchgravel Hills is an island of undeveloped hills surrounded by residential development. Residential development has tripled from 300 residential homes in 1984 to over 1,000 homes today. Additional development is ongoing.

Land that was traditionally used for ranching, forest products, or mining is now being converted to home sites in the Helena Valley. Although these lands had historic human uses, they also provided quality wildlife habitat. These areas historically provided a diversity of habitats that contributed to; big game winter range, travel corridors, habitat for resident and migrating wildlife, as well as foraging, breeding and hiding habitat. Many of the areas currently experiencing residential development are in big game winter range. Because of the loss of winter range on private lands, it is critical that public and state lands maintain quality and secure winter range or improve the habitat in these areas.

For many plant and animal communities, native species richness decreases as housing density increases. Non-native species, however, tend to increase with development (Hansen et al. 2005). Wildlife populations, including carnivores, may be reduced even at very low levels of residential development due to; loss of habitat, an increase in human access (from roads) in areas that previously had low levels of disturbance, and an increase in hunting pressure. Residential development can also lead to an increase in noxious weed infestations that can reduce the quality and quantity of wildlife habitat.

Pets can also have a negative impact to native wildlife. Cats hunt and kill bird and small mammals. Dogs that are allowed to roam can chase, injure, or kill wildlife. This can result in areas becoming unavailable to wildlife.

Approximately 8,000 acres within the TPA is also managed by the National Guard for military maneuvers and training. Some helicopter-based training also occurs there.

Recreation use is well established in the TPA. Primary recreation activities include motorized OHV uses (ATV, motorcycle) and non-motorized uses (hiking, jogging, horseback riding, mountain biking, etc.).

The Scratchgravel Hills contains precious and base metals in both hard rock and placer deposits. Over the years there have been a large number of patented and unpatented mining claims distributed throughout the area. Currently, only a few claims are maintained but increases in mineral prices could lead to increased or renewed mining activity.

In the TPA, there are eight powerlines and six pipelines. There are no existing communication sites in the TPA and, in the future, communication sites on BLM lands will be restricted to existing sites. No future communication sites are expected on BLM lands in the TPA but could occur on private or other public lands. There is the potential for future powerlines and pipelines to be built in this TPA.

There are approximately 26 rights-of-way (ROW) in the TPA and applications for ROW permits to access private property or for commercial development are likely to increase in the future. As a result, public access to BLM lands could increase. Fewer ROWs would be expected under Alternative A because all BLM roads would remain open under this alternative. Alternative B would be expected to have fewer ROWs than Alternative C but more than Alternatives A and D. Alternative C would be expected to have the most ROWs and, of the action alternatives, Alternative D would have the fewest.

From 1981-2004 there have been 14 wildland fires that burned 65 acres of BLM lands (it is unknown how many acres burned in the entire TPA). Eleven of the fires were identified as human-caused and these fires burned the majority of the BLM acres (54). There has been one fuels reduction treatment that consisted of grinding small to medium size understory trees on 150 acres in the Scratchgravel Hills. Timber harvest has occurred on approximately 133 acres of BLM lands in the TPA over the last 17 years. In the foreseeable future, approximately 1,500-2,000 acres of BLM lands will likely be treated in the Scratchgravel Hills to thin dense, overstocked stands of dry Douglas fir and ponderosa pine as well as remove conifer encroachment from meadows. This would improve habitat for dry forest species. Vegetative treatments on BLM lands have had minor effects to wildlife habitat in the TPA. However, timber harvest and development on private lands has substantially altered the landscape and caused a substantial decline in the quality and quantity of wildlife habitat in the TPA.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the TPA. Motorized activities play a large role in the distribution of noxious weeds. The cumulative effects of the spread of noxious weeds from open roads would be greater under Alternative A than all other alternatives. Alternative A would result in more wildlife habitat being lost or degraded due to noxious weed infestations compared to the action alternatives. Alternative B would have fewer open roads than Alternatives A and D resulting in fewer infestations of noxious weeds. Alternative C would close the most roads and would have the fewest cumulative effects from loss of habitat due to noxious weeds of all alternatives. Open roads and development adjacent to BLM lands and the substantial amount of public use this area receives would still allow for the spread of noxious weeds.

Fragmentation of BLM lands in the TPA (only 11 percent of the TPA is in BLM ownership); open roads on BLM (52 miles), private (about 581 miles), and other public lands (about 60 miles); as well as adjacent residential development has reduced the quality of wildlife habitat within the TPA. Roads and development within the TPA can cause disturbance to wildlife along with fragmentation and loss of habitat. Roads are associated with nearly every type of activity that has the potential to occur in the TPA including; vegetation treatments, timber salvage, mining, access to private lands (ROWs), fire suppression, powerline corridors and recreation. Open roads in the Planning Area would likely increase due to development and management of private lands. Alternative A would have the greatest negative cumulative effects to wildlife and wildlife habitat from open roads with 52 miles of open roads. Alternative B would have fewer negative cumulative effects with 9.8 miles of open road than Alternatives A and D (22 miles) but more than Alternative C (7 miles).

Of the action alternatives, Alternative C would have the most beneficial cumulative effects by reducing habitat fragmentation, restoring habitat, and reducing disturbance. Alternative B would be more beneficial than Alternatives A and D but less than Alternative C.

Historic and recent timber cutting (mostly on private lands), past mining activity and firewood gathering in the TPA has reduced the amount of suitable snag habitat for cavity nesting species and the area is snag deficient. Alternative A would allow a substantial amount of access to the area for firewood cutting. This could continue to prevent snag recruitment for snag dependant species and minimize the amount of down woody material. Alternative B would protect more snag and down wood habitat from loss due to firewood cutting than Alternatives A and D but would protect less of this habitat type than Alternative C.

In the Helena TPA, open habitat of grasslands and shrublands along with high road densities in both the Decision and Planning Areas have prevented BLM lands from providing suitable security habitat for big game during the hunting seasons. Under Alternatives A and D, there would be no security habitat in the TPA in the Decision Area and there would be no security habitat in the future. Alternatives B and C would provide some security habitat for big game (257 and 404 acres, respectively). Security habitat would still be limited on private (unless closed to hunting) and other public lands.

There would be no differences in cumulative effects from travel planning with any alternative for core/subcore habitat or wildlife movement corridors in the Helena TPA. Fragmentation of habitat due to development, roads, and disturbance has caused the greatest impact on the amount and quality of core/subcore habitat and wildlife movement corridors. Only 11 percent of the TPA is considered core/subcore habitat and the majority of this is on Forest Service lands.

The cumulative effects of high road densities would continue to negatively affect wildlife species during the breeding season more under Alternative A than under the action alternatives. Alternatives B and C would have the most beneficial cumulative effects to wildlife during the breeding season compared to Alternative D and, especially, Alternative A.

## FISH

For the sake of this discussion, “open” roads include roads that are open with seasonal restrictions as well as roads that are open yearlong. Roads identified as “closed” within 300 feet of streams also include roads that would be “decommissioned” in these areas by alternative. Effects to water quality described in the Water Resources section would affect fish populations and fish habitat quality. Analyses described and tabulated in the Water Resources section are referred to in the context of effects to fish in the discussion below.

### Effects of Alternative A

Under Alternative A, the Helena TPA would have substantially more open roads (52 miles) compared to the action alternatives. Roads can have a wide range of effects on fish and fish habitat. These effects would include, but are not limited to, increased sedimentation from road construction and vehicle use, increased runoff, changes in surface water and drainage patterns from stream crossings, conduits for noxious weeds, loss of riparian vegetation, potential decreases in stream shading that could lead to water temperature increases, and changes in local fish populations when culverts are impassable and limit fish migration.

Watershed (or hydrologic) function can be used as an indicator of relative risk or impacts to fish habitat (Doppelt et al. 1993). Generally, watersheds with high road densities often have the largest negative effects on fish and aquatic resources. To determine the effects on watershed function, a moving windows analysis was conducted on BLM lands to look at the miles of roads that would be decommissioned and removed from the landscape for each alternative. During this analysis, it was assumed that even though closing roads would improve watershed function, closed roads would remain on the landscape and could still have negative impacts to water quality and prevent or impede the restoration of riparian vegetation. Under all alternatives, there would be 461 acres with low road density on BLM lands in the TPA (Table 4-49). Alternatives A and D would have nearly similar acres with moderate road density (1,446 and 1,484 acres, respectively), which would be less than Alternatives B (1,623 acres) and C (1,539 acres). All alternatives would have similar acres with high road density, ranging from 8,117 to 8,294 acres. This comparison shows relatively little difference between Alternative A and the action alternatives. Because the action alternatives close more roads, they would be expected to

have fewer negative effects to fish habitat than Alternative A.

For this discussion, road miles within 300 feet of fish bearing streams on BLM lands would be considered an indicator of direct effects to fish habitat and fish populations. Under all alternatives, there would be 0 miles of closed road and 1.7 miles of open road within 300 feet of fish bearing streams on BLM lands. All miles of open roads would be adjacent to streams (Greenhorn Creek and Skelly Gulch) with BLM special status species (westslope cutthroat trout). There is no difference between alternatives in terms of direct effects to fish habitat in the Helena TPA.

Perennial non-fish bearing streams contribute to fish habitat indirectly by serving as conduits of watershed products (water, sediment, nutrients, contaminants, and in some cases woody material) to fish bearing streams. Under Alternative A, there would be 0 miles of closed road and 5.3 miles of open road within 300 feet of perennial non-fish bearing streams on BLM lands in the TPA. Alternative A would have more miles of open road adjacent to perennial streams than Alternative B (1.2 miles) Alternative C (1.1 miles) and Alternative D (2.8 miles). Alternative A would have the greatest negative impacts to fish and aquatic resources from open roads.

### Effects of Alternative B

Under Alternative B, the Helena TPA would have substantially fewer open roads (9.8 miles) compared to Alternative A (52 miles). Alternative B would have more open roads than Alternative C (7 miles) but less than Alternative D (22 miles).

All alternatives would have the same acreage of BLM lands in the low road density category, and relatively similar acreages of land in moderate and high road density categories (Table 4-49). However, Alternative B would provide the greatest acreage in the moderate road density category, and the lowest acreage in the high road density category of all alternatives. Alternative B would also improve watershed function and slightly lessen impacts to fish compared to Alternative A because the closed roads under Alternative B would make a slight contribution to improved watershed function.

Effects associated with roads within 300 feet of fish bearing streams (Greenhorn Creek and Skelly Gulch) on BLM lands under Alternative B would be the same as under Alternative A.

Alternative B would contribute fewer indirect effects to fish habitat associated with roads within 300 feet of perennial non-fish bearing streams on BLM lands than Alternative A. Under Alternative B there would be 4.1 miles of closed road and 1.2 miles of open road within 300 feet of perennial non-fish bearing streams on BLM lands in the TPA. Under Alternative A there would be no closed roads and 5.3 miles of open road in these riparian areas.

Overall, Alternative B would have fewer negative effects to fish and aquatic habitats from increased fine sediment inputs, loss of large woody material and loss of riparian vegetation than Alternative A.

### Effects of Alternative C

Under Alternative C, the Helena TPA would have substantially fewer open roads (7.0 miles) compared to Alternative A (52 miles). Alternative C would also have fewer open roads than Alternative B (9.8 miles) and Alternative D (22 miles).

All alternatives would have the same acreage of BLM lands in the low road density category, and relatively similar acreages of land in moderate and high road density categories (Table 4-49). However, Alternative C would improve watershed function and slightly lessen impacts to fish compared to Alternatives A and D because the mileage of closed roads under Alternative C (compared to any other alternative) would contribute to improved watershed function.

Effects associated with roads within 300 feet of fish bearing streams (Greenhorn Creek and Skelly Gulch) on BLM lands under Alternative C would be the same as under Alternatives A and B.

Indirect effects associated with roads within 300 feet of perennial non-fish bearing streams on BLM lands under Alternative C would be the same as described under Alternative B.

Alternatives C and B would have similar benefits to fish habitat and would have fewer negative effects to fish and aquatic habitats from increased fine sediment, loss of large woody material and loss of riparian vegetation compared to Alternative A.

### Effects of Alternative D

Under Alternative D, the Helena TPA would have fewer open roads (22 miles) compared to Alternative A (52 miles). Alternative D, however, would have more open roads than Alternative B (9.8 miles) and Alternative C (7 miles).

All alternatives would have the same acreage of BLM lands in the low road density category, and relatively similar acreages of land in moderate and high road density categories (Table 4-49). However, Alternative D would have the greatest acreage of BLM lands in the high road density category and the lowest acreage in the moderate road density category of the action alternatives. Still, Alternative D would contribute to improved watershed function and slightly lessen impacts to fish compared to Alternative A because approximately 30 miles of road would be closed or decommissioned in this alternative compared to all roads being open under Alternative A.

Effects associated with roads within 300 feet of fish bearing streams (Greenhorn Creek and Skelly Gulch) on

BLM lands under Alternative D would be the same as under all other alternatives.

Alternative D would contribute fewer indirect effects to fish habitat associated with roads within 300 feet of perennial non-fish bearing streams on BLM lands than Alternative A. Under Alternative D there would be 2.5 miles of closed road and 2.8 miles of open road within 300 feet of perennial non-fish bearing streams on BLM lands in the TPA. While it would be an improvement over the current condition, Alternative D would contribute more indirect effects to fish habitat from these streams than either Alternative B or Alternative C.

Alternative D would have more adverse effects to fish and aquatic habitats from increased fine sediment, loss of large woody material and loss of riparian vegetation than Alternatives B and C but less than Alternative A.

### Cumulative Effects on Fish

The Helena TPA supports a variety of native and introduced fish species. One of the major human influences to fish in the TPA has been the introduction of non-native trout species including rainbow trout, brook trout, and brown trout throughout the TPA. Rainbow trout have hybridized with the native westslope cutthroat trout in many streams. Brook trout and brown trout have displaced the native cutthroats in other streams; especially those altered by sedimentation and increased water temperatures brought on by human activities.

Like much of the West, the Helena Valley has been experiencing steady human population growth. This trend is expected to continue, along with increased recreational use of this travel planning area. The majority of BLM managed routes for the Helena TPA are located in or adjacent to the Scratchgravel Hills and Birdseye area. Scratchgravel Hills is an island of undeveloped hills surrounded by residential development. Residential development has tripled from 300 residential homes in 1984 to over 1,000 homes today. Additional development is ongoing. There are no perennial streams in the Scratchgravel Hills portion of the TPA that could be affected by this development. However, development and urbanization have had substantial impacts to watershed function in this TPA.

Agricultural activities from farming and ranching also contribute increases in nutrients, sedimentation, and loss of aquatic habitats. Many streams in the TPA have been impacted by historic and on-going livestock grazing that breaks down streambanks, widens channels, removes vegetative cover, and causes an increase in fine sediment and nutrients.

The Scratchgravel Hills contains precious and base metals in both hard rock and placer deposits. Over the years there have been a large number of patented and unpatented mining claims distributed throughout the area. Although some streams in the TPA may have been impacted by historic mining activities, it is expected that

the amount of aquatic habitat impacted has been minimal due to the lack of streams in this portion of the TPA.

Fires, floods, and drought have historically affected fish habitat in the TPA. These disturbances can cause a pulse of sediment or may temporarily reduce the quality of fish habitat in some watersheds while leaving other streams largely unaffected. Natural disturbances are typically followed by periods of stability, during which fish habitats and populations recover. Population recovery in disturbed streams may be facilitated by fish immigration from nearby drainages less affected by the catastrophic event. From 1981-2004 there have been 14 wildland fires that burned 65 acres. Eleven of the fires were identified as human-caused and these fires burned the majority of the acres (54). There has been one fuels reduction treatment that consisted of grinding small to medium size understory trees on 150 acres in the Scratchgravel Hills. This project had no effects to aquatic habitats.

Timber harvest can alter the recruitment of large woody debris, reduce canopy closures, and result in an increase in fine sediment to streams. Timber harvest along with associated roads can contribute substantially to the overall cumulative effects in forested watersheds. Timber harvest has occurred on approximately 133 acres of BLM lands in the TPA over the last 17 years. In the foreseeable future, approximately 1,500-2,000 acres will be treated in the Scratchgravel Hills to thin dense, overstocked stands of dry Douglas fir and ponderosa pine as well as remove conifer encroachment from meadows. This would have no impacts to aquatic habitats or species. Vegetative treatments on BLM lands have had minor effects to aquatic habitats in the TPA. However, timber harvest and development on private lands have substantially altered the landscape and may have caused a decline in the quality and quantity of aquatic habitat in the TPA.

Roads are another major contributor of sediment to streams and a major problem with regards to cumulative watershed effects. Roads and trails can have localized effects on nearby stream segments or at stream crossing sites, especially fords. In some cases, effects are more extensive and may impair fish habitat for longer reaches of streams. Cumulatively, roads degrade aquatic habitat due to sedimentation from road construction and vehicle use, increased runoff, changes in surface water and drainage patterns from stream crossings, loss of riparian vegetation, loss of large woody material, and alteration of stream channels and floodplains. Roads can cause changes in local fish populations when culverts are impassable and limit fish migration. Alternative A would have more negative cumulative effects to watersheds and individual streams due to roads than the action alternatives. Alternative B would have fewer negative cumulative effects than Alternatives A and D but more than Alternative C. Alternative B would improve overall watershed functions as well as improve habitat in individual streams more than Alternatives A and D but less than

C. Alternative C would have the greatest beneficial effects to fish habitat of all alternatives.

## SPECIAL STATUS PLANTS

### Effects Common to All Alternatives

Ground-disturbing activities from road construction and maintenance, as well as road use by vehicles can affect special status plant populations and habitat. These activities can reduce sensitive plant species through disturbance to individual populations, increasing competition from invasive species, and reducing habitat connectivity. Closure of roads and trails can improve or maintain sensitive plant populations or habitat by reducing avenues of noxious weed spread, maintaining habitat connectivity, and improving pollinator habitat. Road and trail restrictions have the same effects but to a lesser degree.

### Effects of the Alternatives

Under Alternative A, 52.2 miles of roads and trails would remain open. The effects would continue as described in the Effects Common to All Alternatives section.

Under Alternative B, 9.8 miles of roads and trails would remain open, 36 miles of roads and trails would be closed, and 6.5 miles would be decommissioned. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The seasonally restricted roads would reduce weed spread a limited amount. Alternative B would reduce risk to and benefit special status plants compared to Alternative A.

Under Alternative C, 7 miles of roads and trails would remain open, 40.7 miles of roads and trails would be closed, and 4.6 miles would be decommissioned. As with Alternative B, on the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The restricted roads would reduce weed spread a limited amount. Alternative C would benefit and reduce the most risk to special status plants the most of all alternatives because it would eliminate disturbance, vehicular use, and spread of noxious weeds on the most road miles.

Under Alternative D, 21.9 miles of roads and trails would remain open, 27.7 miles of roads and trails would be closed, and 3.1 miles would be decommissioned. On the open roads, effects would continue as described in the Effects Common to All Alternatives section. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for special status plants and their pollinators. The restricted roads would reduce weed spread a limited amount. Alternative D would benefit and reduce risk to special status plants compared to Alternative A, but would pose more risk compared to Alternatives B and C.

## Cumulative Effects on Special Status Plants

Under all alternatives there are a number of past, present, and reasonably foreseeable future actions that affect special status plant populations.

Livestock grazing will continue in the area and has the potential to impact sensitive plant populations and habitat. On public lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain sensitive species populations and habitat. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided. Conditions may improve or degrade as management changes.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, sensitive plants would benefit from the reduced competition. Use of herbicides for noxious weed control could cause mortality to special status plants if individual plants are inadvertently sprayed.

Recent and anticipated subdivision growth on private lands will lead to more road construction and maintenance. More roads and development will reduce sensitive plant species habitat and in some cases individual populations. Additionally, subdivisions have the potential to disrupt the connectivity of plant habitat and populations as well as disturbing or eliminating pollinators needed by sensitive species. Some sensitive species that require soil disturbance may benefit.

Timber sale activity disturbance can destroy or degrade sensitive plant habitat. On public lands, projects would be designed to avoid, mitigate, or enhance sensitive plant habitats. The disturbance associated with timber harvest activities does have the potential to increase noxious weed spread which degrades sensitive species habitat and individual plant populations.

The fuels reduction project scheduled for the Scratch-gravel Hills is not anticipated to have any adverse effects on special status plants. Treatments would be designed to minimize surface disturbance in sensitive plant habitat. Additionally, treatment would improve habitat in some areas by opening up parks and edges where trees have expanded into grassland soils and trees have thickened to the point of closing canopies.

At the scale of the entire Helena TPA (all land ownerships), the BLM travel plan alternatives would have slightly variable contributions to cumulative effects on special status plants. Under Alternative B adverse effects on special status plants would be slightly reduced compared to Alternative A because 5.6 percent of all roads in the TPA would be closed or decommissioned. Alternative C would provide the most benefits of all alternatives as 6.5 percent of all roads in the TPA would be closed or decommissioned. Alternative D would provide slightly

more benefits than Alternative A but slightly fewer benefits than either Alternatives B or C as 4.4 percent of all roads in the TPA would be closed or decommissioned. Because BLM lands make up only 11 percent of all lands in the TPA, activities on non-BLM lands would play a greater role in determining the status of special status plants.

## WILDLAND FIRE MANAGEMENT

Travel planning alternatives were analyzed to determine whether they could result in impacts on wildland fire management, causing change to any of the following indicators:

- Fire regime condition class (FRCC)
- Firefighter and public safety
- Reducing threat to Wildland Urban Interface (WUI)

### Effects Common to All Alternatives

Public road access during the fire season provides opportunities for human-caused fires either due to catalytic converters on vehicles igniting dry vegetation, or due to some types of human activities. Roads that are closed to public access reduce the risk of human-caused fire starts in those areas.

Decommissioned roads and roads that are closed and not regularly maintained for navigability reduce access for fire suppression. Closed roads may become impassible due to vegetation regrowth, downfall of trees, or severe erosion. Some roads may be closed with earthen berms or fallen trees and would need to be physically manipulated to make them useable for vehicles again. These roads would extend firefighting response time and have negative impacts on efforts to reduce wildland fire threat to WUI areas and firefighter and public safety. In an emergency fire suppression situation, any navigable closed roads needed for fire suppression would be used immediately. Non-navigable closed roads could also be used if deemed to be needed for fire suppression, after needed improvements are made to make those roads useable. Planning and implementation of fuels reduction treatments could occur in association with closed roads if variances for temporary road use were to be allowed. Variances would be subject to internal BLM review.

In the context of fuels reduction projects, availability of open roads is important to facilitating fuels project location as well as increasing project feasibility and decreasing costs. Open roads also facilitate spread of noxious weeds by transporting weed seed on vehicles and their tires. Presence of large noxious weed populations could delay or cause fuels projects to be cost-prohibitive due to the fact that the weeds may have to be treated before and/or after the fuels treatment. Also, some applications of fuel treatments (e.g., prescribed fire) may promote the spread of some weeds. The presence of weeds and non-

native species are indicators that FRCC has departed from historical conditions.

Noxious weeds and non-native invasive species are well established and spreading in the Helena TPA.

### Effects of Alternative A

Under Alternative A all existing routes in the Helena TPA would continue to be open yearlong (52.2 miles) to wheeled motorized users. Alternative A would allow for the greatest flexibility between alternatives for access for suppression purposes. Fuels project feasibility would be highest under this alternative. However, public access during the fire season would be the greatest under this alternative and would provide the most opportunities for human-caused fire starts.

The distribution of noxious weeds could be the greatest under Alternative A with the most open roads and noxious weeds already well established. This would contribute to reduced feasibility of fuels projects more than under any other alternative.

### Effects of Alternative B

Under Alternative B, wheeled motorized travel (9.8 miles) would be restricted to the following four areas in the Scratchgravel Hills: routes leading to five non-motorized trailheads; a short out-and-back route off of Norris Road; a loop route between Head Lane and Echo Lane; and all existing public access rights-of-way. Roads in these four areas would be open yearlong.

Alternative B would limit the flexibility for access for suppression purposes, and fuels project feasibility would go down compared to Alternative A due to the fact that access would be limited to 9.8 miles of road. Of the 42.5 of closed and decommissioned roads, 6.5 miles would be decommissioned. The risk of human-caused fires associated with motorized use would be limited compared to Alternative A, due to an 81 percent decrease in miles of road open to motorized public travel.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because more roads would be closed under this alternative, Alternative B should help reduce the spread of noxious weeds and may make fuels treatments more feasible than under Alternative A, reducing FRCC departure.

### Effects of Alternative C

Alternative C would restrict wheeled motorized travel to five non-motorized trailheads in the Scratchgravel Hills. This alternative provides the least number of wheeled motorized routes in the Helena TPA (7.0 miles) but provides an extensive network of routes for non-motorized enthusiasts.

Alternative C would limit the flexibility for access for suppression purposes, and fuels project feasibility would go down due to the fact that access would be limited to 7

miles of road. Of the 45.2 miles of closed roads, 4.6 miles would be decommissioned. The risk of human-caused fires associated with motorized use would be reduced more than under either Alternatives A or B, due to an 87 percent decrease in miles of open road compared to Alternative A. However, this may promote more non-motorized users to a concentrated area, increasing the odds for a human-caused fire to occur by another ignition source.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because more roads would be closed than under any other alternative, Alternative C should help reduce the spread of noxious weeds and may make fuels treatment more feasible than any other alternative, reducing FRCC departure.

### Effects of Alternative D

Under Alternative D, 21.9 miles of open routes would be available yearlong for wheeled motorized use and 3.1 miles of the 30.8 of closed roads would be decommissioned. Alternative D would be more flexible than alternatives B and C, but again it would limit flexibility for access for suppression purposes and fuels project feasibility would go down compared to Alternative A. The risk of human-caused fires associated with motorized use would be reduced compared to Alternative A but would be greater than under Alternatives B and C, due to a 58 percent decrease in miles of open road compared to Alternative A.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because an intermediate number of road miles would be closed under this alternative, Alternative D should help reduce the spread of noxious weeds and may make fuels treatments more feasible than under Alternative A, but would increase weed spread and potentially make projects less feasible than Alternatives B or C.

### Cumulative Effects on Wildland Fire Management

Effects on wildland fire management associated with any of the BLM travel plan alternatives would be overshadowed by reasonably foreseeable uncharacteristic fire, continued fire suppression made necessary by WUI and intermingled landownership, and large-scale insect infestations and disease outbreaks that would continue to increase fuel loading for the planning period.

Revision of the Helena National Forest Plan could result in more or less treatment of adjacent areas. Because no decision has been made, the effects are not known. Wildland fire management on USFS lands will be determined in the plan decision, particularly areas where wildland fire use (management of naturally ignited wildland fires to achieve resource objectives) may occur. BLM would need to coordinate with USFS on all wild-

land fire use actions and events. Wildland fire use on USFS lands could affect FRCC on BLM lands. USFS lands make up 25 percent of all lands in the TPA so activities there would likely have more influence on future fire characteristics than activities on BLM lands (10.6 percent of all lands in TPA).

Additionally, decisions to increase the level of wildland fire use, prescribed fire, or open burning by public could impact the BLM's ability to use wildland fire and prescribed fire due to air quality concerns and requirements. This could postpone or eliminate BLM fuel reductions or treatments to improve FRCC.

Access is a critical component of wildland fire suppression. In some cases, access to public lands is being reduced by adjacent landowners gating or closing roads, which could hamper wildland fire suppression efforts and pose a risk to public and firefighter safety. Reducing access would also increase the potential for larger fires to occur due to an increase in time needed to access a fire and control it. Time needed to move in crews would be extended, and the ability to effectively apply and place resources (e.g., engines, water tenders, etc.) would be limited.

Effects on wildland fire management, including FRCC and firefighter and public safety due to management accomplished by other landowners may affect wildland fire management on public lands. When activity fuels (i.e. slash from logging) are not treated adequately, fuel hazard could increase on adjacent lands which could affect fire intensity and severity on public lands. When adjacent landowners treat fuels or implement fire mitigation plans in the WUI, fires are easier to suppress and firefighter safety is increased. In this TPA, activities on private lands (59 percent of all lands in TPA) would have more influence on future fire characteristics in the area overall than activities on BLM lands (10.6 percent of all lands in TPA). Human population increases and subsequent development are likely to expand the WUI and could alter forest management, taking the emphasis off restoring historic composition and structure and focusing more on fuels reduction.

## CULTURAL AND PALEONTOLOGICAL RESOURCES

### Effects Common to All Alternatives

Alternative-specific risks or impacts to cultural and paleontological resources are difficult to discern due to a lack of extensive site-specific knowledge about the presence of these resources in a given TPA. By designating open routes, limiting open-country travel, and closing some routes, inadvertent discovery of cultural and paleontological resources and vandalism to them is reduced. Higher road densities in a given area would allow greater access to more land on the average, but that does not imply greater amounts of vandalism, since the vehicles would remain on designated routes.

## VISUAL RESOURCES

### Effects Common to All Alternatives

Roads (temporary or permanent) may affect visual quality. Roads that remain open for public use may impact visual qualities where noticeable. The quantity of open roads would also influence sensitivity levels since with more open roads, more areas would generally be viewed by more members of the public. Closing or decommissioning roads would generally reduce effects to visual resources and reduce sensitivity levels because fewer members of the public would generally be accessing and viewing areas with closed roads.

### Effects of the Alternatives

Under Alternative A, all 52.2 miles of BLM road would remain open, thereby providing for the greatest level of impact to visual resources of all alternatives.

Under Alternative B there would be 9 miles of open road, 36 miles of closed road, and 6.5 miles of decommissioned road. Road closures and decommissioning under this alternative would reduce effects on visual resources compared to Alternative A. Under Alternative C there would be 7 miles of open road, 40.7 miles of closed road, and 4.6 miles of decommissioned road. Alternative C would have fewer adverse effects and would improve visual resources the most of all alternatives.

Under Alternative D, there would be 21.9 miles of open road, 27.7 miles of closed road, and 3.1 miles of decommissioned road. Alternative D would improve visual resources compared to Alternative A, but would have more adverse effects than Alternatives B and C.

### Cumulative Effects on Visual Resources

Under all alternatives, most activities on BLM lands would generally not adversely affect visual resources to unacceptable degrees because discretionary activities on BLM lands would be required to meet Visual Resource Management objectives within individual project areas. The Scratchgravel Hills fuels reduction project currently being planned would be designed to meet VRM objectives.

Activities on non-BLM lands, particularly activities near BLM lands associated with residential development, urbanization, or vegetation management, could have adverse cumulative effects on visual resources on BLM lands because BLM VRM objectives would obviously not apply to non-BLM activities.

## LIVESTOCK GRAZING

### Effects Common to All Alternatives

Roads and trails can potentially affect livestock grazing management. Roads and trails often act as avenues of noxious weed spread. Noxious and invasive weeds can reduce the quantity and quality of forage available for

livestock. Users of roads and trails can cause management problems for livestock permittees when they leave gates open at fences, vandalize range improvements, or harass livestock either purposely or unintentionally.

Closure of roads and trails can improve or maintain the forage base by reducing vectors of noxious weed spread. Additionally, road and trail closures can reduce management conflicts. On the other hand, closures may increase permittees' time requirements if and when work has to be conducted with horses or afoot. Permittees could minimize effects of closed roads on grazing management by seeking variances from the BLM for temporary use of specific closed roads.

### Effects of the Alternatives

Under Alternative A, 52.2 miles of roads and trails would remain open. Effects associated with these roads would be as described above. All action alternatives would close or decommission more roads and trails than Alternative A. As more roads and trails are closed, noxious and invasive weed spread along with multiple user conflicts would be reduced. On the other hand, permittee management time may increase. Consequently, more effects as described under the Effects Common to All Alternatives section would occur under Alternative C (7 miles open, 45.3 miles closed or decommissioned) than under any other alternative. Alternative B (9.8 miles open, 42.5 miles closed or decommissioned) would produce fewer effects than Alternative than C, but more than Alternative A or Alternative D (21.9 miles open, 30.8 miles closed or decommissioned). Alternative D would have fewer effects than Alternatives B or C, but more than Alternative A.

### Cumulative Effects on Livestock Grazing

A number of past, present, and reasonably foreseeable future actions affect livestock grazing at the scale of the entire Helena TPA. Livestock grazing will continue in the area and has the potential to impact forage quality and quantity. On public lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain forage quality and quantity. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, forage conditions would benefit.

The fuels reduction project scheduled for the Scratchgravel Hills is not anticipated to have any adverse effects on livestock grazing.

Because BLM lands make up only 11 percent of all lands in the Helena TPA, all of the BLM travel plan alternatives would have a minimal contribution to cumula-

tive effects on livestock grazing at the scale of all lands in the Helena TPA.

## MINERALS

### Effects Common to All Alternatives

Road closures and decommissioning could affect access to locatable minerals in areas of moderate or high mineral potential. Operators would be required to seek travel variances from the BLM to use motor vehicles to conduct mineral exploration on closed roads, or to conduct exploration on seasonally restricted routes during the season of closure. Decommissioned roads could not be used for motorized exploration. Travel management

provisions that require a permit or variance could result in reducing access to mining claims or interfere with the ability to conduct exploration work for some operators. Historic knowledge of mineralized areas associated with “closed” roads may be lost after long periods of time if no exploration occurs there. Additional costs and time could be required for exploration and development of mining projects associated with closed or decommissioned roads. Impacts of road closures or decommissioning in areas with low mineral potential would not be substantial to mineral development.

### Effects of the Alternatives

Effects of the alternatives for the Helena TPA on access to mineralized areas are summarized in **Table 4-54**. Alternative A for the Helena TPA would not impact any mineralized areas as all roads would be left open.

Alternative B for the Helena TPA would close 56 percent and would decommission 12 percent of roads in high mineral potential areas. An additional 2 percent of the roads in moderate mineral potential areas would be closed under this alternative (**Table 4-54**). Alternative B would have more impacts than Alternative A.

Alternative C of the Helena TPA would close 72 percent and decommission 9 percent of the roads in areas with high mineral potential. Two percent of the roads in areas with moderate mineral potential would be closed under this alternative for this area (**Table 4-54**). Alternative C would have the most potential to affect access to mineralized areas of all the alternatives.

Alternative D of the Helena TPA would close 49 percent and decommission 6 percent of the roads in areas with high mineral potential. Two percent of the roads in areas with moderate mineral potential would be closed in this alternative in this TPA (**Table 4-54**). Alternative D would have more impacts than Alternative A, but less than Alternatives B and C.

### Cumulative Effects on Access to Mineralized Areas

No other past, present, or reasonably foreseeable future actions in the Helena TPA would adversely affect mineral availability or access.

## RECREATION

Effects of travel plan alternatives on Recreation in the Helena TPA are described qualitatively below.

### Effects of Alternative A

Under Alternative A, all existing routes in the Helena TPA would continue to be open yearlong (52.2 miles) to wheeled motorized users. Cross-country snowmobile travel would continue to be allowed as well as travel on all routes. Alternative A provides the greatest opportunities for motorized users, and the least for non-motorized users (mountain bikers, hikers, cross-country skiers,

<b>Mineral Potential</b>	<b>Open Miles (%)</b>	<b>Seasonally Restricted Miles (%)</b>	<b>Closed Miles (%)</b>	<b>Decom Miles (%)</b>
<b>Alternative A</b>				
High	48.4 (93%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Moderate	1.0 (2%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Low	2.8 (5%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Total Miles = 52.2				
<b>Alternative B</b>				
High	12.9 (25%)	0.0 (0%)	29.1 (56%)	6.5 (12%)
Moderate	0.0 (0%)	0.0 (0%)	1.0 (2%)	0.0 (0%)
Low to none	0.7 (1%)	0.0 (0%)	2.0 (4%)	0.0 (0%)
Total Miles = 52.2				
<b>Alternative C</b>				
High	6.2 (12%)	0.0 (0%)	37.6 (72%)	4.6 (9%)
Moderate	0.0 (0%)	0.0 (0%)	1.0 (2%)	0.0 (0%)
Low to none	0.7 (1%)	0.0 (0%)	2.0 (4%)	0.0 (0%)
Total Miles = 52.2				
<b>Alternative D</b>				
High	20.0 (38%)	0.0 (0%)	25.9 (49%)	3.1 (6%)
Moderate	0.0 (0%)	0.0 (0%)	1.0 (2%)	0.0 (0%)
Low to none	1.9 (4%)	0.0 (0%)	0.8 (1%)	0.0 (0%)
Total Miles = 52.7 (Includes Proposed New Construction)				

Mineral Potential areas have been delineated by the Montana Bureau of Mines and Geology (MBMG)

snowshoers, etc.) of all alternatives. Conflicts between motorized and non-motorized users would be expected to increase under this alternative.

### Effects of Alternative B

Under Alternative B, wheeled motorized travel (9.8 miles) would be restricted to four areas in the Scratchgravel Hills: routes leading to five non-motorized trailheads; a short out-and-back route off of Norris Road; and all existing public access rights-of-ways. Roads in these three areas would be open yearlong. Cross-country snowmobile use would be allowed, as well as snowmobile travel on all existing routes during the season of use (12/2-5/15), conditions permitting. Conflicts between non-motorized users (cross-country skiers, snowshoers) and snowmobilers would be expected to continue or increase as a result.

The effects of closing the Scratchgravel Hills interior area to motorized vehicle uses yearlong would reduce use violations, risks of human caused fires, conflicts with proximity residents and law enforcement incidents.

### Effects of Alternative C

Alternative C would restrict wheeled motorized travel to five non-motorized trailheads in the Scratchgravel Hills. This alternative would provide the least number of wheeled motorized routes in the Helena TPA (7.0 miles), but would provide an extensive network of routes for non-motorized enthusiasts. Under Alternative C, no snowmobile use would be allowed, including the trailhead access routes.

Although closing the entire Scratchgravel Hills area to both motorized and non-motorized recreational uses after dark (dusk to dawn) yearlong would best protect the area from violations. Management and law enforcement demands would increase compared to Alternatives A, B, and D. Impacts on legitimate public users would be negligible as their use of the area after dark is minimal.

### Effects of Alternative D

Under alternative D, 21.9 miles of open routes would be available yearlong for wheeled motorized use. Alternative D would provide the greatest opportunities for motorized users, and the least for non-motorized users. Cross-country snowmobile use would be allowed, as well as travel on all existing routes during the season of use (12/2-5/15), snow conditions permitting. Under Alternative D, conflicts between non-motorized users (cross-country skiers, snowshoers) and snowmobilers would be expected to continue or increase as a result.

### Cumulative Effects on Recreation

Cumulative effects of travel plan alternatives are discussed below in the context of effects of past, present, and reasonably foreseeable future activities in the Helena TPA.

Under Alternative A, current travel management of the Scratchgravel Hills coupled with increased projections in area use and residential developments nearby would increase the potential for greater conflicts between motorized and non-motorized users. Projected fuel treatments, mining activity and inholding developments could adversely impact the natural setting and user experiences. Special Recreation Use Permits (SRP) events (folging, foot racing, horseback riding and mountain biking) would continue although social conflicts could increase. The three trailhead sites would continue to be maintained and user demands would continue to increase. Motorized users would be least impacted under this alternative.

Under Alternative B, closing all major motorized travel routes would greatly enhance non-motorized opportunities during the spring/summer and fall seasons and reduce user violations. Motorized opportunities would be greatly reduced and riders would be displaced to other areas. Increased demands on the area due to additional residential developments, rights-of-way permits, fuel treatments, and possible mining activities would present fewer social conflicts and management concerns given these additional restrictions. Unregulated snowmobile uses in the area could perpetuate future conflicts with non-motorized users and nearby residents during limited periods of favorable snow conditions. SRP events (folging, foot racing, horseback riding and mountain biking) would be enhanced and visitor uses at the established trailheads would be expected to increase moderately.

Under Alternative C, motorized travel management restrictions coupled with all other past, present and reasonably foreseeable actions described under Alternatives A and B would best enhance opportunities for non-motorized uses. Conflicts between motorized and non-motorized users would be minimized to the greatest extent while cumulative impacts on motorized users would be the highest. Other impacts would be similar to Alternative B.

Under Alternative D, travel management of the Scratchgravel Hills coupled with increased projections in area use and nearby residential developments would increase the potential for continued conflicts between motorized and non-motorized users. Projected fuel treatments, mining activity and inholding developments could adversely impact the natural setting and user experiences. SRP events (folging, foot racing, horseback riding and mountain biking) would continue although social conflicts could increase. The trailhead sites would continue to be maintained and user demands would continue to increase. Motorized users would be impacted less than under Alternatives B and C, but more than under Alternative A.

## TRAVEL MANAGEMENT AND ACCESS

### Effects of Alternative A

All existing routes in the Helena TPA would continue to be open yearlong (52.2 miles), providing a greater number of miles to wheeled motorized users than the action alternatives (**Table-4-55**). Cross-country snowmobile travel would continue to be allowed as well as travel on all routes, resulting in conflicts between non-motorized users (cross-country skiers, snowshoers) and snowmobilers. Non-motorized users would have a lower quality recreation experience due to the lack of separate use areas.

Proposed Management	Total Miles			
	Alt A	Alt B	Alt C	Alt D
<b>Wheeled Motorized Routes</b>				
Open Yearlong	52.2	9.8	7.0	21.9
Seasonally Restricted	-	-	-	-
Closed	-	36.0	40.7	27.7
Decommissioned	-	6.5	4.6	3.1
Non-motorized trails <sup>1</sup>	-	42.5	45.3	30.8

<sup>1</sup>Non-motorized trails include all existing trails, closed roads, and decommissioned roads.

Under Alternative A, BLM would continue to allow recreational activities, including motorized vehicle use, would continue 24 hours a day within the Scratchgravel Hills. This would allow more illegal activities to occur than under the action alternatives.

The extent of management activities and costs under Alternative A would be mixed. Less personnel time would be required to monitor travel compliance; however, more effort would be required for initial implementation (signing designated routes, installing bulletin boards).

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be minimal under this alternative, given the availability of motorized access. Estimated costs for road/trail maintenance would be highest of all alternatives.

### Effects Common to Action Alternatives (B, C, and D)

All action alternatives call for a reduction of open routes in the Birdseye area.

User conflicts would be minimized in the Scratchgravel Hills by providing separate recreational opportunities for wheeled motorized and non-motorized users. This would provide for increased enjoyment for non-motorized recreationists and enhanced road and trail safety among all users of the area.

Illegal activities (underage alcohol use, drug use, vandalism, unauthorized travel, and dumping) in the Scratchgravel Hills would be reduced due to closure of at least 60 percent of the roads to motorized use.

Since the Scratchgravel Hills have historically been open to motorized use, a substantial effort would be required to educate the public on its change in use. BLM would need to enforce road closures through law enforcement actions until such a time when motorized users conform to the new restrictions. New signage would be required under all action alternatives; at designated trailheads, along roads and trails, and at other unauthorized access points originating from bordering private property.

### Effects of Alternative B

Motorized wheeled travel in the Scratchgravel Hills would be restricted to designated routes leading to five non-motorized trailheads, and all existing public access rights-of-way. These roads would be managed as Open Yearlong. Alternative B would allow motorized use on 9.8 miles, about 19 percent of the number of open road miles under Alternative A. Alternative B would have 42.5 miles of closed roads that could serve as non-motorized trails, compared to none under Alternative A.

Motorized (wheeled) and non-motorized users would have separate routes and conflicts would be substantially reduced compared to Alternative A.

Route closures across 81 percent of the area would reduce unauthorized travel (illegal off-road use by ATVs and motorcycles) and illegal activities (underage alcohol use, drug use, vandalism, dumping) in the Scratchgravel Hills and elsewhere. With the exception of a few routes needed for residential access, public access would be restricted to non-motorized trailheads.

Cross-country snowmobile use would be allowed, as well as snowmobile travel on all existing routes during the season of use (12/2-5/15), conditions permitting. Conflicts between non-motorized users (cross-country skiers, snowshoers) and snowmobilers would be expected to continue or increase as a result.

The reduction in motorized use in the Scratchgravel Hills would greatly enhance safety for non-motorized users as compared to Alternative A.

The extent of management activities and costs under Alternative B would be mixed. Less personnel time would be required for initial implementation (signing designated routes, installing bulletin boards). However, more effort on the part of the BLM would be required for public education and compliance. Estimated costs for road/trail maintenance would be less than under Alternative A.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would increase under Alternative B compared to Alternative A.

## Effects of Alternative C

Alternative C would restrict wheeled motorized travel to five non-motorized trailheads in the Scratchgravel Hills. This alternative would provide the least number of motorized routes in the Helena TPA (7.0 miles), which is about 85 percent fewer miles than Alternative A, and about 30 percent fewer miles than Alternative B.

This alternative would diminish the opportunity for motorized use of the Scratchgravel Hills, but would provide an extensive network of routes for enjoyment by non-motorized enthusiasts. Alternative C would have 6 percent more miles of closed roads that could serve as non-motorized trails than Alternative B, and would have more closed roads than any other alternative. Under Alternative C, no snowmobile use would be allowed, including on the trailhead access routes. This action would eliminate conflicts between snowmobilers and non-motorized winter users (cross-country skiing, snowshoeing).

Under Alternative C, unauthorized travel (illegal off-road use by ATVs and motorcycles) and illegal activities (underage drinking, vandalism, dumping) would be curtailed due to the restriction of motorized vehicles from the interior of the Scratchgravel Hills and closing the area after dark.

By eliminating motorized use within the interior of the Scratchgravel Hills there would be less potential for accident or injury resulting from conflict between user groups.

The five trailhead parking lots may need to be expanded to accommodate the number of vehicles bringing non-motorized users to the area. Since the Scratchgravel Hills have historically been open to motorized use, a substantial effort would be required to educate the public on its change in use. It is expected that the level of education and signage would be comparable to Alternative B, but less than required under Alternative A.

The extent of management activities and costs under Alternative C would be mixed. Less personnel time would be required for initial implementation (signing designated routes, installing bulletin boards). However, more effort on the part of the BLM would be required for public education and compliance. Estimated costs for road/trail maintenance would be the lowest of all the alternatives.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be the greatest under Alternative C than under any other alternative.

## Effects of Alternative D

Alternative D would have 21.9 miles of open routes available for yearlong wheeled motorized travel (Table-4-55). This would be 58 percent less than under Alternative A, but 55 and 68 percent more than under

Alternatives B and C, respectively. Road system projects would include reconstructing some segments and constructing new connector routes between other segments. Through the development of interconnecting routes, motorized opportunities under Alternative D would be enhanced compared to Alternatives B and C. Non-motorized users would be accommodated through a network of routes that would be restricted from use by vehicles, ATVs and motorcycles, similar to Alternative B.

Under Alternative D, cross-country snowmobile use would be allowed, as well as travel on all existing routes during the season of use (12/2-5/15), snow conditions permitting. Conflicts between non-motorized users (cross-country skiers, snowshoers) and snowmobilers would be expected to continue or increase as a result.

Under Alternative D, illegal activities in the Scratchgravel Hills (underage alcohol use, unattended campfires, vandalism, dumping) are expected to be less than under Alternative A, but more than Alternatives B and C.

The extent of management activities and costs under Alternative D would be mixed. Less personnel time would be required to monitor travel compliance than under Alternatives B and C. However, more effort would be required for initial implementation (signing designated routes, installing bulletin boards). Estimated costs for road/trail maintenance would be higher than under the other action alternatives, but would be greater than under Alternative A.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be greater under Alternative D than under Alternative A, but less than under Alternatives B and C.

## Cumulative Effects on Travel Management and Access

Under all alternatives, there are a number of past, present, and reasonably foreseeable BLM and non-BLM actions and activities affecting Travel management and access in the Helena TPA.

Like much of the west, the Helena Valley has been experiencing steady human population growth. This trend is expected to continue, along with increased recreational use of this travel planning area. These factors could lead to increased public pressure to alter travel planning to accommodate more, or less motorized use.

The majority of BLM managed routes for the Helena Travel Planning area are located in or adjacent to the Scratchgravel Hills and Birdseye areas. Scratchgravel Hills is basically an island of undeveloped hills surrounded by residential development (there is some internal development as well). Residential development has tripled from 300 residential homes in 1984 to over 1,000 homes today. This combination of rapid urbanization and increased recreational use has led to increased social

conflict; between area residents and recreation users, and among recreational users themselves (motorized/non-motorized). As a result, there have been public demands to alter the existing travel management to reduce motorized use.

Recreation use is well established in the TPA. Primary recreation activities include motorized OHV uses (ATV, motorcycle) and non-motorized uses (hiking, jogging, horseback riding, mountain biking, etc.). As recreation use grows, conflicts between non-motorized and motorized recreation users could lead to increased public demands for either more, or less motorized use.

Portions of the TPA provide winter range for mule deer and elk. The Birdseye section is within a wildlife movement corridor that provides a connection between the Northern Continental Divide Ecosystem and the Greater Yellowstone Ecosystem, as well as local daily and seasonal movement between higher elevation summer ranges. Concerns could lead to the need to restrict motorized use.

In some site specific cases, visual resource management may affect or restrict new road/trail construction.

Urban development may lead to an increase in right-of-way permits to accommodate private property/development access. As a result, public access to BLM lands, via these rights-of-way, could increase as well.

Limits or reductions in the BLM's funding and ability to maintain designated routes could lead to an overall reduction in open road miles.

A variety of resource management projects, such as BLM initiated vegetation treatments, or wildland fire fuels reduction projects, could affect travel management. Forest management activities from 1984 to present include 10 acres of forest planting and 133 acres of timber harvest. Wildland fire management activities from 1981 to 2004 include a fuels treatment (150 acres of fuels grinding) in the Scratchgravel Hills. Future projects include a 1,500-2,500 acre mechanical and/or prescribed fire treatment for the Scratchgravel Hills, anticipated to occur over a 5 year period. Depending on the type and scope of project, effects could vary from temporary, short-term area/route closures, to new opportunities (new routes) for motorized or non-motorized access.

The Scratchgravel Hills area contains precious and base metals in both hard rock and placer deposits. While presently, only a few mining claims are maintained on BLM lands, increases in mineral prices could lead to increased or renewed mining activity. Depending on the type and scope of mining activity, effects could vary from temporary, short-term area/route closures, to increased opportunities (new routes) for motorized or non-motorized access.

Noxious weeds and non-native invasive species are well established and spreading in the area. Motorized activi-

ties play a large role in the distribution of noxious weeds. Concerns over the spread of noxious weeds could influence travel management, and lead to fewer motorized opportunities.

Motorized use on dirt roads and trails is a major contributor to soil erosion and stream sedimentation. These concerns may influence travel management, and result in fewer motorized opportunities. This is an important consideration in the Helena area as the Montana Department of Environmental Quality is working on water quality restoration plans in the area.

Trash dumping, drug use, underage alcohol use, unattended camp fires, and vandalism occur throughout the travel planning area, but especially in the rural/urban interface areas. Most of these activities are directly associated with motorized use. Continuing concerns with illegal activities may influence travel management and lead to fewer motorized opportunities.

The National Guard manages approximately 8,000 acres of land (Fort Harrison) in the Helena City area. National Guard activities (helicopter landings, ground maneuvers, off-road travel, etc.) may influence travel management on adjacent BLM lands as well, exerting pressure for either more or less motorized access.

For perspective, BLM managed lands represent approximately 11percent of the total travel planning area (95,492 total acres, 10,162 BLM acres); while BLM managed routes under Alternative A represent approximately 7.5 percent of the total routes available (693 total miles, 52.2 miles BLM roads/trails). Future travel management (for all agencies, nationwide) is likely to lead to fewer opportunities for motorized recreational use than under current management (particularly for OHV use). As a result, BLM routes available to motorized use in this TPA (especially the Scratchgravel Hills area) could experience increased use from displaced users, leading to more concentrated use, increased resource impacts, user conflicts, and pressure to reduce motorized use.

Under all alternatives, increases in human population, urbanization, recreation use, user conflicts; and concerns for wildlife, noxious weed spread, soil erosion/water quality, and illegal activities are likely to lead to increased demands to restrict motorized travel, particularly in areas with urban development, such as the Scratchgravel Hills. Under Alternative A, as urbanization continues around the Scratchgravel Hills, and both motorized (wheeled and snowmobile) and non-motorized use increases, these conflicts would increase. Under Alternative B, these pressures would have less impact on travel management than under Alternatives A and D, due to the overall reduction in motorized opportunities and separation of uses under Alternative B. Alternative C would be more beneficial to reducing these conflicts in light of these pressures than all the other alternatives. Alternative D would lessen conflicts associated with these pres-

tures, but not as much as Alternatives B and C. Both motorized and non-motorized users would have dispersed recreational opportunities under Alternative D.

## TRANSPORTATION FACILITIES

For the sake of this discussion, “open” roads include roads that are open yearlong as well as those that are open with seasonal restrictions.

### Effects of Alternative A

The Helena TPA would have 52.2 miles of open roads and no motorized trails (**Table 4-56**). Estimated costs for annual maintenance and stabilization of roads under Alternative A would be highest of all alternatives; almost three times more than under Alternatives B and D, and six times higher than under Alternative C. Estimated annual costs for both monitoring, compliance and weed control would be much higher under Alternative A than under the action alternatives.

### Effects of Alternative B

Under Alternative B, the Helena TPA would have 9.8 miles of open roads and no motorized trails (**Table 4-56**). Estimated costs for annual maintenance and stabilization of roads under Alternative B would be less than under Alternatives A and D, and more than under Alternative C.

Estimated annual costs for monitoring, compliance and weed control would also be less than under Alternatives A and D, but more than under Alternative C.

Restricting motorized access to the Scratchgravel Hills area to five existing non-motorized trailheads would result in an increase in transportation facility costs for trailhead maintenance and signage. Closing the Scratchgravel Hills to motorized vehicle use after dark would result in a short-term increase in facility costs for installing signs and gates at appropriate access points and a long-term increase in cost for sign maintenance. Effects of this alternative associated with the Scratchgravel Hills nighttime closure would be similar to Alternative C.

### Effects of Alternative C

Under Alternative C, the Helena TPA would have 7 miles of open roads and no motorized trails (**Table 4-56**). Estimated costs for annual maintenance and stabilization of roads under Alternative C would be the least of all the alternatives due to the least number of motorized routes. Estimated annual costs for monitoring, compliance, and weed control would also be less than the other alternatives.

Closing the Scratchgravel Hills to motorized and non-motorized vehicle use after dark would result in a short-term increase in transportation facility costs for installing signs and gates at appropriate access points and a long-term increase in cost for personnel and sign maintenance. Effects of this alternative associated with the

<b>Classification/ Cost</b>	<b>Alt A</b>	<b>Alt B</b>	<b>Alt C</b>	<b>Alt D</b>
Miles of Open/ Restricted Roads	52.2	9.8	7	21.9
Motorized Trails	0	0	0	0
Annual Road Maintenance	\$4,176	\$784	\$560	\$1,752
Annual Trail Maintenance	\$0	\$0	\$0	\$0
Periodic Road Stabilization	\$1,670	\$313	\$224	\$701
Periodic Trail Stabilization	\$0	\$0	\$0	\$0
Monitoring/ Compliance	\$2,610	\$490	\$350	\$1,095
Weed Control	\$783	\$147	\$105	\$329

Scratchgravel Hills nighttime closure would be the same as under Alternative B.

### Effects of Alternative D

Under Alternative D, the Helena TPA would have 21.9 miles of open roads and no motorized trails (**Table 4-56**). Estimated costs for annual maintenance and periodic stabilization of roads under Alternative D would be greater than under Alternatives B and C, but less than under Alternative A. Estimated annual costs for monitoring, compliance and weed control would be less under Alternative D than under Alternative A and more than under Alternatives B and C.

Constructing new connector routes and reconstructing several existing routes would result in a short-term increase in transportation facility costs for signage, and potentially for additional culverts, and a long-term increase for route maintenance.

## LANDS AND REALTY

### Effects Common to All Alternatives

The Butte Field Office administers approximately 57 rights-of-way (ROW) and 1 non-commercial occupancy lease within the boundaries of the Helena TPA, which encumber approximately 481 acres of BLM land (**Table 4-57**).

Various types of road rights-of-way (ROW) are the most common type of grant, accounting for 44 percent, or just under half of the total. Other types of authorized uses include: oil and gas pipelines, lines for electrical distribution and telephone facilities, ditches, railroads, and mineral material sites.

Approximately three right-of-way applications for new facilities as well as amendments, assignments, renewals, or relinquishments of existing right-of-way grants are

processed annually in the TPA. This would not vary by alternative.

Type	Approximate Number	Approximate Acres
Roads	26	359
Power	8	9
Telephone	12	11
O&G Pipelines	6	96
Comm. Sites	0	0
2920 Leases	1	1
Other	5	5
<b>Totals</b>	<b>58</b>	<b>481</b>

The general trend of granting rights-of-way is expected to increase through the planning period as a result of increasing public demands. From a cumulative effects standpoint, development of adjacent federal, state, and private land, increased recreational use and the trend of homeownership away from urban areas, coupled with traditional on-going uses, are all expected to require more guaranteed access involving public land, including BLM lands in this TPA.

## SPECIAL DESIGNATIONS

There would be no effects to any special designation areas such as Wild and Scenic Rivers, Wilderness Study Areas, or Areas of Critical Environmental Concern under any of the travel plan alternatives for the Helena TPA. No areas with special designations are located within the Helena TPA.

## EAST HELENA TPA

The 200,991-acre East Helena TPA contains 20,039 acres of BLM lands. There are approximately 71 miles of BLM road, making up about 8 percent of the approximate total of 892 road miles in the TPA. The majority of roads (690 miles) lie on private lands.

## AIR QUALITY

### Effects Common to All Alternatives

Motorized recreation use is expected to continue to increase, resulting in higher levels of vehicle emissions.

Motorized travel across dry unpaved routes or trails would continue to produce airborne dust.

There could be areas with localized air pollution as a result of higher use numbers, and more concentrated use on fewer miles of available routes.

Drier climate conditions could make soils more susceptible to the effects of motorized travel, resulting in higher levels of airborne dust.

Impacts to air quality vary by alternative and travel plan area. In general, alternatives that reduce the level of motorized use (have fewer available miles) could have a positive impact on air quality; while alternatives that maintain or increase the level of motorized use, could lead to increased air quality impacts. This would not necessarily be a direct relationship, however, because reduction in available road miles for motorized use could redistribute use or focus more use on remaining open routes.

Under all alternatives, impacts from airborne dust could be reduced through mitigation such as hardening native surface roads with gravel or periodically spraying them with water trucks during the dry season. During BLM project work, in addition to watering native surface roadbeds, speed limits could be reduced to further minimize dust emissions.

### Effects of the Alternatives

Under Alternative A (present management), adverse impacts to air quality would be expected to continue, and likely increase, concurrent with higher levels of motorized recreational use. Each of the action alternatives, however, would provide fewer available motorized routes. Alternatives B and C would provide 61 percent and 73 percent fewer motorized routes, respectively, than Alternative A, while Alternative D would provide 14 percent fewer routes than Alternative A. As a result, impacts to air quality associated with airborne dust and vehicle emissions would be taking place on substantially fewer routes under Alternatives B and C, but only slightly fewer routes under Alternative D.

It should be noted that even without motorized use, airborne dust, resulting from wind erosion of exposed native surface roads will continue. Therefore, travel plans with more miles of native surface roads will result in more airborne dust.

Under all alternatives, mitigation measures, such as graveling and/or watering native surface roads, could reduce dust emissions even further, and/or help offset the effects of increased or concentrated use on the remaining open routes.

### Cumulative Effects on Air Quality

Under all alternatives, the cumulative effects to air quality from travel management in the East Helena TPA would arise from a number of past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands.

For perspective, BLM managed lands in the East Helena Travel Plan area represent approximately 10 percent of the total travel planning area (200,991 total acres; 20,039 BLM acres). Under present management (Alternative A), BLM managed routes represent a small portion, approximately 8 percent, of the total routes available (892.2 total miles; 70.7 miles BLM roads/trails).

Potential air quality impacts associated with activities on non-BLM lands and roads would be a greater contributor to cumulative effects to air quality than activities on BLM lands and roads.

In the past, prior to the 2003 Statewide OHV ROD, BLM management allowed unrestricted cross country travel by all forms of wheeled motorized use. Under present management, in the absence of other existing travel plan direction, all motorized wheeled travel is restricted to existing roads and trails. Under current management, approximately 44.3 of the 70.7 miles of existing BLM routes are available for motorized use. This mileage available for use would be reduced under the action alternatives as described above with associated potential differences in effects to air quality.

Under all alternatives, cumulative increases in human population, urbanization, recreation use, user conflicts; and concerns for wildlife, noxious weed spread, soil erosion, air/water quality, and illegal activities may lead to increased demands to restrict motorized travel.

## SOILS

### Effects Common to All Alternatives

Road construction, use, and maintenance affect soils in a number of ways. Soils are often compacted by these activities. Soil compaction can lessen the amount of precipitation that can infiltrate into soil and increase runoff, erosion, and sedimentation – in turn decreasing soil/site stability and hydrologic function, as well as soil productivity and plant vigor and diversity.

Closing or decommissioning roads often leads to beneficial effects to soils through decreased site disturbance and re-establishment of vegetative cover on road surface.

es. This tends to reduce soil erosion and stabilize soils. Decommissioning roads may in some cases entail ripping road surfaces to de-compact them, thus improving water infiltration, hydrologic function, and the ability of the treated area to revegetate more successfully.

Impacts to soils associated with site-specific travel plan alternatives were assessed based on the potential for soil erosion using the following erosion risk criteria:

- High – the area a route travels through has slopes greater than 30 percent gradient.
- Moderate – the area a route travels through has slopes ranging from 15 to 30 percent gradient; or, for granitic soils, slopes ranging from 0 to 30 percent gradient.
- Low – the area a route travels through has slopes ranging from zero to 15 percent gradient and soils are not granitic in origin.
- Unrated – road mapping not available at time of erosion impact rating.

### Effects of the Alternatives

The distribution of road miles by erosion risk category and by proposed road management category by alternative is shown for the East Helena TPA in **Table 4-58**. Roads in the “unrated” category were excluded from detailed consideration and are shown for the purpose of displaying the extent of lacking information.

Under current conditions (Alternative A) approximately 6.9 miles of open BLM roads are located in areas with high erosion risk, and 23.3 miles are in moderate erosion areas. Soil erosion would be reduced under Alternative B because this alternative would reduce those open road

**Table 4-58**  
**BLM Road Miles in Soil Erosion Impact Categories by Alternative for the East Helena TPA**  
(mileages are GIS-generated estimates)

Proposed Road Management	Erosion Risk Category	Alternative A	Alternative B	Alternative C	Alternative D
Open Road Miles (including Open w/restrictions)	High	6.9	6.8	0.8	7.1
	Moderate	23.3	6.4	3.8	18.0
	Low	9.1	7.6	5.2	9.0
	Unrated	2.8	1.2	0.1	1.8
Closed Road Miles	High	6.8	5.8	12.0	5.7
	Moderate	15.5	29.1	31.9	18.8
	Low	3.9	5.3	7.8	3.9
	Unrated	0.2	1.7	2.9	1.2
Decommissioned Road Miles	High	0	1.2	1.0	1.0
	Moderate	0	3.3	3.0	1.9
	Low	0	0	0	0.1
	Unrated	0	0.1	0	0

Note: Open roads include seasonally open roads as well as roads open yearlong.

mileages in high and moderate erosion categories to 6.8 miles and 6.4 miles, respectively. Approximately 34.9 miles of road in the high and moderate classes combined would be closed under Alternative B with an additional 4.5 miles in these categories being decommissioned. This should allow vegetative recovery on these areas and further reduce soil erosion.

Under Alternative C, soil erosion from roads would be reduced more than under any other alternative because the lowest mileage of roads in the high and moderate erosion categories would be left open (4.6 miles combined), while the greatest mileage in these categories combined would be closed (43.9 miles) and decommissioned (4 miles) of all alternatives.

Soil erosion associated with roads would be reduced under Alternative D compared to Alternative A, but would still be higher than under either Alternative B or C. Approximately 25.1 miles of BLM road in the moderate and high erosion categories combined would remain open under Alternative D, while about 24.5 miles in these categories would be closed and 2.9 miles would be decommissioned under this alternative.

### **Cumulative Effects on Soils**

Cumulative effects to soils in the East Helena TPA would arise from many past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands. Within this 200,991-acre TPA, BLM lands comprise about 20,039 acres or 10 percent of total lands. The approximately 71 miles of BLM roads make up about 8 percent of the approximately 892 road miles in the TPA. Therefore road-related effects to soils described by alternative for BLM roads would affect about 8 percent of all roads in the TPA. The majority of lands and roads within the TPA boundary are private property. Non-BLM roads are managed by the local counties, Forest Service, state, Bureau of Reclamation, and private landowners.

Approximately 1,609 BLM acres are permitted for various rights-of-way and leases. About 746 of these acres are for specific road rights-of-way. The remaining 863 acres are associated with powerlines, waterlines, railroads, communication sites, and other utility facilities. Impacts to soils range from compaction and occupation of ground with buildings, roadbeds, railroad tracks, and other facilities, to revegetation and ground cover being re-established to stabilize soils.

Since 1981 wildland fires have burned across approximately 15,577 acres in the East Helena TPA. The majority of these acres (15,535) burned in 2000 across a mixture of land ownerships. The fire burned with variable severity creating a mosaic of effects to soils. More severely burned areas underwent more severe erosion than areas burned less severely. Fire rehabilitation activities such as reseeding with grasses/herbaceous species, contour felling of trees/snags in severely burned areas to trap sediment, waterbarring of firelines, and

post-fire noxious weed treatments helped minimize soil loss due to post-fire erosion. Tree planting on approximately 250 BLM acres (in 2002) of this burned area have contributed to longer term soil stabilization.

From 1995 to the present, timber salvage has occurred on approximately 250 acres of BLM land in this TPA. Adverse effects on soils were minor with treated areas having undergone revegetation and soil stabilization since treatment. Timber harvest has also occurred on private and Forest Service lands and will likely continue into the foreseeable future. These activities will have localized impacts (compaction, erosion) on soils.

While there have been no hazardous fuels treatment projects here in the last 10 years, BLM anticipates treating approximately 500 to 1,500 acres within this TPA to reduce hazardous fuels in Wildland Urban Interface areas within the next several years. Treatments would consist of mechanical and/or prescribed fire treatments. Effects to soils would likely be variable but for the most part would be minor. Prescribed burns would occur under prescriptions to minimize fire severity and impacts to soils. Mechanical treatments would be designed to minimize ground disturbance that could facilitate compaction or erosion. Fuels treatments conducted on private and Forest Service lands will also likely occur for the foreseeable future with variable effects to soils. Reducing fuels under the controlled conditions of deliberate treatments may benefit soils in the long-term by reducing the risk of high severity fires in treated areas.

Livestock grazing on public and private lands throughout much of the TPA has created areas of localized soil erosion and compaction, especially in grassland and shrubland areas. This will continue to occur for the foreseeable future.

Increasing residential development will likely continue for the foreseeable future. Erosion, compaction, and covering of soils would occur due to additional road construction, clearing/leveling for home sites, and establishment of utility infrastructure for residential developments.

Under Alternative A, the contribution to cumulative effects on soils from BLM road management would continue as it occurs today. Retaining approximately 36 miles of road open yearlong and an additional approximately 7 miles open with a seasonal restriction of 10/15 to 12/1 would allow for the same level of compaction and erosion impacts that currently exist.

From a BLM road management perspective, all action alternatives would benefit soil resources compared to Alternative A. Alternative B would benefit soils by providing for a reduced contribution to adverse cumulative effects than would Alternative A because about 68 percent of BLM roads would be closed or decommissioned under Alternative B (compared to 39 percent under Alternative A). Of the approximately 22 miles of open road, nearly one half of them (about 10 miles) would be

seasonally restricted to exclude motorized vehicle use in the wet spring runoff period each year. This would reduce erosion from these BLM roads.

Alternative C would benefit soils the most and provide for the least contribution to adverse cumulative effects of all alternatives. This alternative would provide for closure or decommissioning of about 86 percent of BLM roads in the TPA, thus allowing these areas to vegetatively recover and stabilize soils.

Alternative D would provide for the greatest contribution to adverse cumulative effects on soils of the action alternatives, but would still provide for greater long-term benefits to soils than Alternative A. Alternative D would provide for closure or decommissioning (and therefore vegetative recovery and soil stabilization) of about 48 percent of BLM roads in the TPA, compared to 39 percent for Alternative A, 68 percent for Alternative B, and 86 percent for Alternative C.

Due to the scattered distribution and relatively small proportion of BLM lands (10 percent) and roads (8 percent) relative to the total quantities of lands and roads in the TPA, none of the BLM alternatives would substantially contribute to cumulative effects on soils at the scale of the entire East Helena TPA.

## WATER RESOURCES

### Effects Common to All Alternatives

There are a number of key concepts that are critical to understanding road effects to water resources.

Hydrologic function is an interaction between soil, water, and vegetation. It reflects the capacity of a site to:

- Capture, store, and safely release water from rainfall, runoff, and snowmelt;
- Resist a reduction in this capacity; and
- Recover this capacity following degradation.

Interception of precipitation results when precipitation falls on vegetation. When vegetation is removed, precipitation falls directly on the soil. This can increase surface erosion and sedimentation, and decrease the amount of time between initial precipitation arrival and peak surface runoff – in turn decreasing soil/site stability and hydrologic function. Roads remove vegetation and therefore decrease interception of precipitation.

Infiltration is the process of precipitation entering and traveling through soil. Infiltration reduces the peak runoff during precipitation events by extending the period of runoff after a precipitation event. Infiltration also filters precipitation and reduces erosion and sedimentation. If infiltration is reduced, runoff and erosion will increase and hydrologic function will decrease. Generally, roads are compacted surfaces that have decreased infiltration, thus increasing runoff and potentially increasing erosion.

Runoff can affect the amount of erosion and sedimentation, as well as flooding – both onsite and offsite. If runoff is increased, all of these effects can increase with a result that water quality and hydrologic function will decrease.

Increased sediment entering waterbodies increases turbidity, increases width-to-depth ratios, and consequently increases temperature and dissolved oxygen saturation levels, and creates adverse habitat for aquatic animals and plants.

Alteration of flow routing can also affect water resources. For example, roadcuts into areas with relatively shallow groundwater can intercept groundwater, bring it to the surface, and transport it some distance (i.e. in a roadside ditch) before delivering it to a stream. This can lead to erosion of road ditchlines and subsequent sedimentation of streams during runoff periods, or increased thermal loading of water before delivery to streams during summer periods.

Closure and decommissioning of roads tend to reduce erosion and sedimentation effects stemming from roads on water quality. On an equivalent road mile basis, decommissioning roads would benefit water quality to a greater degree than closing roads because the decommissioning process would often entail implementing measures to restore hydrologic function. During road decommissioning, items such as compaction, drainage, stream crossing culverts, and ground cover are often addressed in a manner that markedly improves hydrologic function. These features are not fully addressed on roads that are merely “closed”. However, the reduced disturbance on newly closed roads combined with the tendency for revegetation to re-establish ground cover on them, reduces erosion and subsequent sedimentation effects to water quality.

### Effects of the Alternatives

Generally, road density is an indicator of overall watershed health and function. Watersheds with higher road densities tend to have lower water quality due to greater disruption of hydrologic function (described above), and potential for erosion and subsequent sedimentation. Road density also is related to the distribution and spread of noxious weeds.

**Table 4-59** shows acres of BLM land in three road density categories by alternative for the East Helena TPA. These data reflect differences between alternatives based on roads proposed for “decommissioning” by alternative. While many “closed” roads would gradually contribute to increased hydrologic function over time, decommissioned roads would more directly contribute to hydrologic function because measures aimed at restoring hydrologic function would likely be part of the treatment during decommissioning. Alternative A would have the greatest amount of BLM land with “high” road densities of greater than 2 mi/mi<sup>2</sup>. Alternative B would have the lowest acreage in the high category with the greatest

**Table 4-59**  
**Acres of BLM land in road density categories by alternative for the East Helena TPA**

TPA Alternative	Road Density Category		
	Low (<1 mi/mi <sup>2</sup> )	Moderate (1 to 2 mi/mi <sup>2</sup> )	High (> 2 mi/mi <sup>2</sup> )
Alt. A	5,969	4,665	9,317
Alt. B	6,557	4,457	8,936
Alt. C	6,500	4,384	9,066
Alt. D	6,502	4,353	9,096

acreage in the low category of all alternatives. Alternatives C and D would be similar but Alternative C would have the next lowest acreage in the high road density category while Alternative D would have more acres in the high category than either Alternative B or C, but less than Alternative A. Overall, all the action alternatives would improve hydrologic function but by this measure Alternative B would make the greatest contribution to improved hydrologic function of all the alternatives.

Motorized routes within 300 feet of streams generally have greater potential to directly impact water quality through erosion and sedimentation, increased water temperatures (due to loss of shading vegetation), and direct alteration of stream channel morphology than those farther away. **Table 4-60** shows the miles of open and closed roads on BLM lands within 300 feet of streams by alternative. Under Alternative A there are about 7 miles of open road within 300 feet of streams. All action alternatives would improve water quality by closing or decommissioning roads in close proximity to perennial streams. Alternative C would create the most benefit followed closely by Alternative B, then Alternative D.

Although the benefits to water resources are fairly similar between alternatives, overall Alternative C would contribute the most benefits to water resources of all alternatives, followed by Alternative B, Alternative D, then Alternative A which would retain the same effects as currently exist.

## Cumulative Effects on Water Resources

Cumulative effects to water resources in the East Helena TPA would arise from many past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands. Within this 200,991-acre TPA, BLM lands comprise about 20,039 acres or 10 percent of total lands. The approximately 71 miles of BLM roads make up about 8 percent of the approximately 892 road miles in the TPA. Therefore road-related effects to water resources described by alternative for BLM roads would affect about 8 percent of all roads in the TPA.

There are approximately 171 miles of perennial non-fish bearing streams and 100 miles of fish bearing streams in the TPA. Of these, there are about 7.6 miles of perennial non-fish bearing streams and 1 mile of fish bearing stream on BLM lands. The majority of lands and roads within the TPA boundary are private property. Non-BLM roads are managed by the local counties, Forest Service, state, Bureau of Reclamation, and private landowners.

Approximately 1,609 BLM acres are permitted for various rights-of-way and leases. About 746 of these acres are for specific road rights-of-way. The remaining 863 acres are associated with powerlines, waterlines, railroads, communication sites, and other utility facilities. Impacts to water resources are generally minor with some localized erosion and sedimentation and some contribution to decreased hydrologic function (decreased infiltration, increased runoff) due to compaction.

Since 1981 wildland fires have burned across approximately 15,577 acres in the East Helena TPA. The majority of these acres (15,535) burned in 2000 across a mixture of land ownerships. The fire burned with variable intensity and severity creating a range of effects to water resources. In burned areas, nutrient inputs to streams increased (perhaps for several years). Streams in more severely burned areas (some near Canyon Ferry Reservoir) underwent more severe erosion and sedimentation than those in areas burned less severely. Water temperatures in some streams may have increased due to loss of stream-side shade from the fires. Wood recruit-

**Table 4-60**  
**Miles of Open and Closed Roads on BLM Lands within 300 ft. of Fish-Bearing Streams and Perennial, Non-Fish-Bearing Streams by Alternative for the East Helena TPA**

	Perennial Fish-Bearing Streams		Perennial Non-Fish-Bearing Streams	
	# Open Road Miles	# Closed Road Miles	# Open Road Miles	# Closed Road Miles
Alt. A	0	0.4	2.0	0.7
Alt. B	0	0.4	0.9	1.8
Alt. C	0	0.4	0.7	2.0
Alt. D	0	0.4	1.0	1.7

Note: Open roads include seasonally open roads as well as roads open yearlong. Closed roads include decommissioned roads.

ment to streams in forested areas of high burn intensity may be increasing due to riparian tree mortality from fires. Stream flows may increase in some streams for several years. Peak flows may increase due to reduced snow interception by vegetation resulting in greater snow accumulations available for snowmelt in warmer periods. Summer flows may increase due to a lack of live vegetation to conduct evapotranspiration of water so more groundwater may reach stream channels. Fire rehabilitation activities such as reseeding burnt ground with grasses/herbaceous species, contour felling of snags in severely burned areas to trap sediment, waterbarring of firelines, and post-fire noxious weed treatments helped stabilize soils and minimize sedimentation effects to streams due to post-fire erosion. Tree planting on approximately 250 BLM acres (in 2002) of this burned area have contributed to longer term soil stabilization and subsequent reduction of stream sedimentation.

From 1995 to the present, timber salvage has occurred on approximately 250 acres of BLM land in this TPA. Adverse effects on water resources were minor to negligible from this activity. Timber harvest has also occurred on private and Forest Service lands and will likely continue into the foreseeable future. Ground disturbance from these activities will have localized impacts to water resources including some sedimentation, loss of woody material recruitment for streams, and potential water temperature increases due to shade loss.

While there have been no hazardous fuels treatment projects here in the last 10 years, BLM anticipates treating approximately 500 to 1,500 acres within this TPA to reduce hazardous fuels in Wildland Urban Interface areas within the next several years. Treatments would consist of mechanical and/or prescribed fire treatments. Prescribed burns would occur under prescriptions to minimize fire severity and impacts to soils and desirable vegetation, thereby minimizing effects to hydrologic function. Mechanical treatments would be designed to minimize ground disturbance that could facilitate compaction or erosion. These project design measures would minimize potential erosion/sedimentation effects to water resources. Fuels treatments conducted on private and Forest Service lands will also likely occur for the foreseeable future with variable effects to water resources. Reducing fuels under the controlled conditions of deliberate treatments may benefit water resources in the long-term by reducing the risk of future high severity fires that could have severe adverse effects on water resources in treated areas.

Livestock grazing on BLM land, other public and private lands throughout much of the East Helena TPA has created areas of localized streambank trampling, soil erosion and compaction, and nutrient inputs to streams. In severe cases stream channel morphology may be altered due to severe loss of riparian vegetation, loss of streambank integrity, channel widening and shallowing, and substantial sediment inputs. These effects to water

quality will continue to occur for the foreseeable future. Agricultural water withdrawals occur on private lands in this TPA. These withdrawals reduce stream flows in the TPA, including within Prickly Pear Creek, one of two streams that flows through BLM lands and is listed as an impaired water body by MDEQ.

Increasing residential development will likely continue for the foreseeable future to variable degrees within the TPA. Impairments to hydrologic function such as erosion, soil compaction, and runoff would likely increase due to additional road construction, clearing/leveling for home sites, and establishment of utility infrastructure for residential developments. Nutrient, chemical pollutant, and pathogen inputs to streams would also likely increase due to leaching from septic systems, urban runoff (fertilizer, chemicals, and petroleum pollutants), and waste from livestock.

Damming of the Missouri River to create Holter Lake, Hauser Lake, and Canyon Ferry Reservoir dramatically altered water resources. Approximately 40 miles of the Missouri River were converted into lake habitat, dramatically altering water quality and quantity.

Canyon Ferry Reservoir and the Missouri River from Canyon Ferry Dam to Hauser Lake are both identified as impaired water bodies on the MDEQ 303(d) list. Canyon Ferry Reservoir has impairments related to excess nitrogen and ammonia as well as excess algal growth, likely related to municipal point source discharges, septic systems, agriculture, and abandoned mine lands. Canyon Ferry also has excessive arsenic and thallium attributed to contamination from abandoned mine lands. Missouri River from Canyon Ferry Dam to Hauser Lake has impairments primarily related to excessive nutrients and dissolved oxygen deficiency. These impairments are attributed to dam construction, grazing in riparian or shoreline zones, municipal point source discharges, and septic systems. These impairments will continue into the foreseeable future although ongoing efforts are gradually addressing some of them.

Hauser Lake (3,800 acres) is listed as impaired on the 303(d) list due to pesticide contamination, mercury, and dissolved oxygen impairments attributed to agriculture, silvicultural activities, natural sources (mercury), impacts from hydrostructure flow regulation, and highway/road/bridge runoff. Holter Lake (5,500 acres) is listed as impaired on the 303(d) list due to mercury contamination attributed to placer mining, inappropriate waste disposal, abandoned mine lands, historic bottom deposits, and atmospheric deposition. Lake Helena (1,600 acres) is listed as impaired on the 303(d) list due primarily to heavy metal contamination attributed to acid mine drainage, abandoned mine lands, hydrostructure flow regulation, irrigated crop production, and natural sources. All of these impairments in these reservoirs will continue for the foreseeable future although ongoing efforts are gradually addressing some of them.

Bureau of Reclamation manages the Canyon Ferry Reservoir and Dam on the Missouri River. The reservoir (35,200 acres, 76 miles of shoreline perimeter) is operated to provide flood control, power generation, irrigation, municipal water, and to enhance recreation, fish, and wildlife benefits. The reservoir is generally managed to stabilize downstream flows. By preventing flows from becoming too low, this management tends to minimize potential further water resource concerns during summer periods.

Pennsylvania Power and Light of Montana manages water flows through Hauser and Holter Lake dams in close coordination with the Bureau of Reclamation at Canyon Ferry upstream. Hauser and Holter Lakes are managed as full-pool, run-of-the-river reservoirs as per FERC re-licensing completed in 2000. Flows are managed to optimize energy production, provide for water right uses, and maintain appropriate conditions for fisheries, wildlife, and recreation values. By preventing flows from becoming too low, this management tends to minimize potential further water resource concerns during summer periods.

Under Alternative A, the contribution to cumulative effects on water resources from BLM road management would continue as it occurs today. Retaining approximately 36 miles of road open yearlong and an additional approximately 7 miles open with a seasonal restriction of 10/15 to 12/1 would allow for the same level of effects on water resources that currently exist.

From a BLM road management perspective, all action alternatives would benefit water resources compared to Alternative A. Alternative B would benefit water resources by providing for a reduced contribution to adverse cumulative effects compared to Alternative A because about 68 percent of BLM roads would be closed or decommissioned under Alternative B (compared to 39 percent closed under Alternative A). Of the approximately 22 miles of open road under Alternative B, nearly one half of them (about 10 miles) would be seasonally restricted to exclude motorized vehicle use in the wet spring runoff period each year. This would reduce erosion from these BLM roads and further benefit water resources.

Although the greatest road mileage would be decommissioned under Alternative B (4.7 miles), Alternative C would likely benefit water resources the most and provide for the least contribution to adverse cumulative effects on water resources of all alternatives. This alternative would provide for closure or decommissioning of about 86 percent of BLM roads in the TPA (compared to about 68 percent for Alternative B), thus allowing these areas to vegetatively recover, stabilize soils, and reduce erosion.

Alternative D would provide for the greatest contribution to adverse cumulative effects on water resources of the action alternatives, but would still provide for greater

long-term benefits to water resources than Alternative A. Alternative D would provide for closure or decommissioning (and therefore vegetative recovery, soil stabilization, and reduced erosion/sedimentation) on about 48 percent of BLM roads in the TPA, compared to 39 percent for Alternative A, 68 percent for Alternative B, and 86 percent for Alternative C.

Due to the scattered distribution and relatively small proportion of BLM lands (10 percent) and roads (8 percent) relative to the total quantities of lands and roads in the TPA, none of the BLM alternatives would substantially contribute to cumulative effects on the streams and reservoirs in the East Helena TPA on the whole.

## **VEGETATIVE COMMUNITIES – FOREST RESOURCES AND FOREST AND WOODLAND PRODUCTS**

### **Effects of the Alternatives**

Under all alternatives, existing roads and roads built to access timber and forest product sales on BLM lands may encourage timber harvest and forest product sales on adjacent lands, particularly where landowners and other agencies are looking to improve economic efficiency or opportunities in the management on their lands.

In general, vegetative treatment contractors tend to bid more readily on projects in areas with vehicle access or valuable products. BLM often prioritizes forest vegetation management activities such as forest products and forest protection activities (e.g. wildfire suppression and forest insect and disease control) in similar areas.

Rehabilitation of roads (decommissioning and in some cases road closure) would revegetate currently unvegetated roadbeds, which would increase vegetation biomass production on the landscape through colonization of sites with grasses, forbs, shrubs, and trees. Increases in revegetated area would occur at a rate of approximately 1.5 to 3 acres per mile of rehabilitated road. Eventually rehabilitated roads would support plant communities consistent with site potentials which would help resist weed invasions. However, road closures and removals (decommissioning) could make vegetation management treatments more difficult and costly, thereby inhibiting proposed treatments, reducing public access for product use and removal, and potentially slowing fire detection and suppression.

Under Alternative A where 37 percent of the existing roads have been historically closed, there would be no increase in project analysis and implementation costs. However, under Alternative B approximately 50 percent of roads into forested areas would be closed. Under Alternative C about 83 percent of roads into forested areas would be closed, while under Alternative D about 46 percent of these roads would be closed. These closures would result in commensurate potential increases in ve-

getative analysis and treatment costs by alternative. These potential cost increases would need to be considered on a case by case basis by the BLM during project feasibility determinations, and additional funding may be needed to analyze and implement the projects that would remain feasible. Road closures could also result in potential decreases in quantities of forest products removed. The extent of the effects described above would be minimized because BLM would likely still be able to plan and implement projects in many areas on closed roads through the variance process for temporary road use. Road-related effects would be greatest under Alternative C, followed in sequence by Alternative B, then Alternative D.

Roaded access to forested areas would also affect the gathering of firewood and other forest products by the general public. Most public parties prefer to drive close to areas of product removal so they do not have to carry products over long distances to their vehicles. There have been few publicly requested small sales of materials in most areas of this TPA. Requests received have been concentrated mainly where the lands are crossed by main access routes or in the vicinity of mining claims and homes. The requests received have generally been few due to the preponderance of pine trees which are generally considered to be low quality firewood and Christmas trees. It is likely that local requests for products would continue as has occurred in the past. For the East Helena TPA, Alternative A would retain the most public opportunities for these activities, followed in sequence of decreasing opportunities by Alternative D, Alternative B, then Alternative C. Alternatives B and D would have similar effects to public access for forest product gathering. Under the action alternatives, public searching for, and removal of personal use and small products would generally be confined to motorized travel corridors along the main roads.

## **Cumulative Effects on Forest and Woodland Resources and Products**

No BLM forest health/silvicultural treatments or resource product removal projects are currently scheduled in this TPA within the next five years. Fuels reduction projects with forest health considerations have a high priority in general and would likely occur in this area in the future due to the close proximity of wildland urban interface areas adjacent to several blocks of BLM lands. The major blocks of BLM forest and woodlands in this TPA are located in the North Hills, the Ward Ranch area by Hauser Lake and the Spokane Hills west of Canyon Ferry Lake. These generally contain stands of low productivity and commercial value as in the northern portions of the North Hills and the Spokane Hills (approximately 40 percent of BLM lands in the TPA) where wildfire has severely damaged the forest and woodland stands over the last 25 years. The formerly privately-owned Ward Ranch area has undergone commercial logging that has removed the larger trees since the early

1900s. The products from the forested areas in this TPA would provide little revenue in timber sale projects. In other vegetation manipulation projects, derived products would provide only small offsets to costs for stewardship projects where goods are exchanged for services.

There would be little cumulative effect from any of the action alternatives to forest management activities on inholding and adjacent private lands, as many of the proposed closed roads end in public lands along the shores of the Missouri River and the Lakes. Those roads used for main access to private lands would continue to provide vehicular access through BLM lands under all alternatives for personal use or authorized purposes for the landowners. Projects on private lands would promote fuels reduction objectives in the area as well.

Forested vegetation on BLM lands would also be affected by approximately 1,609 acres of rights-of-way and leases on BLM land. Forested vegetation located in these areas usually is harvested and/or removed to accommodate the necessary access or facilities. Forest vegetation removal would occur on new authorizations in the future and would occur as necessary to maintain sight distances and safety clearances associated with roads and facilities.

Urbanization is expected to continue on the 128,048 acres of private lands (64 percent of total acreage) within this TPA. Forest products are commonly removed from these areas prior to permanent construction. Urbanization is likely to continue in the future and will affect forested vegetation at an unknown rate. As private construction increases, miles of road on private will most likely increase from the current 690 miles.

Risk to forests from human-caused wildfires is commonly associated with miles of open roads. Risk to forests from wildfire is greatest under Alternative A with 44.3 miles of open roads. Alternative B would have less risk of human-caused fire starts with about 17 miles of open road during summer months. Alternative C would have the least risk to public forests with only 12.0 miles of road open during summer months. Alternative D (38 miles of open road during summer) would have more risk than either Alternatives B or C, but less risk than Alternative A. Given that the majority of roads in the TPA (92 percent) are non-BLM roads, this contribution to reduced fire risk from BLM roads in the action alternatives is relatively small in the context of the entire TPA.

Since BLM roads constitute only 8 percent of all roads in this TPA, and BLM lands make up only 10 percent of all lands in the TPA, urbanization and activities on open non-BLM roads in the vicinity may have more cumulative effects on forested vegetation in the TPA than BLM decisions regarding miles of open and closed road.

## VEGETATIVE COMMUNITIES – NOXIOUS WEEDS

Under all alternatives, any snowmobile use would have negligible effects on noxious weed spread and populations. Invasive noxious weeds and non-native species are degrading wildland health. These are aggressive plants that can outcompete many native plants, as they have few natural enemies to keep them from dominating an ecosystem. These plant species are spread by many means. However, any land disturbing activity in the TPA has the most potential to introduce and spread weed species. Motorized vehicles are one vector for noxious weed spread as weed seed becomes attached to vehicles and their tires, and are transported from one area to another where seeds become detached and germinate to inhabit new areas.

### Effects of Alternative A

Under Alternative A, a total of 44.3 miles of wheeled motorized routes are open (36.6 miles open yearlong, 7.7 miles seasonally restricted, 26.4 miles closed). With the exception of the Ward Ranch, McMasters, and Spokane Hills temporary area closures, the remainder of the travel planning area would remain available to cross-country area snowmobile use, as well as travel on all existing routes during the season of use (12/2-5/15), conditions permitting.

Alternative A would leave the most roads open and in turn would promote the greatest amount of weeds and other undesirable plant spread and production of all alternatives. More herbicide control would be needed to control weeds than under the other alternatives. Under Alternative A the 44.3 miles of open BLM road would make up about 4 percent of all open roads in the East Helena TPA.

### Effects of Alternative B

Under Alternative B, 13.7 miles of wheeled motorized routes would be available yearlong, and 3.3 miles would be open with seasonal restrictions. Cross-country snowmobile travel would be allowed, as well as travel on all existing routes during the season of use (12/2-5/15), except for the North Hills, Dana's Bar, and the area located to the west of Prickly Pear Creek. The remainder of the travel planning area (McMaster Hills, Ward Ranch, and Spokane Hills) would be closed to all cross-country snowmobile use, including travel on existing roads and trails. This alternative would close 41.9 miles of road leaving 13.7 miles open yearlong as compared to 36.6 miles of road open yearlong under Alternative A. This would prevent weed spread caused by motorized vehicles on closed routes, but would increase weed spread on open routes because of the more concentrated use on the fewer available routes. Overall Alternative B would reduce weed spread, but would increase weed treatment costs per road mile on remaining open roads

compared to Alternative A. Under Alternative B the 13.7 miles of BLM road open yearlong along with the 3.3 miles of seasonally restricted road would make up about 2 percent of all open roads in the East Helena TPA.

### Effects of Alternative C

Alternative C would provide the least amount of wheeled motorized access in the East Helena travel planning area. Under Alternative C, 12.0 miles of wheeled motorized routes would be available yearlong. No cross-country snowmobile use would be allowed; use would be restricted to designated routes only during the season of use (12/2-5/15), snow conditions permitting. This alternative would close 54.6 miles of road leaving 12.0 miles open yearlong as compared to 36.6 miles of road open yearlong for Alternative A. This would prevent weed spread caused by motorized vehicles on these closed routes, but would increase weed spread on open routes because of the more concentrated use on the fewer available road miles. Overall Alternative C would reduce weed spread more than any other alternative, but would increase weed treatment costs per road mile on the remaining open roads compared to Alternative A. Under Alternative C the 12 miles of open BLM road would make up about 1 percent of all open roads in the East Helena TPA.

### Effects of Alternative D

Alternative D would provide the highest level of motorized access (of the action alternatives), and the least non-motorized opportunities. Under Alternative D, 36.0 miles of wheeled motorized routes would be available yearlong, and 1.9 miles would be open with seasonal restrictions. Snowmobile management under this alternative would be as follows: cross-country travel would be allowed, as well as travel on all existing routes during the season of use (12/2-5/15), for the North Hills, Dana's Bar, and the area located to the west of Prickly Pear Creek. The Ward Ranch and the Big Bend areas would be closed to all cross-country snowmobile use as well as travel on designated routes. This alternative would close 29.7 miles of road, leaving 36.0 miles open yearlong as compared to 36.6 miles of road open yearlong for Alternative A. This alternative would have very similar environmental effects as Alternative A, though to a slightly lower degree. Under Alternative D the open BLM roads would make up about 4 percent of all open travel routes in the East Helena TPA.

### Cumulative Effects on Noxious Weeds

Under all alternatives, other past, present and reasonably foreseeable future BLM and non-BLM actions and outside influences affect noxious weeds.

Recreation use is well established in the TPA. Primary recreation activities include water based activities, big game hunting, non-motorized uses (hiking, jogging, horseback riding, mountain biking, etc), and OHV uses

(ATV, motorcycle). Motorized recreation uses are one of the leading causes of introduction and spread of noxious weeds and non-native species. Weed seeds are transported by many recreational vectors such as water recreation uses, motorized vehicles including their tires, non-motorized vehicles including their tires, pack animals, and humans.

Urban development may lead to an increase in right-of-way permits to accommodate private property/development access. As a result, soil disturbing activities (i.e. roads, powerlines, telephone lines, etc.), will increase causing weeds to increase.

A variety of resource management projects, such as BLM initiated vegetation treatments, or wildland fire fuels reduction projects, could affect weeds in the TPA. There have been no fuels treatments in this area in the last 10 years. There are as yet unplanned fuels treatments potentially slated for planning and implementation over the next five years for this area, mainly in the area of the North Hills. These treatments would consist of mechanical and/or prescribed burning from 500 to 1,500 acres focused on the urban interface areas. Any project creating soil disturbance has the capability to increase weedy plant species. Prescribed burning projects give the ground surface a fertilization effect and eliminate some plant competition for weedy species giving them a niche for establishment and expansion in some areas. Ground disturbing equipment could also transport noxious weed seed to these project sites. BLM implements weed control measures in the aftermath of such ground-disturbing activities so as to minimize noxious weed establishment and spread.

Wildland fires create good seed beds and supply nutrients for weed species introduction and production. From 1981 to 2004 there have been 18 wildland fires that burned approximately 15,577 acres in this TPA. The 2000 Bucksnot Fire accounts for the large majority of this total. This fire has promoted and increased noxious weed production in this TPA. Part of fire rehabilitation activities involved weed treatments to minimize weed spread.

Mining is a land disturbing activity and the activity itself and potentially weed seed contaminated equipment that is used could promote weeds in the area.

Noxious weeds and non-native invasive species are well established and spreading in the area. Weed control activities by BLM and other entities, while often effective at reducing or minimizing weed spread and weed populations, can also lead to some weed spread. Herbicide spray equipment is driven through weed infestations and weed seeds as well as other weed vegetative parts are spread to other lands during and following treatment. The Bucksnot Wildfire area received ground treatments of about 75 acres in size following the fire. In 2003 herbicide and biological control treatments on the Bucksnot fire area were approximately 500 acres in size.

Much of this treatment acreage was by aerial means coordinated with the Natural Resource Conservation Service (NRCS) and Lewis and Clark County. These weed treatments have varying success in killing undesirable plants, depending on many environmental parameters. The weeds that have been treated are primarily in the urban interface area where heavy motorized use plays a large role in the distribution of noxious weeds.

Timber sales have built in stipulations for mitigating weed production and spread. However, with ground disturbance the potential exists for weed introduction to occur on these sites. Vehicular access for tree plantings could contribute to the spread of existing weeds on site. Since 1995 there has been 250 acres of timber salvage and 250 acres of forest planting (replanted in 2002). Herbicide treatment of existing weeds was coordinated with tree seedling planting locations and timing, so as to minimize potential exacerbation of weed spread.

Future travel management (for all agencies, nationwide) is likely to lead to fewer opportunities for motorized recreational use than under current management (particularly for OHV use). As a result, BLM routes available to motorized use could experience increased use from displaced users, leading to more concentrated use. Such use could cause a larger than anticipated introduction and spread of weeds. An increase in weeds would lead to an increase in needed treatment on BLM lands.

The Bureau of Reclamation (BOR) manages approximately 11,500 acres of land surrounding Canyon Ferry Reservoir. BOR actions (such as new recreation site developments) could influence travel management on adjacent BLM lands. These actions could potentially increase weed spread and production on BLM managed lands.

Portions of the TPA (North Hills, areas adjacent to Canyon Ferry and Hauser Lakes) provide winter range for mule deer and elk. Noxious weed seed are transported and spread by wildlife through their digestive system and by attaching to the animals themselves and then being released at a later time.

Livestock grazing on and off BLM lands also contributes to weed spread either through seed being spread by livestock themselves, or through vehicular uses needed to manage grazing operations.

East Helena Valley has been experiencing steady population growth. This trend is expected to continue, along with increased recreational use of this travel planning area. These factors could lead to increased public pressure to alter travel planning for either more, or less motorized use. The increasing population in the Helena and East Helena areas will in turn lead to an increase in use of this TPA creating more opportunities for weed spread and production.

The majority of BLM managed routes for the East Helena Travel Planning area are located in or adjacent to the

Ward Ranch or North Hills sub-travel planning areas. The remaining routes are located in the Spokane Hills and Townsend sub-travel planning areas. As with the Scratchgravel Hills (Helena TPA), the Ward Ranch and North Hills sub-planning areas are surrounded by residential development (there is some internal development as well). Like the Scratchgravel Hills, they have experienced steady residential development over the past 15-20 years. The Spokane Hills and Townsend sub-travel planning areas are more rural in character, but also have experienced residential/subdivision growth, near the northern and southwest portions of the Spokane Hills and north of Townsend. This development/increase in population has led to an increase in use of the TPA by residents living adjacent to or within this area which in turn leads to an increase in weed spread and propagation.

Only 8 percent of all the travel routes in the East Helena TPA are located on BLM managed lands (under Alternative A). Lands near roads and away from roads in the TPA are infested with weeds. The travel on all roads in the TPA spreading weeds, and weeds off these roads are being spread by the weed plants themselves and other natural means. Because the majority of roads (92 percent) and lands (90 percent) in the TPA are non-BLM, activities in these areas play a stronger role than activities on BLM lands in determining the status of weed spread and weed populations in the TPA overall.

**VEGETATIVE COMMUNITIES –  
RIPARIAN VEGETATION**

**Effects Common to All Alternatives**

This section focuses on effects to riparian vegetation. For additional discussion of effects to water quality and stream channels, see the Water Resources and Fish sections.

Roads in riparian areas constitute ground disturbance that can eliminate or preclude presence of native riparian vegetation. This ground disturbance and loss of riparian vegetation may facilitate erosion and sedimentation of streams. Roads may also interfere with natural stream channel functions by occupying floodplains or active stream channel margins (see Water Resources section for more discussion). Noxious weeds may dominate riparian vegetation communities after some type of disturbance (such as roads, livestock grazing, mining, etc.) has reduced native vegetation. Noxious weed seed can be spread into riparian areas by motor vehicles via open roads. Closure of roads and trails can improve or maintain riparian condition by reducing avenues of noxious weed spread, as well as allowing for bare area revegetation which filters sediment in addition to stabilizing banks in some areas. Road and trail restrictions have the same effects but to a lesser degree, because some traffic will inhibit vegetation growth and recovery.

**Effects of the Alternatives**

As a means of comparing alternatives, **Table 4-61** depicts the miles of wheeled motorized routes that cross or are within 300 feet of streams and wet areas on BLM lands by alternative for the East Helena TPA.

<b>Table 4-61 Miles of Roads and Trails by Proposed Management Category Within 300 feet of Streams (including intermittent streams) in the East Helena Travel Planning Area</b>				
<b>Miles of Wheeled Motorized Routes</b>	<b>ALT A</b>	<b>ALT B</b>	<b>ALT C</b>	<b>ALT D</b>
Open	3.5	3.0	3.0	3.9
Restricted	0	0	0	1.9
Closed	3.6	4.1	4.1	1.2

Under Alternative A, 3.5 miles of BLM roads and trails would remain open that cross or are within 300 feet of streams or wet areas, and 3.6 miles of roads and trails would remain closed. The noxious weed spread, streambank, and sediment delivery effects would continue on the open roads and trails as described above. BLM roads and trails have very minor effects on riparian conditions in this TPA because the roads and trails parallel the Missouri River/Hauser Lake shore for quite short distances or simply dead-end at or before water’s edge.

Under Alternative B, 3.0 miles of BLM roads and trails would remain open that cross or are within 300 feet of streams or wet areas, and 4.1 miles of roads and trails would be closed. The noxious weed spread, streambank, and sediment delivery effects would continue on the open roads and trails as described in the effects common to all section. Alternative B would have slightly reduced effects to riparian areas than Alternative A.

Effects of Alternative C would be the same as those described for Alternative B.

Under Alternative D, 3.9 miles of BLM roads and trails would remain open that cross or are within 300 feet of streams or wet areas, 1.9 miles of roads and trails would have seasonal restrictions, and 1.2 miles of roads and trails would remain closed. The noxious weed spread, streambank, and sediment delivery effects would continue on the open roads and trails as described above. Restricted roads would reduce some of these effects. BLM roads and trails have very minor effects on riparian conditions in this TPA because the roads and trails parallel the Missouri River/Hauser Lake shore for quite short distances or simply dead-end at or before water’s edge. Alternative D could have slightly greater effects than all other alternatives on riparian vegetation on BLM lands, but these differences in effects would be minor.

## Cumulative Effects on Riparian Vegetation

Noxious weed spread, mining, roads and trails, logging operations, and livestock grazing have affected riparian resource conditions in all TPAs, including the East Helena TPA. Some of these factors continue to cause riparian area degradation primarily through direct disturbance or loss of riparian vegetation. Ground disturbance and loss of riparian vegetation facilitate erosion and sedimentation of streams. In the case of noxious weeds, they usually dominate riparian vegetation communities after some type of disturbance (such as roads, livestock grazing, mining, etc.) has reduced native vegetation.

Anticipated subdivision growth on private lands will lead to more road construction and maintenance. More roads and development will increase severity of runoff events which in turn will cause more sediment delivery to creeks and streams. The additional sediment is likely to affect the functioning condition of some riparian areas by causing streambeds to aggrade at unnatural rates. Streambanks may also be affected if road placements do not allow for natural stream movements or meanders.

Logging and forestry practices on public and private lands are subject to streamside management zone (SMZ) requirements designed to maintain water quality and riparian vegetation. The proposed Riparian Management Zones under Butte RMP Alternatives B and C would be wider than SMZs and activities in these areas would be designed to benefit riparian resources, thus providing more riparian protection and more targeted management of riparian vegetation in both forested and non-forested areas than under RMP Alternatives A and D. The disturbance associated with timber activities does have the potential to increase noxious weed spread which degrades riparian area function and health. On public lands noxious weed control is a standard feature of any ground disturbing activities whereas on private lands noxious weed control is variable.

Livestock grazing will continue in the area and has the potential to impact riparian resource conditions. On BLM lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain riparian vegetation health and vigor. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided. Riparian conditions may improve or degrade as management changes.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, riparian conditions would improve because of the streambank protection gained from shrubby root systems and filtering capability of native riparian sedge and rush species.

The Bucksnot Fire of 2000 burned a large portion of the Spokane Hills (approximately 15,535 acres) across mul-

tipale land ownerships. Before the vegetation could recover, subsequent storm events caused considerable sediment delivery to Canyon Ferry Reservoir from a number of ephemeral gulches.

While there are slight differences in effects to riparian vegetation between East Helena travel plan alternatives at the site scale on BLM lands as described above, in the context of cumulative effects the differences between alternatives would be negligible.

Overall, because BLM roads make up only 8 percent of all roads in the TPA (under Alternative A), and BLM lands make up 10 percent of all lands in the TPA, the contributions to riparian vegetation benefits associated with closing riparian roads on BLM lands would be minor at the scale of the entire East Helena TPA. Activities on private lands (64 percent of total acreage in TPA) would play a dominant role in determining riparian conditions at the scale of the entire TPA.

## WILDLIFE

### Effects of Alternative A

Under Alternative A, the East Helena TPA would have substantially more open roads (44 miles) compared to the action alternatives and would have the highest actual road density in elk winter range, 1.1 mi/mi<sup>2</sup> (**Table 4-63**) compared to the action alternatives. Open roads typically increase the level of recreation adjacent to roads which can result in additional disturbance and displacement of wildlife species. Roads can also encourage the public to recreate in areas that had formerly been secluded. Roads can cause direct mortality to wildlife through road kill, prevent wildlife movement, create disturbance to wildlife via vehicular use, cause the spread of noxious weeds, reduce habitat and cause habitat fragmentation on the landscape (Joslin et al. 1999). Open road miles that exceed 1 mi/mi<sup>2</sup> have also been found to provide less than 60 percent functional habitat for elk (Christensen et al. 1993). Permanent and temporary roads could negatively impact wildlife including special status species, particularly if roads are open during critical periods such as during the winter or breeding seasons.

High open road densities under Alternative A could result in the loss of year-round habitat and migration corridors, disturbance and displacement of wildlife, road kill, and fragmentation of habitat. Wildlife, including special status species, that are especially sensitive to roads in the TPA include (but are not limited to) elk, northern goshawk and boreal toads. The detrimental effects of open road densities to wildlife under Alternative A could be minor to major and long-term. This alternative would have the greatest negative impacts to wildlife including special status species from open roads.

Under Alternative A, this TPA would have slightly fewer acres of functional winter range (6,415 acres of area with low road density) compared to Alternative B (6,915

acres), but considerably less than Alternative C (8,899 acres) (Table 4-63). This Alternative, however, would have more functional winter range than Alternative D (5,923 acres).

Under Alternative A, approximately 1,600 acres of the East Helena TPA would be closed to snowmobile use in the Ward Ranch and McMasters areas but approximately 15,000 acres would be open for cross country use by snowmobiles. An additional 3,600 acres would be available for snowmobile use on open routes only (44 miles of open roads). Although the majority of the East Helena TPA is open to cross country snowmobile use or for use on open roads, BLM lands in this TPA do not often get favorable snow conditions for snowmobiling. Due to snow conditions, the use of snowmobiles would be limited and the effects to wintering big game and other wildlife species would be expected to be minimal the majority of the time. However, when snow conditions do become favorable, snowmobile use of the TPA could have considerable negative effects to big game and other wildlife species. The negative effects due to cross-country snowmobile use could include harassment of big game and other species during the high stress winter season (Joslin et al. 1999). This could cause individuals to leave an area (temporarily or permanently) and/or an increase in stress that could lead to mortality.

In evaluating impacts of travel planning on elk and other big game species, it is important to consider impacts on security habitat. Elk security is the inherent protection allowing elk to remain in an area despite increases in stress or disturbance associated with the hunting season or other human activities. Security habitat includes blocks of nonlinear forested habitats greater than 250 acres in size that are at least 0.5 mile from an open road (Hillis et al. 1991). Security habitat should also consist of larger trees (greater than 8 inches DBH) with vegetation dense enough to hide an adult elk (Thomas et al. 2002). There would be less big game security habitat under Alternative A (1,181 acres) compared to Alternatives B (1,447 acres) and C (1,546 acres), but slightly more than Alternative D (1,048 acres) (Table 4-62).

	<b>A</b>	<b>B</b>	<b>C</b>	<b>D</b>
<b>East Helena TPA</b>	1,181	1,447	1,546	1,048

Core areas are areas large enough for wildlife (especially animals with large home ranges such as carnivores and big game) to forage and reproduce. Subcore areas are areas that could act as stepping stones for wildlife as they move through the region (Craighead et al. 2002).

Within the East Helena TPA, there are 20,266 acres of BLM lands. On BLM lands, 2,142 acres provide good quality habitat for core or subcore habitat and 6,361 acres were identified as low quality wildlife movement corridors (Craighead et al. 2002). The remaining 11,763 acres of BLM lands do not provide highly functional or predictable corridors for wildlife movement due to fragmentation of habitat, high road densities, and development.

Within all lands of the East Helena TPA there are approximately 17,292 acres identified as “core/subcore” habitat. Under this alternative, there would be 8,209 acres with low road density (less than 1 mi/mi<sup>2</sup>), 3,270 with moderate road density (1-2 mi/mi<sup>2</sup>) and 5,814 acres with high road density (greater than 2 mi/mi<sup>2</sup>) in the TPA for all land ownerships. Alternative A would provide slightly lower quality habitat in core and subcore habitat at the landscape level compared to the other alternatives.

On BLM lands, there are approximately 2,142 acres in core/subcore habitat. In core/subcore habitat under Alternative A, there would be 1,436 acres with low road density, 311 acres with moderate road density and 395 acres with high road density. Alternative A would provide slightly lower quality habitat in core and subcore habitat in the Decision Area compared to the other alternatives.

	<b>Actual Road Density</b>	<b>Acres of Low Road Density</b>	<b>Acres of Moderate Road Density</b>	<b>Acres of High Road Density</b>
<b>Alternative A</b>	1.1	6,415	2,252	2,547
<b>Alternative B</b>	0.5	6,915	3,349	950
<b>Alternative C</b>	0.3	8,899	1,606	709
<b>Alternative D</b>	0.7	5,923	3,024	2,267

Low Density = 0-1 mi/mi<sup>2</sup>, Moderate Density = 1-2 mi/mi<sup>2</sup>, High Density = >2 mi/mi<sup>2</sup>

Wildlife corridors are areas of predicted movement within or between core and subcore areas. Within the East Helena TPA there are no acres identified as “high quality” wildlife movement corridors under any land ownership. There are approximately 3,374 acres identified as moderate quality corridors for all land ownerships but the majority of movement corridors are considered to be low quality (35,123 acres) due to development and road densities. In moderate quality movement corridors all alternatives would have 1,808 acres with low road density, 1,485 acres with moderate road density and 81 acres with high road density.

Riparian areas provide crucial habitat and critical travel corridors for wildlife including special status species. Riparian areas also provide a refuge for native plants and animals in times of stress such as drought or fire. Roads in riparian areas can prevent use of these crucial areas by wildlife, limit use, or cause loss of habitat (Wisdom et al. 2000). Under Alternative A there would be 3.5 miles of open roads in riparian areas.

### Effects of Alternative B

Under Alternative B, the East Helena TPA would have substantially fewer open roads (17 miles) compared to Alternative A (44 miles). Of the 17 miles of open roads, 13.7 would be open year round and the remaining 3.3 miles would be seasonally restricted. Alternative B would have more open roads than Alternative C (12 miles) but considerably less than Alternative D (38 miles). Alternatives B and C would decrease harassment to wildlife during all seasons of use compared to Alternatives A and D. Alternatives B and C would also improve habitat and reduce fragmentation more than Alternatives A and D.

Under Alternative B, the actual road density in elk winter range in the East Helena TPA would be 0.5 mi/mi<sup>2</sup>, below the maximum of 1 mi/mi<sup>2</sup> recommended by FWP in big game winter range. This is substantially lower than the road density under Alternative A (1.1 mi/mi<sup>2</sup>), higher than Alternative C (0.3 mi/mi<sup>2</sup>) and lower than Alternative D (0.7 mi/mi<sup>2</sup>) (Table 4-63). Christensen et al. (1993) found that reducing open road miles to 0.5 mi/mi<sup>2</sup> would increase the amount of effective habitat available to elk to greater than 70 percent.

Under Alternative B, this TPA would have more acres of functional winter range (6,915 acres) compared to Alternative A (6,416 acres), less than Alternative C (8,899 acres) but more than Alternative D (5,923 acres) (Table 4-63). Alternative B would improve the quality and quantity of winter range in the East Helena TPA compared to Alternatives A and D but would have substantially fewer beneficial effects to winter range than Alternative C.

Alternatives B and C would close more acres to cross country snowmobile use than Alternatives A (15,066 open acres) and D (14,461 open acres). Approximately 6,400 acres would be open to cross country snowmobile

use under Alternative B and Alternative C would limit all snowmobile use to existing roads with no open areas for cross-country snowmobiling. Due to unfavorable snow conditions, the use of snowmobiles would most likely be limited in the TPA and the affects to wintering big game and other wildlife species would be expected to be minimal the majority of the time. However, when snow conditions do become favorable, snowmobile use under Alternative B would have fewer negative effects to big game and other wildlife species than Alternatives A and D.

The amount of big game security habitat would be slightly more under Alternative B (1,447 acres) compared to Alternatives A and D (1,181 and 1,048 acres, respectively) (Table 4-62).

For all land ownerships, Alternatives B and C would have identical acres of core and subcore habitat in low (8,624 acres), moderate (3,180 acres) and high road densities (5,488 acres). Alternatives B and C would have 415 more acres in the low road density category and 326 fewer acres in the high road density category than Alternative A. Alternatives B and C would improve the quality of core/subcore habitat across the landscape more than Alternative A.

Under Alternatives B and C, BLM lands in core and subcore habitat would have slightly higher acres in low road density (1,703 acres) compared to Alternative A (1,436 acres). Alternatives B and C would also have fewer acres with moderate road density (191 acres) compared to Alternative A (311 acres) and slightly fewer acres with higher road density (249 acres) compared to Alternative A (394 acres). Alternatives B and C would improve the quality of core/subcore habitat on BLM lands more than Alternative A.

Alternatives B and C would protect and restore more riparian habitat than Alternative A by reducing the miles of open roads in riparian areas to 3.0 miles (from 3.5 under Alternative A). Reducing roads in riparian habitats under Alternatives B and C would allow for more breeding, foraging and hiding habitat as well as improve movement corridors for a wide variety of species.

### Effects of Alternative C

Under Alternative C, the East Helena TPA would have substantially fewer open roads (12 miles) compared to Alternative A (44 miles). Alternative C would have fewer open roads than Alternative B (17 miles) and considerably less than Alternative D (38 miles). Alternatives C and B would decrease harassment to wildlife during all seasons of use compared to Alternatives A and D. Alternatives C and B would also improve habitat and reduce fragmentation more than Alternatives A and D.

Under Alternative C, the actual road density in elk winter range in the East Helena TPA would be 0.3 mi/mi<sup>2</sup>, below the 1 mi/mi<sup>2</sup> recommended by FWP in big game winter range. This is substantially lower than the road

density under Alternative A (1.1 mi/mi<sup>2</sup>) and also lower than Alternative B (0.5 mi/mi<sup>2</sup>) and Alternative D (0.7 mi/mi<sup>2</sup>) (Table 4-63). Christensen et al. (1993) found that reducing open road miles to 0.3 mi/mi<sup>2</sup> would increase the amount of effective habitat available to elk to greater than 80 percent.

Under Alternative C, this TPA would have substantially more acres of functional winter range (8,899 acres) compared to Alternative A (6,416 acres), Alternative B (6,915 acres) and Alternative D (5,923 acres) (Table 4-63). Alternative C would improve the quality and quantity of winter range in the East Helena TPA more than all other alternatives.

Under Alternative C, snowmobile use throughout the entire East Helena TPA would be limited to open routes (12 miles). This would greatly reduce the negative effects associated with snowmobile use to big game and other wildlife species compared to all other alternatives.

The amount of big game security habitat on BLM lands would be greater under Alternative C (1,546 acres) than under any other alternative (Table 4-62).

Effects associated with core and subcore habitat under Alternative C would be the same as under Alternative B.

Effects associated with riparian habitat under Alternative C would be the same as under Alternative B.

## Effects of Alternative D

Under Alternative D, the East Helena TPA would have fewer open roads (38 miles) compared to Alternative A (44 miles). Of the 38 miles of open roads, 36 would be open year-round and the remaining 1.9 miles would be seasonally restricted. Alternative D would have considerably more open roads than Alternative B (17 miles) and Alternative C (12 miles). Alternatives D and A would allow more harassment to wildlife during all seasons of than Alternatives B and C. Alternatives D and A would restore less habitat and allow more fragmentation of habitats than Alternatives B and C.

Under Alternative D, the actual road density in elk winter range in the East Helena TPA would be 0.7 mi/mi<sup>2</sup>, below the maximum of 1 mi/mi<sup>2</sup> recommended by FWP in big game winter range. This is lower than the road density under Alternative A (1.1 mi/mi<sup>2</sup>), higher than Alternative B (0.5 mi/mi<sup>2</sup>), and considerably higher than Alternative C (0.3 mi/mi<sup>2</sup>) (Table 4-63).

Under Alternative D, this TPA would have the fewest acres of functional winter range (5,923 acres) of any alternative. Alternative A would have 6,416 acres, Alternative B would have 6,915 acres, and Alternative C would have 8,899 acres of functional winter range (Table 4-63). Alternative D would have substantially fewer beneficial effects to winter range than all other alternatives.

Alternative D would close more acres (5,805 closed acres) to cross country snowmobile use than Alternative A, but would close less area than Alternatives B and C. While no areas would actually be “closed” under Alternative C, the entire TPA would be in the “limited” category, meaning that snowmobile use would only be allowed on open roads and trails. Under Alternative D, approximately 14,460 acres would be open to cross country snowmobile use. Alternative D would have more acres open to cross country snowmobile use than Alternatives B and C but fewer than Alternative A. Due to snow conditions, the use of snowmobiles would most likely be limited in the TPA and the effects to wintering big game and other wildlife species would be expected to be minimal the majority of the time. However, when snow conditions do become favorable, snowmobile use under Alternative D would have greater negative effects to big game and other wildlife species than Alternatives B and, especially, C because Alternative C would limit all snowmobile use to open roads (12 miles), with no open cross country use areas.

The amount of big game security habitat under Alternative D would be 1,048 acres, the least of all alternatives (Table 4-62).

For all land ownerships in core and subcore habitat, Alternative D would have more acres (8,434 acres) with low road density than Alternative A (8,209 acres). However, Alternative D would have fewer acres with low road density than the other action alternatives. Alternatives B and C would have approximately 8,624 acres with low road density. Alternative D would also provide more acres in moderate road density (3,359 acres) than Alternative A (3,270 acres) as well as more than Alternatives B and C (3,180 acres). Alternative D would also have fewer acres in high road density (5,500 acres) compared to Alternative A (5,814 acres), but would have slightly more than Alternatives B and C (5,488 acres). Alternative D would improve the quality of core/subcore habitat across the landscape more than Alternative A but slightly less than Alternatives B and C.

Under Alternative D, BLM lands in core and subcore habitat would have slightly higher acreage with low road density (1,549 acres) compared to Alternative A (1,436 acres), but would have fewer acres with low road density compared to Alternatives B and C (1,703 acres). Alternative D would also have more acres with moderate road density than Alternatives A (311 acres), B and C (191 acres for both Alternatives B and C). Alternative D would have the same amount of acres with high road density as Alternatives B and C (249 acres) which would be fewer than those in Alternative A (394 acres). Alternative D would improve the quality of core/subcore habitat on BLM lands more than Alternative A but slightly less than Alternatives B and C.

Alternative D would protect and restore less riparian habitat than all other alternatives. Alternative D would

provide the most negative effects to riparian habitats with 3.9 miles of open roads.

## Cumulative Effects on Wildlife

Wildlife habitat in the East Helena TPA has been affected by roads, historic and current mining, timber harvest and salvage, weed infestations, urbanization and development, recreation, powerline corridor development, and communication sites.

The East Helena Valley has been experiencing steady population growth. This trend is expected to continue, along with increased recreational use of this travel planning area. Primary recreation activities in the TPA include big game hunting, non-motorized uses (hiking, jogging, horseback riding, mountain biking, etc) and OHV uses (ATV, motorcycle).

Land that was traditionally used for ranching, forest products, or mining is now being converted to home sites in the East Helena Valley. Although these lands had historic human uses, they also provided quality wildlife habitat. These areas historically provided a diversity of habitats that contributed to; big game winter range, travel corridors, habitat for resident and migrating wildlife, as well as foraging, breeding and hiding habitat. Many of the areas currently experiencing residential development are in big game winter range. Because of the loss of winter range on private lands, it is critical that public and state lands maintain quality and secure winter range or improve the habitat in these areas.

For many plant and animal communities, native species richness decreases as housing density increases. Non-native species, however, tend to increase with development (Hansen et al. 2005). Wildlife populations, including carnivores, may be reduced even at very low levels of residential development due to; loss of habitat, an increase in human access (from roads) in areas that previously had low levels of disturbance, and an increase in hunting pressure. Residential development can also lead to an increase in noxious weed infestations that can reduce the quality and quantity of wildlife habitat.

Pets can also have a negative impact to native wildlife. Cats hunt and kill bird and small mammals. Dogs that are allowed to roam can chase, injure, or kill wildlife. This can result in areas becoming unavailable to wildlife.

Active mining claims are common in the area, and there are active notices in the travel planning area as well. Increases in mineral prices could lead to increased or renewed mining activity. Mineral activity along with associated road construction and development on both private and public lands could add substantially to the negative cumulative effects to wildlife and wildlife habitats in this TPA.

In the TPA, there are 16 powerlines, three pipelines and four communication sites. In the future, communication sites on BLM lands will be restricted to existing sites but

future communication sites could be built on private and other public lands in the TPA. There is the potential for future powerlines and pipelines to be built in this TPA.

There are approximately 21 right-of-ways (ROW) in the TPA and applications for ROW permits to access private property or for commercial development are likely to increase in the future. As a result, public access to BLM lands could increase. Fewer ROWs would be expected under Alternative A because more BLM roads would remain open under this alternative. Alternatives B and C would be expected to have more ROWs than Alternative D.

From 1981-2004 there have been 18 wildland fires that burned 15,577 acres in the Planning Area. Five of the fires were identified as human-caused and these fires burned the majority of the acres (15,535 acres). After the 2000 Bucksnot Fire, timber salvage occurred on approximately 250 acres of BLM lands as well as on many acres of private lands. Vegetation treatments may occur on BLM lands in the future and timber harvest is expected on private as well as other public lands in the future. Vegetation treatments would be expected to be less under Alternatives A and C than Alternatives B and D. Overall, vegetative treatments on BLM lands have had minor effects to wildlife habitat in the TPA. However, timber salvage on BLM lands has substantially reduced the distribution and amount of snag habitat for snag dependant species in the salvage units. Timber harvest along with residential development on private lands has substantially altered the landscape and caused a decline in the quality and quantity of wildlife habitat in the TPA.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the TPA. Motorized activities play a large role in the distribution of noxious weeds. The cumulative effects of the spread of noxious weeds from open roads would be greater under Alternative A than all other alternatives. Alternative A would result in more wildlife habitat being lost or degraded due to noxious weed infestations compared to the action alternatives. Alternative B would have fewer open roads than Alternatives A and D resulting in fewer infestations of noxious weeds. Alternative C would close the most roads and would have the fewest cumulative effects from loss of habitat due to noxious weeds. Open roads adjacent to BLM land would still be a conduit for the spread of noxious weeds.

Fragmentation of BLM lands in the TPA (only 10 percent of the TPA is in BLM ownership) as well as open roads on BLM lands (about 71 miles), private lands (about 769 miles), and other public lands (about 52 miles) has reduced the quality of wildlife habitat within the TPA. Roads within the TPA can cause disturbance to wildlife along with fragmentation and loss of habitat. Roads are associated with nearly every type of activity that has the potential to occur in the TPA including; vegetation treatments, timber salvage, mining, access to

private lands (ROWs), fire suppression, powerline corridors and recreation. Open roads in the Planning Area would likely increase due to development and management of private lands. Alternative A would have the greatest negative cumulative effects to wildlife and wildlife habitat from open roads with 44 miles of open roads. Alternative B would have fewer negative cumulative effects with 17 miles of open road than Alternatives A and D (38 open miles) but more than Alternative C (12 miles).

Historic and recent timber cutting, salvage harvest, past mining activity and firewood gathering in the TPA may have reduced the amount of suitable snag habitat for cavity nesting species. Alternative A would allow continued access to the area for firewood cutting. This could continue to prevent snag recruitment for snag dependant species and minimize the amount of down woody material. Alternative B would protect more snag and down woody habitat from loss due to firewood cutting than Alternatives A and D but would protect less of this habitat type than Alternative C.

Alternative A would have the greatest negative cumulative effects from open roads to wildlife and wildlife habitat of all alternatives. Under Alternative A, habitat on BLM lands would not be restored and would continue to be degraded over time. Disturbance to wildlife from open roads would continue to impact the distribution and use of the TPA by wildlife. Alternatives B and C would have greater beneficial cumulative effects to wildlife and wildlife habitats from closing roads than Alternatives A and D.

Even though the East Helena TPA is large (approximately 200,991 acres), open habitats of grasslands and shrublands along with high road densities in both the Decision and Planning Areas have prevented BLM lands from providing a large amount of suitable security habitat for big game during the hunting seasons. Under Alternatives A and D, roads would continue to reduce functional security habitat in this TPA more than Alternatives B and C.

Habitat mapped as core and subcore habitat and wildlife movement corridors would continue to have higher road densities and more negative cumulative effects under Alternative A than under the action alternatives. An increase in open roads in both the Decision and Planning Areas could result in a loss of core and subcore habitat under all alternatives but, especially, Alternatives A and D. The cumulative effects to core and subcore habitat and wildlife movement corridors would be beneficial under the action alternatives, especially Alternatives B and C.

The cumulative effects of high road densities would continue to negatively affect wildlife species during the breeding season more under Alternative A than under the action alternatives. Alternatives B and C would have the most beneficial cumulative effects to wildlife during

the breeding season compared to Alternative D and, especially, Alternative A.

## FISH

For the sake of this discussion, “open” roads include roads that are open with seasonal restrictions as well as roads that are open yearlong. Roads identified as “closed” within 300 feet of streams also include roads that would be “decommissioned” in these areas by alternative. Effects to water quality described in the Water Resources section would affect fish populations and fish habitat quality. Analyses described and tabulated in the Water Resources section are referred to in the context of effects to fish in the discussion below.

### Effects of Alternative A

Under Alternatives A, the East Helena TPA would have substantially more open roads (44 miles) compared to the action alternatives. Roads can have a wide range of effects on fish and fish habitat. These effects would include, but are not limited to, increased sedimentation from road construction and vehicle use, increased runoff, changes in surface water and drainage patterns from stream crossings, conduits for noxious weeds, loss of riparian vegetation, potential decreases in stream shading that could lead to water temperature increases, and changes in local fish populations when culverts are impassable and limit fish migration.

Watershed (or hydrologic) function can be used as an indicator of relative risk or impacts to fish habitat (Doppelt et al. 1993). Generally, watersheds with high road densities often have the largest negative effects on fish and aquatic resources. To determine the effects on watershed function, a moving windows analysis was conducted on BLM lands to look at the miles of roads that would be decommissioned and removed from the landscape for each alternative. During this analysis, it was assumed that even though closing roads would improve watershed function, closed roads would remain on the landscape and could still have negative impacts to water quality and prevent or impede the restoration of riparian vegetation. Under Alternative A, there would be 5,969 acres with low road density (**Table 4-59**), 4,665 acres with moderate road density, and 9,317 acres with high road density on BLM lands in the TPA. Alternative A would have fewer acres with low road density and more acres with high road density than the action alternatives. This alternative would be expected to have greater overall negative effects to watershed function due to roads than the action alternatives.

For this discussion, road miles within 300 feet of fish bearing streams on BLM lands would be considered an indicator of direct effects to fish habitat and fish populations. Under all alternatives, there would be 0.4 miles of closed road and 0 miles of open road within 300 feet of fish bearing streams. There are no roads (open or closed)

within 300 feet of streams containing special status fish species on BLM lands in the TPA.

Perennial non-fish bearing streams contribute to fish habitat indirectly by serving as conduits for watershed products (water, sediment, nutrients, contaminants, and in some cases woody material) (Meehan 1991 and Reid et al. 1994) to fish bearing streams (Forest Ecosystem Management Assessment Team 1993 and Takahi et al. 2002). Under Alternative A, there would be 0.7 miles of closed road and 2.0 miles of open road within 300 feet of perennial non-fish bearing streams on BLM lands in the TPA. Alternative A would have 1-1.3 more miles of open roads and 1-1.3 fewer miles of closed roads within 300 feet of perennial streams than the action alternatives.

This alternative would have the greatest negative impacts to fish and aquatic resources from open roads of all the alternatives.

### Effects of Alternative B

Under Alternative B, the East Helena TPA would have substantially fewer open roads (17 miles) compared to Alternative A (44 miles). Alternative B would have more open roads than Alternative C (12 miles) but less than Alternative D (38 miles). In the context of watershed function, Alternative B would have approximately 588 more acres in the low road density category and 381 fewer acres in the high road density category on BLM lands than Alternative A (Table 4-59). Alternative B would contribute to improved hydrologic function more than Alternative A. This analysis does consider “decommissioned” roads, but does not consider “closed” roads as contributing to watershed function. Even though closed roads could still have adverse effects to aquatic habitats, these roads have more potential to become revegetated and lessen sedimentation and runoff, and restore riparian vegetation (thus contributing to improved fish habitat conditions) than open roads. Under Alternative B, there would be approximately 15 more miles of closed roads than under Alternative A, an additional indication that Alternative B would pose less risk to fish habitat than Alternative A.

Effects associated with roads within 300 feet of fish bearing streams on BLM lands under Alternative B would be the same as under Alternative A. Alternative B would contribute fewer indirect effects to fish habitat associated with roads within 300 feet of perennial non-fish bearing streams on BLM lands than Alternative A. Under Alternative B there would be 1.8 miles of closed road and 0.9 mile of open road within 300 feet of perennial non-fish bearing streams on BLM lands in the TPA. Alternative A would leave 1.1 more miles open, and this same mileage less closed in these areas than Alternative B.

Overall, Alternative B would have fewer adverse effects to fish and aquatic habitats from increased fine sediment inputs, loss of large woody material, and loss of riparian vegetation than Alternative A.

### Effects of Alternative C

Under Alternative C, the East Helena TPA would have substantially fewer open roads (12 miles) compared to Alternative A (44 miles). Alternative C would have fewer, but similar, miles of open road as Alternative B (17 miles) and considerably less than Alternative D (38 miles).

In the context of watershed function, Alternative C would have approximately 531 more acres in the low road density category and 251 fewer acres in the high road density category on BLM lands than Alternative A (Table 4-59). This alternative would have 57 fewer acres in the low road density category and 130 more acres in the high road density category than Alternative B. Alternative C would contribute to improved hydrologic function more than Alternative A, but to a similar degree as Alternative B. This analysis does consider “decommissioned” roads, but does not consider “closed” roads as contributing to watershed function. Even though closed roads could still have adverse effects to aquatic habitats, these roads have more potential to become revegetated and lessen sedimentation and runoff, and restore riparian vegetation (thus contributing to improved fish habitat conditions) than open roads. Under Alternative C, there would be approximately 28 more miles of closed roads than under Alternative A, and about 13 more miles than under Alternative B.

Effects associated with roads within 300 feet of fish bearing streams on BLM lands under Alternative C would be the same as under Alternatives A and B.

Alternative C would contribute fewer indirect effects to fish habitat associated with roads within 300 feet of perennial non-fish bearing streams on BLM lands than all other alternatives. Under Alternative C there would be 2.0 miles of closed road and 0.7 mile of open road within 300 feet of perennial non-fish bearing streams on BLM lands in the TPA. This is a range of 0.2-1.3 more closed miles than the other alternatives. Alternatives C and B would have fewer negative effects to fish and aquatic habitats from fine sediment, loss of large woody material and loss of riparian vegetation compared to Alternative D and, especially, Alternative A.

### Effects of Alternative D

Under Alternative D, the East Helena TPA would have fewer open roads (38 miles) compared to Alternative A (44 miles). Alternative D would have considerably more open roads than Alternative B (17 miles) and Alternative C (12 miles).

With regard to hydrologic function, Alternative D is very similar to Alternative C. Alternative D would have approximately 533 more acres in the low road density category and 221 fewer acres in the high road density category on BLM lands than Alternative A (Table 4-59). This alternative would have 55 fewer acres in the low road density category and 160 more acres in the high

road density category than Alternative B. Alternative D would contribute to improved hydrologic function more than Alternative A. Under Alternative D, there would be approximately 3 more miles of closed roads than under Alternative A, about 12 miles less than under Alternative B, and about 25 miles less than under Alternative C. Since Alternative D would have fewer closed roads than Alternatives B and C, overall watershed function would be expected to be less under this alternative.

Effects associated with roads within 300 feet of fish bearing streams on BLM lands under Alternative D would be the same as under the other alternatives.

Alternative D would contribute fewer indirect effects to fish habitat associated with roads within 300 feet of perennial non-fish bearing streams on BLM lands than Alternative A. This alternative would have similar effects as Alternative B in this respect as it would leave 0.1 more mile of road open in these areas. Alternative D would have more road-related adverse effects to fish and aquatic habitats than Alternatives B and C, but would improve conditions over the current conditions in Alternative A.

### Cumulative Effects on Fish

The East Helena TPA supports a variety of native and introduced fish species. One of the major human influences to fish in the TPA has been the introduction of non-native trout species including rainbow trout, brook trout, and brown trout throughout the TPA and also Yellowstone cutthroat trout into Beaver Creek. Rainbow trout have hybridized with the native westslope cutthroat trout in many streams. Brook trout and brown trout have displaced the native cutthroats in other streams especially those altered by sedimentation and increased water temperatures brought on by human activities. Non-native fish stocking has eliminated native westslope cutthroat trout from much of its historic habitat in this TPA.

Damming of the Missouri River to create Holter Lake, Hauser Lake, and Canyon Ferry Reservoir dramatically altered aquatic habitat. Approximately 40 miles of the Missouri River were converted into lake habitat. These alterations, along with long-term stocking of non-native fish and other human-caused impacts have combined to replace native westslope cutthroat trout populations with non-native sport fisheries such as walleye, yellow perch, rainbow trout, and brown trout. These reservoirs now have multiple water quality impairments (see Water Resources section).

The East Helena Valley has been experiencing steady population growth. This trend is expected to continue, along with increased recreational use of this travel planning area. Primary recreation activities in the TPA include big game hunting, non-motorized uses (hiking, jogging, horseback riding, mountain biking, etc) and OHV uses (ATV, motorcycle).

Land development and urbanization has caused substantial impacts to watershed function in this TPA.

Agricultural activities from farming and ranching also contribute increases in nutrients, sedimentation, and loss of aquatic habitats. Many streams in the TPA have been impacted by historic and ongoing livestock grazing that breaks down streambanks, widens channels, removes vegetative cover, and causes an increase in fine sediment and nutrients.

Active mining claims are common in the area and there are active notices in the TPA, as well. Increases in mineral prices could lead to increased or renewed mining activity. Many watersheds and aquatic habitats in the TPA have been degraded by historic mining activities.

Fires, floods, and drought have historically affected fish habitat in the TPA. These disturbances can cause a pulse of sediment or may temporarily reduce the quality of fish habitat in some watersheds while leaving other streams largely unaffected (Reeves et al. 1995 and Dunham et al. 2003). Natural disturbances are typically followed by periods of stability, during which fish habitats and populations recover. Population recovery in disturbed streams may be facilitated by fish immigration from nearby drainages less affected by the catastrophic event (Dunham et al. 2003). From 1981-2004 there have been 18 wildland fires that burned 15,577 acres. Five of the fires were identified as human-caused and these fires burned the majority of the acres (15,535). The largest fire to occur from 1981-present was the 2000 Bucksnot Fire.

Timber harvest can alter the recruitment of large woody debris, reduce canopy closures and resulted in an increase in fine sediment to streams. Timber harvest along with associated roads can contribute substantially to the overall cumulative effects in forested watersheds. After the 2000 Bucksnot Fire, timber salvage occurred on approximately 250 acres of BLM lands as well as on private lands. Additional vegetation restoration may occur on BLM lands in the future. Vegetative treatments would be expected to be less under Alternatives A and C than Alternatives B and D. Overall, vegetative treatments on BLM lands have had minor effects to aquatic habitat in the TPA.

Roads are another major contributor of sediment to streams and a major problem with regards to cumulative watershed effects. Roads and trails can have localized effects on nearby stream segments or at stream crossing sites, especially fords. In some cases, effects are more extensive and may impair fish habitat for longer reaches of streams. Cumulatively, roads degrade aquatic habitat due to sedimentation from road construction and vehicle use, increased runoff, changes in surface water and drainage patterns from stream crossings, loss of riparian vegetation, loss of large woody material and roads can cause changes in local fish populations when culverts are impassable and limit fish migration. Alternative A

would have more negative cumulative effects to watersheds and individual streams due to roads than the action alternatives. Alternative B would have fewer negative cumulative effects than Alternatives A and D but more than Alternative C. Alternative B would improve overall watershed function as well as improve habitat in individual streams more than Alternatives A and D, and to a similar degree as Alternative C.

## SPECIAL STATUS PLANTS

### Effects Common to All Alternatives

Ground-disturbing activities from road construction and maintenance, as well as road use by vehicles can affect special status plant populations and habitat. These activities can reduce sensitive plant species through disturbance to individual populations, increasing competition from invasive species, and reducing habitat connectivity. Closure of roads and trails can improve or maintain sensitive plant populations or habitat by reducing avenues of noxious weed spread, maintaining habitat connectivity, and improving pollinator habitat. Road and trail restrictions have the same effects but to a lesser degree.

### Effects of the Alternatives

Under Alternative A, 36.6 miles of roads and trails would remain open, 7.7 miles of roads and trails would be open with seasonal restrictions, and 26.4 miles of roads and trails would be closed. On the open roads, effects would continue as described in the Effects Common to All Alternatives section. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators.

Under Alternative B, 13.7 miles of roads and trails would remain open, 3.3 miles of roads and trails would be open with seasonal restrictions, 41.9 miles of roads and trails would be closed, and 4.7 miles would be decommissioned. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The restricted roads would reduce weed spread a limited amount. By providing more closed and decommissioned roads, Alternative B would benefit and reduce risk to special status plants more than Alternative A.

Under Alternative C, 12 miles of roads and trails would remain open, 54.6 miles of roads and trails would be closed, and 4.0 miles would be decommissioned. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The restricted roads would reduce weed spread a limited amount. Alternative C would benefit and reduce risk to special status plants the most of all alternatives because it would eliminate disturbance, vehicular use, and spread of noxious weeds on the most road miles.

Under Alternative D, 36 miles of roads and trails would remain open, 1.9 miles of roads and trails would be open with seasonal restrictions, 29.7 miles of roads and trails would be closed, and 3.1 miles would be decommissioned. On the open roads, effects would continue as described in the Effects Common to All Alternatives section. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The restricted roads would reduce weed spread a limited amount. Alternative D would benefit and reduce risk to special status plants compared to Alternative A, but would pose more risk compared to Alternatives B and C.

### Cumulative Effects on Special Status Plants

Under all alternatives there are a number of past, present, and reasonably foreseeable future actions that affect special status plant populations.

Livestock grazing will continue in the area and has the potential to impact sensitive plant populations and habitat. On public lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain sensitive species populations and habitat. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided. Conditions may improve or degrade as management changes.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, sensitive plants would benefit from the reduced competition. Use of herbicides for noxious weed control could cause mortality to special status plants if individual plants are inadvertently sprayed.

Recent and anticipated subdivision growth on private lands will lead to more road construction and maintenance. More roads and development will reduce sensitive plant species habitat and in some cases individual populations. Additionally, subdivisions have the potential to disrupt the connectivity of plant habitat and populations as well as disturbing or eliminating pollinators needed by sensitive species. Some sensitive species that require soil disturbance may benefit.

Timber sale activity disturbance can destroy or degrade sensitive plant habitat. On public lands, projects would be designed to avoid, mitigate, or enhance sensitive plant habitats. The disturbance associated with timber harvest activities does have the potential to increase noxious weed spread which degrades sensitive species habitat and individual plant populations.

The Bucksnot fire of 2000 burned a large portion of the Spokane Hills. The burn encouraged a lot of noxious weed spread, particularly Dalmatian toadflax on south facing slopes, which degraded sensitive plant habitat.

Conifer encroachment into grassland habitats was reversed by the fire thus restoring grassland habitat that could benefit some special status plant species.

At the scale of the entire East Helena TPA (all land ownerships), the BLM travel plan alternatives would have slightly variable contributions to cumulative effects on special status plants. Under Alternative A approximately 3 percent of all roads in the TPA would be closed. Under Alternative B adverse effects on special status plants would be slightly reduced compared to Alternative A because 5.2 percent of all roads in the TPA would be closed or decommissioned. Alternative C would provide the most benefits of all alternatives as 6.6 percent of all roads in the TPA would be closed or decommissioned. Alternative D would provide slightly more benefits than Alternative A but slightly fewer benefits than either Alternatives B or C as 3.7 percent of all roads in the TPA would be closed or decommissioned. Because BLM lands make up only 10 percent of the area in the TPA, activities on non-BLM lands would play a greater role in determining the status of special status plants.

## WILDLAND FIRE MANAGEMENT

Travel planning alternatives were analyzed to determine whether they could result in impact on wildland fire management, causing change to any of the following indicators:

- Fire regime condition class (FRCC)
- Firefighter and public safety
- Reducing threat to Wildland Urban Interface (WUI)

### Effects Common to All Alternatives

Public road access during the fire season provides opportunities for human-caused fires either due to catalytic converters on vehicles igniting dry vegetation, or due to some types of human activities. Roads that are closed to public access reduce the risk of human-caused fire starts in those areas.

Decommissioned roads and roads that are closed and not regularly maintained for navigability reduce access for fire suppression. Closed roads may become impassible due to vegetation regrowth, downfall of trees, or severe erosion. Some roads may be closed with earthen berms or fallen trees and would need to be physically manipulated to make them useable for vehicles again. These roads would extend firefighting response time and have negative impacts on efforts to reduce wildland fire threat to WUI areas and firefighter and public safety. In an emergency fire suppression situation, any navigable closed roads needed for fire suppression would be used immediately. Non-navigable closed roads could also be used if deemed to be needed for fire suppression, after needed improvements are made to make those roads useable. Planning and implementation of fuels reduction

treatments could occur in association with closed roads if variances for temporary road use were to be allowed. Variances would be subject to internal BLM review.

In the context of fuels reduction projects, availability of open roads is important to facilitating fuels project location as well as increasing project feasibility and decreasing costs. Open roads also facilitate spread of noxious weeds by transporting weed seed on vehicles and their tires. Presence of large noxious weed populations could delay or cause fuels projects to be cost-prohibitive due to the fact that the weeds may have to be treated before and/or after the fuels treatment. Also, some applications of fuel treatments (e.g., prescribed fire) may promote the spread of some weeds. The presence of weeds and non-native species are indicators that FRCC has departed from historical conditions.

Noxious weeds and non-native invasive species are well established and spreading in the East Helena TPA.

### Effects of Alternative A

Alternative A provides more motorized opportunities than non-motorized opportunities. Under Alternative A, a total of 44.3 miles of wheeled motorized routes would continue to be open (36.6 open yearlong, 7.7 miles seasonally restricted), while 26.4 miles (37 percent of total) would continue to be closed. Alternative A would allow for the greatest flexibility between alternatives for access for suppression purposes. Fuels project feasibility would be highest under this alternative. However, public access during the fire season would be the greatest under this alternative and would provide the most opportunities for human-caused fire starts.

The distribution of noxious weeds could be the greatest under alternative A with the most open roads and noxious weeds already well established. This would contribute to reduced feasibility of fuels reduction projects more than under any other alternative.

### Effects of Alternative B

Alternative B provides for separate use areas for wheeled motorized and non-motorized recreational opportunities. Under Alternative B, 13.7 miles of wheeled motorized routes would be available yearlong and 3.3 miles would be seasonally restricted. Alternative B would limit the flexibility for access for suppression purposes, and fuels project feasibility would go down compared to Alternative A due to the fact that motorized access would be limited to 17 miles of road. Of the 46.3 miles of closed roads, 4.7 miles would be decommissioned and would likely be unusable for fire suppression. The risk of human-caused fires associated with motorized use would be limited compared to Alternative A, due to a 28 percent decrease in miles of road open to motorized public travel compared to Alternative A.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Motorized

activities play a large role in the distribution of noxious weeds. Because more roads would be closed under this alternative, Alternative B should help reduce the spread of noxious weeds and may make fuels treatments more feasible than under Alternative A, reducing FRCC departure.

### Effects of Alternative C

Alternative C would provide the least amount of wheeled motorized access in the East Helena travel planning area. Under Alternative C, 12.0 miles of wheeled motorized routes would be available yearlong.

Alternative C would limit the flexibility for access for suppression purposes, and fuels project feasibility would go down compared to both Alternatives A and B, due to the fact that access would be limited to 12 miles of road. Of the 58.6 miles of closed roads, 4.0 miles would be decommissioned and would likely be unusable for fire suppression. The risk of human-caused fires associated with motorized use would be the lowest of all alternatives, due to a 45 percent decrease in open road miles compared to Alternative A. However, this degree of reduced motorized access may promote more non-motorized users to a concentrated area, increasing the odds for a human-caused fire to occur by another ignition source.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because more road miles would be closed than under any other alternative, Alternative C should help reduce the spread of noxious weeds more than under any other alternative, and may make fuels treatments more feasible, reducing FRCC departure.

### Effects of Alternative D

Under Alternative D, 36 miles of open routes would be available yearlong for wheeled motorized use and 1.9 miles would be seasonally restricted. Of the 32.8 miles of closed roads, 3.1 miles would be decommissioned and would likely be unusable for fire suppression. Alternative D would be more flexible than Alternatives B and C, but it would limit flexibility for access for suppression purposes, and fuels project feasibility would go down compared to Alternative A. The risk of human-caused fires associated with motorized vehicle use would be reduced compared to Alternative A, but would be greater than under Alternatives B and C, due to a 9 percent decrease in open roads compared to Alternative A.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because an intermediate number of road miles would be closed under this alternative, Alternative D should help reduce the spread of noxious weeds and may make fuels treatments more feasible than under Alternative A, but would increase weed spread and potentially make projects less feasible than under Alternatives B or C.

## Cumulative Effects on Wildland Fire Management

Effects on wildland fire management associated with any of the BLM travel plan alternatives would be overshadowed by reasonably foreseeable uncharacteristic fire, continued fire suppression made necessary by WUI and intermingled landownership, and large-scale forest insect infestations and disease outbreaks that would continue for the planning period. BLM lands make up about 10 percent of all lands while BLM roads make up about 8 percent of all roads in the TPA.

Revision of the Helena National Forest Plan could result in more or less treatment of adjacent areas. Because no decision has been made, the effects are not known. Wildland fire management, particularly where wildland fire use (management of naturally ignited wildland fires to achieve resource objectives) may occur on USFS lands, will be determined in the plan decision. BLM would need to coordinate with USFS on all wildland fire use actions and events. Wildland fire use on USFS lands could affect FRCC on BLM lands. USFS lands make up 6.6 percent of all lands in the TPA.

Additionally, decisions to increase the level of wildland fire use, prescribed fire, or open burning by the public could impact the BLM's ability to use wildland fire and prescribed fire due to air quality concerns and requirements. This could postpone or eliminate BLM fuel reductions or treatments to improve FRCC.

Access is a critical component of wildland fire suppression. In some cases, access to public lands is being reduced by adjacent landowners gating or closing roads, which could hamper wildland fire suppression efforts and pose a risk to public and firefighter safety. Reducing access would also increase the potential for larger fires to occur due to an increase in time needed to access a fire and control it. Time needed to move in crews would be extended, and the ability to effectively apply and place resources (e.g., engines, water tenders, etc.) would be limited.

Effects on wildland fire management, including FRCC and firefighter and public safety due to management accomplished by other landowners may affect wildland fire management on public lands. When activity fuels (such as logging slash) are not treated adequately, fuel hazard could increase on adjacent lands which could affect fire intensity and severity on public lands. When adjacent owners treat fuels or implement fire mitigation plans in the WUI, fires are easier to suppress and firefighter safety is increased. In this TPA, activities on private lands (64 percent of all lands in TPA) would have more influence on future fire characteristics in the area overall than activities on BLM lands (10 percent of all lands in TPA).

Human population increases and subsequent residential development are likely to expand the WUI and could

alter forest management, taking the emphasis off restoring historic composition and structure and focusing more on fuel reduction.

## **CULTURAL AND PALEONTOLOGICAL RESOURCES**

### **Effects Common to All Alternatives**

Alternative-specific risks or impacts to cultural and paleontological resources are difficult to discern due to a lack of extensive site-specific knowledge about the presence of these resources in a given TPA. By designating open routes, limiting open-country travel, and closing some routes, inadvertent discovery of cultural and paleontological resources and vandalism to them is reduced. Higher road densities in a given area would allow greater access to more land on the average, but that does not imply greater amounts of vandalism, since the vehicles would remain on designated routes.

## **VISUAL RESOURCES**

### **Effects Common to All Alternatives**

Roads (temporary or permanent) may affect visual quality. Roads that remain open for public use may impact visual qualities where noticeable. The quantity of open roads would also influence sensitivity levels since with more open roads, more areas would generally be viewed by more members of the public. Closing or decommissioning roads would generally reduce effects to visual resources and reduce sensitivity levels because fewer members of the public would generally be accessing and viewing areas with closed roads.

### **Effects of the Alternatives**

Under Alternative A, 44.3 road miles would be open (including open with seasonal restrictions), 26.4 miles would be closed. Alternative A would have the greatest impact on visual resources of all alternatives.

Under Alternative B there would be 17 miles of open road (including roads open with seasonal restrictions), 41.9 miles of closed road, and 4.7 miles of decommissioned road. Additional road closures and decommissioning under this alternative would reduce effects on visual resources compared to Alternative A.

Under Alternative C there would be 12 miles of open road, 54.6 miles of closed road, and 4 miles of decommissioned road. Alternative C would have fewer adverse effects and would improve visual resources the most of all alternatives.

Under Alternative D there would be 38.6 miles of open road (including roads open with seasonal restrictions), 29.7 miles of closed road, and 3.1 miles of decommissioned road. Effects to visual resources would be similar but slightly less than under Alternative A, the greater than under Alternatives B and C.

## **Cumulative Effects on Visual Resources**

Under all alternatives, most activities on BLM lands would generally not adversely affect visual resources to unacceptable degrees because discretionary activities on BLM lands would be required to meet Visual Resource Management objectives within individual project areas.

Activities on non-BLM lands, particularly activities near BLM lands associated with residential development, urbanization, or vegetation management, could have adverse cumulative effects on visual resources on BLM lands because BLM VRM objectives would obviously not apply to non-BLM activities.

## **LIVESTOCK GRAZING**

### **Effects Common to All Alternatives**

Roads and trails can potentially affect livestock grazing management. Roads and trails often act as avenues of noxious weed spread. Noxious and invasive weeds can reduce the quantity and quality of forage for livestock. Users of roads and trails can cause management problems for livestock permittees when they leave gates open at fences, vandalize range improvements, or harass livestock either purposely or unintentionally.

Closure of roads and trails can improve or maintain the forage base by reducing vectors of noxious weed spread. Additionally, road and trail closures can reduce management conflicts. On the other hand, closures may increase permittees' time requirements if and when work has to be conducted with horses or afoot. Permittees could minimize effects of closed roads on grazing management time by seeking variances from the BLM for temporary use of specific closed roads.

### **Effects of the Alternatives**

Under Alternative A, 44.3 miles of roads and trails would remain open during grazing season, and 26.4 miles of roads and trails would be closed. Effects would continue as described in the Effects Common to All Alternatives section. All action alternatives would close or decommission more roads and trails than Alternative A. As more roads and trails are closed, noxious and invasive weed spread along with multiple user conflicts would be reduced. On the other hand, permittee management time may increase. Consequently, more effects as described under the Effects Common to All Alternatives section would occur under Alternative C (12 miles open, 58.6 miles closed or decommissioned) than under any other alternative. Alternative B (16 miles open during grazing season, 46.6 miles closed or decommissioned) would produce fewer effects than Alternative C, but more than Alternative A or Alternative D (38 miles open during grazing season, 32.8 miles closed or decommissioned). Alternative D would have fewer effects than Alternatives B or C, but more than Alternative A.

## Cumulative Effects on Livestock Grazing

A number of past, present, and reasonably foreseeable future actions affect livestock grazing at the scale of the entire East Helena TPA. Livestock grazing will continue in the area and has the potential to impact forage quality and quantity. On public lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain forage quality and quantity. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, forage conditions would benefit.

The Bucksnot fire of 2000 burned a large portion of the Spokane Hills. The burn encouraged a lot of noxious weed spread, particularly Dalmatian toadflax on south facing slopes. On the other hand, many grasslands were improved with the reduction of conifers; forage production for livestock increased substantially.

Because BLM lands make up only 11 percent of all lands in the East Helena TPA, all of the BLM travel plan alternatives would have a minimal contribution to cumulative effects on livestock grazing at the scale of the entire TPA.

## MINERALS

### Effects Common to All Alternatives

Road closures and decommissioning could affect access to locatable minerals in areas of moderate or high mineral potential. Operators would be required to seek travel variances from the BLM to use motor vehicles to conduct mineral exploration on closed roads, or to conduct exploration on seasonally restricted routes during the season of closure. Decommissioned roads could not be used for motorized exploration. Travel management provisions that require a permit or variance could result in reducing access to mining claims or interfere with the ability to conduct exploration work for some operators. Historic knowledge of mineralized areas associated with “closed” roads may be lost after long periods of time if no exploration occurs there. Additional costs and time could be required for exploration and development of mining projects associated with closed or decommissioned roads. Impacts of road closures or decommissioning in areas with low mineral potential would not be substantial to mineral development.

### Effects of the Alternatives

Effects of the alternatives for the East Helena TPA on access to mineralized areas are summarized in **Table 4-64**. Alternative A would close 18 percent of the roads in high mineral potential areas.

Alternative B for the East Helena area travel plan would seasonally restrict 7 percent and would close 15 percent of the roads in high mineral potential areas (**Table 4-64**). Alternative B would have more impacts than Alternative A.

Alternative C would close 22 percent of the roads in areas with high mineral potential and 1 percent of those with moderate mineral potential (**Table 4-64**). Alternative C would have the most potential to affect access to mineralized areas of all the alternatives.

Alternative D would seasonally restrict 3 percent, and close 9 percent of the roads in areas with high mineral potential (**Table 4-64**). Alternative D would more impacts than Alternative A, but less than Alternatives B and C.

<b>Table 4-64</b>				
<b>Analysis of Access to Mineral Potential Areas</b>				
<b>East Helena TPA</b>				
<b>Mineral Potential</b>	<b>Open Miles (%)</b>	<b>Seasonally Restricted Miles (%)</b>	<b>Closed Miles (%)</b>	<b>Decom Miles (%)</b>
<b>Alternative A</b>				
High	8.8 (12%)	0.0 (0%)	12.4 (18%)	0.0 (0%)
Moderate	1.3 (2%)	0.1 (0%)	0.0 (0%)	0.0 (0%)
Low	26.5 (37%)	7.6 (11%)	14.0 (20%)	0.0 (0%)
Total Miles = 70.7				
<b>Alternative B</b>				
High	6.0 (8%)	4.8 (7%)	10.5 (15%)	0.0 (0%)
Moderate	0.5 (1%)	0.8 (1%)	0.1 (0%)	0.0 (0%)
Low to none	7.2 (10%)	4.8 (7%)	31.3 (44%)	4.7 (7%)
Total Miles = 70.7				
<b>Alternative C</b>				
High	5.4 (8%)	0.0 (0%)	15.8 (22%)	0.0 (0%)
Moderate	0.7 (1%)	0.0 (0%)	0.8 (1%)	0.0 (0%)
Low to none	6.0 (8%)	0.0 (0%)	38.0 (54%)	4.0 (6%)

<b>Alternative D</b>				
High	12.9 (18%)	1.9 (3%)	6.5 (9%)	0.0 (0%)
Moderate	1.4 (2%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Low to none	21.7 (31%)	0.0 (0%)	23.2 (33%)	3.1 (4%)
Total Miles = 70.7				

Mineral Potential areas have been delineated by the Montana Bureau of Mines and Geology (MBMG)

## Cumulative Effects on Access to Mineralized Areas

No other past, present, or reasonably foreseeable future actions in the East Helena TPA would adversely affect mineral availability or access.

Overall, there is low potential for leasable fluid mineral development throughout federal mineral estate lands in the Butte Field Office. However, in this context, the Reasonably Foreseeable Development Scenario for the Butte RMP identified approximately 13,492 acres of federal mineral estate lands in this TPA where oil and gas development potential is slightly higher (low to moderate) and may potentially occur. Potential contribution of this activity to cumulative effects for other resources would be unknown until this activity is site-specifically planned.

## RECREATION

Effects of travel plan alternatives on Recreation in the East Helena TPA are described qualitatively below.

### Effects of Alternative A

Alternative A would provide more motorized opportunities than non-motorized opportunities. Under Alternative A, a total of 44.3 miles of wheeled motorized routes would be open (36.6 miles open yearlong, 7.7 miles seasonally restricted). With the exception of the Ward Ranch, McMasters, and Spokane Hills temporary area closures, the remainder of the travel planning area would remain available to cross-country area snowmobile use, as well as travel on all existing routes during the season of use (12/2-5/15), conditions permitting.

### Effects of Alternative B

Alternative B would provide for separate use areas for wheeled motorized and non-motorized recreational opportunities. Under Alternative B, 13.7 miles of wheeled motorized routes would be available yearlong, and 3.3 miles would be seasonally restricted. Cross-country snowmobile travel would be allowed, as well as travel on all existing routes during the season of use (12/2-5/15), except for the North Hills, Dana's Bar, and the area located to the west of Prickly Pear Creek. The remainder of the travel planning area (McMasters Hills, Ward Ranch, and Spokane Hills) would be closed to all cross-country snowmobile use, including travel on existing roads and trails. Conflicts between non-motorized users (cross-country skiers, snowshoers) and snowmobilers would be expected to continue or increase in areas with shared use.

### Effects of Alternative C

Alternative C would provide the least amount of wheeled motorized access in the East Helena travel planning area of all alternatives. Under Alternative C, 12.0 miles of wheeled motorized routes would be avail-

able yearlong. No cross-country snowmobile use would be allowed; use would be restricted to designated routes only during the season of use (12/2-5/15), snow conditions permitting. This would likely reduce conflicts with non-motorized winter users (cross-country skiing, snowshoeing).

### Effects of Alternative D

Alternative D would provide the highest level of motorized access and the fewest non-motorized opportunities of the action alternatives. Under Alternative D, 36.0 miles of wheeled motorized routes would be available yearlong, and 1.9 miles would be seasonally restricted. Snowmobile management under would be as follows: cross-country travel would be allowed, as well as travel on all existing routes during the season of use (12/2-5/15), for the North Hills, Dana's Bar, and the area located to the west of Prickly Pear Creek. The Ward Ranch and the Big Bend areas would be closed to all cross-country snowmobile use as well as travel on designated routes.

### Cumulative Effects on Recreation

Under Alternative A, motorized travel opportunities would be the greatest under this alternative given the miles of roads available to wheeled vehicles and the acres available to snowmobile use. Big game hunting opportunities within the North Hills, McMaster Hills, Ward Ranch and Spokane Hills would continue. Existing travel restrictions in these areas would encourage big game retention, quality walk-in hunting and game retrieval challenges as motorized vehicle use would be limited. During the non-hunting season conflicts between non-motorized and motorized users would remain relatively high within the North Hills. Public access and management of developed recreation sites along the Missouri River would continue to provide for a wide spectrum of water based opportunities and visitor trends are expected to increase. The newly constructed 30-unit campground and day-use facility at White Sandy on lower Hauser Lake scheduled to be open 5/25/07 will help meet growing visitation needs and better distribute use on the 15-mile lake.

Under Alternative B, motorized travel opportunities would be decreased while non-motorized opportunities would be enhanced overall. Big game hunting opportunities within the North Hills, McMaster Hills, Ward Ranch, and Spokane Hills would continue. Additional travel restrictions in these areas would promote more big game retention on public lands and better walk-in hunting experiences. Opportunities for individuals who are physically challenged would be improved in the Spokane Hills. In addition, game retrieval would be enhanced since motorized routes would be provided in the Spokane Hills. More emphasis would be placed on maintaining undeveloped open space areas for dispersed recreation. Given the increasing development pressures on adjoining private lands throughout the Missouri River

corridor, it is anticipated that these open areas will be more important with time. Use levels within the North Hills are expected to increase while conflicts between non-motorized and motorized users should be reduced. Although available travel routes and motorized riding opportunities would be limited, access to higher elevation lands and quality walk-in areas would be retained to help disperse users and ensure natural settings. Cumulative impacts on developed recreation sites and water based activities would be similar to Alternative A.

Alternative C would impose the greatest impacts on motorized travel opportunities while opportunities for non-motorized experiences would be the most benefited. Recreation Opportunity Spectrum management and big game hunting opportunities within the TPA would be similar to Alternative B with the exception that no motorized routes would be provided for big game retrieval or handicapped hunting in the Spokane Hills. Cumulative impacts on developed recreation sites and water based activities would be similar to Alternative A.

Under Alternative D, cumulative effects of the travel management actions coupled with all other existing and reasonably foreseeable actions would be similar to Alternative A.

## TRAVEL MANAGEMENT AND ACCESS

### Effects of Alternative A

Under Alternative A in the East Helena TPA, there would be 36.6 miles of BLM road open yearlong, 7.7 miles open with seasonal restrictions, and 26.4 miles of closed roads (Table 4-65). Alternative A would provide for the greatest degree of motorized opportunities, and the lowest degree of non-motorized opportunities of all alternatives. With the exception of the Ward Ranch, McMasters, and Spokane Hills temporary area closures, the remainder of the TPA would remain available to cross-country area snowmobile use, as well as travel on all existing routes during the season of use (12/2-5/15), conditions permitting.

The extent of management activities and costs under Alternative A would be mixed. Less personnel time would be required to monitor travel compliance than

under any alternative. However, more effort would be required for initial implementation (signing designated routes, installing bulletin boards) than under any other alternative. Estimated costs for road/trail maintenance would be highest of all alternatives.

The need for BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be minimal under this alternative, given the availability of motorized access.

### Effects of Alternative B

Alternative B in the East Helena TPA would help provide separate use areas for wheeled motorized and non-motorized recreational opportunities. Motorized access in the North Hills area would decrease compared to Alternative A (Table 4-65). Other than route 516, the primary access route to a non-motorized trailhead in the North Hills, the remaining road network would be seasonally restricted to prevent soil erosion. The result of these management actions would increase opportunities for non-motorized users and enhance their enjoyment through the increase in trails exclusively for hiking, mountain biking, horseback riding, and other non-motorized activities.

Under Alternative B, cross-country snowmobile travel would be allowed, as well as travel on all existing routes during the season of use (12/2-5/15), for the North Hills, Dana's Bar, and the area located to the west of Prickly Pear Creek. The remaining areas (McMasters Hills, Ward Ranch, and Spokane Hills) would be closed to all cross-country snowmobile use, including travel on existing roads and trails. Conflicts between non-motorized users (cross-country skiers, snowshoers) and snowmobilers would be expected to continue or increase in areas with shared use.

Motorized access for the McMasters area would be reduced compared to Alternative A.

One additional non-motorized trailhead would be established in the Big Bend area, increasing opportunities for hiking, horseback riding, and other non-motorized pursuits.

Opportunities for disabled hunters would increase compared to the other alternatives. Motorized access to the southern portion of the Spokane Hills would be allowed for hunters with a disability for a two-week period each year. These same motorized routes would be available during the general hunting season for game retrieval opportunities.

Route closures across 60 percent of the area would reduce unauthorized travel (illegal off-road use by ATVs and motorcycles) and illegal activities (underage alcohol use, drug use, vandalism, dumping) in the North Hills and elsewhere.

The reduction in motorized use under Alternative B would enhance safety among users of the East Helena

Proposed Management	Total Miles			
	Alt A	Alt B	Alt C	Alt D
<b>Wheeled motorized routes</b>				
Open Yearlong	36.6	13.7	12.0	36.0
Seasonally Restricted	7.7	3.3	0	1.9
Closed	26.4	41.9	54.6	29.7
Decommissioned	0	4.7	4.0	3.1
Non-motorized trails <sup>1</sup>	26.4	47.1	59.1	32.6

<sup>1</sup> Non-motorized trails include all existing trails, closed roads, and decommissioned roads.

TPA, compared to Alternatives A and D, and to a similar extent as under Alternative C.

Trailhead development costs would be greater under Alternative B than under Alternative A due to the development of new non-motorized trailheads in the North Hills and Big Bend areas.

The extent of management activities and costs under Alternative B would be mixed. Less personnel time would be required for initial implementation (signing designated routes, installing bulletin boards) than under Alternative A. However, more effort would be required for public education and compliance than under Alternative A. Estimated costs for road/trail maintenance would be less than under Alternative A.

The need for BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be greater under Alternative B than under Alternative A.

### Effects of Alternative C

Alternative C would provide the least amount of wheeled motorized access in the East Helena TPA of all alternatives. The area would feature only 12.0 miles of motorized access under Alternative C, which is about 73 percent less than under Alternative A, and 29 percent less than Alternative B (**Table 4-65**).

Closure and decommissioning of routes in the East Helena TPA would result in an increase in non-motorized opportunities with a corresponding decrease in motorized opportunities. Alternative C would provide 55 percent more miles of non-motorized trails than Alternative A, and 20 percent more than Alternative B.

No cross-country snowmobile use would be allowed. Use would be restricted to designated routes only during the season of use (12/2-5/15), snow conditions permitting. This would likely reduce conflicts between snowmobilers and non-motorized winter users (cross-country skiing, snowshoeing).

Having routes 0516A and 0516 provide the only motorized access to the North Hills would result in decreased motorized opportunities but increased opportunities for non-motorized recreation (and low levels of conflict).

Keeping route 050133A closed at its current location (regardless if the Ward Ranch is vacated in the future) would result in fewer motorized opportunities in the Ward Ranch area than under Alternative B. However, non-motorized opportunities would increase under Alternative C because visitors could park at the current motorized closure area, and walk approximately 0.25 mile to the ranch complex.

Motorized access to the McMasters area would be the same under Alternatives B and C, representing a reduction in motorized use to the area compared to Alternative A.

Allowing motorized access to only the primary residential access routes in the Prickly Pear Creek area (south of Black Sandy) and no motorized access in the Big Bend area would result in an increase in non-motorized recreational opportunities in both these areas. Motorized access for these areas would be more restricted under Alternative C than under all other alternatives.

Restricting motorized access in the Spokane Hills area to a non-motorized trailhead at the end of route EH07A would result in an increase in non-motorized opportunities in this area. Alternative C would be more restrictive than the other alternatives and would result in a decrease in motorized opportunities in this area.

Not developing a non-motorized trailhead in the Big Bend area would result in a decrease in travel management costs under Alternative C compared to Alternative B.

The extent of management activities (and costs) under Alternative C would be mixed. Less personnel time would be required for initial implementation (signing designated routes, installing bulletin boards) than under any other alternative. However, more effort would be required for public education and compliance than under any other alternative. Estimated costs for road/trail maintenance would be the lowest of the alternatives.

The need for BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be greater under Alternative C than under any other alternative.

### Effects of Alternative D

Alternative D would provide the highest level of motorized access in the East Helena TPA of the action alternatives, featuring approximately 33 percent more open routes than under Alternatives B and C (**Table 4-65**). All of the designated routes would be available for motorized use in the North Hills compared to the seasonally restricted closures under Alternatives A, B, and C. Snowmobile management under Alternative D would be as follows: cross-country travel would be allowed, as well as travel on all existing routes during the season of use (12/2-5/15), for the North Hills, Dana's Bar, and the area located to the west of Prickly Pear Creek. The Ward Ranch and the Big Bend areas would be closed to all cross-country snowmobile use as well as travel on designated routes. Opportunities for snowmobile use would be less than under Alternative A, but greater than under Alternatives B and C.

Alternative D would not minimize or reduce conflicts between motorized and non-motorized recreation in the North Hills, where conflicts are most evident within the East Helena TPA, because dispersed recreational opportunities would not be provided. User conflict would be greater under Alternatives A and D than Alternatives B and C.

Increasing motorized access in the McMasters area by adding a new loop route would result in increased opportunities for motorized vehicle users. Reducing the number of non-motorized trailheads would result in a decrease in non-motorized opportunities in this area.

Increasing motorized access west of Prickly Pear Creek, in the Big Bend area, the Spokane Hills, and in the Townsend area would result in increased motorized opportunities. Conflict between motorized and non-motorized users would increase as well.

Relocating the trailhead in the Spokane Hills would result in increased travel management costs compared to Alternative A.

The extent of management activities and costs under Alternative D would be mixed. Less personnel time would be required to monitor travel compliance than under Alternatives B and C, but slightly more would be needed than under Alternative A. However, more effort would be required for initial implementation (signing designated routes, installing bulletin boards) than under Alternatives B and C, but less would be needed than under Alternative A. Estimated costs for road/trail maintenance would be higher than under the other action alternatives.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be greater under Alternative D than under Alternative A, but less than under Alternatives B and C.

## Cumulative Effects on Travel Management and Access

Under all alternatives, there are a number of past, present, and reasonably foreseeable future BLM and non-BLM actions and activities affecting travel management and access in the East Helena TPA.

East Helena Valley has been experiencing steady human population growth. This trend is expected to continue, along with increased recreational use of this travel planning area. These factors could lead to increased public pressure to alter travel planning to accommodate either more, or less motorized use.

The majority of BLM managed routes for the East Helena Travel Planning area are located in or adjacent to the McMaster Hills/Spokane Bay, Mt. Bend, and North Hills sub-planning areas. As with the Scratchgravel Hills (Helena TPA), these areas are surrounded by residential development, and have experienced steady residential development over the past 15-20 years. This combination of rapid urbanization and increased recreational use has led to increased social conflict; between area residents and recreation users, and among recreational users themselves (motorized/non-motorized). As a result, there have been public demands to alter the existing travel management for these areas, to accommodate either

more, or less motorized use. The remaining routes for the TPA are located in the Spokane Hills and Townsend sub-travel planning areas. The Spokane Hills and Townsend sub-travel planning areas are more rural in character, but also have potential for urbanization.

Recreation use is well established in the TPA. Primary recreation activities include water based activities, big game hunting, non-motorized uses (hiking, jogging, horseback riding, mountain biking, etc.), and OHV uses (ATV, motorcycle). As recreation use grows, conflicts between non-motorized and motorized recreation users could lead to increased public demands for either more, or less motorized use.

Spokane Creek (Hauser Lake) is an important habitat for spawning fish. Portions of the TPA (North Hills, areas adjacent to Canyon Ferry and Hauser Lakes) provide winter range for mule deer and elk. Concerns could lead to demands to restrict motorized use in these areas.

The Lewis and Clark National Historic Trail, proposed Spokane Creek ACEC, and Missouri River eligible WSR segment (3 mile portion located below Hauser Dam) being considered in the RMP revision are located within the TPA. These special designations could influence (restrict) travel management for existing roads and trails as well as for new proposed roads and trails.

In some site specific cases, visual resource management may affect or restrict new road/trail construction.

Urban development may lead to an increase in right-of-way permits to accommodate private property/development access. As a result, public access to BLM lands, via these rights-of-ways, could increase as well.

Limits or reductions in the BLM's funding and ability to maintain designated routes could lead to an overall reduction in open road miles.

A variety of resource management projects, such as BLM initiated vegetation treatments, or wildland fire fuels reduction projects, could affect travel management. Forest management activities from 1984 to present include 250 acres of fire replanting and 250 acres of timber salvage. Future wildland fire management activities include a 500-1,500 acre mechanical and/or prescribed fire treatment for the North Hills, focused on the urban interface areas. This project is anticipated to begin in 2009, and last several years. Depending on the type and scope of project, effects could vary from temporary, short-term area/route closures, to new opportunities (new routes) for motorized or non-motorized access.

Active claims are common in the areas with high potential and there are active notices in the travel planning area as well. Increases in mineral prices could lead to increased or renewed mining activity. Depending on the type and scope of mining activity, effects could vary from temporary, short-term area/route closures, to in-

creased opportunities (new routes) for motorized or non-motorized access.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Motorized activities play a large role in the distribution of noxious weeds. Concerns over the spread of noxious weeds could influence travel management, and lead to fewer motorized opportunities.

Motorized use on dirt roads and trails is a major contributor to soil erosion and stream sedimentation. These concerns may influence travel management, and result in fewer motorized opportunities. This is an important consideration in the East Helena area as the Montana Department of Environmental Quality is working on water quality restoration plans in the area.

Trash dumping, drug use, underage alcohol use, unattended camp fires, and vandalism occur throughout the travel planning area, but especially in the rural/urban interface areas. Most of these activities are directly associated with motorized use. Continuing concerns with illegal activities may influence travel management and lead to fewer motorized opportunities.

The Bureau of Reclamation (BOR) manages approximately 11,500 acres of land surrounding Canyon Ferry Reservoir. BOR actions (such as new recreation site developments) could influence travel management on adjacent BLM lands as well, exerting pressure for either more or less motorized access.

For perspective, BLM managed lands represent approximately 10 percent of the total travel planning area (200,991 total acres, 20,039 BLM acres); while BLM managed routes represent approximately 8 percent of the total routes available (892.2 total miles, 70.7 miles BLM roads/trails). Future travel management (for all agencies, nationwide) is likely to lead to fewer opportunities for motorized recreational use than under current management (particularly for OHV use).

As a result, BLM routes available to motorized use could experience increased use from displaced users, leading to more concentrated use, increased resource impacts, user conflicts, and pressure to reduce motorized use.

Under all alternatives, overall increases in human population, urbanization, recreation use, user conflicts; and concerns for wildlife, noxious weed spread, soil erosion/water quality, and illegal activities are likely to lead to increased demands to restrict motorized travel, particularly in areas with urban development, such as the McMaster Hills/Spokane Bay, Mt. Bend, and North Hills areas. Under Alternative A, as urbanization continues and both motorized (wheeled and snowmobile) and non-motorized use increases, user conflict would increase in the East Helena TPA. Under the action alternatives, separate use areas and decreased road density would reduce user conflicts. Under Alternative B, these

pressures would have less impact on travel management than under Alternatives A and D, due to the overall reduction in motorized opportunities and separation of uses. Under Alternative C, these pressures would have the least impact on travel management than under the other alternatives, due to the reduction in motorized opportunities. Under Alternative D, these pressures may lead to increased demands to restrict motorized travel, particularly in areas with urban development, such as the McMaster Hills/Spokane Bay, Mt. Bend, and the North Hills areas.

## TRANSPORTATION FACILITIES

For the sake of this discussion, “open” roads include roads that are open yearlong as well as those that are open with seasonal restrictions.

### Effects of Alternative A

Under Alternative A, the East Helena TPA would have 44.3 miles of open roads and no motorized trails (**Table 4-66**). Estimated costs for annual maintenance and stabilization of roads under Alternative A would be similar to Alternative D and much less than under Alternatives B and C. Estimated annual costs for monitoring, compliance and weed control would be higher than under the action alternatives, but close to the same as under Alternative D.

### Effects of Alternative B

Under Alternative B, the East Helena TPA would have 17 miles of open roads and no motorized trails (**Table 4-66**). Estimated costs for annual maintenance and stabilization of roads under Alternative B would be less than under Alternatives A and D but more than under Alternative C. Estimated annual costs for monitoring, compliance and weed control would also be less than under Alternatives A and D but more than under Alternative C.

The addition of a non-motorized trailhead at the end of route 50108 in the North Hills and on the ridge top near the end of EH 037 in the Big Bend area would result in an increase in transportation facility costs for trailhead development and maintenance. Designation of the “hunters with a disability” access in the South Hills would also represent an increase in transportation facility costs for signage and sign maintenance. These increases would be offset by reduced costs associated with having fewer open road miles to maintain in the long-term.

### Effects of Alternative C

Under Alternative C, the East Helena TPA would have 12 miles of open roads and no motorized trails (**Table 4-66**). Estimated costs for annual maintenance and stabilization of roads under Alternative C would be the least of all the alternatives due to the least number of motorized routes. Estimated annual costs for monitoring,

compliance, and weed control would also be less than under the other alternatives.

There would be a short-term increase in transportation facility costs under Alternative C resulting from the increase in signage required to mark closed and restricted routes. Indirect costs associated with sign maintenance and replacement would be greater under Alternative C than under the other alternatives; however, this effect would be short term because the public would become accustomed to the route changes over time.

### Effects of Alternative D

Under Alternative D, the East Helena TPA would have 37.9 miles of open roads and no motorized trails (**Table 4-66**). Estimated costs for annual maintenance and periodic stabilization of roads under Alternative D would be similar to Alternative A, and less than under Alternatives B and C. Estimated annual costs for monitoring, compliance and weed control would be less under Alternative D than Alternative A and more than under Alternatives B and C.

Constructing several new designated routes under Alternative D would result in a short-term increase in transportation facility costs for the signage and potentially for more culverts, and a long-term increase for route maintenance associated with new routes. These costs would be offset in the long-term by reduced costs associated

with having fewer road miles to maintain than under Alternative A.

Relocation of the trailhead in the Spokane Hills area would result in a short-term increase in transportation facility costs for trailhead development and signage.

## LANDS AND REALTY

### Effects Common to All Alternatives

The Butte Field Office administers approximately 62 rights-of-way (ROW) and 3 non-commercial occupancy leases within the boundaries of the East Helena TPA, which encumber approximately 1,609 acres of BLM land (**Table 4-67**). Various types of road rights-of-way are the most common type of grant, accounting for 34 percent, or about one third of the total. Other types of authorized uses include: oil and gas pipelines, lines for electrical distribution and telephone facilities, communication sites, ditches, railroads, and mineral material sites.

Approximately two right-of-way applications for new facilities as well as amendments, assignments, renewals, or relinquishments of existing right-of-way grants are processed annually in the TPA. This would not vary by alternative.

The general trend of granting rights-of-way is expected to increase through the planning period as a result of increasing public demands. From a cumulative effects

**Table 4-66**  
**East Helena TPA Route/Trail/Maintenance Costs**

Classification/Cost	Alt A	Alt B	Alt C	Alt D
Miles of Open/Restricted Roads	44.3	17	12	37.9
Motorized Trails	0	0	0	0
Annual Roads Maintenance	\$3,544	\$1,360	\$960	\$3,032
Annual Trails Maintenance	\$0	\$0	\$0	\$0
Periodic Road Stabilization	\$1,418	\$544	\$384	\$1,213
Periodic Trails Stabilization	\$0	\$0	\$0	\$0
Monitoring/Compliance	\$2,215	\$850	\$600	\$1,895
Weed Control	\$665	\$255	\$180	\$569

**Table 4-67**  
**East Helena TPA ROWs/Leases**

Type	Approximate Number	Approximate Acres
Roads	21	746
Power	16	257
Telephone	12	45
O&G Pipelines	3	84
Comm. Sites	4	8
2920 Leases	3	1
Other	6	468
<b>Totals</b>	<b>65</b>	<b>1,609</b>

standpoint, development of adjacent federal, state, and private land, increased recreational use and the trend of homeownership away from urban areas, coupled with traditional on-going uses, are all expected to require more guaranteed access involving public land.

## SPECIAL DESIGNATIONS

There would be no effects to any special designation areas such as Wild and Scenic Rivers, Wilderness Study Areas, or Areas of Critical Environmental Concern under any of the travel plan alternatives for the East Helena TPA.

## LEWIS AND CLARK COUNTY NW TPA

The 406,700-acre Lewis and Clark County Northwest TPA contains approximately 17,037 acres of BLM lands. There are approximately 68 miles of BLM roads, making up about 4.7 percent of the approximate total of 1,448 road miles in the TPA. The majority of roads (819 miles) lie on private lands.

## AIR QUALITY

### Effects Common to All Alternatives

Motorized recreation use is expected to continue to increase, resulting in higher levels of vehicle emissions.

Motorized travel across dry unpaved routes or trails would continue to produce airborne dust.

There could be areas with localized air pollution as a result of higher use numbers, and more concentrated use on fewer miles of available routes.

Drier climate conditions could make soils more susceptible to the effects of motorized travel, resulting in higher levels of airborne dust.

Impacts to air quality vary by alternative and travel plan area. In general, alternatives that reduce the level of motorized use (have fewer available miles) could have a positive impact on air quality; while alternatives that maintain or increase the level of motorized use, could lead to increased air quality impacts. This would not necessarily be a direct relationship, however, because reduction in available road miles for motorized use could redistribute use or focus more use on remaining open routes.

Under all alternatives, impacts from airborne dust could be reduced through mitigation such as hardening native surface roads with gravel or periodically spraying them with water trucks during the dry season. During BLM project work, in addition to watering native surface roadbeds, speed limits could be reduced to further minimize dust emissions.

## Effects of the Alternatives

Under Alternative A (present management), adverse impacts to air quality would be expected to continue, and likely increase, concurrent with higher levels of motorized recreational use. Each of the action alternatives, however, would provide fewer available motorized routes. Alternatives B and C would provide 56 percent and 69 percent fewer motorized routes, respectively, than Alternative A, while Alternative D would provide 47 percent fewer routes than Alternative A. As a result, airborne dust and vehicle emissions would be taking place on fewer BLM routes and could be reduced.

It should be noted that even without motorized use, airborne dust, resulting from wind erosion of exposed native surface roads will continue. Therefore, travel plans with more miles of dirt roads would result in more airborne dust.

Under all alternatives, mitigation measures, such as graveling and/or watering native surface roads, could reduce dust emissions even further, and/or help offset the effects of increased or concentrated use on the remaining open routes.

## Cumulative Effects on Air Quality

Under all alternatives, the cumulative effects to air quality from travel management in the Lewis and Clark County NW TPA would arise from a number of past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands.

For perspective, BLM managed lands in the Lewis and Clark County NW TPA area represent approximately 4.2 percent of the total travel planning area (406,700 total acres; 17,037 BLM acres). Under present management (Alternative A) BLM managed routes represent a small portion, approximately 4.7 percent, of the total routes available (1,447.7 total miles; 67.6 miles BLM roads/trails). Potential air quality impacts associated with activities on non-BLM lands and roads would be a greater contributor to cumulative effects to air quality than activities on BLM lands and roads.

In the past, prior to the 2003 Statewide OHV ROD, BLM management allowed unrestricted cross country travel by all forms of wheeled motorized use. Under present management, in the absence of other existing travel plan direction, all motorized wheeled travel is restricted to existing roads and trails. Under current management, approximately 64.2 of the 67.6 miles of existing BLM routes are available for motorized use. This mileage available for use would be reduced under the action alternatives as described above with associated potential differences in effects to air quality.

Under all alternatives, cumulative increases in human population, urbanization, recreation use, user conflicts; and concerns for wildlife, noxious weed spread, soil

erosion, air/water quality, and illegal activities may lead to increased demands to restrict motorized travel.

## SOILS

### Effects Common to All Alternatives

Road construction, use, and maintenance affect soils in a number of ways. Soils are often compacted by these activities. Soil compaction can lessen the amount of precipitation that can infiltrate into soil and increase runoff, erosion, and sedimentation – in turn decreasing soil/site stability and hydrologic function, as well as soil productivity and plant vigor and diversity.

Ground disturbance associated with road construction, use, and maintenance can result in erosion. Erosion affects soil/site stability and hydrologic function. Erosion and sedimentation can destabilize the surface and sub-surface cohesion of the soil, resulting in soil loss from erosion sites. Loss of soil can impede or prevent establishment and development of vegetation communities.

Closing or decommissioning roads often leads to beneficial effects to soils through decreased site disturbance and re-establishment of vegetative cover on road surfaces. This tends to reduce soil erosion and stabilize soils. Decommissioning roads may in some cases entail ripping road surfaces to de-compact them, thus improving water infiltration, hydrologic function, and the ability of the treated area to revegetate more successfully.

Impacts to soils associated with site-specific travel plan alternatives were assessed based on the potential for soil erosion using the following erosion risk criteria:

- High – the area a route travels through has slopes greater than 30 percent gradient.

- Moderate – the area a route travels through has slopes ranging from 15 to 30 percent gradient; or, for granitic soils, slopes ranging from 0 to 30 percent gradient.
- Low – the area a route travels through has slopes ranging from zero to 15 percent gradient and soils are not granitic in origin.
- Unrated – road mapping not available at time of erosion impact rating.

### Effects of the Alternatives

The distribution of road miles by erosion impact category and by proposed road management category for all the alternatives is shown for the Lewis and Clark County NW TPA in **Table 4-68**. Roads in the “unrated” category were excluded from detailed consideration and are shown for the purpose of displaying the extent of lacking information.

Most roads in this TPA are in either the high or moderate erosion impact category. Under current conditions (Alternative A) approximately 45.6 miles of open BLM roads are located in areas with high erosion risk, and 16 miles are in moderate erosion areas. Soil erosion would be reduced under Alternative B because this alternative would reduce those mileages in the high and moderate erosion categories to 20.1 miles and 5.9 miles, respectively. Approximately 26.6 miles of road in the high and moderate categories combined would be closed under Alternative B with an additional 10.4 miles in these categories being decommissioned. Vegetative recovery should occur to varying degrees on closed and decommissioned roads, with a beneficial effect on soils of reducing erosion from these areas.

Proposed Road Management	Erosion Risk Category	Alternative A	Alternative B	Alternative C	Alternative D
<b>Open Road Miles</b> (incl. Open w/restrictions)	High	45.6	20.1	12.6	24.6
	Moderate	16.0	5.9	6.1	7.9
	Low	0.2	0.2	0.2	0.2
	Unrated	2.4	1.9	0.9	1.8
<b>Closed Road Miles</b>	High	3.1	19.7	31.4	14.6
	Moderate	0.3	6.9	8.8	5.6
	Low	0	0	0	0
	Unrated	0.1	0.2	1.3	0.1
<b>Decommissioned Road Miles</b>	High	0	8.6	4.2	6.8
	Moderate	0	1.8	0.8	1.5
	Low	0	0	0	0
	Unrated	0	0	0	0.5

Note: Open roads include seasonally open roads as well as roads open yearlong.

Soil erosion would be reduced more under Alternative C than under any other alternative because the lowest mileage of roads in the high and moderate erosion categories would be left open (18.7 miles combined), while the greatest mileage in these categories would be closed (40.2 miles combined) of all alternatives. An additional 5 miles in these categories would be decommissioned under Alternative C.

Soil erosion associated with roads would be reduced under Alternative D compared to Alternative A, but would still be higher than under either Alternative B or C. Approximately 32.5 miles of BLM road in the moderate and high erosion categories combined would remain open under Alternative D, while about 20.2 miles in these categories would be closed and 8.3 miles would be decommissioned under this alternative.

### Cumulative Effects on Soils

Cumulative effects to soils in the Lewis and Clark County NW TPA would arise from a number of past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands. Within this 406,700-acre TPA, BLM lands comprise about 17,037 acres or 4 percent of total lands. The approximately 68 miles of BLM roads make up about 4.7 percent of the approximately 1,448 road miles in the TPA. Therefore road-related effects to soils described by alternative for BLM roads would affect about 4.7 percent of all roads in the TPA. The majority of lands and roads (over 50 percent of each) within the TPA boundary are private property. Non-BLM roads are managed by the county, Forest Service, state, and private landowners.

The Bald Butte Mine is located within this TPA. Currently this is a small scale open cut molybdenum mine of less than 5 acres in size on private land. It is anticipated to expand into approximately 5 acres of BLM land in the future and may occupy up to 30 acres of open area collectively at any one time in the future. Impacts to soils from this activity will include complete soil removal and displacement, erosion, compaction, and covering by facilities. Reclamation work would provide for stabilization of soils in the aftermath of mining activity.

Approximately 1,961 BLM acres are permitted for various rights-of-way and leases. About 558 of these acres are for specific road rights-of-way. An additional approximately 1,050 acres are associated with the Great Divide Ski Area. The remaining 353 acres are associated with powerlines, waterlines, communication sites, oil and gas pipelines, and other utility facilities. Impacts to soils range from compaction and occupation of ground with buildings, roadbeds, and other facilities, to revegetation and ground cover being re-established to stabilize soils. Much of the Great Divide Ski Area is a mosaic of ski runs and chair lifts nestled within forested or otherwise naturally vegetated areas. Impacts to soils from these features are minor.

From 1984 to 1995 timber harvest took place on about 82 acres of BLM land in this TPA (including timber salvage on 42 acres). From 1995 to the present timber harvest (predominantly selective harvest) has occurred on about 116 acres of BLM land in the TPA. Adverse effects on soils were generally minor with treated areas having undergone revegetation and soil stabilization since treatment. Timber harvest has also occurred on private and Forest Service lands and will likely continue for the foreseeable future, having localized compaction and erosion effects on soils.

From 1981 to 2004, wildland fire has burned across approximately 83 acres in the Lewis and Clark County NW TPA, creating a range of soil effects with more severely burned areas experiencing localized erosion and with other areas being relatively little affected.

There have been no fuels reduction treatments on BLM lands in the TPA in the last 10 years. While treatments of 1,500 to 3,000 acres (combination of mechanical and prescribed fire) may occur on BLM lands in the future, these treatments are not yet planned or designed. They would be designed to minimize effects to soils by minimizing compaction/disturbance from mechanical equipment and designing prescribed burns to be cool enough so as not to release nutrients from fuels but not scorch soils. Fuels treatments conducted on private and Forest Service lands will likely occur for the foreseeable future with variable effects to soils. Reducing fuels under the controlled conditions of deliberate treatments may benefit soils in the long-term by reducing the risk of high severity fires in treated areas.

Livestock grazing on public and private lands throughout much of the TPA has created areas of localized soil erosion and compaction, particularly in grassland and shrubland areas. This will continue to occur for the foreseeable future.

Increasing residential development will likely continue for the foreseeable future to variable degrees within the TPA. Erosion, compaction, and covering of soils would occur due to additional road construction, clearing/leveling for home sites, and establishment of utility infrastructure for residential developments.

Under Alternative A, the contribution to cumulative effects on soils from BLM road management would continue as it occurs today. Retaining approximately 58 miles of road open yearlong and an additional 7 miles open with seasonal restrictions would allow for the same level of compaction and erosion impacts that currently exist.

From a BLM road management perspective, all action alternatives would benefit soil resources compared to Alternative A. Alternative B would benefit soils by providing for a reduced contribution to adverse cumulative effects than would Alternative A because about 55 percent of BLM roads would be closed or decommissioned under Alternative B (compared to 5 percent under Alter-

native A). Erosion should be reduced on these closed/decommissioned roads as disturbance is eliminated and revegetation occurs and stabilizes soils. Of the approximately 28 miles of open road under Alternative B, about 14 miles would be seasonally restricted from motorized vehicle use from 12/2 to 5/15. This would prevent erosion associated with motorized use during the wet snowmelt/runoff period.

Alternative C would benefit soils the most and provide for the least contribution to adverse cumulative effects on soils of all alternatives. This alternative would provide for closure or decommissioning of about 69 percent of BLM roads in the TPA, thus allowing these areas to vegetatively recover and stabilize soils. Of the approximately 20 miles of open road in this alternative, about 12 of those miles would be seasonally restricted (12/2 to 5/15) to exclude motorized use during the wet snowmelt/runoff period. This would prevent erosion associated with this wet season use.

Alternative D would provide for the greatest contribution to adverse cumulative effects on soils of the action alternatives, but would still provide for greater long-term benefits to soils than Alternative A. Alternative D would provide for closure or decommissioning (and subsequent vegetative recovery and/or soil stabilization) of about 43 percent of BLM roads in the TPA, compared to 5 percent for Alternative A, 55 percent for Alternative B, and 69 percent for Alternative C.

Due to the scattered distribution and relatively small proportion of BLM lands (4 percent) and roads (4.7 percent) relative to the total quantities of lands and roads in the TPA, none of the BLM alternatives would substantially contribute to cumulative effects on soils at the scale of the Lewis and Clark County NW TPA.

## WATER RESOURCES

### Effects Common to All Alternatives

There are a number of key concepts that are critical to understanding road effects to water resources.

Hydrologic function is an interaction between soil, water, and vegetation and reflects the capacity of a site to:

- Capture, store, and safely release water from rainfall, runoff, and snowmelt;
- Resist a reduction in this capacity; and
- Recover this capacity following degradation.

Interception of precipitation results when precipitation falls on vegetation. When vegetation is removed, precipitation falls directly on the soil. This can increase surface erosion and sedimentation, and decrease the amount of time between initial precipitation arrival and peak surface runoff – in turn decreasing soil/site stability and hydrologic function. Roads remove vegetation and therefore decrease interception of precipitation.

Infiltration is the process of precipitation entering and traveling through soil. Infiltration reduces the peak runoff during precipitation events by extending the period of runoff after a precipitation event. Infiltration also filters precipitation and reduces erosion and sedimentation. If infiltration is reduced, runoff and erosion will increase and hydrologic function will decrease. Generally, roads are compacted surfaces that have decreased infiltration, thus increasing runoff and potentially increasing erosion.

Runoff can affect the amount of erosion and sedimentation, as well as flooding – both onsite and offsite. If runoff is increased, all of these effects can increase with a result that water quality and hydrologic function will decrease.

Increased sediment entering waterbodies increases turbidity, increases width-to-depth ratios, and consequently increases temperature and dissolved oxygen saturation levels, and creates an adverse habitat for aquatic animals and plants.

Alteration of flow routing can also affect water resources. For example, roadcuts into areas with relatively shallow groundwater can intercept groundwater, bring it to the surface, and transport it some distance (i.e. in a roadside ditch) before delivering it to a stream. This can lead to erosion of road ditchlines and subsequent sedimentation of streams during runoff periods, or increased thermal loading of water before delivery to streams during summer periods.

Closure and decommissioning of roads tend to reduce erosion and sedimentation effects stemming from roads on water quality. On an equivalent road mile basis, decommissioning roads would benefit water quality to a greater degree than closing roads because the decommissioning process would often entail implementing measures to restore hydrologic function. During road decommissioning items such as compaction, drainage, stream crossing culverts, and ground cover are often addressed in a manner that markedly improves hydrologic function. These features are not fully addressed on roads that are merely “closed”. However, the reduced disturbance on newly closed roads combined with the tendency for revegetation to re-establish ground cover on them would reduce erosion and subsequent sedimentation effects to water quality.

### Effects of the Alternatives

Generally, road density is an indicator of overall watershed health and function. Watersheds with higher road densities tend to have lower water quality due to greater disruption of hydrologic function (described above), and potential for erosion and subsequent sedimentation. Road density also is related to the distribution and spread of noxious weeds.

**Table 4-69** shows acres of BLM land in three road density categories by alternative for the Lewis and Clark County NW TPA. These data reflect differences between alternatives based on roads proposed for “de-

TPA Alternative	Road Density Category		
	Low ( <1 mi/mi <sup>2</sup> )	Moderate ( 1 to 2 mi/mi <sup>2</sup> )	High ( > 2 mi/mi <sup>2</sup> )
<b>Alternative A</b>	2,614	3,444	10,979
<b>Alternative B</b>	3,075	4,526	9,436
<b>Alternative C</b>	2,693	4,076	10,268
<b>Alternative D</b>	2,935	4,446	9,655

commissioning” by alternative. While many “closed” roads would gradually contribute to increased hydrologic function over time, decommissioned roads would more directly contribute to hydrologic function because measures aimed at restoring hydrologic function would likely be part of the treatment during decommissioning. Alternative A would have the greatest amount of BLM land with “high” road densities of greater than 2 mi/mi<sup>2</sup>. Alternative B would have the lowest acreage in the high category with the greatest acreage in the low category of all alternatives. Alternative D would benefit hydrologic function more than Alternative C but less than Alternative B by virtue of its greater acreage in the low and moderate road density categories than Alternative C. Alternative C would have the highest acreage in the high road density category of the action alternatives. Overall, all the action alternatives would improve hydrologic function but by this measure Alternative B would make the greatest contribution to improved hydrologic function of all the alternatives, followed by Alternative D, Alternative C, then Alternative A.

Motorized routes within 300 feet of streams generally have greater potential to directly impact water quality through erosion and sedimentation, increased water temperatures (due to loss of shading vegetation), and direct alteration of stream channel morphology than those farther away. **Table 4-70** shows the miles of open and closed roads on BLM lands within 300 feet of streams by alternative. Under Alternative A there are about 7.4 miles of open road within 300 feet of fish bearing streams and an additional 5 miles within 300 feet of perennial non-fish bearing streams. All action alternatives

would improve water quality by closing or decommissioning roads in close proximity to streams but Alternative C would provide for the greatest mileage. By this measure, Alternative C (total of 6.2 miles closed or decommissioned) would create the most benefit to water resources followed by Alternative B (5.4 miles), then Alternative D (4.6 miles).

### Cumulative Effects on Water Resources

Cumulative effects to water resources in the East Helena TPA would arise from many past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands. Within this 406,700-acre TPA, BLM lands comprise about 17,037 acres or 4 percent of total lands. The approximately 68 miles of BLM roads make up about 4.7 percent of the approximately 1,448 road miles in the TPA. Therefore road-related effects to water resources described by alternative for BLM roads would be associated with management of about 4.7 percent of all roads in the TPA. There are approximately 292 miles of fish bearing stream and an additional 238 miles of perennial non-fish bearing stream in the TPA. On BLM lands there are about 11 miles of fish bearing stream and an additional 11 miles of perennial non-fish bearing stream. The majority of lands and roads (over 50 percent of each) within the TPA boundary are private property. Non-BLM roads are managed by the county, Forest Service, state, and private landowners.

Many of the main access roads (non-BLM) follow valley bottoms and parallel streams. Many of these roads are directly affecting stream channel and floodplain function by filling or impinging on stream channels or flood-

TPA Alternative	Perennial Fish-Bearing Streams		Perennial Non-Fish-Bearing Streams	
	# Open Road Miles	# Closed Road Miles	# Open Road Miles	# Closed Road Miles
<b>Alt. A</b>	7.4	0	5.0	0
<b>Alt. B</b>	5.3	2.1	1.7	3.3
<b>Alt. C</b>	4.8	2.6	1.4	3.6
<b>Alt. D</b>	5.3	2.1	2.5	2.5

Note: Open roads include seasonally open roads as well as roads open yearlong. Closed roads include decommissioned roads.

plains, precluding the presence of riparian vegetation (including large woody material in forested locations), producing sedimentation in streams (from road surfaces, ditchlines, winter “road sanding” operations) and potentially increasing thermal loading by lessening streamside shade. These effects are dominant in shaping stream channel and water quality conditions in many areas and will continue into the foreseeable future.

Approximately 1,961 BLM acres are permitted for various rights-of-way and leases. About 558 of these acres are for specific road rights-of-way. An additional approximately 1,050 acres are associated with the Great Divide Ski Area. The remaining 353 acres are associated with powerlines, waterlines, communication sites, oil and gas pipelines, and other utility facilities. Much of the Great Divide Ski Area is a mosaic of ski runs and chairlifts nestled within forested or otherwise naturally vegetated areas. Impacts to water resources are generally minor with some localized erosion and sedimentation and some contribution to decreased hydrologic function (decreased infiltration, increased runoff) due to compaction.

From 1984 to 1995 timber harvest took place on about 82 acres of BLM land in this TPA (including timber salvage on 42 acres). From 1995 to the present timber harvest (predominantly selective harvest) has occurred on about 116 acres of BLM land in the TPA. Adverse effects on water resources were minor from this activity. Timber harvest has also occurred on private and Forest Service lands and will likely continue for the foreseeable future. Ground disturbance from these activities will have localized impacts to water resources including some sedimentation, loss of woody material recruitment for streams, and potential water temperature increases due to riparian shade loss.

From 1981 to 2004, wildland fire has burned across approximately 83 acres in the Lewis and Clark County NW TPA, having negligible effects on water resources.

There have been no fuels reduction treatments on BLM lands in the TPA in the last 10 years. While treatments of 1,500 to 3,000 acres (combination of mechanical and prescribed fire) may occur on BLM lands in the future, these treatments are not yet planned or designed. They would be designed to minimize effects to water quality by minimizing compaction/disturbance from mechanical equipment and designing prescribed burns to be cool enough so as not to scorch soils and facilitate severe erosion. Fuels treatments conducted on private and Forest Service lands will likely occur for the foreseeable future with variable effects to soils. Reducing fuels under the controlled conditions of deliberate treatments may benefit water resources in the long-term by reducing the risk of high severity fires that could have severe adverse water quality effects in treated areas.

Livestock grazing on public and private lands throughout much of the Lewis and Clark County NW TPA has

created areas of localized streambank trampling, soil erosion and sedimentation, and nutrient inputs to streams. In severe cases stream channel morphology may be altered due to severe loss of riparian vegetation, loss of streambank integrity, channel widening and shallowing, and substantial sediment inputs. These effects to water quality will continue to occur for the foreseeable future. Agricultural water withdrawals occur on private lands in this TPA. These withdrawals reduce stream flows in the TPA, including within Little Prickly Pear Creek, one of several streams that flow through BLM lands and is listed as an impaired water body by MDEQ on the 303(d) list.

Several other streams listed as impaired by MDEQ flow through BLM lands in this TPA. Heavy metal contamination from abandoned mine lands has affected Virginia Creek, about 2 miles of which flows through BLM lands. The Blackfoot River (1.9 miles on BLM lands) is impaired by heavy metal contamination, sedimentation, and alteration of riparian vegetation. Probable sources of impairment include hard rock mining, agriculture, and timber harvest. Jennies Fork (0.2 miles on BLM lands) is impaired by lead contamination, nutrient inputs, and sedimentation. Probable sources of impairment are hard rock mining, riparian grazing, and roads. In the case of each of these impaired streams, BLM roads are not located in such a manner and are not a great enough proportion of ongoing activities as to play a substantial role in affecting water resource conditions.

Increasing residential development will likely continue for the foreseeable future to variable degrees within the TPA. Erosion, soil compaction, and runoff would likely increase due to additional road construction, clearing/leveling for home sites, and establishment of utility infrastructure for residential developments. Nutrient, chemical pollutant, and pathogen inputs to streams would also likely increase due to leaching from septic systems, urban runoff (fertilizer, chemicals, and petroleum pollutants), and waste from livestock.

Under Alternative A, the contribution to cumulative effects on water resources from BLM road management would continue as it occurs today. Retaining approximately 58 miles of road open yearlong and an additional approximately 7 miles open with seasonal restrictions would allow for the same level of effects to water resources that currently exists.

From a BLM road management perspective, all action alternatives would benefit water resources compared to Alternative A. Alternative B would benefit water resources by providing for a reduced contribution to adverse cumulative effects than would Alternative A because about 56 percent of BLM roads would be closed or decommissioned under Alternative B (compared to 5 percent closed under Alternative A). Of the approximately 28 miles of open road under Alternative B, nearly one half of them would be seasonally restricted to exclude motorized vehicle use in the wet spring runoff

period each year. This would reduce erosion from these roads and further benefit water resources.

Overall, Alternative B would likely benefit water resources the most and provide for the least contribution to adverse cumulative effects on water resources of all alternatives. Under this alternative the greatest mileage of BLM roads would be decommissioned (10.9 miles), benefiting hydrologic function to the greatest degree. Alternative C would provide for the greatest quantity of closed roads, but would only provide for 5.2 miles of decommissioning and would therefore have less benefit to hydrologic function. Alternative D would provide for 8.8 miles of decommissioning and would therefore have less benefits to hydrologic function than Alternative B, but more than Alternative C. Overall, Alternative D would provide for closure or decommissioning on about 43 percent of BLM roads in the TPA, compared to 5 percent for Alternative A, 56 percent for Alternative B, and 69 percent for Alternative C.

Due to the scattered distribution and relatively small proportion of BLM lands (4 percent) and roads (4.7 percent) relative to the total quantities of lands and roads in the TPA, none of the BLM alternatives would substantially contribute to cumulative effects on water resources in the Lewis and Clark County NW TPA.

## **VEGETATIVE COMMUNITIES – FOREST RESOURCES AND FOREST AND WOODLAND PRODUCTS**

### **Effects of the Alternatives**

Under all alternatives, existing roads and roads built to access timber and forest product sales on BLM lands may encourage timber harvest and forest product sales on adjacent lands, particularly where landowners and other agencies are looking to improve economic efficiency or opportunities in the management on their lands.

In general, vegetative treatment contractors tend to bid more readily on projects in areas with vehicle access or valuable products. BLM often prioritizes forest vegetation management activities such as forest products and forest protection activities (e.g. wildfire suppression and forest insect and disease control) in similar areas.

Rehabilitation of roads (decommissioning and in some cases road closure) would revegetate currently unvegetated roadbeds, which would increase vegetation biomass production on the landscape through colonization of sites with grasses, forbs, shrubs, and trees. Increases in revegetated area would occur at a rate of approximately 1.5 to 3 acres per mile of rehabilitated road. Eventually rehabilitated roads would support plant communities consistent with site potentials which would help resist weed invasions. However, road closures and removals could make vegetation management treatments more

difficult and costly, thereby inhibiting proposed treatments, reducing public access for product use and removal, and potentially slowing fire detection and suppression.

Under Alternative A there would be no increase in project analysis and implementation costs. However, under Alternative B approximately 55 percent of roads into forested areas would be closed. Under Alternative C about 69 percent of roads into forested areas would be closed, while under Alternative D about 43 percent of these roads would be closed. These closures would result in commensurate potential increases in vegetative analysis and treatment costs by alternative. These potential cost increases would be considered on a case by case basis by the BLM during project feasibility determinations, and additional funding may be needed to analyze and implement the projects that would remain feasible. Road closures could also result in potential decreases in quantities of forest products removed. The extent of the effects described above would be minimized because BLM would likely still be able to plan and implement projects in many areas on closed roads through the variance process for temporary road use. Road-related effects would be greatest under Alternative C, followed in sequence by Alternative B, then Alternative D.

Treatment projects that are small in nature or limited in scope such as vegetative manipulations of 50 acres or less, or restoration treatments removing only small proportions of stands (i.e. low intensity burns, selective thinning, interplanting), would have the greatest risk of becoming unfeasible in areas of closed roads under the action alternatives. However the higher productivity of the stands and higher value of the available products in most treatment areas in this TPA would be able of absorb the anticipated higher costs of treatments incurred by the BLM, and would increase the likelihood of successful project implementation.

Roaded access to forested areas would also affect the gathering of firewood and other forest products by the general public. The forested areas in the Marysville area are relatively heavily roaded and have received the highest public demand for forest products in the TPA due to their moderately productive forest and road accessibility. The smaller blocks of public land in the Stemple Pass area and the Sieben Ranch locality tend to be away from the main travel routes in their areas and thus being isolated, tend to have low demand for products. Most public parties prefer to drive close to areas of product removal so they do not have to carry products over long distances to their vehicles. With the low demand for products from the smaller blocks, implementation of alternatives B, C, and D would have little if any effect on product removal in those areas. However, Alternatives B, C and D would close roads in many forested portions of the Marysville area, generally restricting public searching for and removal of personal use and small products to motorized travel corridors along the

main roads. For the Lewis and Clark County NW TPA, Alternative A would retain the most public opportunities for these activities, followed in sequence of decreasing opportunities by Alternative D, Alternative B, then Alternative C. Alternatives B and D would have similar effects to public access for forest product gathering.

### **Cumulative Effects on Forest and Woodland Resources and Products**

The western spruce budworm is present and heavily affecting forests within the TPA at higher levels than experienced in the last twenty years, with high levels of defoliation occurring around Marysville and in the Virginia Creek area. This insect is currently reducing the health of Douglas-fir stands, such that other pests such as the Douglas-fir beetle can take advantage of the low vigor and reduced resistance in the trees, and become entrenched and kill trees in the infested stands. Current insect levels are expected to remain high in the future. This insect moves freely between Douglas-fir on all ownerships and open roads can assist with control. Alternative A would provide the highest opportunity for control on BLM lands and adjacent lands under other ownerships in the TPA. Alternative D would provide the next greatest degree of opportunity, followed in sequence by Alternative B, then Alternative C.

Forested vegetation will also be affected by approximately 1,961 acres of rights-of-way and leases on BLM land. Forested vegetation located in these areas usually is harvested and/or removed to accommodate the necessary access or facilities. Forest vegetation removal will occur on new authorizations in the future and will occur as necessary to maintain sight distances and safety clearances associated with roads and facilities.

Urbanization is expected to continue on the 213,847 acres of private lands (53 percent of all lands) within this TPA. Forest products are commonly removed from these areas prior to permanent construction. Urbanization is likely to continue in the future and will affect forested vegetation at an unknown rate. As private construction increases, miles of road on private will most likely increase from the current 819 miles (57 percent of all roads in TPA).

Risk to forests from human-caused wildfires is commonly associated with open roads. Risk to forests from wild-fire would be greatest under Alternative A with 64.2 miles of road open during the summer (and yearlong). Alternative B would have less risk of human-caused fire starts with about 28 miles of open road during summer. Alternative C would have the least risk to public forests with only 19.7 miles of road open during summer months. Alternative D (34.1 miles of open road during summer) would have more risk than either Alternative B or C, but less risk than Alternative A. Given that the majority of roads in the TPA (95.3 percent) are non-BLM roads, this contribution to reduced fire risk from

BLM roads in the action alternatives is relatively small in the context of the entire TPA.

Since BLM roads constitute only 4.7 percent of all roads in this TPA, and BLM lands make up only 4.2 percent of all lands in the TPA, urbanization and activities on open non-BLM roads in the vicinity may have more cumulative effects on forested vegetation in the TPA than BLM decisions regarding miles of open and closed road.

### **VEGETATIVE COMMUNITIES – NOXIOUS WEEDS**

Under all alternatives, any snowmobile use would have negligible effects on noxious weed spread and populations. Invasive noxious weeds and non-native species are degrading wildland health. These are aggressive plants that can outcompete many native plants, as they have few natural enemies to keep them from dominating an ecosystem. These plant species are spread by many means. However, any land disturbing activity in the TPA has the most potential to introduce and spread weed species. Motorized vehicles are one vector for noxious weed spread as weed seed and plant parts become attached to vehicles and their tires, and are transported from one area to another where seeds become detached and germinate to inhabit new areas.

#### **Effects of Alternative A**

Under Alternative A, the majority of routes in the Lewis and Clark County NW TPA would be available for wheeled motorized use (57.5 miles open yearlong, 6.7 miles seasonally restricted, 3.4 miles closed). Area wide snowmobile (cross-country travel) use would be available on 16,997 acres. Under Alternative A the open BLM roads would represent about 4.7 percent of all open roads in the Lewis and Clark County NW TPA.

Alternative A would have the most roads open and in turn would promote the greatest amount of weeds and other undesirable plant spread and production. More herbicide control would be needed to control weeds under Alternative A than under the other alternatives.

#### **Effects of Alternative B**

Under Alternative B, a total of 28.1 miles of routes would be available for motorized wheeled use (13.8 miles open yearlong, 14.3 miles seasonally restricted). The majority of routes located in the Stemple Pass and Lincoln areas would be closed. This alternative would close 26.8 miles of road leaving 13.8 miles open yearlong as compared to 57.5 miles of road open yearlong for Alternative A. This would prevent weed spread caused by motorized vehicles on these closed routes, but would increase spread on the open routes because of the more concentrated use of these routes. Overall Alternative B would reduce weed spread, but would increase weed treatment costs per road mile on the remaining open roads compared to Alternative A. Under Alterna-

tive B the 28.1 miles of open BLM road (including seasonally restricted miles) would constitute about 2 percent of all open road miles in the Lewis and Clark County NW TPA.

### Effects of Alternative C

Alternative C would provide the least amount of wheeled motorized opportunities: 8.0 miles of routes open yearlong, and 11.7 miles seasonally restricted. Closure of the routes located in the northwest corner of the Marysville area would result in an enhancement of non-motorized opportunities and reduced weed spread there. Opportunities for cross-country snowmobile travel would be eliminated. Snowmobiles would be restricted to designated routes during the season of use (12/2-5/15), snow conditions permitting. This alternative would close 41.6 miles of road leaving 8.0 miles open yearlong as compared to 57.5 miles of road open yearlong for Alternative A. This would prevent weed spread caused by motorized vehicles on these closed routes, but would increase weed spread on the open routes because of the more concentrated use of these routes. Overall Alternative C would reduce weed spread more than any other alternative, but would increase weed treatment costs per road mile on the remaining open road miles compared to Alternative A. Under Alternative C the 19.7 miles of open BLM road (including seasonally restricted miles) would make up about 1.4 percent of all open roads in the TPA.

### Effects of Alternative D

Under this alternative, a total of 34.1 miles of routes (19.6 miles open yearlong, 14.5 miles seasonally restricted) would be available for motorized use. Opportunities for ATV riders and hunters would be enhanced through the addition of a yearlong ATV-Only route and a game retrieval route. Motorized users would also have more opportunities in the Lincoln and Stemple Pass areas than under Alternatives B and C, facilitating continued weed spread via roads in these areas. Cross-country snowmobile travel would be allowed throughout the TPA with two exceptions, the Great Divide Ski area, and the northwest portion of the TPA. Travel in these areas would be restricted to existing routes only during the season of use (12/2-5/15), providing some dispersed recreation opportunities for non-motorized users. This alternative would close 20.3 miles of road leaving 19.6 miles open yearlong as compared to 57.5 miles of road open yearlong for Alternative A. This would prevent weed spread caused by motorized vehicles on these closed routes, but would increase weed treatment costs per road mile on the remaining open road miles compared to Alternative A. The 34.1 miles of open BLM road (including seasonally restricted routes) would Alternative D would make up about 2.4 percent of all open travel routes in the Lewis and Clark Northwest TPA.

### Cumulative Effects on Noxious Weeds

Under all the alternatives, other past, present, and reasonably foreseeable future BLM and non-BLM actions affect noxious weeds.

Recreation use is well established in the TPA, especially for winter sports. Winter sport activities include: snowmobiling, downhill skiing, backcountry skiing, ski racing, snowboarding, and snowshoeing. An extensive network of roads and trails support a wide range of off-season activities. Non-winter motorized activities are also common in the TPA. Motorized recreation uses are one of the leading causes of introduction and spread of noxious weeds and non native species. Weed seeds are transported by many recreational vectors i.e. motorized vehicles including their tires, non-motorized vehicles including their tires, pack animals, and humans.

Urban development may lead to an increase in right-of-Way permits to accommodate private property/development access. As a result, soil disturbing activities (i.e. roads, powerlines, telephone lines, etc.), will increase causing weeds to increase.

A variety of resource management projects, such as BLM initiated vegetation treatments, or wildland fire fuels reduction projects, could affect weeds in the TPA. There have been no fuels treatments in this area in the last 10 years. There are fuels treatments scheduled for planning for this area in the next five years, mainly in the general area around Marysville. These treatments would consist of mechanical and/or prescribed burning from 1,500 to 3,000 acres focused on the urban interface areas. Any project creating soil disturbance has the capability to increase weedy plant species. Prescribed burning projects give the ground surface a fertilization effect and eliminate some plant competition for weedy species giving them a niche for establishment and expansion in some areas. Ground-disturbing equipment could also transport noxious weed seed to these project sites. BLM implements weed control measures in the aftermath of such ground-disturbing activities so as to minimize noxious weed spread.

Wildland fires create good seed beds and supply nutrients for weed species introduction and production. From 1981 to 2004 there have been 14 wildland fires that burned approximately 83 acres. These areas likely experienced an increase in weed spread.

Historical information indicates that since 1977, 3,357 claims have been made throughout the Marysville area. Today only 40 claims remain active, including the Bald Butte Mine, an open cut molybdenum mine. While currently a small scale operation (5 acres), there is a strong likelihood that Bald Butte will expand onto approximately 5 acres of BLM land in the future, and as many as 30 acres of open area collectively at one time. Activity began in 2006, and is anticipated to continue until at least 2015. Mining is a land disturbing activity and the

activity itself and weed seed contaminated equipment that is used could promote weeds in the area.

Noxious weeds and non-native invasive species are well established and spreading in the area. Weed control activities by BLM and other entities, while often effective at reducing or minimizing weed spread and weed populations, can also lead to some weed spread. Herbicide spray equipment is driven through weed infestations and weed seeds as well as other weed vegetative parts are spread to other lands during and following treatment. Herbicide and biological control treatments in recent years have been accomplished on approximately 20 to 30 acres in the Marysville area of the TPA. These weed treatments have varying success in killing undesirable plants, depending on many environmental parameters.

Timber sales have built-in stipulations for mitigating weed production and spread. However, with ground disturbance the potential exists for weed introduction to occur on these sites. Vehicular access for tree plantings could contribute to the spread of existing weeds on site. Since 1995 there have been 24 acres of timber salvage, 92 acres of timber harvest, and 48 acres of forest planting (replanted in 1998). Herbicide treatment of existing weeds is coordinated with tree seedling planting locations and timing, so as to minimize potential exacerbation of weed spread.

Future travel management (for all agencies, nationwide) is likely to lead to fewer opportunities for motorized recreational use than under current management (particularly for OHV use). As a result, BLM routes available to motorized use could experience increased use from displaced users, leading to more concentrated use and the potential for increased weed spread.

The TPA includes important wildlife habitat. The western half of the TPA is a wildlife movement corridor between the Northern Continental Divide Ecosystem and the Greater Yellowstone Ecosystem. Portions of the TPA are in the occupied range of grizzly bear range. Mule deer winter range is located along the eastern half of the TPA (158,140 acres) as well as near Lincoln (21,500 acres). Elk winter range is also located in the lower elevations along the eastern half of the TPA (193,800 acres) as well as around Lincoln (55,500 acres). Noxious weed seeds are transported and spread by wildlife through their digestive system and by attaching to the animals themselves and then being released at a later time.

Livestock grazing on and off BLM lands also contributes to weed spread either through seed being introduced/spread by livestock themselves, or through vehicular uses needed to manage grazing operations.

The majority of BLM routes in the Lewis and Clark County NW TPA are located in and around the town of Marysville, located approximately 25 miles northwest of Helena, Montana. Much of the use in the Marysville area (especially winter use) comes from Helena Valley resi-

dents. The Helena Valley has been experiencing steady human population growth. This trend is expected to continue, along with increased recreational use of this TPA. These factors could lead to increased public pressure to alter travel planning. The remaining BLM managed routes are located in three sub-planning areas: Stemple Pass, Sieben Ranch, and Lincoln (west of the small town of Lincoln, Montana). There is some residential development adjacent to the Lincoln sub-planning area that could influence travel management. The increasing population in the Helena area will in turn lead to an increase in use of this TPA creating more opportunities for weed spread and production.

The Marysville area is experiencing increased residential development, but to a lesser extent than the central Helena Valley area. This development/increase in population has led to an increase in use of the TPA by residents living adjacent to or within this area which in turn leads to an increase in weed spread and propagation. About 4.7 percent of all the open travel routes in the Lewis and Clark county NW TPA are located on BLM managed lands (under Alternative A). Lands near roads and away from roads in the TPA are infested with weeds. The travel on these roads is spreading weeds and weeds off these roads are being spread by the weed plants themselves and other natural means. Because the majority of roads (95.3 percent) and lands (95.8 percent) in the TPA are non-BLM, activities in these areas play a stronger role than activities on BLM lands in determining the status of weed spread and weed populations in the TPA overall.

## **VEGETATIVE COMMUNITIES – RIPARIAN VEGETATION**

### **Effects Common to All Alternatives**

This section focuses on effects to riparian vegetation. For additional discussion of effects to water quality and stream channels, see the Water Resources and Fish sections.

Roads in riparian areas constitute ground disturbance that can eliminate or preclude presence of native riparian vegetation. This ground disturbance and loss of riparian vegetation may facilitate erosion and sedimentation of streams. Roads may also interfere with natural stream channel functions by occupying floodplains or active stream channel margins (see Water Resources section for more discussion). Noxious weeds may dominate riparian vegetation communities after some type of disturbance (such as roads, livestock grazing, mining, etc.) has reduced native vegetation. Noxious weed seed can be spread into riparian areas by motor vehicles via open roads. Closure of roads and trails can improve or maintain riparian condition by reducing avenues of noxious weed spread, as well as allowing for bare area revegetation which filters sediment in addition to stabilizing banks in some areas. Road and trail restrictions have

the same effects but to a lesser degree, because some traffic will inhibit vegetation growth and recovery.

### Effects of the Alternatives

As a means of comparing alternatives, **Table 4-71** depicts the miles of wheeled motorized routes that cross or are within 300 feet of streams or wet areas on BLM lands for the Lewis and Clark County NW TPA.

<b>Miles of Wheeled Motorized Routes</b>	<b>ALT A</b>	<b>ALT B</b>	<b>ALT C</b>	<b>ALT D</b>
Open	19.6	5.1	4.1	7.8
Restricted	0.4	3.4	2.8	3.4
Closed	0	11.5	13.2	8.8

Under Alternative A, 19.6 miles of BLM roads and trails would remain open that cross or are within 300 feet of streams or wet areas, and 0.4 miles of roads and trails would have seasonal restrictions. The noxious weed spread, streambank, and sediment delivery effects would continue as described in the Effects Common to All Alternatives section for the open roads. The BLM roads and trails most affecting riparian conditions along Ottawa Gulch, Woodchopper Gulch, Empire Creek, and Towsley Gulch would remain open. Alternative A would have the greatest adverse effects on riparian vegetation of all alternatives.

Under Alternative B, 5.1 miles of BLM roads and trails would remain open that cross or are within 300 feet of streams or wet areas; 3.4 miles of roads and trails would have seasonal restrictions; and 11.5 miles of roads and trails near riparian areas would be closed. The noxious weed spread, streambank, and sediment delivery effects would continue as described in the Effects Common to All Alternatives section for the open roads. The BLM trail that travels up Woodchopper Gulch would be closed which would allow the serious erosion problem there to re-vegetate. Additionally, a number of smaller riparian areas would improve in condition from road and trail closures. Roads and trails most affecting riparian conditions along Ottawa Gulch, Empire Creek, and Towsley Gulch would remain open for access purposes. Alternative B would benefit riparian vegetation greater than Alternative A as the closed riparian roads would have some opportunity to revegetate and stabilize.

Under Alternative C, 4.1 miles of BLM roads and trails would remain open that cross or are within 300 feet of streams or wet areas, 2.8 miles of roads and trails would have seasonal restrictions, and 13.2 miles of roads and trails near riparian areas would be closed. The noxious weed spread, streambank, and sediment delivery effects

would continue as described in the Effects Common to All Alternatives section for the open roads. As under Alternative B, the BLM trail that travels up Woodchopper Gulch would be closed which would allow the serious erosion problem there to re-vegetate. Additionally, a number of smaller riparian areas would improve in condition from road and trail closures. Roads and trails most affecting riparian conditions along Ottawa Gulch, Empire Creek, and Towsley Gulch would remain open for access purposes. Alternative C would provide the most benefit to riparian vegetation than all other alternatives.

Under Alternative D, 7.8 miles of BLM roads and trails would remain open that cross or are within 300 feet of streams or wet areas, 3.4 miles of roads and trails would have seasonal restrictions, and 8.8 miles of roads and trails near riparian areas would be closed. The noxious weed spread, streambank, and sediment delivery effects would continue as described in the Effects Common to All Alternatives section for the open roads. As under Alternatives B and C, the BLM trail that travels up Woodchopper Gulch would be closed which would allow the serious erosion problem there to re-vegetate. Additionally, a number of smaller riparian areas would improve in condition from road and trail closures. Roads and trails most affecting riparian conditions along Ottawa Gulch, Empire Creek, and Towsley Gulch would remain open for access purposes. Alternative D would provide greater benefits to riparian vegetation than Alternative A, but less than either Alternatives B or C.

### Cumulative Effects on Riparian Vegetation

Noxious weed spread, mining, roads and trails, logging operations, and livestock grazing have affected riparian resource conditions in all TPAs, including the Lewis and Clark County NW TPA. Some of these factors continue to cause riparian area degradation primarily through direct disturbance or loss of riparian vegetation. Ground disturbance and loss of riparian vegetation facilitate erosion and sedimentation of streams. In the case of noxious weeds, they usually dominate riparian vegetation communities after some type of disturbance (such as roads, livestock grazing, mining, etc.) has reduced native vegetation.

Anticipated subdivision growth on private lands will lead to more road construction and maintenance. More roads and development will increase severity of runoff events which in turn will cause more sediment delivery to creeks and streams. The additional sediment is likely to affect the functioning condition of some riparian areas by causing streambeds to aggrade at unnatural rates. Streambanks may also be affected if road placements do not allow for natural stream movements or meanders.

Logging and forestry practices on public and private lands are subject to streamside management zone (SMZ) requirements designed to maintain water quality and

riparian vegetation. The proposed Riparian Management Zones under Butte RMP Alternatives B and C would be wider than SMZs and activities in these areas would be designed to benefit riparian resources, thus providing more riparian protection and more targeted management of riparian vegetation in both forested and non-forested areas than under RMP Alternatives A and D. The disturbance associated with timber activities does have the potential to increase noxious weed spread which degrades riparian area function and health. On public lands noxious weed control is a standard feature of any ground disturbing activities whereas on private lands noxious weed control is variable.

Livestock grazing will continue in the area and has the potential to impact riparian resource conditions. On BLM lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain riparian vegetation health and vigor. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided. Riparian conditions may improve or degrade as management changes.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, riparian conditions would improve because of the streambank protection gained from shrubby root systems and filtering capability of native riparian sedge and rush species.

A molybdenum mine was started on private land above Bald Butte. The mine may expand on other private and public lands in the future. The mine is at the headwaters of American Gulch and Dog Creek. Mine road traffic and maintenance has the potential to add extra sediment into the Ottawa Gulch and Dog Creek drainages. Abandoned mine lands were reclaimed in the Empire Creek and Piegan Creek watersheds in the 1990's. Riparian vegetation has recovered and improved in both drainages.

A number of privately owned blocks of land in the Dog Creek and Ottawa Creek drainages were logged within the past 20 years. Riparian vegetation was impacted at that time but has recovered to some degree.

Cumulatively the positive effects of Alternative B would be more than Alternative A. The closure and restrictions on 14.9 miles of roads would improve riparian conditions on several reaches. This may mitigate some of the predicted subdivision and potential mine road impacts.

Cumulatively the positive effects of Alternative C would be more than under either Alternatives A or B. The closure and restrictions on 16 miles of roads would improve riparian conditions on several reaches. This may mitigate some of the predicted subdivision and potential mine road impacts.

Cumulatively the positive effects of alternative D would be more than under Alternative A, but less than under either Alternatives B or C. The closure and restrictions on 11.4 miles of roads would improve riparian conditions on several reaches. This may mitigate some of the predicted subdivision and potential mine road impacts.

Overall, because BLM roads make up only 4.7 percent of all roads in the TPA (under Alternative A), and BLM lands make up 4.2 percent of all lands in the TPA, the contributions to riparian vegetation benefits associated with closing riparian roads on BLM lands would be relatively minor at the scale of the entire Lewis and Clark County NW TPA. Activities on private lands (53 percent of total acreage in TPA) and USFS lands (35 percent of total acreage in TPA) would play a dominant role in determining riparian conditions at the scale of the entire TPA.

## WILDLIFE

### Effects of Alternative A

Under Alternative A, the Lewis and Clark TPA would have considerably more open roads (64 miles) compared to the action alternatives and would have the highest actual road density in elk winter range, 2.6 mi/mi<sup>2</sup> (Table 4-72) compared to the action alternatives. Open roads typically increase the level of recreation adjacent to roads. This can result in additional disturbance and displacement of wildlife species. Roads can also encourage the public to recreate in areas that had formerly been secluded. Roads can cause direct mortality to wildlife through road kill, prevent wildlife movement, create

**Table 4-72**  
**Decision Area Road Densities (mi/mi<sup>2</sup>) within Elk Winter Range in the Lewis and Clark County NW Travel Planning Area by Alternative**

	<b>Actual Road Density</b>	<b>Acres of Low Road Density</b>	<b>Acres of Moderate Road Density</b>	<b>Acres of High Road Density</b>
<b>Alt. A</b>	2.6	2,241	3,424	10,263
<b>Alt. B</b>	0.9	4,945	4,283	7,060
<b>Alt. C</b>	0.7	6,245	4,722	5,321
<b>Alt. D</b>	1.2	3,828	4,597	7,862

Low Density = 0-1 mi/mi<sup>2</sup>, Moderate Density = 1-2 mi/mi<sup>2</sup>,  
High Density = >2 mi/mi<sup>2</sup>

disturbance to wildlife via vehicular use, cause the spread of noxious weeds, reduce habitat and cause habitat fragmentation on the landscape (Joslin et al. 1999). Open road miles that are greater than 2.5 mi/mi<sup>2</sup> have also been found to provide less than 45 percent of functional habitat for elk (Christensen et al. 1993). Permanent and temporary roads could negatively impact wildlife including special status species, particularly if roads are open during critical periods such as in lynx winter habitat and during the summer months within occupied grizzly bear habitat.

High open road densities under Alternative A could result in the loss of year-round habitat and migration corridors, disturbance and displacement of wildlife, road kill and fragmentation of habitat. Wildlife, including special status species, that are especially sensitive to roads in the TPA include (but are not limited to) elk, grizzly bear, lynx, wolverine and some raptors. The detrimental effects of open road densities to wildlife under Alternative A could be minor to major and long-term. This alternative would have the greatest negative impacts to wildlife including special status species from open roads.

Under Alternative A, this TPA would have substantially fewer acres of functional winter range (2,241 acres with low road density) compared to the action alternatives (Table 4-72). Alternative A would cause more disturbance and displacement of big game in winter range than all other alternatives.

Under Alternative A, approximately 900 acres of the Lewis and Clark TPA would be closed to snowmobile use with the remaining 17,000 acres open for cross country snowmobile use. Snowmobiling occurs in both the Decision and Planning Areas and the use of snowmobiles could have substantial negative effects to wintering big game, lynx, wolverine, and other wildlife species. Cross-country snowmobile use could cause harassment of wildlife during the high stress winter season, which could lead to individuals leaving an area (temporarily or permanently) and/or an increase in stress that could lead to mortality. Alternative A would have more detrimental effects to wildlife from cross-country snowmobile use than the action alternatives.

In evaluating impacts of travel planning on elk and other big game species, it is important to consider impacts on security habitat. Elk security is the inherent protection allowing elk to remain in an area despite increases in stress or disturbance associated with the hunting season or other human activities. Security habitat includes blocks of nonlinear forested habitats greater than 250 acres in size that are at least 0.5 mile from an open road (Hillis et al. 1991). Security habitat should also consist of larger trees (greater than 8 inches DBH) with vegetation dense enough to hide an adult elk (Thomas et al. 2002). Under Alternative A, there would be no functional security habitat for big game species on BLM lands

(Table 4-73). All of the action alternatives provide at least some security habitat on BLM lands.

	<b>A</b>	<b>B</b>	<b>C</b>	<b>D</b>
<b>Lewis and Clark County NW TPA</b>	0	1,510	2,183	701

Core areas are areas large enough for wildlife (especially animals with large home ranges such as carnivores and big game) to forage and reproduce. Subcore areas are areas that could act as stepping stones for wildlife as they move through the region (Craighead et al. 2002). Within all lands of the Lewis and Clark TPA there are approximately 236,024 acres identified as “core/subcore” habitat. In core/subcore habitat under Alternative A, there would be 65,283 acres with low road density, 37,754 acres with moderate road density and 132,987 acres with high road density in the TPA for all land ownerships. Alternative A would provide the lowest quality core and subcore habitat across the landscape of all the alternatives due to open roads.

On BLM lands, there are approximately 12,349 acres in core/subcore habitat. Under Alternative A, there would be 1,244 acres with low road density, 2,419 acres with moderate road density, but the majority of acres have high road density (8,685 acres), within core and subcore habitat. On BLM lands, Alternative A would provide substantially lower quality habitat in core and subcore habitat due to open roads of all alternatives.

Wildlife corridors are areas of predicted movement within or between core and subcore areas. Within the Lewis and Clark TPA there are no areas in the TPA mapped as high quality wildlife movement corridors. There are 20,184 acres mapped as moderate quality movement corridors throughout the entire TPA. In moderate quality movement corridors under Alternatives A, B and D there would be 13,715 acres with low road density, 4,674 acres with moderate road density, and 1,795 acres would have high road densities. These alternatives would have fewer acres with low road density and more acres with high road density compared to Alternative C at the landscape level.

On BLM lands in the TPA there are only 831 acres mapped as moderate quality movement corridors. Under Alternatives A, B and D there would be 360 acres with low road density, 89 with moderate density, and 381 with high road density in moderate quality movement corridors. These alternatives would have fewer acres with low road density and more acres with high road density compared to Alternative C on BLM lands.

Riparian areas provide crucial habitat and critical travel corridors for wildlife including special status species. Riparian areas also provide a refuge for native plants and animals in times of stress such as drought or fire. Roads in riparian areas can prevent use of these crucial areas by wildlife, limit use or cause loss of habitat (Wisdom et al. 2000). Under Alternative A there would be 19.6 miles of open road (roads within 300 feet of streams) in riparian areas.

Road densities within occupied grizzly bear habitat were analyzed using a moving windows analysis, which can more accurately evaluate road density. **Table 4-74** displays the results of the moving windows analysis within the Lewis and Clark TPA in both the Planning and Decision Areas. The moving windows analysis displays the acres in low, moderate and high road densities. Higher densities of open roads can impact the quality and quantity of grizzly bear habitat. Research has indicated that grizzly bears underutilize habitat near roads and other human activities (Mace et al. 1996; Mace et al. 1998, McLellan and Shackleton 1989). Restricting motorized access can aid in minimizing negative impacts on bears related to disturbance and interactions with humans.

As shown in **Table 4-74**, occupied grizzly bear habitat in the Lewis and Clark TPA is dominated by acres with high road density in both the Planning and Decision Areas. However, the percentage of acres with low road densities is greater in the Planning Area (21 percent) compared to the Decision Area (6 percent). Alternative A would have substantially fewer acres with low road density compared to the action alternatives and would have the greatest negative effects to grizzly bears and other special status species from open roads.

The actual road density on BLM lands within occupied grizzly bear habitat overlaying the Lewis and Clark TPA would be 2.4 mi/mi<sup>2</sup> under Alternative A. Alternative A would have the highest road density in occupied grizzly bear habitat of all the alternatives and would have road densities above those recommended by MFWP. Montana Fish, Wildlife and Parks recommends that land management agencies manage for an open road density of 1 mi/mi<sup>2</sup> or less in grizzly bear habitat (this is consistent with MFWP's statewide Elk Management Plan guidelines as well).

Because Alternative A would have the least amount of closed roads compared to the action alternatives, this alternative would have higher road densities within occupied grizzly bear habitat of the Lewis and Clark TPA in both the Planning and Decision Areas than the action alternatives and would result in more negative effects to grizzly bears from open roads.

### Effects of Alternative B

Under Alternative B, the Lewis and Clark TPA would have substantially fewer open roads (28 miles) compared to Alternative A (64 miles). Of the 28 miles of open roads, only 13.8 miles would be open year-round and the remaining 14.3 miles would be seasonally restricted. Alternative B would have more open roads than Alternative C (20 miles) but less than Alternative D (34 miles). Alternative B would decrease harassment to wildlife during all seasons of use but especially during the winter and spring compared to Alternatives A and D. This alternative would also improve habitat and reduce fragmentation more than Alternatives A and D, but less than Alternative C.

Under Alternative B, the actual road density in elk winter range in the Lewis and Clark TPA would be 0.9 mi/mi<sup>2</sup>, less than the maximum of 1 mi/mi<sup>2</sup> recommended by FWP in big game winter range. This is substantially lower than the road density under Alternative A, 2.6 mi/mi<sup>2</sup>, slightly higher than Alternative C (0.7 mi/mi<sup>2</sup>) and higher than Alternative D (1.2 mi/mi<sup>2</sup>) (**Table 4-72**). Open road miles that are 1 mi/mi<sup>2</sup> have been found to provide roughly 60 percent of functional habitat for elk (Christensen et al. 1993).

Under Alternative B, this TPA would have more BLM acres of functional winter range (4,945 acres in the low road density category) compared to Alternative A (2,241 acres), less than Alternative C (6,245 acres) and more than Alternative D (3,828 acres) (**Table 4-72**). Alternative B would improve the quality and quantity of winter range in the Lewis and Clark TPA compared to Alternatives A and D but would have substantially fewer beneficial effects to winter range than Alternative C.

All alternatives would have 888 acres closed to cross country snowmobile use. Alternatives B and D would have 12,650 acres open to cross country snowmobile use which would be lower than the acres open under Alter-

**Table 4-74**  
**Road Density within the Northern Continental Divide Ecosystem Distribution Zone of Grizzly Bear**

Travel Plan Area	Low Density (0-1 mi/mi <sup>2</sup> )				Moderate Density (1-2 mi/mi <sup>2</sup> )				High Density (2-3 mi/mi <sup>2</sup> )			
	A	B	C	D	A	B	C	D	A	B	C	D
Lewis and Clark TPA Planning Area	64,231	67,482	68,256	66,028	82,972	84,436	84,370	84,878	158,291	148,752	146,901	150,781
Lewis and Clark TPA Decision Area	665	3,097	3,781	1,976	2,348	3,563	3,650	3,696	9,059	3,390	2,660	4,635

native A (16,111 acres) but substantially more than would be open under Alternative C (0). Alternatives B and D would limit snowmobile use on 3,460 acres to open roads (49 miles). Alternatives B and D would have fewer negative effects to big game and other wildlife species than Alternatives A, but could have considerably more negative effects compared to Alternative C.

The amount of big game security habitat would be low, but still greater under Alternative B (1,510 acres) than Alternative A which would have no functional security habitat, and Alternative D which would have only 701 acres (**Table 4-73**). Alternative B would increase security habitat for big game more than Alternatives A and D.

For all land ownerships, Alternative B would increase the amount of core and subcore habitat with low road density to 68,109 acres, compared to 65,283 acres under Alternative A. Alternative B would also increase the acreage with moderate road density (38,719 acres) over Alternative A (37,754 acres), but would decrease acreage with high road density (129,195 acres) compared to Alternative A (132,987 acres). Alternative B would substantially improve core and subcore habitat across the landscape more than Alternatives A and D but less than Alternative C.

On BLM lands in core/subcore habitat, Alternative B would substantially increase the acreage with low road density (3,608 acres) compared to Alternative A (1,244 acres). Alternative B would also increase the acreage with moderate road density to 3,022 acres compared to Alternative A (2,419 acres) and would reduce the acreage with high road density to 5,719 acres compared to the 8,685 acres found under Alternative A. Alternative B would substantially improve core and subcore habitat on BLM lands in the TPA more than Alternatives A and D but less than Alternative C.

Effects of Alternative B on wildlife movement corridors would be the same as under Alternative A.

Alternative B would protect and restore more riparian habitat than Alternative A by reducing the miles of open roads in riparian areas to 5.1 miles (from 19.6 under Alternative A). Alternative B would allow for more breeding, foraging, and hiding habitat as well as improve more movement corridors for a wide variety of species than Alternatives A and D but less than Alternative C.

Under Alternative B, the actual road density within occupied grizzly bear habitat of the Lewis and Clark TPA and the Decision Area would be lower than under Alternatives A and D, but higher than under Alternative C. Under Alternative B, road densities in occupied grizzly bear habitat within the Lewis and Clark TPA would be 0.8 mi/mi<sup>2</sup> within the Decision Area. This would be below MFWP's maximum recommended road density in grizzly bear habitat of 1 mi/mi<sup>2</sup>.

Road densities and open roads can impact the quality and quantity of grizzly bear habitat. Research has indi-

cated that grizzly bears underutilize habitat near roads and other human activities (Mace et al. 1996; McLellan and Shackleton 1989). Restricting motorized access can aid in minimizing negative impacts on bears related to disturbance and interactions with humans.

Under Alternative B, grizzly bear habitat with acres of low road density within the Decision Area of the Lewis and Clark County NW TPA would be 26 percent (3,097 acres) of the total available habitat (**Table 4-74**). This would be a higher percentage of acres with low road densities compared to those available at the Planning Area scale within the Lewis and Clark TPA (22 percent). This would be substantially more acres in low road densities than Alternative A (665 acres). Grizzly bears generally adjust to disturbance associated with roads by avoiding the area. This results in a reduction in the amount of habitat available to the bears in heavily roaded areas. Roads also provide increased access into remote areas and encourage human settlement, recreational use, and other land uses. These activities can increase the frequency of human-bear conflicts and ultimately reduce habitat availability and grizzly populations. By increasing low road density areas, Alternative B would provide more suitable habitat for grizzly bears than Alternatives A and D but less suitable habitat compared to Alternative C (**Table 4-74**).

## Effects of Alternative C

Under Alternative C, the Lewis and Clark TPA would have substantially fewer open roads (20 miles) compared to Alternative A (64 miles). Of the 20 miles of open roads, only 8.0 miles would be open year-round and the remaining 12 miles would be seasonally restricted. Alternative C would also have fewer open roads than Alternative B (28 miles) and Alternative D (34 miles). Alternative C would decrease harassment to wildlife during all seasons of use but especially during the winter and spring more than all other alternatives. This alternative would also improve habitat and reduce fragmentation more than all other alternatives.

Under Alternative C, the actual road density in elk winter range in the Lewis and Clark TPA would be 0.7 mi/mi<sup>2</sup>, less than the maximum of 1 mi/mi<sup>2</sup> recommended by FWP in big game winter range. This is substantially lower than the road density under Alternative A (2.6 mi/mi<sup>2</sup>), slightly lower than Alternative B (0.9 mi/mi<sup>2</sup>), and higher than Alternative D (1.2 mi/mi<sup>2</sup>) (**Table 4-72**).

Under Alternative C, this TPA would have substantially more BLM acres of functional elk winter range (6,245 acres in low road density) compared to Alternative A (2,241 acres) and Alternative D (3,828 acres). This alternative would also have more acres of functional winter range than Alternative B (4,945 acres) (**Table 4-72**). Alternative C would improve the quality and quantity of winter range in the Lewis and Clark TPA more than all other alternatives.

As with Alternatives A, B and D, this alternative would have 888 acres closed to cross country snowmobile use. The remaining 16,111 acres would be limited to use on open routes (8 miles). This would greatly reduce the negative effects associated with snowmobile use to big game and other wildlife species more than all other alternatives because there would be no acreage open to cross country use.

Under Alternative C, the amount of big game security habitat on BLM lands (2,183 acres) would be greater than under any other alternative (**Table 4-73**).

For all land ownerships, Alternative C would increase the acreage of core and subcore habitat with low road density to 69,476 acres, compared to 68,109 acres under Alternative B and 65,283 acres under Alternative A. The acreage with moderate road densities would be similar under both Alternatives C and B (38,924 and 38,719 acres, respectively), but would be an increase over Alternative A (37,754 acres). Alternative C would decrease the acreage in high road density to 127,624 acres, which would be lower than Alternative B (129,195 acres) and Alternative A (132,987 acres). Alternative C would substantially improve core and subcore habitat across the landscape more than all other alternatives.

On BLM lands in core/subcore habitat, Alternative C would substantially increase the acreage with low road density (4,640 acres) compared to Alternative A (1,244 acres) and Alternative B (3,608 acres). Alternatives C and B would have similar acreages with moderate road density (3,079 acres and 3,022 acres, respectively), which would be more than Alternative A (2,419 acres). Alternative C would also decrease the acreage with high road density to 4,631 acres, which would be lower than both Alternative A (8,685 acres) and Alternative B (5,719 acres). Alternative C would substantially improve core and subcore habitat on BLM lands in the TPA more than all other alternatives.

For all land ownerships in moderate quality movement corridors, Alternative C would increase the acreage with low road density to 13,812 acres, increase the acreage with moderate road density to 5,009 acres, and decrease the acreage with high road density to 1,363 acres. Alternatives A, B and D would have the same acreages with low (13,715 acres), moderate (4,674 acres), and high (1,795 acres) road densities.

Under Alternative C, BLM lands in moderate quality movement corridors would have more acreage with low road density (444 acres), more acreage with moderate road density (383 acres), and less acreage with high road density (3 acres) compared to Alternatives A, B and D. Alternatives A, B and D would have the same acreages in low (360 acres), moderate (89 acres), and high (381 acres) road densities. Alternative C would improve the quality of movement corridors more than all other alternatives.

Alternative C would protect and restore more riparian habitat than Alternative A by reducing the mileage of open roads in riparian areas to 4.1 miles (from 19.6 under Alternative A). Alternative C would also have fewer open roads in riparian areas than Alternative B (5.1 miles) and Alternative D (7.8 miles). Alternative C would allow for more breeding, foraging and hiding habitat as well as improve more movement corridors for a wide variety of species than all other alternatives.

Under Alternative C, the actual road density within occupied grizzly bear habitat of the Lewis and Clark TPA and the Decision Area would be lower than with all other alternatives. Under Alternative C, road densities in occupied grizzly bear habitat within the Lewis and Clark TPA would be 0.6 mi/mi<sup>2</sup> within the Decision Area. This would be well below the maximum road densities recommended by MFWP of 1 mi/mi<sup>2</sup> or less in grizzly bear habitat.

Within occupied grizzly bear habitat, the number of acres with low road density in the Lewis and Clark TPA would be 31 percent (3,781 acres) of total available habitat (**Table 4-74**). This would be higher than the percent of habitat available at the Planning Area scale (22 percent). Alternative C would have substantially more BLM acres with low road density in occupied grizzly bear habitat than Alternative A (665 acres) and moderately more than Alternative D (1,976 acres). Alternative C would provide slightly more acres with low road density compared to Alternative B (3,097 acres).

Through travel management, Alternative C would provide the greatest benefit to grizzly bears and other special status species by reducing fragmentation of habitats, protecting larger blocks of habitat and reducing disturbance in occupied grizzly bear habitat.

## Effects of Alternative D

Under Alternative D, the Lewis and Clark TPA would have considerably fewer open roads (34 miles) compared to Alternative A (64 miles). Of the 34 miles of open roads, 19.6 miles would be open year-round and the remaining 14.5 miles would be seasonally restricted. Alternative D would have more open roads than Alternative B (28 miles) and Alternative C (20 miles). Alternative D would allow more harassment to wildlife during all seasons of use, especially during the winter and spring, than Alternatives B and C but less than Alternative A. This alternative would also improve habitat and reduce fragmentation more than Alternative A but less than Alternatives B and C.

Under Alternative D, the actual road density in elk winter range in the Lewis and Clark TPA would be 1.2 mi/mi<sup>2</sup>, more than the 1 mi/mi<sup>2</sup> recommended by MFWP in big game winter range. This is lower than the road density under Alternative A (2.6 mi/mi<sup>2</sup>), but higher than Alternative B (0.9 mi/mi<sup>2</sup>) and Alternative C (0.7 mi/mi<sup>2</sup>) (**Table 4-72**).

Under Alternative D, this TPA would have more BLM acres of functional winter range (3,828 acres in low road density) compared to Alternative A (2,241 acres) but considerably less than Alternative B (4,945 acres) and Alternative C (6,245 acres) (**Table 4-72**). Alternative D would improve the quality and quantity of winter range in the Lewis and Clark TPA more than Alternative A but would have substantially fewer beneficial effects to winter range than Alternatives B and C.

Effects associated with snowmobile use under Alternative D would be the same as under Alternative B.

The amount of big game security habitat on BLM lands would be low under Alternative D with 701 acres, but more than under Alternative A which would have no functional acres of security habitat. Alternative D would have fewer acres of security habitat than any other action alternative (**Table 4-73**).

For all land ownerships in core and subcore habitat, Alternative D would have more acreage with low road density (66,988 acres) compared to Alternative A (65,283 acres). Alternative D, however, would have fewer acres with low road density compared to Alternative B (68,109 acres) and Alternative C (69,476). The acreage with moderate road density under Alternative D (39,136 acres) would be more than with Alternative A (37,754 acres), Alternative B (38,719 acres) and Alternative C (38,924 acres). Alternative D would have fewer acres (129,900) with high road density than Alternative A (132,987 acres) but would have more acres with high road density than Alternatives B (129,195) and Alternative C (127,624). Alternative D would improve core and subcore habitat across the landscape more than Alternative A but less than Alternatives B and C.

On BLM lands in core/subcore habitat, Alternative D would increase the acreage with low road density (2,706 acres) compared to Alternative A (1,244 acres), but would have considerably fewer acres with low road density than Alternative B (3,608 acres) and Alternative C (4,640 acres). Alternative D would have more acreage with moderate road density (3,192 acres) than Alternative A (2,419 acres), but less than either Alternative B or Alternative C. Alternative D would decrease the acreage with high road density to 6,452 acres compared to Alternative A (8,685 acres), but would have more acres with high road density than Alternative B (5,719 acres) and Alternative C (4,631 acres). Alternative D would improve core and subcore habitat on BLM lands in the TPA more than Alternative A but less than Alternatives B and C.

Effects of Alternative D on wildlife movement corridors would be the same as under Alternatives A and B.

Alternative D would protect and restore more riparian habitat than Alternative A by reducing the miles of open roads in riparian areas to 7.8 miles (from 19.6 under Alternative A). Alternative D would have more open roads in riparian areas than Alternative B (5.1 miles) and

Alternative C (4.1 miles). Alternative D would allow for more breeding, foraging and hiding habitat as well as improve more movement corridors for a wide variety of species than Alternative A but less than Alternatives B and C.

The actual road density, under Alternative D, in occupied grizzly bear habitat within the Lewis and Clark TPA would be 1.3 mi/mi<sup>2</sup> within the Decision Area. This would be above the maximum MFWP recommended road density in occupied grizzly bear habitat of 1 mi/mi<sup>2</sup>.

Under Alternative D, the percent of total available grizzly bear habitat with low road density in the Lewis and Clark TPA would be 19 percent (1,976 acres) (**Table 4-74**). This would be a lower percentage compared to the percentage available at Planning Area scale (22 percent). Alternative D would have more acres in low road density in occupied grizzly bear habitat than Alternative A (665 acres), but substantially fewer acres than Alternative B (3,097 acres) and Alternative C (3,781 acres).

Alternative D would provide more acres of suitable habitat for grizzly bears than Alternative A but fewer acres of suitable habitat compared to Alternatives B and C.

## Cumulative Effects on Wildlife

Wildlife habitat in the Lewis and Clark TPA has been affected by roads, historic and current mining, timber harvest, weed infestations, urbanization and development, recreation, powerline corridor development, and communication sites.

The majority of BLM managed routes for the Lewis and Clark TPA are located in and around the town of Marysville, located approximately 25 miles northwest of Helena. The Marysville area is experiencing increased residential development, but to a lesser extent than the central Helena Valley area. Much of the use in the Marysville area (especially winter use) comes from Helena Valley residents. The Helena Valley has been experiencing steady population growth. This trend is expected to continue, along with increased recreational use of this travel planning area. The remaining BLM-managed routes are located in 3 sub-planning areas: Stemple Pass, Sieben Ranch, and Lincoln.

Land that was traditionally used for ranching, forest products, or mining is now being converted to home sites around Marysville and throughout the rest of the TPA. Although these lands had historic human uses, they also provided quality wildlife habitat. These areas historically provided a diversity of habitats that contributed to; big game winter range, travel corridors, habitat for resident and migrating wildlife, as well as foraging, breeding and hiding habitat. Many of the areas currently experiencing residential development are in big game winter range. Because of the loss of winter range on private lands, it is critical that public and state lands maintain quality and secure winter range or improve the habitat in these areas.

For many plant and animal communities, native species richness decreases as housing density increases. Non-native species, however, tend to increase with development (Hansen et al. 2005). Wildlife populations, including carnivores, may be reduced even at very low levels of residential development due to; loss of habitat, an increase in human access (from roads) in areas that previously had low levels of disturbance, and an increase in hunting pressure. Residential development can also lead to an increase in noxious weed infestations that can reduce the quality and quantity of wildlife habitat.

Pets can also have a negative impact to native wildlife. Cats hunt and kill bird and small mammals. Dogs that are allowed to roam can chase, injure, or kill wildlife. This can result in areas becoming unavailable to wildlife.

Recreation use is well established in the TPA, especially for winter sports. Winter sport activities include: snowmobiling, downhill skiing (Great Divide Ski Area), backcountry skiing, ski racing, snowboarding, and snowshoeing. An extensive network of roads and trails support a wide range of off-season activities, including: camping, hunting, target practice, hiking, jogging, horseback riding, mountain bike riding, and motorized use (motorcyclists, OHV riders, and 4-wheel drive enthusiasts). As recreation use grows, conflicts between non-motorized and motorized recreation users could lead to increased public demands for either more, or less motorized use.

Since 1977, approximately 3,360 mining claims have been active throughout the Marysville area. Currently, only 40 claims are active, including the Bald Butte Mine, an open cut molybdenum mine. While currently a small scale operation (5 acres), there is a strong likelihood that Bald Butte will expand to approximately 30 acres in the future with roughly 5 acres on BLM lands. Activity began in 2006, and is anticipated to continue until at least 2015. Increases in mineral prices could lead to additional increased or renewed mining activity.

In the TPA, there are 17 powerlines and 4 pipelines. There are eight existing communication sites in the TPA but, in the future, communication sites on BLM lands will be restricted to existing sites. No future communication sites are expected in the TPA on BLM lands but they could occur on private or other public lands. There is the potential for future powerlines and pipelines to be built in this TPA.

There are approximately 44 rights-of-way (ROW) in the TPA and applications for ROW permits to access private property or for commercial development are likely to increase in the future. As a result, public access to BLM lands could increase. Fewer ROWs would be expected under Alternative A because more BLM roads would remain open under this alternative. Alternative B would be expected to have fewer ROWs than Alternative C but more than Alternatives A and D. Alternative C would be

expected to have the most ROWs and, of the action alternatives, Alternative D would have the fewest.

From 1981-2004 there have been 14 wildland fires that burned 83 acres of BLM lands (it is unknown how many acres burned in the entire TPA). Seven of the fires were identified as human-caused and these fires burned the majority of the BLM acres (75). Fuels reduction activities could occur around the town of Marysville. Timber harvest has occurred on approximately 130 acres of BLM lands in the TPA over the last 23 years and there have been approximately 70 acres of timber salvage. Vegetative treatments on BLM lands have had minor effects to wildlife habitat in the TPA. However, timber harvest, salvage, past mining activities and development on private lands have altered the landscape and may have caused a decline in the quality and quantity of wildlife habitat in the TPA.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the TPA. Motorized activities play a large role in the distribution of noxious weeds. The cumulative effects of the spread of noxious weeds from open roads would be greater under Alternative A than all other alternatives. Alternative A would result in more wildlife habitat being lost or degraded due to noxious weed infestations compared to the action alternatives. Alternative B would have fewer open roads than Alternatives A and D resulting in fewer infestations of noxious weeds. Alternative C would close the most roads and would have the fewest cumulative effects from loss of habitat due to noxious weeds of all alternatives. Open roads and development adjacent to BLM lands and the substantial amount of public use this area receives would still allow for the spread of noxious weeds.

Fragmentation of BLM lands in the TPA (only 4 percent in BLM ownership); open roads on BLM lands (about 68 miles), on private lands (about 900 miles) and other public lands (about 480 miles); as well as adjacent development has reduced the quality of wildlife habitat within the TPA. Large blocks of Forest Service lands (35 percent of TPA) are found in the TPA and do provide high quality wildlife habitat. However, open Forest Service roads as well as roads and development throughout the rest of the TPA cause disturbance to wildlife along with fragmentation and loss of habitat in the TPA. Roads are associated with nearly every type of activity that has the potential to occur in the TPA including vegetation treatments, timber salvage, mining, access to private lands (ROWs), fire suppression, powerline corridors, and recreation. Open roads in the Planning Area would likely increase due to development and management of private lands. Alternative A would have the greatest negative cumulative effects to wildlife and wildlife habitat from open roads with 64 miles of open roads. Alternative B would have fewer negative cumulative effects with 28 miles of open road than Alternatives

A and D (34 miles) but more than Alternative C (20 miles).

Of the action alternatives, Alternative C would have the most beneficial cumulative effects by reducing habitat fragmentation, restoring habitat and reducing disturbance. Alternative B would be more beneficial than Alternatives A and D but less than Alternative C.

Historic and recent timber cutting (mostly on private lands), timber salvage, past and present mining activity and firewood gathering in the TPA have reduced the amount of suitable snag habitat for cavity nesting species. Alternative A would allow a substantial amount of access to the area for firewood cutting. This could continue to prevent snag recruitment for snag dependant species and minimize the amount of down woody material. Alternative B would protect more snag and down wood habitat from loss due to firewood cutting than Alternatives A and D, but would protect less of this habitat type than Alternative C.

In the Lewis and Clark TPA high road densities in both the Decision and Planning Areas have prevented BLM lands from providing suitable security habitat for big game during the hunting seasons under Alternative A. Alternatives B and C would provide the most security habitat for big game on BLM lands (1,510 and 2,183 acres, respectively) and Alternative D would provide 701 acres. Security habitat would still be limited on private (unless closed to hunting) and other public lands. The reduction of open roads during the hunting season would help mitigate for the loss of security habitat on adjacent lands under Alternatives B and C.

Approximately 58 percent of the TPA is mapped as core and subcore habitat. All of the core and subcore habitat is in the western half of the TPA and is predominately Forest Service lands. Fragmentation of habitat due to development of private lands, open roads, and disturbance, has impacted the quality of core/subcore habitat and wildlife movement corridors in the TPA.

Habitat mapped as core and subcore habitat and wildlife movement corridors having high road densities would continue to be of lower value to wildlife under Alternative A. An increase in open roads in both the Decision and Planning Areas could result in a loss of core and subcore habitat under all alternatives but, especially, Alternative A. Although core/subcore habitat and wildlife movement corridors would continue to be impacted by development on private lands, Alternatives B and C would allow more BLM lands to function as core/subcore habitat and wildlife movement corridors. Alternatives B and C would have fewer negative cumulative effects to core/subcore and wildlife habitat than Alternatives A and D.

The cumulative effects of high road densities would continue to negatively affect wildlife species during the breeding season more under Alternative A than under the action alternatives. Alternatives B and C would have

the most beneficial cumulative effects to wildlife during the breeding season compared to Alternative D and, especially, Alternative A.

## FISH

For the sake of this discussion, “open” roads include roads that are open with seasonal restrictions as well as roads that are open yearlong. Roads identified as “closed” within 300 feet of streams also include roads that would be “decommissioned” in these areas by alternative. Effects to water quality described in the Water Resources section would affect fish populations and fish habitat quality. Analyses described and tabulated in the Water Resources section are referred to in the context of effects to fish in the discussion below.

### Effects of Alternative A

Under Alternative A, the Lewis and Clark TPA would have considerably more open roads (64 miles) compared to the action alternatives. Roads can have a wide range of effects on fish and fish habitat. These effects would include, but are not limited to, increased sedimentation from road construction and vehicle use, increased runoff, changes in surface water and drainage patterns from stream crossings, conduits for noxious weeds, loss of riparian vegetation, potential decreases in stream shading that could lead to water temperature increases, and changes in local fish populations when culverts are impassable and limit fish migration.

Watershed (or hydrologic) function can be used as an indicator of relative risk or impacts to fish habitat. Generally, watersheds with high road densities often have the largest negative effects on fish and aquatic resources. To determine the effects on watershed function, a moving windows analysis was conducted on BLM lands to look at the miles of roads that would be decommissioned and removed from the landscape for each alternative. During this analysis, it was assumed that even though closing roads would improve watershed function, closed roads would remain on the landscape and could still have negative impacts to water quality and prevent or impede the restoration of riparian vegetation. Under Alternative A, there would be 2,614 acres with low road density, 3,444 acres with moderate road density and 10,979 acres with high road density on BLM lands in the TPA (**Table 4-69**). Alternative A would have fewer acres with low road density and more acres with high road density than the action alternatives. This alternative would be expected to have greater overall negative effects to watershed function due to roads than the action alternatives.

For this discussion, road miles within 300 feet of fish bearing streams would be considered an indicator of direct effects to fish habitat and fish populations. Under Alternative A, there would be 0 miles of closed road and 7.4 miles of open road within 300 feet of fish bearing streams on BLM lands. Alternative A would have 2.1-

2.6 fewer miles of closed roads (and the same number more of open road miles) adjacent to fish bearing streams than the action alternatives. Of the 7.4 miles of open road adjacent to fish bearing streams under Alternative A, 4.6 miles are along streams with BLM special status fish species (bull trout and/or westslope cutthroat trout). Alternative A would have more long-term negative impacts to westslope cutthroat trout (the effects to bull trout would be the same for all alternatives) as well as to other fish species than the action alternatives.

Perennial non-fish bearing streams contribute to fish habitat indirectly by serving as conduits for watershed products (water, sediment, nutrients, contaminants, and in some cases woody material) to fish bearing streams. Under Alternative A, there would be 0.1 miles of closed road and 5.1 miles of open road within 300 feet of perennial non-fish bearing streams on BLM lands in the TPA. Alternative A would have substantially more miles of open road adjacent to perennial streams than Alternatives B (1.7 miles), C (1.4 miles) and D (2.5 miles).

This alternative would have the greatest negative impacts to fish and aquatic resources from open roads.

### Effects of Alternative B

Under Alternative B, the Lewis and Clark TPA would have substantially fewer open roads (28 miles) compared to Alternative A (64 miles). Alternative B would have more open roads than Alternative C (20 miles) but less than Alternative D (34 miles).

In the context of watershed function, Alternative B would have approximately 461 more acres in the low road density category, 1,082 more acres in the moderate road density category, and 1,543 fewer acres in the high road density category on BLM lands than Alternative A (**Table 4-69**). Alternative B would contribute to improved watershed function more than Alternative A. This analysis does consider “decommissioned” roads, but does not consider “closed” roads as contributing to watershed function. Even though closed roads could still have adverse effects to aquatic habitats, these roads have more potential to become revegetated and lessen sedimentation and runoff, and restore riparian vegetation (thus contributing to improved fish habitat conditions) than open roads. Under Alternative B, there would be approximately 23 more miles of closed roads than under Alternative A, an additional indication that Alternative B would pose less of an impact to fish habitat than Alternative A. Alternatives B and D would have 2.1 miles of closed road and 5.3 miles of open road within 300 feet of fish bearing streams on BLM lands. Of the 5.3 miles of open roads, 3.2 miles would be adjacent to streams with special status species (westslope cutthroat trout and/or bull trout). Alternative B would reduce effects to fish bearing streams (including streams with special status species) more than Alternative A because all of these riparian roads would remain open under Alternative A. Alternative B would contribute fewer indirect effects to

fish habitat associated with roads within 300 feet of perennial non-fish bearing streams than Alternative A. Under Alternative B there would be 3.3 miles of closed road and 1.7 miles of open road in these riparian areas on BLM lands. This would pose less impact to these areas than under Alternative A where all 5.0 miles would be open.

Alternatives B would have fewer road-related adverse effects to fish and aquatic habitats than Alternative A.

### Effects of Alternative C

Under Alternative C, the Lewis and Clark TPA would have substantially fewer open roads (20 miles) compared to Alternative A (64 miles). Alternative C would also have fewer open roads than Alternative B (28 miles) and Alternative D (34 miles).

In the context of watershed function, Alternative C would result in approximately 79 more acres in the low road density category, 632 more acres in the moderate road density category, and 711 fewer acres in the high road density category on BLM lands than Alternative A (**Table 4-69**). This alternative would have 382 fewer acres in the low road density category, 450 more acres in the moderate road density category, and 832 more acres in the high road density category than Alternative B. Under Alternative C there would be approximately 38 more miles of closed roads than under Alternative A, and about 15 more miles of closed roads than under Alternative B. Alternative C would lessen effects to fish habitat through improved watershed function more than Alternative A, but less than Alternative B.

Alternative C would have the most miles of closed roads (2.6) and the fewest miles of open roads (4.8) within 300 feet of fish bearing streams on BLM lands of all alternatives. Of the 4.8 miles of open roads, 2.9 miles would be adjacent to streams with special status species (westslope cutthroat trout and/or bull trout). In terms of direct effects from roads adjacent to fish bearing streams, Alternative C would have the most benefits to fish habitat of all alternatives.

Alternative C would contribute fewer indirect effects to fish habitat associated with roads within 300 feet of perennial non-fish bearing streams on BLM lands than all other alternatives. Under Alternative C there would be 3.6 miles of closed road and 1.4 miles of open road within 300 feet of perennial non-fish bearing streams on BLM lands in the TPA. This is a range of 0.3-3.6 more closed road miles in these areas than under the other alternatives.

Alternative C would provide more benefits to fish and aquatic habitats associated with roads in close proximity to streams than any other alternative. This alternative would provide less benefit to aquatic resources from improvements to hydrologic function than Alternative B, but more than Alternative A.

## Effects of Alternative D

Under Alternative D, the Lewis and Clark TPA would have considerably fewer open roads (34 miles) compared to Alternative A (64 miles). Alternative D would have more open roads than Alternative B (28 miles) and Alternative C (20 miles).

In the context of watershed function, Alternative D would result in approximately 321 more acres in the low road density category, 1,002 more acres in the moderate road density category, and 1,324 fewer acres in the high road density category on BLM lands than Alternative A (Table 4-69). This alternative would have 140 fewer acres in the low road density category, 80 fewer acres in the moderate road density category, and 219 more acres in the high road density category than Alternative B. Under Alternative D there would be approximately 17 more miles of closed roads than under Alternative A, approximately 6 fewer miles of closed roads than under Alternative B, and approximately 21 fewer miles of closed roads than under Alternative C. Alternative D would lessen effects to fish habitat through improved watershed function more than Alternatives A and C, and to a similar degree as Alternative B.

Alternative D would have fewer miles of closed road (2.1) and more miles of open road (5.3) within 300 feet of fish bearing streams on BLM lands than Alternatives B and C. Of the 5.3 miles of open roads, 3.2 miles would be adjacent to streams with special status species (westslope cutthroat trout and/or bull trout). Alternative D would reduce direct effects to fish bearing streams (including streams with special status species) more than Alternative A but less than Alternatives B and C.

Alternative D would contribute more indirect effects to fish habitat associated with roads within 300 feet of perennial non-fish bearing streams on BLM lands than Alternatives B and C but less than Alternative A. Under Alternative D there would be 2.5 miles of closed road and 2.5 miles of open road within 300 feet of perennial non-fish bearing streams on BLM lands in the TPA. Alternative D would contribute fewer direct effects to aquatic habitats (fish bearing and non-fish bearing) from roads than Alternative A but more than Alternatives B and C.

Although Alternative D would contribute to improved fish habitat conditions from a hydrologic function standpoint to a similar degree as Alternative B, overall this alternative would have more adverse effects to fish and aquatic habitats than Alternatives B and C, but less than Alternative A.

## Cumulative Effects on Fish

The Lewis and Clark TPA supports a variety of native and introduced fish species. One of the major human influences to fish in the TPA has been the introduction of non-native trout species including rainbow trout, brook trout, and brown trout throughout the TPA. Rain-

bow trout have hybridized with the native westslope cutthroat trout in many streams. Brook trout and brown trout have displaced the native cutthroats in other streams, especially those altered by sedimentation and increased water temperatures brought on by human activities.

Due to their life history requirements, bull trout are more sensitive to increased water temperatures, poor water quality, and low flow conditions than many other salmonids. Past and continuing land management activities have degraded stream habitat, especially along larger river systems and stream areas located in valley bottoms, to the point where bull trout can no longer survive or reproduce successfully across their range. Brook trout easily hybridize with bull trout producing sterile offspring. Brook trout also reproduce earlier and at a higher rate than bull trout. Hybridization with brown trout may also be a problem in some areas of the TPA.

The majority of BLM managed routes for the Lewis and Clark TPA are located in and around the town of Marysville. The Marysville area is experiencing increased residential development, but to a lesser extent than the central Helena Valley area. The remaining BLM managed routes are located in three sub-planning areas: Stemple Pass, Sieben Ranch, and Lincoln. Bull trout are only found in the Blackfoot watershed that would be impacted by travel planning in the Lincoln Area.

Recreation use is well established in the TPA, especially for winter sports. Winter sport activities include: snowmobiling, downhill skiing (Great Divide Ski Area), backcountry skiing, ski racing, snowboarding, and snowshoeing. An extensive network of roads and trails support a wide range of off-season activities, including: camping, hunting, target practice, hiking, jogging, horseback riding, mountain bike riding, and motorized use.

Agricultural activities from farming and ranching contribute increases in nutrients, sedimentation, and loss of aquatic habitats through direct stream channel alterations. Many streams in the TPA have been impacted by historic and ongoing livestock grazing that breaks down streambanks, widens channels, removes vegetative cover and causes an increase in fine sediment and nutrients.

Since 1977, approximately 3,357 mining claims have been active throughout the Marysville area. Today 40 claims remain active, including the Bald Butte Mine, an open cut molybdenum mine. Increases in mineral prices could lead to increased or renewed mining activity. Many watersheds in the TPA have been degraded by historic mining activities.

Aquatic habitats have been affected by stream channel alteration and heavy metal contamination associated with historic mining and abandoned mine lands in some portions of this TPA. See the Water Resources section for this TPA for more details.

Fires, floods, and drought have historically affected fish habitat in the TPA. These disturbances can cause a pulse of sediment or may temporarily reduce the quality of fish habitat in some watersheds while leaving other streams largely unaffected. Population recovery in disturbed streams may be facilitated by fish immigration from nearby drainages less affected by the catastrophic event. Some natural disturbances may have short-term adverse effects but long-term beneficial effects to fish habitat such as increasing large wood recruitment to streams and floodplains. From 1981-2004 there have been 14 wildland fires that burned 83 acres. Seven of the fires were identified as human-caused and these fires burned the majority of the acres (75). Fuels reduction activities could occur around the town of Marysville in the future. Effects to fish habitat from these activities would likely be minimal.

Timber harvest can alter the recruitment of large woody debris, reduce canopy closures and result in an increase in fine sediment to streams. Timber harvest along with associated roads can contribute substantially to the overall cumulative effects in forested watersheds. Timber harvest has occurred on approximately 130 acres of BLM lands in the TPA over the last 23 years and there have been approximately 70 acres of timber salvage. Vegetative treatments on BLM lands have had minor effects to aquatic habitats in the TPA. However, timber harvest, salvage and past mining activities on private lands have altered the landscape and may have caused a decline in the quality and quantity of aquatic habitat in the TPA. Roads are another major contributor of sediment to streams and a major problem with regards to cumulative watershed effects. Roads and trails can have localized effects on nearby stream segments or at stream crossing sites, especially fords. Cumulatively, roads degrade aquatic habitat due to sedimentation from road construction and vehicle use, increased runoff, changes in surface water and drainage patterns from stream crossings, loss of riparian vegetation, loss of large woody material and roads can cause changes in local fish populations when culverts are impassable and limit fish migration. Alternative A would have more negative cumulative effects to watersheds and individual streams due to roads than the action alternatives. Alternative B would have fewer negative cumulative effects than Alternatives A and D but more than Alternative C. Alternative B would improve overall watershed function as well as improve habitat in individual streams more than Alternatives A and D but less than C. Alternative C would have the greatest beneficial effects overall.

## **SPECIAL STATUS PLANTS**

### **Effects Common to All Alternatives**

Ground-disturbing activities from road construction and maintenance, as well as road use by vehicles can affect special status plant populations and habitat. These activities can reduce sensitive plant species through distur-

bance to individual populations, increasing competition from invasive species, and reducing habitat connectivity. Closure of roads and trails can improve or maintain sensitive plant populations or habitat by reducing avenues of noxious weed spread, maintaining habitat connectivity, and improving pollinator habitat. Road and trail restrictions have the same effects but to a lesser degree.

### **Effects of the Alternatives**

Under Alternative A, 57.5 miles of BLM roads and trails would remain open, 6.7 miles of roads and trails would be open with seasonal restrictions, and 3.4 miles of roads and trails would be closed. On the open roads, effects would continue as described in the Effects Common to All Alternatives section. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators.

Under Alternative B, 13.8 miles of BLM roads and trails would remain open, 14.3 miles of roads and trails would be open with seasonal restrictions, 26.8 miles of roads and trails would be closed, and 10.9 miles would be decommissioned. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The restricted roads would reduce weed spread a limited amount. Because more road miles would be closed under this alternative, Alternative B would benefit and reduce risk to special status plants more than Alternative A.

Under Alternative C, 8 miles of BLM roads and trails would remain open, 11.7 miles of roads and trails would be open with seasonal restrictions, 41.6 miles of roads and trails would be closed, and 5.2 miles would be decommissioned. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The restricted roads would reduce weed spread a limited amount. Alternative C would benefit and reduce risk to special status plants more than any other alternative because it would eliminate disturbance, vehicular use, and spread of noxious weeds on the most road miles.

Under Alternative D, 19.6 miles of BLM roads and trails would remain open, 14.5 miles of roads and trails would be open with seasonal restrictions, 20.3 miles of roads and trails would be closed, and 8.8 miles would be decommissioned. On the open roads, effects would continue as described in the Effects Common to All Alternatives section. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The restricted roads would reduce weed spread a limited amount. Alternative D would benefit and reduce risk to special status plants more than Alternative A, but would pose more risk compared to Alternatives B and C.

## Cumulative Effects on Special Status Plants

Under all alternatives there are a number of past, present, and reasonably foreseeable future actions that affect special status plant populations.

Livestock grazing will continue in the area and has the potential to impact sensitive plant populations and habitat. On public lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain sensitive species populations and habitat. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided. Conditions may improve or degrade as management changes.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, sensitive plants would benefit from the reduced competition. Use of herbicides for noxious weed control could cause mortality to special status plants if individual plants are inadvertently sprayed.

Recent and anticipated subdivision growth on private lands will lead to more road construction and maintenance. More roads and development will reduce sensitive plant species habitat and in some cases individual populations. Additionally, subdivisions have the potential to disrupt the connectivity of plant habitat and populations as well as disturbing or eliminating pollinators needed by sensitive species. Some sensitive species that require soil disturbance may benefit.

Timber sale activity disturbance can destroy or degrade sensitive plant habitat. On public lands, projects would be designed to avoid, mitigate, or enhance sensitive plant habitats. The disturbance associated with timber harvest activities does have the potential to increase noxious weed spread which degrades sensitive species habitat and individual plant populations.

A molybdenum mine was started on private land above Bald Butte. The mine may expand on other private and public lands in the future. Impacts are not expected from this activity, because no sensitive plant species or habitat have been identified in the area at this time. A survey would be conducted prior to any disturbance on public land.

At the scale of the entire Lewis and Clark County NW TPA (all land ownerships), the BLM travel plan alternatives would have slightly variable contributions to cumulative effects on special status plants. Under Alternative A less than 1 percent of all roads in the TPA would be closed. Under Alternative B adverse effects on special status plants would be slightly reduced compared to Alternative A because 2.6 percent of all roads in the TPA would be closed or decommissioned. Alternative C would provide the most benefits of all alternatives as 3.2 percent of all roads in the TPA would be closed or de-

commissioned. Alternative D would provide slightly more benefits than Alternative A but slightly fewer benefits than either Alternatives B or C as 2 percent of all roads in the TPA would be closed or decommissioned. Because BLM lands make up only 4.2 percent of all lands in the TPA, activities on non-BLM lands would play a greater role in determining the status of special status plants.

## WILDLAND FIRE MANAGEMENT

Travel planning alternatives were analyzed to determine whether they could result in impact on wildland fire management, causing change to any of the following indicators:

- Fire regime condition class (FRCC)
- Firefighter and public safety
- Reducing threat to Wildland Urban Interface (WUI)

## Effects Common to All Alternatives

Public road access during the fire season provides opportunities for human-caused fires either due to catalytic converters on vehicles igniting dry vegetation, or due to some types of human activities. Roads that are closed to public access reduce the risk of human-caused fire starts in those areas.

Decommissioned roads and roads that are closed and not regularly maintained for navigability reduce access for fire suppression. Closed roads may become impassible due to vegetation regrowth, downfall of trees, or severe erosion. Some roads may be closed with earthen berms or fallen trees and would need to be physically manipulated to make them useable for vehicles again. These roads would extend firefighting response time and have negative impacts on efforts to reduce wildland fire threat to WUI areas and firefighter and public safety. In an emergency fire suppression situation, any navigable closed roads needed for fire suppression would be used immediately. Non-navigable closed roads could also be used if deemed to be needed for fire suppression, after needed improvements are made to make those roads useable. Planning and implementation of fuels reduction treatments could occur in association with closed roads if variances for temporary road use were to be allowed. Variances would be subject to internal BLM review.

In the context of fuels reduction projects, availability of open roads is important to facilitating fuels project location as well as increasing project feasibility and decreasing costs. Open roads also facilitate spread of noxious weeds by transporting weed seed on vehicles and their tires. Presence of large noxious weed populations could delay or cause fuels projects to be cost-prohibitive due to the fact that the weeds may have to be treated before and/or after the fuels treatment. Also, some applications of fuel treatments (e.g., prescribed fire) may promote the

spread of some weeds. The presence of weeds and non-native species are indicators that FRCC has departed from historical conditions.

Noxious weeds and non-native invasive species are well established and spreading in the Lewis and Clark County NW TPA.

### Effects of Alternative A

Under Alternative A, the majority of routes in the Lewis and Clark County NW TPA would be available for wheeled motorized use (57.5 miles open yearlong, 6.7 miles seasonally restricted), while 3.4 miles would continue to be closed. Alternative A would allow for the greatest flexibility between alternatives for access for suppression purposes. Fuels project feasibility would be highest under this alternative. However, public access during the fire season would be the greatest under this alternative and would provide the most opportunities for human-caused fire starts.

The distribution of noxious weeds could be the greatest in alternative A with the most open roads and noxious weeds already well established. This would contribute to reduced feasibility of fuels reduction projects more than under any other alternative.

### Effects of Alternative B

Alternative B provides for separate use areas for wheeled motorized and non-motorized recreational opportunities. Under Alternative B, a total of 28.1 miles of routes would be available for motorized wheeled use (13.8 miles open yearlong, 14.3 miles seasonally restricted). The majority of routes located in the Stemple Pass and Lincoln areas would be closed, providing additional non-motorized opportunities. Alternative B would limit the flexibility for access for suppression purposes and fuels project feasibility would go down compared to Alternative A due to the fact that access would be limited to 28.1 miles of road. Of the 36.7 miles of closed roads, 10.9 miles would be decommissioned and would likely be unusable for fire suppression. The risk of human-caused fires associated with motorized use would be limited compared to Alternative A, due to a 49 percent decrease in miles of road open to motorized public travel compared to Alternative A.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because more roads would be closed under this alternative, Alternative B should help reduce the spread of noxious weeds and may make fuels treatments more feasible than under Alternative A, reducing FRCC departure.

### Effects of Alternative C

Alternative C would provide the least amount of wheeled motorized opportunities with 8 miles of routes open yearlong, and an additional 11.7 miles seasonally restricted.

Alternative C would limit the flexibility for access for suppression purposes, and fuels project feasibility would go down compared to both Alternatives A and B, due to the fact that access would be limited to 19.7 miles of road. Of the 46.8 miles of closed roads, 5.2 miles would be decommissioned and would likely be unusable for fire suppression. The risk of human-caused fires associated with motorized use would be the lowest of all alternatives, due to a 64 percent decrease in miles of road open to public travel compared to Alternative A. However, this degree of reduced motorized access may promote more non motorized users to a concentrated area, increasing the chances for a human-caused fire to occur.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because more roads would be closed than under any other alternative, Alternative C should help reduce the spread of noxious weeds more than any other alternative, and may make fuels treatment more feasible, reducing FRCC departure.

### Effects of Alternative D

Under Alternative D, 19.6 miles of open routes would be available yearlong for wheeled motorized use and an additional 14.5 miles would be seasonally restricted routes. Of the 29.1 miles of closed roads, 8.8 miles would be decommissioned and would likely be unusable for fire suppression. Alternative D would be more flexible than Alternatives B and C but would limit flexibility for access for suppression purposes, and fuels project feasibility would go down compared to Alternative A. The risk of human-caused fires associated with motorized vehicle use would be reduced compared to Alternative A, but would be greater than under Alternatives B and C, due to a 38 percent decrease in miles of road open to public travel compared to Alternative A.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because an intermediate number of road miles would be closed under this alternative, Alternative D should help reduce the spread of noxious weeds compared to Alternative A and may make fuels treatment more feasible, but would promote more weed spread and potentially make projects less feasible than Alternatives B and C.

## Cumulative Effects on Wildland Fire Management

Effects on wildland fire management associated with any of the BLM travel plan alternatives would be overshadowed by reasonably foreseeable uncharacteristic fire, continued fire suppression made necessary by WUI and intermingled landownership, and large-scale forest insect infestations and disease outbreaks that would continue for the planning period. BLM lands make up about 4.2 percent of all lands while BLM roads make up about

4.7 percent of all roads in the Lewis and Clark County NW TPA.

Revision of the Helena National Forest Plan could result in more or less treatment of adjacent areas. Because no decision has been made, the effects are not known. Wildland fire management, particularly where wildland fire use (management of naturally ignited wildland fires to achieve resource objectives) may occur on USFS lands, will be determined in the plan decision. BLM would need to coordinate with USFS on all wildland fire use actions and events. Wildland fire use on USFS lands could affect FRCC on BLM lands. USFS lands make up 35 percent of all lands in the Lewis and Clark County NW TPA so activities there would likely have more influence on future fire characteristics than activities on BLM lands (4.2 percent of all lands in TPA).

Additionally, decisions to increase the level of wildland fire use, prescribed fire, or open burning by the public could impact the BLM's ability to use wildland fire and prescribed fire due to air quality concerns and requirements. This could postpone or eliminate BLM fuel reductions or treatments to improve FRCC.

Access is a critical component of wildland fire suppression. In some cases, access to public lands is being reduced by adjacent landowners gating or closing roads, which could hamper wildland fire suppression efforts and pose a risk to public and firefighter safety. Reducing access would also increase the potential for larger fires to occur due to an increase in time needed to access a fire and control it. Time needed to move in crews would be extended, and the ability to effectively apply and place resources (e.g., engines, water tenders, etc.) would be limited.

Effects on wildland fire management, including FRCC and firefighter and public safety due to management accomplished by other landowners may affect wildland fire management on public lands. When activity fuels (such as logging slash) are not treated adequately, fuel hazard could increase on adjacent lands which could affect fire intensity and severity on public lands. When adjacent owners treat fuels or implement fire mitigation plans in the WUI, fires are easier to suppress and firefighter safety is increased. In the Lewis and Clark County NW TPA, activities on private lands (53 percent of all lands in TPA) would have more influence on future fire characteristics in the area overall than activities on BLM lands (4.2 percent of all lands in TPA).

Human population increases and subsequent residential development are likely to expand the WUI and could alter forest management, taking the emphasis off restoring historic composition and structure and focusing more on fuel reduction.

## CULTURAL AND PALEONTOLOGICAL

### Effects Common to All Alternatives

Alternative-specific risks or impacts to cultural and paleontological resources are difficult to discern due to a lack of extensive site-specific knowledge about the presence of these resources in a given TPA. By designating open routes, limiting open-country travel, and closing some routes, inadvertent discovery of cultural and paleontological resources and vandalism to them is reduced. Higher road densities in a given area would allow greater access to more land on the average, but that does not imply greater amounts of vandalism, since the vehicles would remain on designated routes.

## VISUAL RESOURCES

### Effects Common to All Alternatives

Roads (temporary or permanent) may affect visual quality. Roads that remain open for public use may impact visual qualities where noticeable. The quantity of open roads would also influence sensitivity levels since with more open roads, more areas would generally be viewed by more members of the public. Closing or decommissioning roads would generally reduce effects to visual resources and reduce sensitivity levels because fewer members of the public would generally be accessing and viewing areas with closed roads.

### Effects of the Alternatives

Under Alternative A, there would be 64.2 miles of open road (including roads open with seasonal restrictions), and 3.4 miles of closed roads. This alternative would have the greatest impacts to visual resources of all alternatives.

Under Alternative B there would be 28.1 miles of open road (including roads open with seasonal restrictions), 26.8 miles of closed road, and 10.9 miles of decommissioned road. Road closures and decommissioning under this alternative would reduce effects on visual resources compared to Alternative A.

Under Alternative C there would be 19.7 miles of open road (including roads open with seasonal restrictions), 41.6 miles of closed road, and 5.2 miles of decommissioned roads. Alternative C would have fewer adverse effects and would improve visual resources the most of all alternatives.

Under Alternative D there would be 35.1 miles of open road (including roads open with seasonal restrictions), 20.3 miles of closed road, and 8.8 miles of decommissioned road. Alternative D would improve visual resources compared to Alternative A, but would have more adverse effects than Alternatives B and C.

## Cumulative Effects on Visual Resources

Under all alternatives, most activities on BLM lands would generally not adversely affect visual resources to unacceptable degrees because discretionary activities on BLM lands would be required to meet Visual Resource Management objectives within individual project areas. The Bald Butte Mine will continue to impact visual resources for the foreseeable future as the mine expands on both private and public lands. The Great Divide Ski Area reduces visual quality in some portions of the Marysville area and will continue to do so for the foreseeable future.

Activities on non-BLM lands, particularly activities near BLM lands associated with residential development, urbanization, or vegetation management, could have adverse cumulative effects on visual resources on BLM lands because BLM VRM objectives would obviously not apply to non-BLM activities.

## LIVESTOCK GRAZING

### Effects Common to All Alternatives

Roads and trails can potentially affect livestock grazing management. Roads and trails often act as avenues of noxious weed spread. Noxious and invasive weeds can reduce the quantity and quality of forage for livestock. Users of roads and trails can cause management problems for livestock permittees when they leave gates open at fences, vandalize range improvements, or harass livestock either purposely or unintentionally.

Closure of roads and trails can improve or maintain the forage base by reducing vectors of noxious weed spread. Additionally, road and trail closures can reduce management conflicts. On the other hand, closures may increase permittees' time requirements if and when work has to be conducted with horses or afoot. Permittees could minimize effects of closed roads on grazing management time by seeking variances from the BLM for temporary use of specific closed roads.

### Effects of the Alternatives

Under Alternative A, 64.2 miles of roads and trails would remain open during grazing season, and 3.4 miles of roads and trails would be closed. The effects would continue as described in the Effects Common to All Alternatives section. All action alternatives would close or decommission more roads and trails than Alternative A. As more roads and trails are closed, noxious and invasive weed spread along with multiple user conflicts would be reduced. On the other hand, permittee management time may increase. Consequently, more effects as described under the Effects Common to All Alternatives section would occur under Alternative C (19.7 miles open during grazing season, 46.8 miles closed or decommissioned) than under any other alternative. Alternative B (28.1 miles open during grazing season, 37.7

miles closed or decommissioned) would produce fewer effects than Alternative C, but more than Alternative A or Alternative D (34.1 miles open during grazing season, 29.1 miles closed or decommissioned). Alternative D would have fewer effects than Alternatives B or C, but more than Alternative A.

## Cumulative Effects on Livestock Grazing

A number of past, present, and reasonably foreseeable future actions affect livestock grazing at the scale of the entire Lewis and Clark County NW TPA. Livestock grazing will continue in the area and has the potential to impact forage quality and quantity. On public lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain forage quality and quantity. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, forage conditions would benefit.

A molybdenum mine was started on private land above Bald Butte. The mine may expand on other private and public lands in the future. Some forage base may be reduced in the Drumlummon-Skelly and Empire Creek allotments.

Because BLM lands make up only 4.2 percent of all lands in the Lewis and Clark County NW TPA, all of the BLM travel plan alternatives would have a minimal contribution to cumulative effects on livestock grazing at the scale of the entire TPA.

## MINERALS

### Effects Common to All Alternatives

Road closures and decommissioning could affect access to locatable minerals in areas of moderate or high mineral potential. Operators would be required to seek travel variances from the BLM to use motor vehicles to conduct mineral exploration on closed roads, or to conduct exploration on seasonally restricted routes during the season of closure. Decommissioned roads could not be used for motorized exploration. Travel management provisions that require a permit or variance could result in reducing access to mining claims or interfere with the ability to conduct exploration work for some operators. Historic knowledge of mineralized areas associated with "closed" roads may be lost after long periods of time if no exploration occurs there. Additional costs and time could be required for exploration and development of mining projects associated with closed or decommissioned roads. Impacts of road closures or decommissioning in areas with low mineral potential would not be substantial to mineral development.

## Effects of the Alternatives

Effects of the alternatives for the Lewis and Clark County NW TPA on access to mineralized areas are summarized in **Table 4-75**. Alternative A would seasonally restrict access on 10 percent of the roads and would close an additional 5 percent of roads in high mineral potential areas; roads in moderate mineral potential areas would be left open.

Alternative B would seasonally restrict 17 percent of the roads, close 20 percent, and decommission 8 percent of the roads in high mineral potential areas. This same alternative would close 15 percent and decommission 8 percent of roads in the moderate mineral potential areas

<b>Table 4-75</b>				
<b>Analysis of Access to Mineral Potential Areas Lewis and Clark County NW TPA</b>				
<b>Mineral Potential</b>	<b>Open Miles (%)</b>	<b>Seasonally Restricted Miles (%)</b>	<b>Closed Miles (%)</b>	<b>Decom Miles (%)</b>
<b>Alternative A</b>				
High	30.0 (44%)	6.7 (10%)	3.4 (5%)	0.0 (0%)
Moderate	19.6 (29%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Low	8.0 (12%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Total Miles = 67.6				
<b>Alternative B</b>				
High	9.7 (14%)	11.2 (17%)	13.5 (20%)	5.6 (8%)
Moderate	4.1 (6%)	0.2 (0%)	9.9 (15%)	5.3 (8%)
Low to none	0.0 (0%)	4.6 (7%)	3.4 (5%)	0.0 (0%)
<b>Total Miles = 67.6</b>				
<b>Alternative C</b>				
High	5.6 (8%)	9.9 (15%)	22.6 (33%)	1.9 (3%)
Moderate	2.4 (4%)	0.4 (0%)	13.5 (20%)	3.3 (5%)
Low to none	0.0 (0%)	2.5 (4%)	5.5 (8%)	0.0 (0%)
Total Miles = 67.6				
<b>Alternative D</b>				
High	12.5 (18%)	12.6 (19%)	11.2 (17%)	4.0 (6%)
Moderate	5.8 (8%)	2.0 (3%)	7.0 (10%)	4.8 (7%)
Low to none	1.3 (2%)	4.6 (7%)	2.0 (3%)	0.0 (0%)
Total Miles = 67.9 (Includes Proposed New Construction)				

Mineral Potential areas have been delineated by the Montana Bureau of Mines and Geology (MBMG)

(**Table 4-75**). A total of 51 percent of the roads accessing mineralized areas in the Lewis and Clark County NW TPA would have either a seasonal restriction or closure on it under Alternative B.

Alternative C would close 33 percent and decommission 3 percent of the roads in high mineral potential areas. This same alternative would close 20 percent and decommission 5 percent of roads in areas with moderate mineral potential in this TPA (**Table 4-75**). A total of 61 percent of the roads accessing mineralized areas would be closed or decommissioned under Alternative C.

Alternative D would seasonally restrict 19 percent, close 17 percent, and decommission 6 percent of the roads in high mineral potential areas. This same alternative would seasonally restrict 3 percent, close 10 percent, and decommission 7 percent of roads in areas with moderate mineral potential. A total of 40 percent of the roads accessing mineralized areas would be either closed or decommissioned under Alternative D in the Lewis and Clark County NW TPA (**Table 4-75**).

## Cumulative Effects on Access to Mineralized Areas

No other past, present, or reasonably foreseeable future actions in the Lewis and Clark County NW TPA would adversely affect mineral availability or access.

Overall, there is low potential for leasable fluid mineral development throughout federal mineral estate lands in the Butte Field Office. However, in this context, the Reasonably Foreseeable Development Scenario for the Butte RMP identified approximately 20,640 acres of federal mineral estate lands in this TPA where oil and gas development potential is slightly higher (low to moderate) and may potentially occur. Potential contribution of this activity to cumulative effects for other resources would be unknown until this activity is site-specifically planned.

## RECREATION

Effects of travel plan alternatives on Recreation in the Lewis and Clark County NW TPA are described qualitatively below.

### Effects of Alternative A

Alternative A would provide more motorized opportunities than non-motorized opportunities. Under Alternative A, the majority of routes in the Lewis and Clark County NW TPA would be available for wheeled motorized use (57.5 miles open yearlong, 6.7 miles seasonally restricted). Area wide snowmobile (cross-country travel) use would be available on 16,997 acres. The Continental Divide Trail would continue to be managed for both motorized and non-motorized uses which would result in user conflicts.

## Effects of Alternative B

Alternative B would provide for separate use areas for wheeled motorized and non-motorized recreational opportunities. Under Alternative B, a total of 28.1 miles of routes would be available for motorized wheeled use (13.8 miles open yearlong, 14.3 seasonally restricted). The majority of routes located in the Stemple Pass and Lincoln areas would be closed, providing additional non-motorized opportunities. Opportunities for cross-country snowmobile travel would be reduced with the area identified in the northwest portion of the TPA (Marysville area) being restricted to designated routes only, during the season of use (12/2-5/15), conditions permitting. Winter use conflicts would be reduced under Alternative B, as cross-country skiers could use the area in the upper northwest portion of the Marysville area for non-motorized use as well as the Great Divide Ski Area.

## Effects of Alternative C

Alternative C would provide the least amount of wheeled motorized opportunities: 8.0 miles of routes managed open yearlong, and 11.7 miles managed as seasonally restricted. Closure of the routes located in the northwest corner of the Marysville area would result in an enhancement of non-motorized opportunities. Opportunities for cross-country snowmobile travel would be eliminated. Snowmobiles would be restricted to designated routes only during the season of use (12/2-5/15), snow conditions permitting.

## Effects of Alternative D

Alternative D would provide the highest level of wheeled motorized access of the action alternatives. Under this alternative, a total of 34.1 miles of routes (19.6 miles open yearlong, 14.5 miles seasonally restricted) would be available for motorized use. Opportunities for ATV riders and hunters would be enhanced through the addition of a yearlong ATV-Only route and a game retrieval route. Motorized users would also have more opportunities in the Lincoln and Stemple Pass areas. Cross-country snowmobile travel would be allowed throughout the TPA with 2 exceptions, the Great Divide Ski area and the northwest portion of the TPA. Travel in these areas would be restricted to existing routes only during the season of use (12/2-5/15), providing some dispersed recreation opportunities for non-motorized users.

## Cumulative Effects on Recreation

Alternative A would provide the greatest opportunities for motorized uses especially in the Marysville area. Given the population growth trends in the nearby Helena Valley it is expected that visitation levels on BLM lands in the Marysville area will increase along with conflicts between non-motorized and motorized users, especially during the big game hunting season. In addition, poten-

tial impacts to the natural settings within this area are expected to increase given increasing mineral values, vegetative treatments, road improvements, noxious weed spread, residential home building, prescribed fires, and additional rights-of-way requests for access. Under this alternative no Recreation Opportunity Spectrum designations would be made to guide discretionary developments and impacts to non-motorized users would be most likely to increase at the greatest rate.

Under Alternative B about 55 percent of the BLM roads within the TPA would be closed. This action coupled with other existing and potential actions would enhance non-motorized Recreation Opportunity Spectrum settings and user opportunities, reduce conflicts between non-motorized and motorized users, and promote more retention of big-game species on BLM thus improving walk-in hunting opportunities. Designating Recreation Opportunity Spectrum settings would help to ensure that varied opportunities are provided throughout the TPA and that expected experiences are provided to the public.

Alternative C would impose the greatest impacts on motorized travel opportunities while opportunities for non-motorized experiences would be the most benefited. Recreation Opportunity Spectrum management and big game hunting opportunities within the TPA would be similar to Alternative B with the exception that no motorized routes would be open in the northwest extremity of the Marysville area and thus a Semi-Primitive Non-motorized setting would be a management objective.

Under Alternative D, cumulative effects of the travel management actions coupled with all other existing and reasonably foreseeable actions would be similar to Alternative A with the exception that fewer roads would be open to public use.

## TRAVEL MANAGEMENT AND ACCESS

### Effects of Alternative A

Most roads in the Lewis and Clark County NW TPA would continue to be managed as open yearlong (57.5 miles) (**Table-4-76**). This would be about 66 percent more routes open yearlong than under the action alternatives. When considering both open routes and routes with seasonal restrictions, 47 percent more routes would be open to motorized use than under the action alternatives. Non-motorized users would have a lower quality recreation experience compared to under the action alternatives.

Alternative A would allow the greatest snowmobile use of all alternatives, with area-wide cross-country use available on 16,997 acres. Outside the Great Divide Ski Area, cross-country snowmobile access would be allowed on approximately 25 percent more acres than under any of the action alternatives. Separate use areas for non-motorized winter sports enthusiasts would be less under Alternative A.

<b>Proposed Management</b>	<b>Total Miles</b>			
	<b>Alt A</b>	<b>Alt B</b>	<b>Alt C</b>	<b>Alt D</b>
<b>Wheeled motorized routes</b>				
Open Yearlong	57.5	13.8	8.0	19.6
Seasonally Restricted	6.7	14.3	11.7	14.5
Closed	3.4	26.8	41.6	20.3
Decommissioned	0	10.9	5.2	8.8
Non-motorized trails <sup>1</sup>	5.27	37.7	46.7	29.1

<sup>1</sup> Non-motorized trails include all existing trails, closed roads, and decommissioned roads.

User conflicts would be evident during the winter in the Lewis and Clark County NW TPA since cross-country snowmobile use would be allowed in all areas (except the Great Divide Ski Area), leaving no areas for dispersed cross-country ski opportunities.

The Continental Divide Trail would continue to be managed for both motorized and non-motorized uses which would result in user conflicts.

The extent of management activities and costs under Alternative A would be mixed. Less personnel time would be required to monitor travel compliance than under the action alternatives. However, more effort would be required for initial implementation (signing designated routes, installing bulletin boards) than under the action alternatives. Estimated costs for road/trail maintenance would be highest of all alternatives.

The need for BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be minimal under this alternative, given the availability of motorized access.

### **Effects Common to Action Alternatives**

Re-routing the motorized portion of the Continental Divide Trail in the Lewis and Clark County NW TPA would enhance non-motorized opportunities and remove motorized conflicts.

### **Effects of Alternative B**

Under Alternative B, the Lewis and Clark County NW TPA would provide four times fewer routes open yearlong to motorized access than under Alternative A (Table-4-76). Opportunities for motorized users would be less under Alternative B, than under Alternative A.

With 37.7 miles of non-motorized trails, there would be more opportunities for non-motorized users than under Alternative A. Closing most of the routes located in the Stemple Pass and Lincoln areas would provide additional non-motorized opportunities in these areas.

Compared to Alternative A, opportunities for cross-country snowmobile travel would be reduced with the area identified in the northwest portion of the TPA (Marysville area) restricted to designated routes only, during the season of use (12/2-5/15), conditions permitting.

Dispersed recreational opportunities would be created that allow motorized and non-motorized users to recreate separately. Winter use conflicts would also be reduced under Alternative B compared to Alternatives A and D, as cross-country skiers could use the area in the upper northwest portion of the Marysville area for non-motorized use as well as the Great Divide Ski Area.

The extent of management activities and costs under Alternative B would be mixed. Less personnel time would be required for initial implementation (signing designated routes, installing bulletin boards) than under Alternative A. However, more effort would be required for public education and compliance than under Alternative A. Estimated costs for road/trail maintenance would be less than under Alternative A.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would increase under Alternative B compared to Alternative A.

### **Effects of Alternative C**

Alternative C would provide the least amount of wheeled motorized access in the Lewis and Clark County NW TPA of all the alternatives (19.7 miles) (Table-4-76) and therefore, fewer opportunities for motorized users would be available. Alternative C would provide 70 percent fewer motorized miles than Alternative A, and 30 percent fewer than Alternative B. Closure of routes in the northwest corner of the Marysville area under Alternative C would result in an enhancement of non-motorized opportunities in that area.

Closure and decommissioning of routes in the Lewis and Clark County NW TPA would result in an increase in non-motorized opportunities. Alternative C would have 43 percent more miles of non-motorized trails than Alternative A, and 19 percent more than Alternative B.

Opportunities for cross-country snowmobile travel would be eliminated. Snowmobiles would be restricted to designated routes only during the season of use (12/2-5/15), snow conditions permitting. Non-motorized winter sports opportunities would increase because of the restrictions.

The extent of management activities and costs under Alternative C would be mixed. Less personnel time would be required for initial implementation (signing designated routes, installing bulletin boards) than under any other alternative. However, more effort would be required for public education and compliance than under the other alternatives. Estimated costs for road/trail maintenance would be the lowest of the alternatives.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be the greatest under Alternative C than under any of the other alternatives.

## Effects of Alternative D

Alternative D would have 34.1 miles of motorized routes (open and seasonally restricted) (**Table-4-76**) and would provide more motorized access than any of the other action alternatives. Motorized access under Alternative D would be about 47 percent less than under Alternative A, but 18 and 42 percent more than under Alternatives B and C, respectively.

Opportunities for ATV riders and hunters would be enhanced above all other alternatives through the addition of a yearlong ATV-Only route and a game retrieval route, respectively. Motorized users would also have more opportunities under Alternative D in the Lincoln and Stemple Pass area than under Alternatives B or C.

Allowing snowmobile access on closed routes would result in an increase in motorized winter opportunities compared to Alternatives B and C; however, cross-country snowmobile travel would be restricted to existing routes in the northwest portion of the TPA and Great Divide Ski Area during the season of use (12/2-5/15), similar to Alternative B. Snowmobile management would result in fewer dispersed opportunities for non-motorized winter user compared to Alternative C.

Restricting snowmobile access in the northwest portion of the TPA and Great Divide Ski Area would provide dispersed recreation opportunities and result in a decrease in winter use conflicts. These effects would be similar under Alternatives D and B, greater than under Alternative A, but less under Alternatives C.

The extent of management activities and costs under Alternative D would be mixed. Less personnel time would be required to monitor travel compliance than under Alternatives B and C, but more would be needed than under Alternative A. However, more effort would be required for initial implementation (signing designated routes, installing bulletin boards) than under the other action alternatives. Estimated costs for road/trail maintenance would be higher than under the other action alternatives, but less than under Alternative A.

## Cumulative Effects on Travel Management and Access

Under all alternatives, there are a number of past, present, and reasonably foreseeable BLM and non-BLM actions and activities affecting travel management and access in the Lewis and Clark County NW TPA.

The majority of BLM-managed routes in the Lewis and Clark Northwest travel planning area is located in and around the town of Marysville, located approximately 25 miles northwest of Helena. Much of the use in the Ma-

rysville area (especially winter use) comes from Helena Valley residents. The Helena Valley has been experiencing steady population growth. This trend is expected to continue, along with increased recreational use of this travel planning area. These factors could lead to increased public pressure to accommodate either more, or less motorized use.

The remaining BLM managed routes are located in 3 sub-planning areas: Stemple Pass, Sieben Ranch, and Lincoln (west of the small town of Lincoln, Montana). There is some residential development adjacent to the Lincoln sub-planning area that could influence travel management as well.

The Marysville area is experiencing increased residential development, but to a lesser extent than the central Helena Valley area. Urbanization and increased recreational use may lead to increased social conflict; between area residents and recreation users, and among recreational users themselves (motorized/non-motorized). As a result, there may be increased public demands to alter the existing travel management to accommodate either more, or less motorized use.

Recreation use is well established in the TPA, especially for winter sports. Winter sport activities include: snowmobiling, downhill skiing, backcountry skiing, ski racing, snowboarding, and snowshoeing. An extensive network of roads and trails support a wide range of off-season activities, including: camping, hunting, target practice, hiking, jogging, horseback riding, mountain bike riding, and motorized use (motorcyclists, OHV riders, and 4-wheel drive enthusiasts). As recreation use grows, conflicts between non-motorized and motorized recreation users could lead to increased public demands for either more, or less motorized use.

The TPA (all land ownerships) includes a number of wildlife and aquatics/fisheries concerns. The western half of the TPA is a wildlife movement corridor between the Northern Continental Divide Ecosystem and the Greater Yellowstone Ecosystem, portions of the TPA are in the occupied range of grizzly bear range, and the entire TPA is within the former Northwest Montana Recovery Area for the gray wolf. Mule deer winter range is located along the eastern half of the TPA (158,140 acres) as well as near Lincoln (21,500 acres). Elk winter range is also located in the lower elevations along the eastern half of the TPA (193,800 acres) as well as around Lincoln (55,500 acres). Approximately 112,250 acres of cool, moist forest in the TPA provide habitat for the Canada lynx. Two BLM sensitive amphibians have been found within the Lewis and Clark County NW TPA, the boreal toad and the Northern leopard frog. Another BLM sensitive species, the wolverine, has also been documented west of the Continental Divide in the TPA. Over 66 fish-bearing streams are located in the Lewis and Clark County NW TPA with 61 providing habitat for westslope cutthroat trout, as well as for river

otter, beaver, and moose. Concerns could lead to demands to restrict motorized use.

The TPA contains a 3 mile long section of the Continental Divide Trail (road) that is currently shared by motorized vehicles and hikers. Rerouting the trail off this road would reduce use conflicts between motorized and non-motorized users.

In some site specific cases, visual resource management may affect or restrict new road construction.

Continuing residential development may lead to an increase in right-of-way permits to accommodate private property/development access. As a result, public access to BLM lands, via these rights-of-way, could increase as well.

Limits or reductions in the BLM's funding and ability to maintain designated routes could lead to an overall reduction of maintained motorized routes.

A variety of resource management projects, such as BLM initiated vegetation treatments, or wildland fire fuels reduction projects, could affect travel management. BLM forest management activities from 1984 to present include 48 acres of forest planting, 66 acres of timber salvage, and 132 acres of timber harvest. Future activities may include approximately 1,200 acres of forest and woodland treatment (thinning, selective harvest), although no planning is underway on these activities. Wildland fire management activities may include a future 1,500-3,000 acre mechanical and/or prescribed fire treatment for the Marysville area, focused on the urban interface areas. Depending on the type and scope of project, effects could vary from temporary, short-term area/route closures, to new opportunities (new routes) for motorized or non-motorized access.

Historical information indicates that since 1977, 3,357 claims have been active throughout the Marysville area. Today only 40 claims remain active, including the Bald Butte Mine, an open cut molybdenum mine. Increases in other mineral prices could lead to additional increased or renewed mining activity. Depending on the type and scope of mining activity, effects could vary from temporary, short-term area/route closures, to increased opportunities (new routes) for motorized or non-motorized access.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Motorized activities play a large role in the distribution of noxious weeds. Concerns over the spread of noxious weeds could influence travel management, and lead to fewer motorized opportunities.

Motorized use on dirt roads and trails is a major contributor to soil erosion and stream sedimentation. These concerns may influence travel management, and result in fewer motorized opportunities.

Most illegal activities (trash dumping, drug use, underage alcohol use, unattended camp fires, vandalism, etc.) are directly associated with motorized use. At present, illegal activities in this TPA pose less of an issue than for the Helena and East Helena TPAs. However, increased future motorized use activity is likely to lead to increased illegal activity, and could lead to fewer motorized opportunities.

For perspective, BLM managed lands represent approximately 4.2 percent of the total travel planning area (406,700 total acres, 17,037 BLM acres); while BLM managed routes represent approximately 4.7 percent of the total routes available (1,447.7 total miles, 67.6 miles BLM roads/trails). Future travel management (for all agencies, nationwide) is likely to lead to fewer opportunities for motorized recreational use than under current management (particularly for OHV use).

As a result, BLM routes available to motorized use (especially in the Marysville area) could experience increased use from displaced users, leading to more concentrated use, increased resource impacts, user conflicts, and pressure to reduce or increase motorized use.

Under Alternative A, overall increases in human population, urbanization, recreation use, user conflicts; and concerns for wildlife, fisheries, noxious weed spread, soil erosion/water quality, and illegal activities are likely to lead to increased demands to restrict motorized travel. Under Alternative B, these pressures would have less impact on travel management than under Alternatives A and D, due to the overall reduction in motorized opportunities and separation of motorized and non-motorized uses. Under Alternative C, these pressures would have the least impact on travel management than under the other alternatives, due to the reduction in motorized opportunities. Under Alternative D, these pressures may lead to increased demands to restrict motorized travel.

## TRANSPORTATION FACILITIES

For the sake of this discussion, "open" roads include roads that are open yearlong as well as those that are open with seasonal restrictions.

### Effects of Alternative A

Under Alternative A, the Lewis and Clark County NW TPA would have 64.2 miles of open roads and no motorized trails (**Table 4-77**). Estimated costs for annual maintenance and stabilization of roads under Alternative A would be much greater than under any of the action alternatives because of the highest level of open roads. Estimated annual costs for monitoring and compliance, and weed control would be higher for Alternative A than under the action alternatives.

## Effects of Alternative B

Under Alternative B, the Lewis and Clark County NW TPA would have 28.1 miles of open roads and no motorized trails (**Table 4-77**).

Estimated costs for annual maintenance and stabilization of roads under Alternative B would be similar but slightly lower than under Alternative D, less than under Alternative A and more than under Alternative C. Estimated annual costs for monitoring, compliance, and weed control would also be less than under Alternative A, more than under Alternative C, and similar but slightly less than under Alternative D.

Closing the upper northwest portion of the Marysville area to motorized vehicles and to cross-country snowmobile travel would result in a slight increase in transportation facility costs for additional signage and sign maintenance.

## Effects of Alternative C

Under Alternative C, the Lewis and Clark County NW TPA would have 19.7 miles of open roads and no motorized trails (**Table 4-77**). Estimated costs for annual maintenance and stabilization of roads under Alternative C would be the least of all the alternatives due to the least number of motorized routes. Estimated annual costs for monitoring, compliance and weed control would also be less than under the other alternatives.

Closing the entire northwest portion of the Marysville area to motorized vehicles and to cross-country snowmobile travel would result in a slight increase in transportation facility costs for additional signage and sign maintenance.

## Effects of Alternative D

Under Alternative D, the Lewis and Clark County NW TPA would have 34.1 miles of open roads and one motorized trail (**Table 4-77**). Estimated costs for annual maintenance and periodic stabilization of roads under Alternative D would be greater than under Alternatives B and C, but less than under Alternative A. Alternative D is the only alternative with a motorized trail that would receive annual and periodic stabilization. Estimated annual costs for monitoring, compliance, and

weed control would be less under Alternative D than under Alternative A and more than under Alternatives B and C.

The addition of several routes in the Marysville area including an ATV-Only route and a game retrieval route would result in an increase in transportation facility costs due to new signage and sign maintenance.

Closing the northwest portion of the Marysville area to cross-country snowmobile travel would also result in an increase in transportation facility costs for additional signage and sign maintenance.

## LANDS AND REALTY

### Effects Common to All Alternatives

The Butte Field Office administers approximately 96 rights-of-way (ROW), 1 non-commercial occupancy lease, and 2 commercial occupancy leases within the boundaries of the Lewis and Clark TPA, which encumber approximately 1,961 acres of BLM land (**Table 4-78**). Various types of road rights-of-way are the most common type of grant, accounting for 46 percent, or just under half of the total. Other types of authorized uses include: oil and gas pipelines, lines for electrical distribution and telephone facilities, communication sites, ditches, railroads, and mineral material sites.

Type	Approximate Number	Approximate Acres
Roads	44	558
Power	17	101
Telephone	12	21
O&G Pipelines	4	59
Comm. Sites	8	4
2920 Leases	3	1,050
Other	11	168
<b>Totals</b>	<b>99</b>	<b>1,961</b>

Approximately four right-of-way applications for new facilities as well as amendments, assignments, renewals, or relinquishments of existing right-of-way grants are

Classification/Cost	Alt A	Alt B	Alt C	Alt D
Miles of Open/Restricted Roads	64.2	28.1	19.7	34.1
Motorized Trails	0	0	0	2.2
Annual Roads Maintenance	\$5,136	\$2,248	\$1,576	\$2,728
Annual Trails Maintenance	\$0	\$0	\$0	\$147
Periodic Road Stabilization	\$2,054	\$899	\$630	\$1,091
Periodic Trails Stabilization	\$0	\$0	\$0	\$29
Monitoring/Compliance	\$3,210	\$1,405	\$985	\$1,705
Weed Control	\$963	\$422	\$296	\$512

processed annually in the TPA. This would not vary by alternative.

The general trend of granting rights-of-way is expected to increase through the planning period as a result of increasing public demands. From a cumulative effects standpoint, development of adjacent federal, state, and private land, increased recreational use and the trend of homeownership away from urban areas, coupled with traditional on-going uses, are all expected to require more guaranteed access involving public land, including BLM lands.

## SPECIAL DESIGNATIONS

### Effects of the Alternatives

BLM currently manages a three-mile segment of the Continental Divide Scenic Trail in cooperation with the Forest Service in this TPA. This trail segment is subject to increasing impacts from numerous resource uses including motorized travel, rights-of ways, private home developments, and grazing improvements. Under Alternative A, current travel management direction is not providing protection of the trail corridor and user experience levels are impacted by conflicting intrusions. The Continental Divide Trail would continue to be managed for both motorized and non-motorized uses which would result in continued user conflicts.

Under Alternative B, travel management prescriptions would not remove motorized conflicts on the Continental Divide Scenic Trails as the trail would continue to follow an open motorized travel route. Under this alternative, alternate trail routes would be evaluated with the Forest Service to minimize conflicts, enhance hiker experiences, reduce human intrusions, and decrease the need for easement acquisitions.

Under Alternative C, effects would be similar to Alternative B although some additional secondary roads in close proximity to the Continental Divide Scenic Trails would be closed.

Under Alternative D, effects on the Continental Divide Trail would be similar to Alternative B although more intersecting secondary roads would remain open to public use and therefore motorized use conflicts would be slightly higher.

### Cumulative Effects on Special Designations

No other past, present, or reasonably foreseeable future actions in the Lewis and Clark County NW TPA would adversely affect Special Designations.

## BOULDER/JEFFERSON CITY TPA

The 60,418-acre Boulder/Jefferson City TPA contains approximately 14,487 acres of BLM lands. There are approximately 61 miles of BLM roads, making up about 15.6 percent of the approximate total of 392 road miles

in the TPA. The majority of roads (212 miles) lie on private lands.

## AIR QUALITY

### Effects Common to All Alternatives

Motorized recreation use is expected to continue to increase, resulting in higher levels of vehicle emissions.

Motorized travel across dry unpaved routes or trails would continue to produce airborne dust.

There could be areas with localized air pollution as a result of higher use numbers, and more concentrated use on fewer miles of available routes.

Drier climate conditions could make soils more susceptible to the effects of motorized travel, resulting in higher levels of airborne dust.

Impacts to air quality vary by alternative and travel plan area. In general, alternatives that reduce the level of motorized use (have fewer available miles) could have a positive impact on air quality; while alternatives that maintain or increase the level of motorized use, could lead to increased air quality impacts. This would not necessarily be a direct relationship, however, because reduction in available road miles for motorized use could redistribute use or focus more use on remaining open routes.

Under all alternatives, impacts from airborne dust could be reduced through mitigation such as hardening native surface roads with gravel or periodically spraying them with water trucks during the dry season. During BLM project work, in addition to watering native surface roadbeds, speed limits could be reduced to further minimize dust emissions.

### Effects of the Alternatives

Under Alternative A (present management), adverse impacts to air quality would be expected to continue, and likely increase, concurrent with higher levels of motorized recreational use. Each of the proposed Action Alternatives, however, would provide fewer available motorized routes. Alternatives B and C would provide 52 percent and 61 percent fewer open motorized routes, respectively, than Alternative A, while Alternative D would provide 37 percent fewer routes than Alternative A. As a result, airborne dust and vehicle emissions would be taking place on fewer BLM routes and could be reduced.

It should be noted that even without motorized use, airborne dust, resulting from wind erosion of exposed native surface roads will continue. Therefore, travel plans with more miles of native surface roads will result in more airborne dust.

Under all alternatives, mitigation measures, such as graveling and/or watering native surface roads, could reduce dust emissions even further, and/or help offset

the effects of increased or concentrated use on the remaining open routes.

## Cumulative Effects on Air Quality

Under all alternatives, the cumulative effects to air quality from travel management in the Boulder Jefferson City TPA would arise from a number of past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands.

For perspective, BLM managed lands in the Boulder Jefferson City TPA area represent approximately 24 percent of the total travel planning area (60,418 total acres; 14,487 BLM acres). Under present management (Alternative A) BLM managed routes represent approximately 15.4 percent, of the total routes available (392 total miles; 60.5 miles BLM roads/trails under Alternative A). Potential air quality impacts associated with activities on non-BLM lands and roads would be a greater contributor to cumulative effects to air quality than activities on BLM lands and roads.

In the past, prior to the 2003 Statewide OHV ROD, BLM management allowed unrestricted cross country travel by all forms of wheeled motorized use. Under present management, in the absence of other existing travel plan direction, all motorized wheeled travel is restricted to existing roads and trails. Under current management, all existing BLM routes are available for motorized use yearlong. This mileage available for use would be reduced under the action alternatives as described above with associated potential differences in effects to air quality.

Under all alternatives, cumulative increases in human population, urbanization, recreation use, user conflicts; and concerns for wildlife, noxious weed spread, soil erosion, air/water quality, and illegal activities may lead to increased demands to restrict motorized travel.

## SOILS

### Effects Common to All Alternatives

Road construction, use, and maintenance affect soils in a number of ways. Soils are often compacted by these activities. Soil compaction can lessen the amount of precipitation that can infiltrate into soil and increase runoff, erosion, and sedimentation – in turn decreasing soil/site stability and hydrologic function, as well as soil productivity and plant vigor and diversity.

Ground disturbance associated with road construction, use, and maintenance can result in erosion. Erosion affects soil/site stability and hydrologic function. Erosion and sedimentation can destabilize the surface and sub-surface cohesion of the soil, resulting in soil loss from erosion sites. Loss of soil can impede or prevent establishment and development of vegetation communities.

Closing or decommissioning roads often leads to beneficial effects to soils through decreased site disturbance

and re-establishment of vegetative cover on road surfaces. This tends to reduce soil erosion and stabilize soils. Decommissioning roads may in some cases entail ripping road surfaces to de-compact them, thus improving water infiltration, hydrologic function, and the ability of the treated area to revegetate more successfully.

Impacts to soils associated with site-specific travel plan alternatives were assessed based on the potential for soil erosion using the following erosion risk criteria:

- High – the area a route travels through has slopes greater than 30 percent gradient.
- Moderate – the area a route travels through has slopes ranging from 15 to 30 percent gradient; or, for granitic soils, slopes ranging from 0 to 30 percent gradient.
- Low – the area a route travels through has slopes ranging from zero to 15 percent gradient and soils are not granitic in origin.
- Unrated – road mapping not available at time of erosion impact rating.

## Effects of the Alternatives

The distribution of road miles by erosion risk category and by proposed road management category for all alternatives is shown for the Boulder/Jefferson City TPA in **Table 4-79**. Roads in the “unrated” category were excluded from detailed consideration and are shown for the purpose of displaying the extent of lacking information.

The table shows that under current conditions (Alternative A) approximately 27.7 miles of BLM roads are located in areas with high erosion risk, and 23.1 miles are in moderate erosion areas. Soil erosion would be reduced under Alternative B because this alternative would reduce those mileages to 13.7 miles and 12 miles, respectively. Approximately 23.2 miles of road in the high and moderate classes would be closed under Alternative B. This should allow soil stabilization and/or vegetative recovery on these areas and further reduce soil erosion.

Soil erosion from roads would be reduced more under Alternative C than under any other alternative because the lowest mileage of roads in the high and moderate erosion risk categories would be left open (21.1 miles combined), while the greatest mileage in these categories would be closed (27.5 miles) of all alternatives.

Soil erosion associated with roads would be reduced under Alternative D compared to Alternative A, but would still be higher than under either Alternative B or C. This is because 34.9 miles of road in the moderate and high erosion risk categories combined would be open under Alternative D, while only about 11.8 miles in these categories would be closed under this alternative.

<b>Proposed Road Management</b>	<b>Erosion Risk Category</b>	<b>Alternative A</b>	<b>Alternative B</b>	<b>Alternative C</b>	<b>Alternative D</b>
<b>Open Road Miles (including Open w/restrictions)</b>	High	27.7	13.7	11.9	19.9
	Moderate	23.1	12.0	9.2	15.0
	Low	0.3	0.6	0.6	0.6
	Unrated	8.7	0.8	1.0	2.4
<b>Closed Road Miles</b>	High	0	12.6	14.3	6.3
	Moderate	0	10.6	13.2	5.5
	Low	0	0.7	0.7	0.7
	Unrated	0	7.1	6.7	7.3
<b>Decommissioned Road Miles</b>	High	0	1.4	1.4	1.4
	Moderate	0	0.6	0.6	0.6
	Low	0	0	0	0
	Unrated	0	0.7	0.7	0.7

Note: Open roads include seasonally open roads as well as roads open yearlong.

## Cumulative Effects on Soils

Cumulative effects to soils in the Boulder/Jefferson City TPA would arise from many past, present, and foreseeable future actions on BLM lands as well as non-BLM lands. Within this 60,418-acre TPA, BLM lands make up 14,487 acres or 24 percent of lands. The approximately 60 miles of BLM roads make up about 15 percent of the approximately 392 road miles in the entire TPA. Therefore road-related effects to soils described by alternative above would affect about 15 percent of all roads in the TPA. Remaining roads are managed by Jefferson County, the Forest Service, state, and private landowners.

Reclamation of abandoned mine lands has contributed to improved revegetation and subsequent stabilization of soils at a number of locations throughout this TPA. Riparian areas along about 3.7 miles of High Ore Creek underwent removal of contaminated tailings and waste rock and subsequent revegetation in 1999-2000. Riparian areas along Big Limber Gulch (tributary to Cataract Creek) and Spring Creek (tributary to Prickly Pear Creek in Upper Missouri River watershed) have also undergone recent reclamation and revegetation work that has improved soil stability and reduced erosion.

Ongoing ground disturbing activity associated with mining for lead, zinc, gold, and silver from an open pit mine (Montana Tunnels Mine) near Jefferson City is likely to continue through approximately 2008. The permitted mine area is approximately 1,500 acres in size with 130 of those acres on BLM land. Varying degrees of soil stability exist at the site with some removal of topsoil, erosion, and compaction mixed with undisturbed, vegetated areas within the permitted boundary.

Approximately 2,051 acres of BLM lands are permitted for various rights-of-way and leases. Approximately 1,256 of these acres are for road rights-of-way. The remaining 795 acres are associated with powerlines, communication sites, and other utility facilities. Impacts to soils range from compaction and occupation of ground with buildings and facilities to revegetation and ground cover being re-established to stabilize soils. Of this total area, approximately 682 acres are associated with powerlines and have substantial vegetative ground cover over much of the ground to stabilize soils.

Selective timber harvest has occurred on approximately 259 acres of BLM lands in the TPA from 1984 to 1995. From 1995 to the present timber harvest occurred on 7 BLM acres while post-wildland fire timber salvage occurred on about 559 BLM acres as well as an unknown amount of private land. These activities have generally had relatively minor adverse effects on soils causing some localized erosion and compaction but generally allowing for revegetation post-timber harvest. Timber harvest has also occurred on private and Forest Service lands, will likely continue, and will have localized impacts on soils for the foreseeable future.

In 2000, a wildland fire burned approximately 10,800 acres in this TPA, approximately 4,670 of which were BLM lands. The fire burned with variable severity creating a mosaic of effects to soils. More severely burned areas underwent more severe erosion than areas burned less severely. Fire rehabilitation activities such as re-seeding with grasses/herbaceous species, waterbarring of firelines, and post-fire noxious weed treatments helped minimize soil loss due to post-fire erosion. Tree planting on approximately 690 BLM acres of this burned area have contributed to longer term soil stabilization.

Deliberate fuels treatments conducted on private and Forest Service lands will also likely occur for the foreseeable future with variable effects to soils. Reducing fuels under the controlled conditions of deliberate treatments may benefit soils in the long-term by reducing the risk of high severity fires in treated areas.

Livestock grazing on public and private lands throughout much of the TPA has created areas of localized soil erosion and compaction throughout the TPA. This will continue to occur for the foreseeable future.

Increasing residential development will likely continue for the foreseeable future. Erosion, compaction, and covering of soils would occur due to additional road construction, clearing/leveling for home sites, and establishment of utility infrastructure for residential developments.

Under Alternative A, the contribution to cumulative effects on soils from BLM road management would continue as it occurs today. Retaining approximately 60 miles of road open yearlong would allow for the same level of compaction and erosion impacts that currently exist.

From a BLM road management perspective, all action alternatives would benefit soil resources compared to Alternative A. Alternative B would provide for a reduced contribution to adverse cumulative effects on soils than would Alternative A because about 55 percent of BLM roads would be closed or decommissioned under Alternative B. Of the remaining approximately 27 miles of open road, most of them (about 23 miles) would be seasonally restricted to exclude motorized vehicle use between 12/2 to 5/15 each year. This would prevent motorized use during the wet spring snowmelt/runoff period and would therefore reduce erosion from BLM roads.

Alternative C would provide for the least contribution to adverse cumulative effects on soils of all alternatives. This alternative would provide for closure or decommissioning of about 62 percent of BLM roads in the TPA, thus allowing these areas to vegetatively recover and stabilize soils. The majority of open roads under this alternative (approximately 20 out of 23 miles) would be seasonally restricted to exclude motorized use between 12/2 to 5/15 each year. As with Alternative B, this seasonal closure would prevent motorized use during the wet spring snowmelt/runoff period and would therefore reduce soil erosion.

Alternative D would provide for the greatest contribution to adverse cumulative effects on soils of the action alternatives, but would still provide for greater long-term benefits to soils than Alternative A. Alternative D would provide for closure or decommissioning (and therefore vegetative recovery and soil stabilization) of about 40 percent of BLM roads in the TPA. As with Alternatives B and C, the majority of open BLM roads (about 33 out of 38 miles) would be seasonally restricted to exclude motorized use between 12/2 to 5/15 each year. This

would allow for the same types of beneficial effects to soils described above for Alternatives B and C.

Due to the scattered distribution and relatively small proportion of BLM lands (24 percent) and roads (15 percent) relative to the total quantities of lands and roads in the TPA, none of the BLM alternatives would substantially contribute to cumulative effects on soils at the scale of the Boulder/Jefferson City TPA.

## WATER RESOURCES

### Effects Common to All Alternatives

There are a number of key concepts that are critical to understanding road effects to water resources.

Hydrologic function is an interaction between soil, water, and vegetation and reflects the capacity of a site to:

- Capture, store, and safely release water from rainfall, runoff, and snowmelt;
- Resist a reduction in this capacity; and
- Recover this capacity following degradation.

Interception of precipitation results when precipitation falls on vegetation. When vegetation is removed, precipitation falls directly on the soil. This can increase surface erosion and sedimentation, and decrease the amount of time between initial precipitation arrival and peak surface runoff – in turn decreasing soil/site stability and hydrologic function. Roads remove vegetation and therefore decrease interception of precipitation.

Infiltration is the process of precipitation entering and traveling through soil. Infiltration reduces the peak runoff during precipitation events by extending the period of runoff after a precipitation event. Infiltration also filters precipitation and reduces erosion and sedimentation. If infiltration is reduced, runoff and erosion will increase and hydrologic function will decrease. Generally, roads are compacted surfaces that have decreased infiltration, thus increasing runoff and potentially increasing erosion.

Runoff can affect the amount of erosion and sedimentation, as well as flooding – both onsite and offsite. If runoff is increased, all of these effects can increase with a result that water quality and hydrologic function will decrease.

Increased sediment entering waterbodies increases turbidity, increases width-to-depth ratios, and consequently increases temperature and dissolved oxygen saturation levels, and creates adverse habitat for aquatic animals and plants.

Alteration of flow routing can also affect water resources. For example, roadcuts into areas with relatively shallow groundwater can intercept groundwater, bring it to the surface, and transport it some distance (i.e. in a roadside ditch) before delivering it to a stream. This can lead to erosion of road ditchlines and subsequent sedimentation of streams during runoff periods, or increased

thermal loading of water before delivery to a stream during summer periods.

Closure and decommissioning of roads tend to reduce erosion and sedimentation effects stemming from roads on water quality. On an equivalent road mile basis, decommissioning roads would benefit water quality to a greater degree than closing roads because the decommissioning process would often entail implementing measures to restore hydrologic function. During road decommissioning items such as compaction, drainage, stream crossing culverts, and ground cover are often addressed in a manner that markedly improves hydrologic function. These features are not fully addressed on roads that are merely “closed”. However, the reduced disturbance on newly closed roads combined with the tendency for revegetation to re-establish ground cover on them would reduce erosion and subsequent sedimentation effects to water quality.

### Effects of the Alternatives

Generally, road density is an indicator of overall watershed health and function. Watersheds with higher road densities tend to have lower water quality due to greater disruption of hydrologic function (described above), and potential for erosion and subsequent sedimentation. Road density also is related to the distribution and spread of noxious weeds. **Table 4-80** shows acres of BLM land in three road density categories by alternative for the Boulder/Jefferson City TPA. These data reflect any differences between alternatives based on roads proposed for “decommissioning” by alternative. While many “closed” roads would gradually contribute to increased hydrologic function over time, decommissioned roads would more directly contribute to hydrologic function because measures aimed at restoring hydrologic function would likely be part of the treatment during decommissioning.

Alternative A would have the greatest amount of BLM land with “high” road densities of greater than 2 mi/mi<sup>2</sup>. Alternatives B, C, and D would all have the same acreage in each road density category, reflecting that each of these alternatives provides for the same mileage (2.7 miles) of road decommissioning. By this measure, each of the action alternatives would benefit hydrologic

TPA Alternative	Road Density Category		
	Low (<1 mi/mi <sup>2</sup> )	Moderate (1 to 2 mi/mi <sup>2</sup> )	High (> 2 mi/mi <sup>2</sup> )
Alt. A	472	2,353	11,662
Alt. B	863	2,377	11,247
Alt. C	863	2,377	11,247
Alt. D	863	2,377	11,247

function equally. All action alternatives would improve hydrologic function compared to Alternative A.

Motorized routes within 300 feet of streams generally have greater potential to directly impact water quality through erosion and sedimentation, increased water temperatures (due to loss of shading vegetation), and direct alteration of stream channel morphology than those farther away. **Table 4-81** shows the miles of open and closed roads on BLM lands within 300 feet of streams by alternative. Under Alternative A there are about 2.5 miles of open road within 300 feet of fish bearing streams and 7.7 road miles within 300 feet of perennial non-fish bearing streams. Alternatives B and C would improve water quality to the same degree by closing or decommissioning the same mileage of roads in close proximity to perennial streams (total of 3.7 miles).

Alternative D would close or decommission 2.9 road miles in these areas and would therefore have greater improvements to water resources than Alternative A, but fewer improvements than Alternatives B and C. Each action alternative would improve water resources to some degree compared to Alternative A.

### Cumulative Effects on Water Resources

Cumulative effects to water resources in the Boulder/Jefferson City TPA would arise from many past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands. Within this 60,418-acre TPA, BLM lands make up 14,487 acres or 24 percent of lands. The approximately 60 miles of BLM roads make up about 15 percent of the approx-

	Perennial Fish-Bearing Streams		Perennial Non-Fish-Bearing Streams	
	# Open Road Miles	# Closed Road Miles	# Open Road Miles	# Closed Road Miles
Alt. A	2.5	0	7.7	0
Alt. B	2.0	0.5	4.5	3.2
Alt. C	2.0	0.5	4.5	3.2
Alt. D	2.0	0.5	5.3	2.4

Note: Open roads include seasonally open roads as well as roads open yearlong. Closed roads include decommissioned roads.

imately 392 road miles in the entire TPA. Therefore road-related effects to water resources described by alternative would be related to about 15 percent of all roads in the TPA. There are about 32 miles of fish bearing stream and an additional 81 miles of perennial non-fish bearing stream in the TPA. On BLM lands there are about 4 miles of fish bearing stream and an additional 13.5 miles of perennial non-fish bearing stream. The majority of lands and roads (about 50 percent of each) within the TPA boundary are private property. Remaining roads are managed by Jefferson County, the Forest Service, state, and private landowners.

Some of the main access roads (non-BLM) follow valley bottoms and parallel streams. Many of these roads are directly affecting stream channel or floodplain function by filling or impinging on stream channels or floodplains, precluding the presence of riparian vegetation (including large woody material in forested locations), producing sedimentation in streams (from road surfaces, ditchlines, winter "road sanding" operations) and potentially increasing thermal loading by lessening streamside shade. These effects are dominant in shaping stream channel and water quality conditions in many areas and will continue into the foreseeable future.

Reclamation of abandoned mine lands has contributed to improved water quality at a number of locations throughout this TPA. Riparian areas along about 3.7 miles of High Ore Creek underwent removal of contaminated tailings and waste rock and subsequent revegetation in 1999-2000. Big Limber Gulch (tributary to Cataract Creek) and Spring Creek (tributary to Prickly Pear Creek in Upper Missouri River watershed) have also undergone recent reclamation to reduce heavy metal contamination from mine waste dumps and a smelter site near the community of Wickes. Another site near Wickes is also being reclaimed to address potential acid mine drainage that could lead to heavy metal and other water quality concerns.

Ongoing ground disturbing activity associated with mining for lead, zinc, gold, and silver from an open pit mine (Montana Tunnels Mine) near Jefferson City is likely to continue through approximately 2008. The permitted mine is approximately 1,500 acres in size with 130 of those acres on BLM land. This mine is likely to be expanded in the near future in a manner that will eliminate approximately 0.5 mile of fish-bearing aquatic habitat in Clancy Creek.

Approximately 2,051 acres of BLM lands are permitted for various rights-of-way and leases. Approximately 1,256 of these acres are for road rights-of-way. The remaining 795 acres are associated with powerlines, communication sites, and other utility facilities. Of these acres, approximately 682 acres are associated with powerlines and have substantial vegetative ground cover over most areas to prevent erosion/sedimentation effects to water resources. Impacts to water resources are generally minor with some localized erosion and sedimenta-

tion and some contribution to decreased hydrologic function (decreased infiltration, increased runoff) due to compaction.

Selective timber harvest has occurred on approximately 259 acres of BLM lands in the TPA from 1984 to 1995. From 1995 to the present timber harvest occurred on 7 BLM acres while post-wildland fire timber salvage occurred on about 559 BLM acres as well as an unknown amount of private land. Adverse effects on water resources were minor from this activity. Timber harvest has also occurred on private and Forest Service lands and will likely continue to have variable effects on water resources for the foreseeable future. Ground disturbance from these activities will have localized impacts to water resources including some sedimentation, loss of woody material recruitment for streams, and potential water temperature increases due to shade loss.

In 2000, a wildland fire burned approximately 10,800 acres in this TPA, approximately 4,670 of which were BLM lands. Tree planting on approximately 690 BLM acres of this burned area have contributed to longer term soil stabilization. The fire burned with variable intensity and severity creating a range of effects to water resources. In burned areas, nutrient inputs to streams increased, perhaps for several years. Streams in more severely burned areas underwent more severe erosion and sedimentation than those in areas burned less severely. Water temperatures in some streams may have increased due to loss of stream-side shade from the fires. Wood recruitment to streams in areas of high burn intensity may be increasing due to riparian tree mortality from fires. Stream flows may increase in some streams for several years. Peak flows may increase due to reduced snow interception by vegetation resulting in greater snow accumulations available for snowmelt in warmer periods. Summer flows may increase due a lack of live vegetation to conduct evapotranspiration of water so more groundwater may reach stream channels. Fire rehabilitation activities such as reseeding burnt ground with grasses/herbaceous species, waterbarring of firelines, and post-fire noxious weed treatments helped stabilize soils and minimize sedimentation effects to streams due to post-fire erosion. Tree planting on approximately 690 BLM acres of this burned area have contributed to longer term soil stabilization and subsequent reduction of stream sedimentation.

Fuels treatments conducted on private and Forest Service lands will likely occur for the foreseeable future with variable effects to soils. Reducing fuels under the controlled conditions of deliberate treatments may benefit water resources in the long-term by reducing the risk of high severity fires that could have severe adverse water quality effects in treated areas.

Increasing residential development will likely continue for the foreseeable future to variable degrees within the TPA. Erosion, soil compaction, and runoff would likely increase due to additional road construction, clear-

ing/leveling for home sites, and establishment of utility infrastructure for residential developments. Nutrient, chemical pollutant, and pathogen inputs to streams would also likely increase due to leaching from septic systems, urban runoff (fertilizer, chemicals, and petroleum pollutants), and waste from livestock.

Livestock grazing on public and private lands throughout much of the Boulder/Jefferson City TPA has created areas of localized streambank trampling, soil erosion and compaction, and nutrient inputs to streams. In severe cases stream channel morphology may be altered due to severe loss of riparian vegetation, loss of streambank integrity, channel widening and shallowing, and substantial sediment inputs. These effects to water quality will continue to occur for the foreseeable future.

Several streams listed as impaired by MDEQ flow through BLM lands in this TPA. Boulder River (0.9 mile on BLM lands) is affected by heavy metal contamination due to acid mine drainage and abandoned mine lands, as well as direct habitat alteration due to highways, bridges, and impacts from historic mining. Big Limber Gulch (1.6 miles on BLM) is still listed as impaired due to heavy metal contamination from acid mine drainage and abandoned mine lands. High Ore Creek (2.1 miles on BLM) remains listed as impaired for heavy metal contamination, sedimentation, alteration of aquatic habitat, water temperature, and total suspended solids impairments. Probable causes of impairments include acid mine drainage, abandoned mine lands, rangeland grazing, roads (most notably a non-BLM valley bottom road), and timber harvest. Cataract Creek (0.4 mile on BLM) is impaired by heavy metal contamination from acid mine drainage and abandoned mine lands. Clancy Creek (0.2 mile on BLM) is impaired by aquatic habitat alteration, sedimentation, and heavy metal contamination. Probable causes of impairments include abandoned mine lands, acid mine drainage, animal feeding operations, riparian grazing, and road impacts (a non-BLM valley bottom road). These impairments will continue for the foreseeable future. In the case of each of these impaired streams, BLM roads are not located in such a manner and are not a great enough proportion of ongoing activities as to play a substantial role in affecting water resource conditions. In each case where roads are listed as probable causes of impairment, there is a non-BLM valley bottom road paralleling the stream.

Under Alternative A for the Boulder/Jefferson City TPA, the contribution to cumulative effects on water resources from BLM road management would continue as it occurs today. Retaining approximately 60 miles of road open yearlong would allow for the same level of effects to water resources that currently exists.

From a BLM road management perspective, all action alternatives would benefit water resources compared to Alternative A. Alternative B would benefit water resources by providing for a reduced contribution to adverse cumulative effects than would Alternative A be-

cause about 55 percent of BLM roads would be closed or decommissioned under Alternative B. Of the approximately 27 miles of open road under Alternative B, most of them (23 miles) would be seasonally restricted to exclude motorized vehicle use in the wet spring runoff period each year. This would reduce erosion from these roads and further benefit water resources.

Although the action alternatives provide for the same degree of road decommissioning overall and road closure/decommissioning within 300 feet of streams, Alternative C would provide for the least contribution to adverse cumulative effects (greatest benefits) on water resources of all alternatives. This alternative would provide for closure or decommissioning of about 62 percent of BLM roads in the TPA, thus allowing these areas to vegetatively recover, stabilize soils, and reduce erosional outputs to streams. The majority of open roads under this alternative (approximately 20 out of 23 miles) would be seasonally restricted to exclude motorized use between 12/2 to 5/15 each year. As with Alternative B, this seasonal closure would prevent motorized use during the wet spring snowmelt/runoff period and would therefore reduce soil erosion and subsequent sedimentation effects to streams.

Of the action alternatives, Alternative D would provide for the greatest contribution to adverse cumulative effects on water resources, but would still provide for greater long-term benefits than Alternative A. Alternative D would provide for closure or decommissioning of about 40 percent of BLM roads in the TPA. As with Alternatives B and C, the majority of open BLM roads (about 33 out of 38 miles) would be seasonally restricted to exclude motorized use between 12/2 to 5/15 each year. This would allow for the same type of beneficial effects to soils described above for Alternatives B and C though to a slightly lesser degree because more roads would remain open under Alternative D.

Due to the scattered distribution and relatively small proportion of BLM lands (24 percent) and roads (15 percent) relative to the total quantities of land and roads in the TPA, none of the BLM alternatives would substantially contribute to cumulative effects on water resources in the Boulder/Jefferson City TPA.

## **VEGETATIVE COMMUNITIES – FOREST RESOURCES AND FOREST AND WOODLAND PRODUCTS**

### **Effects of the Alternatives**

Under all alternatives, existing roads and roads built to access timber and forest product sales on BLM lands may encourage timber harvest and forest product sales on adjacent lands, particularly where landowners and other agencies are looking to improve economic efficiency or opportunities in the management on their lands.

In general, vegetative treatment contractors tend to bid more readily on projects in areas with vehicle access or valuable products. BLM often prioritizes forest vegetation management activities such as forest products and forest protection activities (e.g. wildfire suppression and forest insect and disease control) in similar areas.

Rehabilitation of roads (decommissioning and in some cases road closure) would revegetate currently unvegetated roadbeds, which would increase vegetation biomass production on the landscape through colonization of sites with grasses, forbs, shrubs, and trees. Increases in revegetated area would occur at a rate of approximately 1.5 to 3 acres per mile of rehabilitated road. Eventually rehabilitated roads would support plant communities consistent with site potentials which would help resist weed invasions. However, road closures and removals could make vegetation management treatments more difficult and costly, thereby inhibiting proposed treatments, reducing public access for product use and removal, and potentially slowing fire detection and suppression.

Under Alternative A there would be no increase in project analysis and implementation costs. However, under Alternative B approximately 55 percent of BLM roads would be closed. Under Alternative C about 61 percent of roads would be closed, while under Alternative D about 38 percent of these roads would be closed. These closures would result in commensurate potential increases in vegetative analysis and treatment costs by alternative. These potential cost increases would be considered on a case by case basis by the BLM during project feasibility determinations, and additional funding may be needed to analyze and implement the projects that would remain feasible. Road closures could also result in potential decreases in quantities of forest products removed. Temporary roads have been commonly built in the Boulder/Jefferson TPA to access forest treatment areas and probably will continue to be used in the future. In the Boulder/Jefferson TPA forest product values are typically low, contributing to reduced feasibility of some projects in areas with closed roads. The extent of the effects described above would be minimized because BLM would likely still be able to plan and implement projects in many areas on closed roads through the variance process for temporary road use. Road-related effects would be greatest under Alternative C, followed in sequence by Alternative B, then Alternative D.

Roaded access to forested areas would also affect the gathering of firewood and other forest products by the general public. Most public parties prefer to drive close to areas of product removal so they do not have to carry products over long distances to their vehicles. Alternative A would have the greatest opportunity for firewood and other product removal with 60.5 miles of BLM road open yearlong. Alternative B would provide fewer opportunities than Alternative A with 27.3 miles of open

road. Alternative C would provide the fewest opportunities of all alternatives with 23.5 miles of open road. Alternative D (38.1 open road miles) would provide more opportunities than Alternatives B and C, but fewer than Alternative A. Winter seasonal closures on many roads (closed 12/2-5/15) could affect firewood and Christmas tree harvest in the Boulder/Jefferson TPA under the action alternatives. Alternatives B, C, and D contain winter closures that affect from one third (20.6 miles) to more than one half (34.2 miles) of total open BLM roads in the TPA. For the Boulder/Jefferson City TPA, Alternative A would retain the most public opportunities for these activities, followed in sequence of decreasing opportunities by Alternative D, Alternative B, and then Alternative C.

## Cumulative Effects on Forest and Woodland Resources and Products

Forested vegetation in the Boulder/Jefferson TPA was greatly impacted by a large wildfire during the summer of 2000. The resulting forest condition includes widespread tree mortality with burned understory vegetation on 32 percent of BLM lands within the TPA. In the BLM burned area, 690 acres were salvage logged, followed by restoration tree planting. Adjacent areas of private ownership were also salvage logged following the wildfire. Since 1984, timber harvest has also occurred on 266 acres of green forest. These activities resulted in the removal of forest products and the associated forest restoration, resulting in open stands with more diverse understories. Approximately 500 forested acres have also been prescribe burned, resulting in some tree mortality, short-term erosion, and more open stand conditions in forested areas. Current planning includes additional treatment of 650 acres in the Boulder/Jefferson TPA.

Currently, western spruce budworm and Douglas-fir beetle are present in forests within the Boulder/Jefferson TPA. These insects have been present at similar levels in the past and are expected to remain in the future. These species can reduce forest health and individual tree vigor, sometimes resulting in mortality. Because 32 percent of BLM land in the TPA was burned with 690 acres subsequently replanted, many stands in the central portion of the TPA are in early successional stages and therefore are not at risk for insect infestation. Differences between travel planning alternatives would be negligible in regard to effects on or from the insect populations.

Road decommissioning (2.7 road miles) and associated rehabilitation proposed under all action alternatives would not have major cumulative effects on forest resources or forest products in the Boulder/Jefferson TPA. Approximately 6 acres of road could be colonized by trees under the action alternatives, while no roads would be decommissioned under Alternative A.

Forested vegetation in the Boulder/Jefferson TPA will also be affected by approximately 2,051 acres of rights-of-way and leases on BLM land. Large trees in these areas will generally be harvested for product to accommodate the necessary access or facilities. Forest vegetation removal would occur on new authorizations in the future and would occur as necessary to maintain sight distances and safety clearances associated with roads and facilities.

Urbanization is expected to continue on the 31,705 acres of private land (52 percent of all lands) within the Boulder/Jefferson TPA. Forest products are commonly removed from these areas prior to permanent construction. Urbanization is likely to continue in the future and will affect forested vegetation at an unknown rate. Due to the preponderance of private lands in the TPA, urbanization and activities on open roads in the vicinity may have more cumulative effects on forested vegetation in the TPA than BLM decisions regarding miles of open and closed road.

Risk to forests from human-caused wildfires is commonly associated with open roads. Risk to forests from wildfire is greatest under Alternative A with 60.5 miles of road open during the summer (and yearlong). Alternative B would have less risk of human-caused fire starts with 27.3 miles of road open during summer. Alternative C would have the least risk to forests with only 23.5 miles of road open during summer months. Alternative D (38.1 miles of open road during summer) would have more risk than either Alternatives B or C, but less risk than Alternative A. Since a high percentage of the forested acreage in the central portion of this TPA has already burned, fewer acres are anticipated to be affected by wildfire in the foreseeable future. Given that the majority of roads in the TPA (84.6 percent) are non-BLM roads, this contribution to reduced fire risk from BLM roads in the action alternatives is relatively small in the context of the entire TPA.

Since BLM roads constitute only 15.4 percent of all roads in this TPA, and BLM lands make up only 24 percent of all lands in the TPA, urbanization and activities on open non-BLM roads in the vicinity may have more cumulative effects on forested vegetation in the TPA than BLM decisions regarding miles of open and closed road.

## VEGETATIVE COMMUNITIES -NOXIOUS WEEDS

Under all alternatives, any snowmobile use would have negligible effects on noxious weed spread and populations. Invasive noxious weeds and non-native species are degrading wildland health. These are aggressive plants that can outcompete many native plants, as they have few natural enemies to keep them from dominating an ecosystem. These plant species are spread by many means. However, any land disturbing activity in the TPA has the most potential to introduce and spread weed spe-

cies. Motorized vehicles are one vector for noxious weed spread as weed seed becomes attached to vehicles and their tires, and are transported from one area to another where seeds become detached and germinate to inhabit new areas.

### Effects of Alternative A

Under Alternative A all BLM managed routes in the Boulder/Jefferson City TPA would continue to be managed as open yearlong (60.5 miles, 0 miles seasonally restricted or closed). No non-motorized routes or trails are available under this alternative. Snowmobile use would continue to be managed as open to area-wide cross country travel as well as travel on all existing routes (during the season of use, 12/2-5/15, conditions permitting). Alternative A would have the most roads open and in turn would promote the greatest amount of weeds and other undesirable plant spread and production. More herbicide control would be needed to control weeds in Alternative A than the other alternatives. Under Alternative A the open BLM roads would represent about 15.4 percent of all open roads in the Boulder/Jefferson City TPA.

### Effects of Alternative B

Under Alternative B, 28.8 miles of routes would be available for wheeled motorized use (3.7 miles open yearlong, 25.1 miles seasonally restricted). Closure and decommissioning of routes in the southwest corner of the TPA would help create a non-motorized use area and reduce weed spread related to motorized use. This alternative would close 29.0 miles of road leaving 3.7 miles open yearlong as compared to 60.5 miles of road open yearlong for Alternative A. This would prevent weed spread caused by motorized vehicles on these closed routes, but would increase weed spread on the open routes because of the more concentrated use of these routes. Overall Alternative B would reduce weed spread, but would increase weed treatment costs per road mile on the remaining open roads compared to Alternative A. Under Alternative B, the 28.8 open road miles (including seasonally restricted routes) would make up about 7 percent of all open roads in the Boulder/Jefferson City TPA.

### Effects of Alternative C

Under Alternative C, 23.5 miles of routes would be available for wheeled motorized use (3.0 miles open yearlong, 20.5 miles seasonally restricted). Closure and decommissioning of routes in the southwest corner of the TPA would help create a non-motorized use area and reduce weed spread related to motorized use in this area. This alternative would close 34.2 miles of road leaving 3.0 miles open yearlong as compared to 60.5 miles of road open yearlong for Alternative A. This would prevent weed spread caused by motorized vehicles on these closed routes, but would increase spread on the open routes because of the more concentrated use of these

routes. Overall Alternative C would reduce weed spread more than any other alternative, but would increase weed treatment costs per road mile on the remaining open road miles compared to Alternative A. Under Alternative C the 23.5 miles of open BLM road would make up about 6 percent of all open roads in the TPA.

### Effects of Alternative D

Under Alternative D, 38.1 miles of routes would be available for wheeled motorized use (5.3 miles open yearlong, 20.5 miles seasonally restricted). This alternative would close 20.6 miles of road leaving 5.3 miles open yearlong as compared to 60.5 miles of road open yearlong for Alternative A. This would prevent weed spread caused by motorized vehicles on the closed routes, but would increase spread on the open routes because of the more concentrated use of these routes. Over Alternative D would reduce weed spread more than Alternative A but less than Alternatives B and C, but would increase weed treatment costs per road miles on the remaining open roads miles compared to Alternative A. Under Alternative D, the 38.1 miles of open BLM road would make up about 9.7 percent of all open road miles in the Boulder/Jefferson TPA.

### Cumulative Effects on Noxious Weeds

Under all alternatives, other past, present and reasonably foreseeable future BLM and non-BLM actions affect noxious weeds.

Recreational activities for this TPA include big game hunting, motorized OHV travel (motorcycles, ATVs, snowmobiles), and to a lesser extent, non-motorized uses (hiking, horseback riding, and mountain biking). Motorized recreation uses are one of the leading causes of introduction and spread of noxious weeds and non native species. Weed seeds are transported by many recreational vectors i.e. motorized vehicles including their tires, non-motorized vehicles including their tires, pack animals, and humans. Applications for right-of-way permits on public lands to access private property or for commercial development are likely to increase in the future as urban development increases. As a result, soil disturbing activities (i.e. roads, powerlines, telephone lines, etc.), will likely increase, causing weeds to increase.

A variety of resource management projects, such as BLM initiated vegetation treatments, or wildland fire fuel reduction projects, could affect the TPA. There have been no fuels treatments in this area in the last 10 years and there are none planned on BLM lands for the foreseeable future. Any project creating soil disturbance has the capability to increase weedy plant species. Prescribed burning projects give the ground surface a fertilization effect and eliminate some plant competition for weedy species giving them a niche for establishment and expansion in some areas. Ground disturbing equipment could also transport noxious weed seed to these project sites. BLM implements weed control measures in the

aftermath of such ground-disturbing activities so as to minimize noxious weed spread.

Wildland fires create good seed beds and supply nutrients for weed species introduction and production. From 1981 to 2004 there has been one wildland fire (the 2000 High Ore Fire) that burned approximately 4,600 acres of BLM land. This fire has promoted and increased noxious weed production in this TPA. BLM implemented weed control measures as part of the fire rehabilitation work associated with this fire.

The TPA has a rich history of mining for lead, zinc, gold, copper, and silver. With the exception of the Montana Tunnels Mine, the remaining mines are no longer active; many have been reclaimed by either the BLM or state of Montana. The Montana Tunnels Mine continues to produce lead and zinc with associated gold and silver from an open pit. The mine is located near Jefferson City, and is approx. 1,500 acres in size (including 130 acres of BLM land). Increases in mineral prices could lead to additional increased or renewed mining activity. Mining is a land disturbing activity and the activity itself and weed seed contaminated equipment that is used could promote weeds in the area. Abandoned mine reclamation work conducted by BLM can also contribute to increased weed spread. BLM implements weed control measures associated with these projects to minimize this impact.

Noxious weeds and non-native invasive species are well established and spreading in the area. Weed control activities by BLM and other entities, while often effective at reducing or minimizing weed spread and weed populations, can also lead to some weed spread. Herbicide spray equipment is driven through weed infestations and weed seeds as well as other weed vegetative parts are spread to other lands during and following treatment. The High Ore Wildfire area received ground and aerial herbicide treatments of about 300 to 400 acres in size following the fire. In recent years, treatments using herbicide (ground) and biological controls have been accomplished on approximately 250 acres. These weed treatments have varying success in killing undesirable plants, depending on many environmental parameters. Timber sales have built-in stipulations for mitigating weed production and spread. However, with ground disturbance the potential exists for weed introduction to occur on these sites. Since 1995 there have been 559 acres of timber salvage and 7 acres of timber harvest and 690 acres of forest planting (replanted in 2002). Vehicular access for tree plantings could contribute to the spread of existing weeds on site. Herbicide treatment of existing weeds is coordinated with tree seedling planting locations and timing, so as to minimize potential exacerbation of weed spread.

Future travel management (for all agencies, nationwide) is likely to lead to fewer opportunities for motorized recreational use than under current management (particularly for OHV use). As a result, BLM routes available

to motorized use could experience increased use from displaced users, leading to more concentrated use, increased resource impacts, and user conflicts.

The TPA mainly provides habitat for big game. The entire area is considered winter range for elk while the lower elevations along the eastern half of the travel plan are winter range for mule deer. Noxious weed seeds are transported and spread by wildlife through their digestive system and by attaching to the animals themselves and then being released at a later time.

Livestock grazing on and off BLM lands also contributes to weed spread either through seed being spread or introduced by livestock themselves, or through vehicular uses needed to manage grazing operations.

The Boulder-Jefferson City TPA is located adjacent to the upper Boulder Valley. Human population growth for the upper Boulder Valley (Boulder town statistics) is approximately 2 percent per year. This rate of growth is expected to continue, along with increased recreational use from local residents and area users (residents of Helena and Butte). The increasing population in the Butte and Helena area will in turn lead to an increase in use of this TPA creating more opportunities for weed spread and production.

The small towns of Boulder (population 1,436) and Jefferson City (population 295) are located adjacent to the TPA. The present rate of growth is approximately 2 percent per year, but could increase as Helena Valley area development begins to branch out. The residential development between Jefferson City and Boulder is increasing. Use of the TPA by the residents living adjacent to or within this area will lead to an increase in weed spread and propagation.

About 15.4 percent of all the travel routes in the Boulder/Jefferson City TPA are located on BLM managed lands (under Alternative A). Lands near roads and away from roads in the TPA are infested with weeds. The travel on these roads is spreading weeds and weeds off these roads are being spread by the weed plants themselves and other natural means. Because the majority of roads (85 percent) and lands (76 percent) in the TPA are non-BLM, activities in these areas play a stronger role than activities on BLM lands in determining the status of weed spread and weed populations overall at the scale of the entire TPA.

## VEGETATIVE COMMUNITIES -RIPARIAN VEGETATION

### Effects Common to All Alternatives

This section focuses on effects to riparian vegetation. For additional discussion of effects to water quality and stream channels, see the Water Resources and Fish sections.

Roads in riparian areas constitute ground disturbance that can eliminate or preclude presence of native riparian vegetation. This ground disturbance and loss of riparian vegetation may facilitate erosion and sedimentation of streams. Roads may also interfere with natural stream channel functions by occupying floodplains or active stream channel margins (see Water Resources section for more discussion). Noxious weeds may dominate riparian vegetation communities after some type of disturbance (such as roads, livestock grazing, mining, etc.) has reduced native vegetation. Noxious weed seed can be spread into riparian areas by motor vehicles via open roads. Closure of roads and trails can improve or maintain riparian condition by reducing avenues of noxious weed spread, as well as allowing for bare area revegetation which filters sediment in addition to stabilizing banks in some areas. Road and trail restrictions have the same effects but to a lesser degree, because some traffic will inhibit vegetation growth and recovery.

### Effects of the Alternatives

As a means of comparing alternatives, **Table 4-82** depicts the miles of wheeled motorized routes that cross or are within 300 feet of streams or wet areas on BLM lands in the Boulder/Jefferson City TPA.

<b>Miles of Wheeled Motorized Routes</b>	<b>ALT A</b>	<b>ALT B</b>	<b>ALT C</b>	<b>ALT D</b>
Open	21.7	9.4	9.4	9.5
Restricted	0	4.6	4.5	7.7
Closed	0	7.7	7.8	4.5

Under Alternative A, 21.7 miles of BLM roads and trails would remain open that cross or are within 300 feet of streams or wet areas on BLM lands. The noxious weed spread, streambank, and sediment delivery effects would continue as described in the Effects Common to All Alternatives section. The BLM roads and trails most affecting riparian conditions along Kady Gulch, Boomerang Gulch, Black Jim Gulch, Stagecoach Gulch, and Big Limber Gulch would remain open. Alternative A would pose the greatest adverse effects to riparian vegetation of all alternatives.

Under Alternative B, 9.4 miles of roads and trails would remain open that cross or are within 300 feet of streams or wet areas, 4.6 miles of roads and trails would have seasonal restrictions, and 7.7 miles of roads and trails would be closed. The noxious weed spread, streambank, and sediment delivery effects would be reduced in comparison to Alternative A. Big Limber Gulch, High Ore Creek and Spring Creek roads and trails which impact

riparian areas would remain open because these roads provide access to private lands. Riparian impacted roads and trails along Spencer Creek, Stagecoach Gulch, Black Jim Gulch, and Lower Boomerang Gulch would be closed. Roads and trails along Peters Gulch, the west fork of Boomerang Gulch, and Kady Gulch would have seasonal restrictions on use (closed 12/2-5/15).

Under Alternative C, 9.4 miles of roads and trails would remain open that cross or are within 300 feet of riparian areas, 4.5 miles of roads and trails would have restrictions, and 7.8 miles of roads and trails would be closed. The noxious weed spread, streambank, and sediment delivery effects would be reduced in comparison to Alternative A to the same degree as under Alternative B. Big Limber Gulch, High Ore Creek and Spring Creek roads and trails which impact riparian areas would remain open because these roads provide access to private lands. Riparian impacted roads and trails along Spencer Creek, Stagecoach Gulch, Black Jim Gulch, and Lower Boomerang Gulch would be closed. Roads and trails along Peters Gulch, the west fork of Boomerang Gulch, and Kady Gulch would have seasonal restrictions on use (closed 12/2-5/15).

Under Alternative D, 9.5 miles of roads and trails would remain open that cross or are within 300 feet of riparian areas, 7.7 miles of roads and trails would have restrictions, and 4.5 miles of roads and trails would be closed. The noxious weed spread, streambank, and sediment delivery effects would be reduced in comparison to Alternative A, but would be greater than under Alternatives B or C. As with all other alternatives, Big Limber Gulch, High Ore Creek and Spring Creek roads and trails which impact riparian areas would remain open because these roads provide access to private lands. Riparian impacted trails along Stagecoach Gulch, Black Jim Gulch, and Lower Boomerang Gulch would be closed. Also as with Alternatives B and C, roads and trails along Peters Gulch, Spencer Creek, the west fork of Boomerang Gulch, and Kady Gulch would have seasonal restrictions on use (closed 12/2-5/15).

## **Cumulative Effects on Riparian Vegetation**

Noxious weed spread, mining, roads and trails, logging operations, and livestock grazing have affected riparian resource conditions in all TPAs, including the Boulder/Jefferson City TPA. Some of these factors continue to cause riparian area degradation primarily through direct disturbance or loss of riparian vegetation. Ground disturbance and loss of riparian vegetation facilitate erosion and sedimentation of streams. In the case of noxious weeds, they usually dominate riparian vegetation communities after some type of disturbance (such as roads, livestock grazing, mining, etc.) has reduced native vegetation.

Anticipated subdivision growth on private lands will lead to more road construction and maintenance. More

roads and development will increase severity of runoff events which in turn will cause more sediment delivery to creeks and streams. The additional sediment is likely to affect the functioning condition of some riparian areas by causing streambeds to aggrade at unnatural rates. Streambanks may also be affected if road placements do not allow for natural stream movements or meanders.

Logging and forestry practices on public and private lands are subject to streamside management zone (SMZ) requirements designed to maintain water quality and riparian vegetation. The proposed Riparian Management Zones under Butte RMP Alternatives B and C would be wider than SMZs and activities in these areas would be designed to benefit riparian resources, thus providing more riparian protection and more targeted management of riparian vegetation in both forested and non-forested areas than under RMP Alternatives A and D. The disturbance associated with timber activities does have the potential to increase noxious weed spread which degrades riparian area function and health. On public lands noxious weed control is a standard feature of any ground disturbing activities whereas on private lands noxious weed control is variable.

Livestock grazing will continue in the area and has the potential to impact riparian resource conditions. On BLM lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain riparian vegetation health and vigor. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided. Riparian conditions may improve or degrade as management changes.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, riparian conditions would improve because of the streambank protection gained from shrubby root systems and filtering capability of native riparian sedge and rush species.

Reclamation of abandoned mine lands along Big Limber Gulch, High Ore Creek, Clancy Creek and Spring Creek near Wickes have improved riparian function and health in these watersheds. The removal of contaminated soil and improvement in water quality has caused riparian vegetation to recover and thrive. The future reclamation of the Montana Tunnels mine would ensure a consistent base flow of acceptable water quality to the headwaters of Clancy Creek.

The Boulder complex fires of 2000 burned parts of the High Ore, Boomerang, Spring Creek, and Amazon watersheds. Before the vegetation could recover, subsequent storm events caused streambank scouring to occur on parts of several streams in these watersheds. The fire was of sufficient size to allow several colonies of aspen along riparian reaches and uplands to regenerate. Because a large acreage burned, post-fire use by herbivores

and ungulates was dispersed enough that it did not suppress young aspen suckers.

Cumulative effects under all the action alternatives would be similar to Alternative A at the scale of the entire TPA. The additional road and trail closures and seasonal restrictions on BLM roads in the action alternatives may slightly offset the cumulative road and trail impacts associated with subdivision development and other lands uses as compared to Alternative A. Alternative D would contribute less to riparian vegetation benefits than Alternatives B and C, but would contribute more benefits than Alternative A.

Overall, because BLM roads make up only 15.4 percent of all roads in the TPA (under Alternative A), and BLM lands make up 24 percent of all lands in the TPA, the contributions to riparian vegetation benefits associated with closing riparian roads on BLM lands under the action alternatives, while potentially substantial at the site scale, could be masked by activities on other lands at the scale of the entire Boulder/Jefferson City TPA. Activities on private lands (52 percent of total acreage in TPA) and USFS lands (23 percent of total acreage in TPA) would play a substantial role in determining riparian conditions at the scale of the entire TPA.

## WILDLIFE

### Effects of Alternative A

Under Alternative A, the Boulder/Jefferson City TPA would have substantially more open roads (60.5 miles) compared to the action alternatives and would have the highest actual road density, 3.3 mi/mi<sup>2</sup> (Table 4-83) of all alternatives. Open roads typically increase the level of recreation adjacent to roads which can result in additional disturbance and displacement of wildlife species. Roads can also encourage the public to recreate in areas that had formerly been secluded. Roads can cause direct mortality to wildlife through road kill, prevent wildlife movement, create disturbance to wildlife via vehicular use, cause the spread of noxious weeds, reduce habitat and cause habitat fragmentation on the landscape (Joslin et al. 1999). Open road miles that are greater than 3.0 mi/mi<sup>2</sup> have also been found to provide less than 40 percent of functional habitat for elk (Christensen et al. 1993). Permanent and temporary roads could negatively impact wildlife including special status species, particularly if roads are open during critical periods such as wintering or during the breeding season.

High open road densities under Alternative A could result in the loss of year-round habitat and migration corridors, disturbance and displacement of wildlife, road kill and fragmentation of habitat. Wildlife, including special status species, that are especially sensitive to roads in the TPA include (but are not limited to) elk and northern goshawk. The detrimental effects of open road densities to all wildlife species found in this TPA under Alternative A could be minor to major and long-term.

This alternative would have the greatest negative impacts to wildlife including special status species from open roads.

This TPA would also have substantially fewer acres of functional big game winter range (approximately 483 acres with low road density) compared to the action alternatives (Table 4-83). Functional winter range is similar under the action alternatives with 3,985 acres under Alternative B, 4,035 acres under Alternative C and 3,938 acres under Alternative D.

	<b>Actual Road Density</b>	<b>Acres of Low Road Density</b>	<b>Acres of Moderate Road Density</b>	<b>Acres of High Road Density</b>
<b>Alt. A</b>	3.3	483	2,341	11,662
<b>Alt. B</b>	0.8	3,985	5,304	5,198
<b>Alt. C</b>	0.8	4,035	5,571	4,881
<b>Alt. D</b>	0.9	3,938	4,967	5,582

Low Density = 0-1 mi/mi<sup>2</sup>, Moderate Density = 1-2 mi/mi<sup>2</sup>, High Density = >2 mi/mi<sup>2</sup>

With Alternatives A, B and D, the TPA would be open to cross country snowmobile use. BLM lands in this TPA, however, do not often get favorable snow conditions for snowmobile use. Due to snow conditions, the use of snowmobiles would be limited and the effects to wintering big game and other wildlife species would be expected to be minimal the majority of the time. However, when snow conditions do become favorable, snowmobile use of the TPA could have considerable negative effects to big game and other wildlife species. The negative effects due to cross-country snowmobile use could include harassment of big game during the high stress winter season (Joslin et al. 1999). This could cause individuals to leave an area (temporarily or permanently) and/or increase stress that could lead to mortality.

In evaluating impacts of travel planning on elk and other big game species, it is important to consider impacts on security habitat. Elk security is the inherent protection allowing elk to remain in an area despite increases in stress or disturbance associated with the hunting season or other human activities. Security habitat includes blocks of nonlinear forested habitats greater than 250 acres in size that are at least 0.5 mile from an open road (Hillis et al. 1991). Security habitat should also consist of larger trees (greater than 8 inches DBH) with vegetation dense enough to hide an adult elk (Thomas et al. 2002). Due to the fragmentation of BLM lands and high road densities adjacent to BLM lands, none of the alter-

natives would provide big game security habitat in the Boulder/Jefferson TPA.

Core areas are areas large enough for wildlife (especially animals with large home ranges such as carnivores and big game) to forage and reproduce. Subcore areas are areas that could act as stepping stones for wildlife as they move through the region (Craighead et al. 2002). Within all lands of the Boulder/Jefferson City TPA there are approximately 20,631 acres identified as “core/subcore” habitat. Under Alternative A, there would be 1,113 acres of core/subcore habitat with low road density (less than the action alternatives), 4,015 acres with moderate road density and 15,503 acres with high road density (more than all action alternatives) for all land ownerships.

On BLM lands, there are 2,958 acres in core/subcore habitat. Within the Boulder/Jefferson City TPA, all but 20 acres would have high road densities in core and subcore habitat under Alternative A.

Wildlife corridors are areas of predicted movement within or between core and subcore areas. Within the TPA, there are approximately 13,180 acres identified as “high quality” wildlife movement corridors under all land ownerships. All alternatives would have a similar number of acres with low road densities (677 acres) in movement corridors. Alternative A, however, would have fewer acres with moderate road density (3,556 acres) than the action alternatives and the majority of acres under this alternative (8,948 acres) would have high road densities. Although these areas have been mapped as “high quality” movement corridors, the presence of high road densities could reduce or limit the quality of habitat available to wildlife.

On BLM lands in the TPA, there are 6,659 acres mapped as high quality movement corridors. Under Alternative A, the majority of habitat in mapped high quality movement corridors would have high road densities (4,264 acres) with 1,944 acres in moderate road densities and only 450 acres with low road densities. Alternative A would provide the lowest quality habitat in wildlife movement corridors compared to all other alternatives.

Riparian areas provide crucial habitat and critical travel corridors for wildlife including special status species. Riparian areas also provide a refuge for native plants and animals in times of stress such as drought or fire. Roads in riparian areas can prevent use of these crucial areas by wildlife, limit use, or cause loss of habitat (Wisdom et al. 2000). Under Alternative A, there would be 21.7 miles of open roads in riparian areas.

## Effects of Alternative B

Under Alternative B, the Boulder/Jefferson City TPA would have substantially fewer open roads (27 miles) compared to Alternative A (60.5 miles). Of the 27 miles of open roads, only 3.7 miles would be open year-round and the remaining 23.6 miles would be seasonally re-

stricted. Alternative B would have more open roads than Alternative C (23.5 miles) but less than Alternative D (38 miles). Alternative B would decrease harassment to wildlife during all seasons of use, especially during the winter and spring, over Alternatives A and D. This alternative would improve habitat and reduce fragmentation more than Alternatives A and D but less than Alternative C.

Under Alternative B, the actual road density in elk winter range would be 0.8 mi/mi<sup>2</sup>, below the maximum of 1 mi/mi<sup>2</sup> recommended by MFWP in big game winter range (Table 4-83). This is substantially lower than the road density under Alternative A (3.3 mi/mi<sup>2</sup>), the same as under Alternative C and similar to Alternative D (0.9 mi/mi<sup>2</sup>). Christensen et al. (1993) found that reducing open road miles to less than 1.0 mi/mi<sup>2</sup> increases the amount of functional elk habitat by over 60 percent.

Under Alternative B there would be substantially more acres of functional winter range (3,985 acres in low road density) compared to Alternative A (483 acres) but this alternative would have a similar number of acres compared to Alternatives C and D (4,035 and 3,938 acres respectively) (Table 4-83).

Like Alternatives A and D, the entire Boulder/Jefferson City TPA would be open for cross country snowmobile use with Alternative B. The effects would be the same as described under Alternative A.

Under all land ownerships in core and subcore habitat, Alternative B would have the same acres in low road densities as Alternatives C and D (1,704 acres) which would be more than under Alternative A (1,113 acres). Alternative B would also have the same or similar acres in moderate (5,685 acres) and high (13,242 acres) road densities as Alternatives C and D. These acreages are higher than the moderate road density acreage (4,015 acres), and lower than the high road density acreage (15,503 acres) of Alternative A.

On BLM lands, there are approximately 2,958 acres in core/subcore habitat. Under Alternative A, all but 20 acres would have high road densities in core and subcore habitat on BLM lands. Although core and subcore habitat on BLM lands under the action alternatives would still be primarily in high road density (1,550 acres) there would also be 440 acres in low road density areas and 966 acres in moderate road density areas. Although the amount of functional core and subcore habitat would remain extremely low in this TPA, the action alternatives would improve the quality of core and subcore habitat compared to Alternative A.

In high quality wildlife movement corridors for all land ownerships, Alternative B would substantially increase the acreage with low road density (approximately 3,770 acres) compared to Alternative A (677 acres). Alternatives B would also increase the acreage with moderate road density (5,235 acres) over Alternative A and would substantially lower the acreage with high road density to

4,170 acres compared to Alternative A (8,948 acres). All action alternatives would greatly improve habitat in high quality movement corridors over Alternative A but Alternatives B and C would have more beneficial effects than Alternative D. Even though the action alternatives would improve movement corridors, the amount of quality corridors would remain extremely low due to fragmentation of public lands and high road densities on adjacent lands.

The quality of BLM lands mapped as high quality movement corridors would improve under Alternative B compared to Alternative A. All action alternatives would increase the acreage in low road density to (approximately 3,200 acres) compared to Alternative A (450 acres). Alternatives B and C would also increase the acreage with moderate road densities to (about 2,550 acres) compared to Alternative A (1,944 acres), and decrease the number of acres in high road densities to approximately 865 acres compared to 4,170 acres under Alternative A. All action alternatives would improve habitat in high quality movement corridors on BLM lands over Alternative A but Alternatives B and C would have more beneficial effects than Alternative D.

All action alternatives would protect and restore more riparian habitat than Alternative A by reducing the miles of open roads in riparian areas to 9.5 miles (from 21.7 under Alternative A). Reducing roads in riparian habitats under the action alternatives would allow for more breeding, foraging, and hiding habitat as well as improved movement corridors for a wide variety of species.

### Effects of Alternative C

Under Alternative C, the Boulder/Jefferson City TPA would have substantially fewer open roads (23.5 miles) compared to Alternative A (60.5 miles). Of the 23.5 miles of open roads, only 3.0 miles would be open year-round and the remaining 20.5 miles would be seasonally restricted. Alternative C also would have fewer open roads than Alternative B (27.3 miles) and Alternative D (38 miles). Alternative C would decrease harassment to wildlife during all seasons of use, especially during the winter and spring, over all alternatives. This alternative would also improve habitat and reduce fragmentation more than all other alternatives.

Under Alternative C, the actual road density in elk winter range would be 0.8 mi/mi<sup>2</sup>, below the maximum of 1 mi/mi<sup>2</sup> recommended by MFWP in big game winter range. This is substantially lower than the road density under Alternative A (3.3 mi/mi<sup>2</sup>), the same as under Alternative B, and similar to Alternative D (0.9 mi/mi<sup>2</sup>) (Table 4-83).

Under Alternative C there would be substantially more acres of functional winter range (4,035 acres in low road density) compared to Alternative A (483 acres), but this alternative would have a similar amount of acres com-

pared to Alternatives B and D (3,985 and 3,938 acres, respectively) (Table 4-83).

Alternative C would limit snowmobile use in the entire Boulder/Jefferson City TPA to open roads only (3 miles). This would substantially reduce the negative effects to wildlife from snowmobile use and be the most protective of all alternatives.

There would be no big game security habitat provided on BLM lands under Alternative C.

Effects associated with core and subcore habitat under Alternative C would be the same as under Alternative B. In high quality movement corridors for all land ownerships, Alternative C would substantially increase the acreage with low road density (approximately 3,770 acres) compared to Alternative A (677 acres). Alternative C would also increase the acreage with moderate road density (5,282 acres) over Alternative A (3,556 acres), and would lower the acreage with high road density to 4,113 acres compared to 8,948 acres under Alternative A. All action alternatives would improve habitat in high quality movement corridors over Alternative A but Alternatives C and B would have more beneficial effects than Alternative D.

The quality of BLM lands mapped as high quality movement corridors would improve under Alternative C compared to Alternative A. All action alternatives would increase the acres in low road density (approximately 3,200) compared to Alternative A (450 acres). Alternatives C and B would also increase the acreage with moderate road density to about 2,550 acres, compared to Alternative A (1,944 acres). Alternative C would decrease the number of acres in high road density to approximately 865 acres, compared to 4,170 acres under Alternative A. All action alternatives would improve habitat in high quality movement corridors on BLM lands over Alternative A but Alternatives B and C would have more beneficial effects than Alternative D.

Effects associated with roads in riparian areas under Alternative C would be the same as under Alternative B.

### Effects of Alternative D

Under Alternative D, the Boulder/Jefferson City TPA would have substantially fewer open roads (38 miles) compared to Alternative A (60.5 miles). Of the 38 miles of open roads, 5.3 miles would be open year-round and the remaining 32.8 miles would be seasonally restricted. Alternative D would have considerably more open roads than Alternative B (27 miles) and Alternative C (23.5 miles). Alternative D would decrease harassment to wildlife during all seasons of use, especially during the winter and spring, more than Alternative A but less than Alternatives B and C. This alternative would also improve habitat and reduce fragmentation more than Alternative A but less than Alternatives B and C.

Under Alternative D, the actual road density in elk winter range would be 0.9 mi/mi<sup>2</sup>, below the maximum of 1

mi/mi<sup>2</sup> recommended by MFWP in big game winter range. This is substantially lower than the road density under Alternative A (3.3 mi/mi<sup>2</sup>) and slightly higher than Alternatives B and C (0.8 mi/mi<sup>2</sup>) (**Table 4-83**).

Under Alternative D, there would be substantially more acres of functional winter range (3,938 acres in low road density) compared to Alternative A (483 acres). This alternative would have a similar amount of acres in functional winter range compared to Alternatives B and C (3,985 and 4,035 acres, respectively) (**Table 4-83**).

Like Alternatives A and B, the entire Boulder/Jefferson City TPA would be open for cross country snowmobile use with Alternative D. The effects would be the same as described under Alternative A.

There would be no big game security habitat on BLM lands under Alternative D.

Under all land ownerships in core and subcore habitat, Alternative D would have the same acres in low road density as Alternatives B and C (1,704 acres) which would be more compared to Alternative A (1,113). Alternative D would also have nearly the same acreages in moderate (5,663 acres) and high (13,264) road densities as Alternatives B and C. These values would be more acres in moderate road density and fewer acres in high road density compared to Alternative A (4,015 and 15,503 acres, respectively).

Effects of Alternative D on core and subcore habitat on BLM lands would be the same as under Alternatives B and C.

In high quality movement corridors for all land ownerships, Alternative D would substantially increase the acreage with low road density to 3,772 acres compared to Alternative A (677 acres). This would be similar to Alternatives B and C. Alternative D would also increase the acreage with moderate road density to 4,966 acres, compared to Alternative A (3,556 acres), but this would be less than Alternatives B and C (5,282 acres). Alternative D would also have slightly more acres with high road density (4,443 acres) compared to Alternatives B and C (4,113 acres), but would have fewer acres with high road density than Alternative A (8,948 acres). All action alternatives would improve habitat in high quality movement corridors over Alternative A but Alternative D would have fewer beneficial effects than Alternatives B and C.

In high quality movement corridors on BLM lands, Alternative D would have a similar acreage (3,203 acres) in low road density as Alternatives B and C but would have more than Alternative A (450 acres). Alternative D would have slightly fewer acres in moderate road density compared to Alternatives B and C (2,532 acres) but would have more when compared to Alternative A (1,944 acres). Alternative D would decrease the number of acres with high road density to 1,019 compared to Alternative A (4,170 acres), but would have more acres

with high road density than Alternatives B and C (810 acres). All action alternatives would improve habitat in high quality movement corridors on BLM lands over Alternative A but Alternative D would have fewer beneficial effects than Alternatives B and C.

Effects associated with roads in riparian areas would be the same as under Alternatives B and C.

## Cumulative Effects on Wildlife

Wildlife habitat in the Boulder/Jefferson City TPA has been affected by roads, historic and current mining, timber harvest and salvage, weed infestations, urbanization and development, recreation, powerline corridor development and communication sites.

Human population growth for the upper Boulder Valley is approximately 2 percent per year. This rate of growth is expected to continue, along with increased recreational use from local residents and area users (residents of Helena and Butte). Recreational activities in the Boulder/Jefferson City TPA include hunting, motorized OHV travel (motorcycles, ATVs, snowmobiles), and to a lesser extent, non-motorized uses (hiking, horseback riding, and mountain biking).

Land that was traditionally used for ranching, forest products, or mining is now being converted to home sites in the Boulder/Jefferson City TPA. Although these lands had historic human uses, they also provided quality wildlife habitat. These areas historically provided a diversity of habitats that contributed to; big game winter range, travel corridors, habitat for resident and migrating wildlife, as well as foraging, breeding and hiding habitat.

For many plant and animal communities, native species richness decreases as housing density increases. Non-native species, however, tend to increase with development (Hansen et al. 2005). Wildlife populations, including carnivores, may be reduced even at very low levels of residential development due to; loss of habitat, an increase in human access (from roads) in areas that previously had low levels of disturbance, and an increase in hunting pressure. Residential development can also lead to an increase in noxious weed infestations that can reduce the quality and quantity of wildlife habitat.

Pets can also have a negative impact to native wildlife. Cats hunt and kill bird and small mammals. Dogs that are allowed to roam can chase, injure, or kill wildlife. This can result in areas becoming unavailable to wildlife.

The Boulder/Jefferson City TPA is within an area that was heavily affected by historic mining. There are five large mines which are no longer active and have had some level of reclamation by either the BLM or the State of Montana. Montana Tunnels is the only active mine and continues to produce lead and zinc with associated gold and silver from an open pit. The mine is located near Jefferson City, and is approximately 1,500 acres in size (including 130 acres of BLM land). It is expected

that exploration for minerals would continue in the future. Mineral activity along with associate road construction and development on both private and public lands could add substantially to the negative cumulative effects to wildlife and wildlife habitats in this TPA.

In the TPA, there are 11 powerlines, two pipelines and seven communication sites. In the future, communication sites on BLM lands will be restricted to existing sites. There is the potential for future powerlines and pipelines to be built in this TPA and for additional communication sites to be built on private and other public lands.

There are approximately 26 rights-of-way (ROW) in the TPA and applications for ROW permits to access private property or for commercial development are likely to increase in the future. As a result, public access to BLM lands could increase. Fewer ROWs would be expected under Alternative A because all BLM roads would remain open under this alternative. Alternative B would be expected to have fewer ROWs than Alternative C but more than Alternatives A and D. Alternative C would be expected to have the most ROWs and, of the action alternatives, Alternative D would have the fewest.

Between 1984 and 1995 only 260 acres of timber harvest occurred on BLM lands in the TPA although more occurred on adjacent private lands. In 2000, the Boulder Fire burned approximately 10,800 acres of the entire TPA and approximately 4,670 acres in the Decision Area. After the fire, approximately 560 acres of timber salvage occurred on BLM lands and a substantial amount of acres on private lands were also heavily salvaged. Approximately 700 acres of BLM lands have been replanted. Since private lands were heavily salvaged after the fire, it is not expected that timber harvest would occur on these lands for the next 20-40 years. Additional timber harvest or vegetation restoration may occur on BLM lands in the future, especially within meadows that were not burned and are experiencing conifer encroachment. Forest and fuels reduction treatments would be expected to be less under Alternatives A and C than under Alternatives B and D. Overall, vegetative treatments on BLM lands have had minor effects to wildlife habitat in the TPA. However, timber salvage on BLM lands has substantially reduced the distribution and amount of snag habitat for snag dependant species in the salvage units. Timber harvest and salvage on private lands has altered the landscape and caused a decline in the quality and quantity of wildlife habitat in the TPA.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the TPA. Motorized activities play a large role in the distribution of noxious weeds. The cumulative effects of the spread of noxious weeds from open roads would be greater under Alternative A than all other alternatives. Alternative A would result in more wildlife habitat being lost or degraded due to noxious weed infestations compared to the action alternatives. Alternative B would have fewer open roads

than Alternatives A and D resulting in fewer infestations of noxious weeds. Alternative C would close the most roads and would have the fewest cumulative effects from loss of habitat due to noxious weeds of all alternatives. Open roads adjacent to BLM land would still be a conduit for the spread of noxious weeds.

Fragmentation of BLM lands in the TPA (only 24 percent of the TPA is in BLM ownership) and open roads on BLM lands (about 60.5 miles), on private lands (about 283 miles), and other public lands (about 48 miles) have reduced the quality of wildlife habitat within the TPA. Roads within the TPA cause disturbance to wildlife along with fragmentation and loss of habitat. Roads are associated with nearly every type of activity that has the potential to occur in the TPA including vegetation treatments, timber salvage, mining, access to private lands (ROWs), fire suppression, powerline corridors, and recreation. Open roads in the Planning Area would likely increase due to development and management of private lands. Alternative A would have the greatest negative cumulative effects to wildlife and wildlife habitat from open roads with 60.5 miles of open roads. Alternative B would have fewer negative cumulative effects with 27 miles of open road than Alternatives A and D (38 open miles) but more than Alternative C (23.5 miles).

Alternative A would have the greatest negative cumulative effects from open roads to wildlife and wildlife habitat of all alternatives. Under Alternative A, habitat on BLM lands would not be restored and would continue to be degraded over time. Disturbance to wildlife from open roads would continue to impact the distribution and use of the TPA by wildlife under Alternative A. Alternatives B and C would have greater beneficial cumulative effects to wildlife and wildlife habitats from closing roads than Alternatives A and D.

Historic and recent timber cutting, salvage harvest, past mining activity and firewood gathering in the TPA may have reduced the amount of suitable snag habitat for cavity nesting species as well as down woody material. Alternative A would allow continued access to the area for firewood cutting. This could continue to prevent snag recruitment for snag dependant species and minimize the amount of down woody material. Alternative B would protect more snag and down wood habitat from loss due to firewood cutting than Alternatives A and D but would protect less of this habitat type than Alternative C.

High road densities in both the Decision and Planning Areas have prevented BLM lands from providing suitable security habitat for big game during the hunting seasons under any alternative. Lack of security habitat in this TPA would continue to be an issue with all alternatives although Alternatives B and C would slightly increase the amount of security habitat.

Habitat mapped as core and subcore habitat, and wildlife movement corridors having high road densities would

continue to be of low value to wildlife under Alternative A. An increase in open roads in both the Decision and Planning Areas could result in a loss of core and subcore habitat under all alternatives but, especially, Alternative A. However, the cumulative effects to core and subcore habitat and wildlife movement corridors would be beneficial under the action alternatives, especially Alternatives B and C.

The cumulative effects of high road densities would continue to negatively affect wildlife species during the breeding season more with Alternative A than under the action alternatives. Alternatives B and C would have the most beneficial cumulative effects to wildlife during the breeding season compared to Alternative D and Alternative A.

## FISH

For the sake of this discussion, “open” roads include roads that are open with seasonal restrictions as well as roads that are open yearlong. Roads identified as “closed” within 300 feet of streams also include roads that would be “decommissioned” in these areas by alternative. Effects to water quality described in the Water Resources section would affect fish populations and fish habitat quality. Analyses described and tabulated in the Water Resources section are referred to in the context of effects to fish in the discussion below.

### Effects of Alternative A

Under Alternative A, the Boulder/Jefferson City TPA would have substantially more open roads (60.5 miles) compared to the action alternatives. Generally, watersheds with high road densities often have the largest negative effects on fish and aquatic resources. Roads can have a wide range of effects on fish and fish habitat. These effects would include, but are not limited to, increased sedimentation from road construction and vehicle use, increased runoff, changes in surface water and drainage patterns from stream crossings, conduits for noxious weeds, loss of riparian vegetation, potential decreases in stream shading that could lead to water temperature increases, loss of instream habitats and changes in local fish populations when culverts are impassable and limit fish migration.

Watershed (or hydrologic) function can be used as an indicator of relative risk or impacts to fish habitat. To determine the effects on watershed functions, a moving windows analysis was conducted on BLM lands to look at the miles of roads that would be decommissioned and removed from the landscape for each alternative. During this analysis, it was assumed that even though closing roads would improve watershed function, closed roads would remain on the landscape and could still have negative impacts to water quality and prevent or impede the restoration of riparian vegetation. Under Alternative A, there would be 472 acres with low road density (based on open and closed roads), 2,353 acres with moderate

road density and 11,662 acres with high road density on BLM lands in this TPA (**Table 4-80**). Alternative A would have fewer acres with low road density and more acres with high road density than the action alternatives and this alternative would be expected to have more overall negative effects to watershed function due to roads than the other alternatives.

For this discussion, road miles within 300 feet of fish bearing streams would be considered an indicator of direct effects to fish habitat and fish populations. Under Alternative A, there would be 0 miles of closed road and 2.5 miles of open road within 300 feet of fish bearing streams on BLM lands. Under the action alternatives, there would be 0.5 mile of closed road and 2 miles of open road adjacent to fish bearing streams. Of the 2.5 miles of open roads adjacent to fish bearing streams under Alternative A, 2.1 miles would be adjacent to streams with westslope cutthroat trout (BLM sensitive species). In this context, Alternative A would have more potential long-term negative impacts to westslope cutthroat trout as well as to all fish species compared to the action alternatives.

Perennial non-fish bearing streams contribute to fish habitat indirectly by serving as conduits for watershed products (water, sediment, nutrients, contaminants, and in some cases woody material) to fish bearing streams. Under Alternative A, there would be 0 miles of closed road and 7.7 miles of open road within 300 feet of non-fish bearing streams on BLM lands in the TPA. Under all action alternatives there would be 3.2 miles of closed road and 4.5 miles of open road in these areas. Alternative A would have more miles of open roads adjacent to perennial streams and would have more adverse effects to fish and aquatic habitat than the action alternatives.

This alternative would have the greatest negative impacts to fish and aquatic resources from open roads.

### Effects of Alternative B

Under Alternative B, the Boulder/Jefferson City TPA would have substantially fewer open roads (27 miles) compared to Alternative A (60.5 miles). Alternative B would have more open roads than Alternative C (23.5 open miles) but less than Alternative D (38 open miles). In the context of watershed function, Alternative B would have approximately 863 acres in the low road density category, 2,377 acres in the moderate road density category, and 11,247 acres in the high road density category on BLM lands (**Table 4-80**). This would be 391 more acres in low road density, 24 acres more in moderate road density, and 415 acres less in high road density than Alternative A. These acreages would be the same for Alternatives C and D. This analysis does consider “decommissioned” roads, but does not consider “closed” roads as contributing to watershed function. Even though closed roads could still have adverse effects to aquatic habitats, these roads have more potential to become revegetated and lessen sedimentation and

runoff, and restore riparian vegetation (thus contributing to improved fish habitat conditions) than open roads. Under Alternative B there would be approximately 30 miles of closed roads that would remain open under Alternative A, an additional indication that Alternative B would pose less of an impact to fish habitat than Alternative A. Under Alternative B (and all action alternatives), there would be 0.5 mile of closed road and 2 miles of open road adjacent to fish bearing streams on BLM lands. Of the 2 miles of open roads adjacent to fish bearing streams, 1.6 miles would be adjacent to streams with westslope cutthroat trout (BLM sensitive species). Alternative B would have 0.5 fewer miles of open road adjacent to fish bearing streams including streams with westslope cutthroat trout than Alternative A. This alternative would have fewer direct and indirect long-term negative effects to westslope cutthroat trout as well as other fish species than Alternative A.

Alternative B would also have fewer indirect effects to fish habitat associated with roads within 300 feet of perennial non-fish bearing streams compared to Alternative A. Under Alternative B there would be 3.2 miles of closed road and 4.5 miles of open road within 300 feet of perennial non-fish bearing streams on BLM lands in the TPA. All 7.7 of these road miles would remain open under Alternative A so Alternative B would have fewer impacts to fish and aquatic habitat than Alternative A from these roads.

This alternative would have fewer negative effects to fish (including special status species) and aquatic resources from open roads than Alternative A.

### Effects of Alternative C

Under Alternative C, the Boulder/Jefferson City TPA would have substantially fewer open roads (23.5 miles) compared to Alternative A (60.5 miles) and Alternative D (38 miles). Alternative C also would have fewer miles of open roads than Alternative B (27.3 open miles).

In the context of watershed function, Alternative C would have the same acreages in the low, moderate and high road density categories on BLM lands as Alternative B (Table 4-80). This analysis does consider “decommissioned” roads, but does not consider “closed” roads as contributing to watershed function. Even though closed roads could still have adverse effects to aquatic habitats, these roads have more potential to become revegetated and lessen sedimentation and runoff, and restore riparian vegetation (thus contributing to improved fish habitat conditions) than open roads. Under Alternative C there would be approximately 34 miles of closed roads that would remain open under Alternative A, and approximately 4 more miles of closed road than under Alternative B. Alternative C **could have** slightly less impact to fish habitat than Alternative B, and would provide the greatest improvement to watershed function of all the alternatives. Effects associated with roads within 300 feet of fish bearing streams on BLM lands

under Alternative C would be the same as under Alternative B. Effects associated with roads within 300 feet of perennial non-fish bearing streams on BLM lands would be the same under Alternative C as under Alternative B. Alternative C would provide the greatest benefit to fish and aquatic habitats of all alternatives, having slightly greater benefits than Alternative B.

### Effects of Alternative D

Under Alternative D, the Boulder/Jefferson City TPA would have substantially fewer open roads (38 miles) compared to Alternative A (60.5 miles). Alternative D, however, would have considerably more open road than Alternative B (27 open miles) and Alternative C (23.5 open miles).

In the context of watershed function, Alternative D would have the same acreages in the low, moderate and high road density categories on BLM lands as Alternatives B and C (Table 4-80). This analysis does consider “decommissioned” roads, but does not consider “closed” roads as contributing to watershed function. Even though closed roads could still have adverse effects to aquatic habitats, these roads have more potential to become revegetated and lessen sedimentation and runoff, and restore riparian vegetation (thus contributing to improved fish habitat conditions) than open roads. Under Alternative D there would be approximately 21 miles of closed roads that would remain open under Alternative A.

All action alternatives would have more acres with low road density (863) (based on open and closed roads), slightly more acres with moderate road density (2,377) and fewer acres with high road density (11,247) than Alternative A. The action alternatives would be expected to have fewer overall negative effects to watershed function due to roads than Alternative A. Because Alternative D would close fewer roads, this alternative would be expected to have more negative watershed effects than Alternatives B and C. Alternative D would have more negative effects from roads on overall watershed function than Alternatives B and C but less than Alternative A.

Effects associated with roads within 300 feet of fish bearing streams on BLM lands under Alternative D would be the same as under Alternatives B and C. Alternative D would have more indirect effects to fish habitat associated with roads within 300 feet of perennial non-fish bearing streams on BLM lands than Alternatives B and C, but less than Alternative A. Under Alternative D, there would be 2.4 miles of closed road and 5.3 miles of open road in these areas.

This alternative would have more negative direct and indirect effects to fish and aquatic habitats and overall watershed function from open roads than Alternatives B and C. Alternative D would provide more benefits to fish and aquatic habitats than Alternative A.

## Cumulative Effects on Fish

The Boulder/Jefferson City TPA supports a variety of native and introduced fish species. One of the major human influences to fish in the TPA has been the introduction of non-native trout species including rainbow trout, brook trout, and brown trout throughout the TPA and also Yellowstone cutthroat trout into Cataract Creek. Rainbow trout have hybridized with the native westslope cutthroat trout in many streams, and brook trout and brown trout have displaced the native cutthroats in other streams, especially those altered by sedimentation and increased water temperatures brought on by human activities.

Human population growth for the upper Boulder Valley is approximately 2 percent per year. This rate of growth is expected to continue, along with increased recreational use from local residents and area users (residents of Helena and Butte). Recreational activities in the Boulder/Jefferson City TPA include hunting, motorized OHV travel (motorcycles, ATVs, snowmobiles), and to a lesser extent, non-motorized uses (hiking, horseback riding, and mountain biking).

Development and urbanization can have substantial impacts to fish habitat and may pose the greatest threats to watershed function.

Agricultural activities from farming and ranching also contribute increases in nutrients, sedimentation and cause loss of aquatic habitats. Many streams in the TPA have been impacted by historic and on-going livestock grazing that breaks down streambanks, widens channels, removes vegetative cover, and causes an increase in fine sediment and nutrients.

The Boulder/Jefferson City TPA is within an area that was heavily impacted by historic mining and numerous drainages have been degraded by historic mining activities. See the Cumulative Effects discussion in the Water Resources section for a description of streams impacted by heavy metal contamination related to historic mining. There are five large mines which are no longer active and have had some level of reclamation by either the BLM or the State of Montana. These activities should gradually improve water quality and allow further recovery of fish populations, but full restoration could take decades to achieve. Montana Tunnels is the only active mine and continues to produce lead and zinc with associated gold and silver from an open pit. The mine is located near Jefferson City, and is approximately 1,500 acres in size (including 130 acres of BLM land). It is expected that exploration for minerals would continue in the future. Montana Tunnels is currently planning an expansion of the mine which would remove or degrade approximately 0.5 mile of Clancy Creek, a westslope cutthroat trout stream. Expansion of Montana Tunnels would create a barrier to westslope cutthroat trout in Clancy Creek as well as result in the loss of aquatic habitat.

Fires, floods, and drought have historically affected fish habitat in the TPA. These disturbances can cause a pulse of sediment or may temporarily reduce the quality of fish habitat in some watersheds while leaving other streams largely unaffected. Natural disturbances are typically followed by periods of stability during which fish habitats and populations recover. Population recovery in disturbed streams may be facilitated by fish immigration from nearby drainages less affected by the catastrophic event. In 2000, the Boulder Fire burned approximately 10,800 acres of the entire TPA and approximately 4,670 acres in the Decision Area. The fire did cause runoff and sedimentation as well as the loss of riparian vegetation to some streams.

After the 2000 Boulder Fire, approximately 560 acres of timber salvage occurred on BLM lands and a substantial amount of acres on private lands were also heavily salvaged. This may have had substantial negative effects on riparian and aquatic habitats in the TPA. Additional timber harvest or vegetation restoration may occur on BLM lands in the future, especially within meadows that were not burned and are experiencing conifer encroachment. Vegetative treatments would be expected to be less under Alternatives A and C than Alternatives B and D.

Timber harvest can alter the recruitment of large woody debris, reduce canopy closures, and result in an increase in fine sediment to streams. Timber harvest along with associated roads can contribute substantially to the overall cumulative effects in forested watersheds. Between 1984 and 1995 only 260 acres of timber harvest occurred on BLM lands in the TPA although more occurred on adjacent private lands.

Roads are another major contributor of sediment to streams and a major problem with regards to cumulative watershed effects. Roads and trails can have localized effects on nearby stream segments or at stream crossing sites, especially fords. In some cases, effects are more extensive and may impair fish habitat for longer reaches of streams. Cumulatively, roads degrade aquatic habitat due to sedimentation from road construction and vehicle use, increased runoff, changes in surface water and drainage patterns from stream crossings, loss of riparian vegetation, loss of large woody material and roads can cause changes in local fish populations when culverts are impassable and limit fish migration. Alternative A would have more negative cumulative effects to watersheds and individual streams due to roads than the action alternatives. Alternative B would have fewer negative cumulative effects than Alternatives A and D but more than Alternative C. Alternative B would improve overall watershed functions as well as improve habitat in individual streams more than Alternatives A and D but less than C. Alternative C would have the greatest beneficial cumulative effects.

## SPECIAL STATUS PLANTS

### Effects Common to All Alternatives

Ground-disturbing activities from road construction and maintenance, as well as road use by vehicles can affect special status plant populations and habitat. These activities can reduce sensitive plant species through disturbance to individual populations, increasing competition from invasive species, and reducing habitat connectivity. Closure of roads and trails can improve or maintain sensitive plant populations or habitat by reducing avenues of noxious weed spread, maintaining habitat connectivity, and improving pollinator habitat. Road and trail restrictions have the same effects but to a lesser degree.

### Effects of the Alternatives

Under Alternative A, 60.5 miles of BLM roads and trails would remain open. The effects of these open routes would continue as described above in the Effects Common to All Alternatives section.

Under Alternative B, 3.7 miles of BLM roads and trails would remain open, 25.1 miles of roads and trails would be open with seasonal restrictions, 29.0 miles of roads and trails would be closed, and 2.7 miles of roads would be decommissioned. On the closed and decommissioned routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The restricted roads would reduce weed spread a limited amount. Alternative B would benefit and reduce risk to special status plants compared to Alternative A.

Under Alternative C, 3.0 miles of BLM roads and trails would remain open, 20.5 miles of roads and trails would be open with seasonal restrictions, 34.2 miles of roads and trails would be closed, and 2.7 miles of roads would be decommissioned. On the closed and decommissioned routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The restricted roads would reduce weed spread a limited amount. Alternative C would benefit and reduce risk to special status plants more than any other alternative because it would eliminate disturbance, vehicular use, and spread of noxious weeds on the most road miles.

Under Alternative D, 5.3 miles of BLM roads and trails would remain open, 32.8 miles of roads and trails would be open with seasonal restrictions, 20.6 miles of roads and trails would be closed, and 2.7 miles of roads would be decommissioned. On the open roads, effects would continue as described in the Effects Common to All Alternatives section above. On the closed and decommissioned routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The restricted roads would reduce weed spread a limited amount. Alternative D would benefit and reduce risk to

special status plants more than Alternative A, but would pose more risk than Alternatives B and C.

### Cumulative Effects on Special Status Plants

Under all alternatives there are a number of past, present, and reasonably foreseeable future actions that affect special status plant populations.

Livestock grazing will continue in the area and has the potential to impact sensitive plant populations and habitat. On public lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain sensitive species populations and habitat. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided. Conditions may improve or degrade as management changes.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, sensitive plants would benefit from the reduced competition. Use of herbicides for noxious weed control could cause mortality to special status plants if individual plants are inadvertently sprayed.

Recent and anticipated subdivision growth on private lands will lead to more road construction and maintenance. More roads and development will reduce sensitive plant species habitat and in some cases individual populations. Additionally, subdivisions have the potential to disrupt the connectivity of plant habitat and populations as well as disturbing or eliminating pollinators needed by sensitive species. Some sensitive species that require soil disturbance may benefit.

Timber sale activity disturbance can destroy or degrade sensitive plant habitat. On public lands, projects would be designed to avoid, mitigate, or enhance sensitive plant habitats. The disturbance associated with timber harvest activities does have the potential to increase noxious weed spread which degrades sensitive species habitat and individual plant populations.

The Boulder complex fires of 2000 burned parts of the High Ore, Boomerang, Spring Creek, and Amazon watersheds. The burn encouraged noxious and invasive weed spread in some areas. On the other hand, potential habitat for special status plants that was being overtopped by conifers was opened up and improved by the fire.

At the scale of the entire Boulder/Jefferson City TPA (all land ownerships), the BLM travel plan alternatives would have slightly variable contributions to cumulative effects on special status plants. Under Alternative A none of the roads in the TPA would be closed. Under Alternative B adverse effects on special status plants would be slightly reduced compared to Alternative A because 8.5 percent of all roads in the TPA would be

closed or decommissioned. Alternative C would provide the most benefits of all alternatives as 9.4 percent of all roads in the TPA would be closed or decommissioned. Alternative D would provide slightly more benefits than Alternative A but slightly fewer benefits than either Alternatives B or C as 5.9 percent of all roads in the TPA would be closed or decommissioned. Because BLM lands make up only 24 percent of all lands in the TPA, activities on non-BLM lands would play a dominant role in determining status of special status plants.

## WILDLAND FIRE MANAGEMENT

Travel planning alternatives were analyzed to determine whether they could result in impact on wildland fire management, causing change to any of the following indicators:

- Fire regime condition class (FRCC)
- Firefighter and public safety
- Reducing threat to Wildland Urban Interface (WUI)

### Effects Common to All Alternatives

Public road access during the fire season provides opportunities for human-caused fires either due to catalytic converters on vehicles igniting dry vegetation, or due to some types of human activities. Roads that are closed to public access reduce the risk of human-caused fire starts in those areas.

Decommissioned roads and roads that are closed and not regularly maintained for navigability reduce access for fire suppression. Closed roads may become impassible due to vegetation regrowth, downfall of trees, or severe erosion. Some roads may be closed with earthen berms or fallen trees and would need to be physically manipulated to make them useable for vehicles again. These roads would extend firefighting response time and have negative impacts on efforts to reduce wildland fire threat to WUI areas and firefighter and public safety. In an emergency fire suppression situation, any navigable closed roads needed for fire suppression would be used immediately. Non-navigable closed roads could also be used if deemed to be needed for fire suppression, after needed improvements are made to make those roads useable. Planning and implementation of fuels reduction treatments could occur in association with closed roads if variances for temporary road use were to be allowed. Variances would be subject to internal BLM review.

In the context of fuels reduction projects, availability of open roads is important to facilitating fuels project location as well as increasing project feasibility and decreasing costs. Open roads also facilitate spread of noxious weeds by transporting weed seed on vehicles and their tires. Presence of large noxious weed populations could delay or cause fuels projects to be cost-prohibitive due to the fact that the weeds may have to be treated before and/or after the fuels treatment. Also, some applications

of fuel treatments (e.g., prescribed fire) may promote the spread of some weeds. The presence of weeds and non-native species are indicators that FRCC has departed from historical conditions.

Noxious weeds and non-native invasive species are well established and spreading in the Boulder/Jefferson City TPA.

### Effects of Alternative A

Under Alternative A, all BLM managed routes in the Boulder-Jefferson City travel planning area would continue to be managed as open yearlong (60.5 miles). Alternative A would allow for the greatest flexibility between alternatives for access for suppression purposes. Fuels project feasibility would be highest under this alternative. However, public access during the fire season would be the greatest under this alternative and would provide the most opportunities for human-caused fire starts.

The distribution of noxious weeds could be the greatest under Alternative A with the most open roads and noxious weeds already well established. This would contribute to reduced feasibility of fuels reduction projects more than under any other alternative.

### Effects of Alternative B

Alternative B provides a more balanced approach towards travel management and should help reduce user conflicts. Under Alternative B, 27.3 miles of routes (3.7 miles open yearlong, 23.6 miles seasonally restricted) would be available for wheeled motorized use. Alternative B would limit the flexibility for access for suppression purposes, and fuels project feasibility would go down compared to Alternative A due to the fact that access would be limited to 27.3 miles of road. Of the 33.2 miles of closed roads, 2.7 miles would be decommissioned and would likely be unusable for fire suppression. The risk of human-caused fires associated with motorized use would be limited compared to Alternative A, due to a 55 percent decrease in miles of road open to motorized public travel.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because more roads would be closed under this alternative, Alternative B should help reduce the spread of noxious weeds and may make fuels treatment more feasible than under Alternative A, reducing FRCC departure.

### Effects of Alternative C

Alternative C would provide the least amount of motorized wheeled access among the action alternatives. Under Alternative C, 23.5 miles of routes would be available for wheeled motorized use (3.0 miles open yearlong, 20.5 miles seasonally restricted).

Alternative C would limit the flexibility for access for suppression purposes, and fuels project feasibility would

go down compared to both Alternatives A and B, due to the fact that access would be limited to 23.5 miles of road. Of the 37 miles of closed roads, 2.7 miles would be decommissioned and would likely be unusable for fire suppression. The risk of human-caused fires associated with motorized use would be the lowest of all alternatives, due to a 61 percent decrease in miles of road open to motorized public travel compared to Alternative A. Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because more roads would be closed than under any other alternative, Alternative C should help reduce the spread of noxious weeds more than any other alternative, and may make fuels treatment more feasible, reducing FRCC departure.

### Effects of Alternative D

Under alternative D, 5.3 miles of open routes would be available yearlong for wheeled motorized use and an additional 32.8 miles would be seasonally restricted routes. Of the 22.4 miles of closed roads, 2.7 miles would be decommissioned and would likely be unusable for fire suppression. Alternative D would be more flexible than Alternatives B and C, but would limit flexibility for access for suppression purposes, and fuels project feasibility would go down compared to Alternative A. The risk of human-caused fires associated with motorized vehicle use would be reduced compared to Alternative A, but would be greater than under Alternatives B and C, due to a 37 percent decrease in open roads compared to Alternative A.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because an intermediate number of road miles would be closed under this alternative, Alternative D should help reduce the spread of noxious weeds and may make fuels treatments more feasible than Alternative A, but would promote more weed spread and potentially make projects less feasible than Alternatives B and C.

### Cumulative Effects on Wildland Fire Management

Effects on wildland fire management associated with any of the BLM travel plan alternatives would be overshadowed by reasonably foreseeable uncharacteristic fire, continued fire suppression made necessary by WUI and intermingled landownership, and large-scale forest insect infestations and disease outbreaks that would continue for the planning period. BLM lands make up about 24 percent of all lands while BLM roads make up about 15.4 percent of all roads in the Boulder/Jefferson City TPA.

Revision of the Helena and Beaverhead-Deerlodge National Forest Plans could result in more or less treatment of adjacent areas. Because no decision has been made, the effects are not known. Wildland fire management, particularly where wildland fire use (management of

naturally ignited wildland fires to achieve resource objectives) may occur on USFS lands, will be determined in the plan decision. BLM would need to coordinate with USFS on all wildland fire use actions and events. Wildland fire use on USFS lands could affect FRCC on BLM lands. USFS lands make up 23 percent of all lands in the Boulder/Jefferson City TPA so activities there would likely have a similar degree of influence on future fire characteristics as activities on BLM lands (24 percent of all lands in TPA).

Decisions to increase the level of wildland fire use, prescribed fire, or open burning by the public could impact the BLM's ability to use wildland fire and prescribed fire due to air quality concerns and requirements. This could postpone or eliminate BLM fuel reductions or treatments to improve FRCC.

Access is a critical component of wildland fire suppression. In some cases, access to public lands is being reduced by adjacent landowners gating or closing roads, which could hamper wildland fire suppression efforts and pose a risk to public and firefighter safety. Reducing access would also increase the potential for larger fires to occur due to an increase in time needed to access a fire and control it. Time needed to move in crews would be extended, and the ability to effectively apply and place resources (e.g., engines, water tenders, etc.) would be limited.

Effects on wildland fire management, including FRCC and firefighter and public safety due to management accomplished by other landowners may affect wildland fire management on public lands. When activity fuels (such as logging slash) are not treated adequately, fuel hazard could increase on adjacent lands which could affect fire intensity and severity on public lands. When adjacent owners treat fuels or implement fire mitigation plans in the WUI, fires are easier to suppress and firefighter safety is increased. In the Boulder/Jefferson City TPA, activities on private lands (53 percent of all lands in TPA) would have more influence on future fire characteristics in the area overall than activities on BLM lands (24 percent of all lands in TPA).

Human population increases and subsequent residential development are likely to expand the WUI and could alter forest management, taking the emphasis off restoring historic composition and structure and focusing more on fuel reduction.

## CULTURAL AND PALEONTOLOGICAL RESOURCES

### Effects Common to All Alternatives

Alternative-specific risks or impacts to cultural and paleontological resources are difficult to discern due to a lack of extensive site-specific knowledge about the presence of these resources in a given TPA. By designating open routes, limiting open-country travel, and closing

some routes, inadvertent discovery of cultural and paleontological resources and vandalism to them is reduced. Higher road densities in a given area would allow greater access to more land on the average, but that does not imply greater amounts of vandalism, since the vehicles would remain on designated routes.

## VISUAL RESOURCES

### Effects Common to All Alternatives

Roads (temporary or permanent) may affect visual quality. Roads that remain open for public use may impact visual qualities where noticeable. The quantity of open roads would also influence sensitivity levels since with more open roads, more areas would generally be viewed by more members of the public. Closing or decommissioning roads would generally reduce effects to visual resources and reduce sensitivity levels because fewer members of the public would generally be accessing and viewing areas with closed roads.

### Effects of the Alternatives

Under Alternative A, all 60.5 miles of BLM road would remain open, thereby providing for the greatest level of impact to visual resources of all alternatives.

Under Alternative B, there would be 28.8 miles of open road (including open with seasonal restrictions), 29.0 miles of closed road, and 2.7 miles of decommissioned road. Road closures and decommissioning under this alternative would reduce effects on visual resources compared to Alternative A.

Under Alternative C there would be 23.5 miles of open road, 34.2 miles of closed road, and 2.7 miles of decommissioned road. Alternative C would have fewer adverse effects and would improve visual resources the most of all alternatives.

Under Alternative D, there would be 38.1 miles of open road, 20.6 miles of closed road, and 2.7 miles of decommissioned road. Alternative D would improve visual resources compared to Alternative A, but would have more adverse effects than Alternatives B and C.

### Cumulative Effects on Visual Resources

Under all alternatives, most activities on BLM lands would generally not adversely affect visual resources to unacceptable degrees because discretionary activities on BLM lands would be required to meet Visual Resource Management objectives within individual project areas.

As the entire Boulder/Jefferson City TPA is highly mineralized and has seen extensive mining activity in the past, this activity is likely to continue for the foreseeable future. Mining activity often has visually intrusive effects on the landscape. On BLM lands, the Montana Tunnels Mine near Jefferson City has adversely affected visual resources and will continue to do so for the foreseeable future. The permitted area for this mine is ap-

proximately 1,500 acres with 130 of those acres on BLM lands, but intrusive modification of the landscape has only occurred on a subset of these acres.

Activities on non-BLM lands, particularly activities near BLM lands associated with residential development, urbanization, additional mining, or vegetation management, could have adverse cumulative effects on visual resources on BLM lands because BLM VRM objectives would obviously not apply to non-BLM activities.

## LIVESTOCK GRAZING

### Effects Common to All Alternatives

Roads and trails can potentially affect livestock grazing management. Roads and trails often act as avenues of noxious weed spread. Noxious and invasive weeds can reduce the quantity and quality of forage. Users of roads and trails can cause management problems for livestock permittees when they leave gates open at fences, vandalize range improvements, or harass livestock, either purposely or unintentionally.

Closure of roads and trails can improve or maintain the forage base by reducing vectors of noxious weed spread. Additionally, road and trail closures can reduce management conflicts. On the other hand, closures may increase permittees' time requirements if and when work has to be conducted with horses or afoot. Permittees could minimize effects of closed roads on grazing management time by seeking variances from the BLM for temporary use of specific closed roads.

### Effects of the Alternatives

Under Alternative A, 60.5 miles of roads and trails would remain open. The effects would continue as described above.

All action alternatives would close or decommission more roads and trails than Alternative A. As more roads and trails are closed, noxious and invasive weed spread along with multiple user conflicts would be reduced. On the other hand, permittee management time may increase. Consequently, more effects as described under the Effects Common to All Alternatives section would occur under Alternative C (23.5 miles open during grazing season, 36.9 miles closed or decommissioned) than under any other alternative. Alternative B (28.8 miles open during grazing season, 31.7 miles closed or decommissioned) would produce fewer effects than Alternative C, but more than Alternative A or Alternative D (38.1 miles open during grazing season, 23.3 miles closed or decommissioned). Alternative D would have fewer effects than Alternatives B or C, but more than Alternative A.

## Cumulative Effects on Livestock Grazing

Livestock grazing will continue in the area and has the potential to impact forage quality and quantity. On public lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain forage quality and quantity. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, forage conditions would benefit.

The Boulder complex fires of 2000 burned parts of the High Ore, Boomerang, Spring Creek, and Amazon watersheds. The burn encouraged noxious and invasive weed spread in some areas. On the other hand, many grasslands were improved with the reduction of conifers. Forage production (for livestock and wildlife) increased substantially.

Because BLM lands make up only 24 percent of all lands in the Boulder/Jefferson City TPA, all of the BLM travel plan alternatives would have a minor contribution to cumulative effects on livestock grazing at the scale of the entire TPA.

## MINERALS

### Effects Common to All Alternatives

Road closures and decommissioning could affect access to locatable minerals in areas of moderate or high mineral potential. Operators would be required to seek travel variances from the BLM to use motor vehicles to conduct mineral exploration on closed roads, or to conduct exploration on seasonally restricted routes during the season of closure. Decommissioned roads could not be used for motorized exploration. Travel management provisions that require a permit or variance could result in reducing access to mining claims or interfere with the ability to conduct exploration work for some operators. Historic knowledge of mineralized areas associated with “closed” roads may be lost after long periods of time if no exploration occurs there. Additional costs and time could be required for exploration and development of mining projects associated with closed or decommissioned roads. Impacts of road closures or decommissioning in areas with low mineral potential would not be substantial to mineral development.

### Effects of the Alternatives

All of the roads in the Boulder/Jefferson City TPA are located in areas rated as having high mineral potential by the Montana Bureau of Mines and Geology.

Effects of the alternatives for the Boulder/Jefferson City TPA on access to mineralized areas are summarized in

**Table 4-84.** Alternative A for the Boulder/Jefferson City TPA would not impact roads in mineralized areas as all roads would remain open yearlong under this alternative.

<b>Table 4-84 Analysis of Access to Mineral Potential Areas Boulder/Jefferson City TPA</b>				
<b>Mineral Potential</b>	<b>Open Miles (%)</b>	<b>Seasonally Restricted Miles (%)</b>	<b>Closed Miles (%)</b>	<b>Decom Miles (%)</b>
<b>Alternative A</b>				
High	60.5 (100%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Moderate	0.0 (0%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Low	0.0 (0%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Total Miles = 60.5				
<b>Alternative B</b>				
High	3.7 (6%)	25.1 (41%)	29.0 (48%)	2.7 (5%)
Moderate	0.0 (0%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Low to none	0.0 (0%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Total Miles = 60.5				
<b>Alternative C</b>				
High	3.0 (5%)	20.5 (34%)	34.2 (56%)	2.7 (5%)
Moderate	0.0 (0%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Low to none	0.0 (0%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Total Miles = 60.5				
<b>Alternative D</b>				
High	5.3 (9%)	31.8 (53%)	20.6 (34%)	2.7 (4%)
Moderate	0.0 (0%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Low to none	0.0 (0%)	0.0 (0%)	0.0 (0%)	0.0 (0%)
Total Miles = 60.5				
Mineral Potential areas have been delineated by the Montana Bureau of Mines and Geology (MBMG)				

Alternative B would seasonally restrict access to 39 percent of these roads, close 50 percent of them, and decommission an additional 5 percent (**Table 4-84**). Alternative B would have more impacts than Alternative A.

Alternative C would seasonally restrict access to 34 percent of these roads, close 56 percent of them, and decommission an additional 5 percent (**Table 4-84**). Alternative C would have the most potential to affect access to mineralized areas than any of the other alternatives.

Alternative D would seasonally restrict access to 53 percent of these roads, close 34 percent of them, and de-

commission an additional 4 percent (**Table 4-84**). Alternative D would have more impacts than Alternative A, but less than Alternatives B and C.

## Cumulative Effects on Access to Mineralized Areas

No other past, present, or reasonably foreseeable future actions in the Boulder/Jefferson City TPA would adversely affect mineral availability or access.

## RECREATION

Effects of travel plan alternatives on Recreation in the Boulder/Jefferson City TPA are described qualitatively below.

### Effects of Alternative A

Under Alternative A, all BLM managed routes in the Boulder-Jefferson City travel planning area would continue to be managed as open yearlong (60.5 miles). No non-motorized routes or trails would be available under this alternative. Snowmobile use would continue to be managed as open to area-wide cross country travel as well as travel on all existing routes (during the season of use, 12/2-5/15, conditions permitting).

### Effects of Alternative B

Alternative B would provide a more balanced approach towards travel management, and should help reduce user conflicts compared to Alternative A. Under Alternative B, 28.8 miles of routes (3.7 miles open yearlong, 25.1 miles seasonally restricted) would be available for wheeled motorized use.

Area-wide cross-country snowmobile use would be allowed, as well as travel on all existing routes during the season of use, 12/2-5/15, conditions permitting. Conflicts between cross-country skiers, snowshoers, and snowmobilers would be expected to continue or increase as a result.

### Effects of Alternative C

Alternative C would provide the least amount of motorized wheeled access among the action alternatives. Under Alternative C, 23.5 miles of routes would be available for wheeled motorized use (3.0 open yearlong, 20.5 miles seasonally restricted). Closure and decommissioning of routes in the southwest corner of the TPA would help create a non-motorized use area. Snowmobile use would be restricted to designated routes only, during the season of use (12/2-5/15), snow conditions permitting; reducing conflicts between motorized and non-motorized winter users.

### Effects of Alternative D

Alternative D would provide the highest level of motorized wheeled access among the action alternatives. Under Alternative D, 38.1 miles of routes would be availa-

ble for wheeled motorized use (5.3 open yearlong, 20.5 miles seasonally restricted). Area wide cross-country snowmobile use would continue to be allowed, as well as travel on all existing routes during the season of use (12/2-5/15), snow conditions permitting.

## Cumulative Effects on Recreation

This area presents management challenges given the fragmented BLM ownership pattern and the lack legal access roads. Many of the currently open roads result from historic mining activities and are dead-end segments that do not provide loop riding opportunities. Alternative A would provide the greatest opportunities for motorized recreation given the miles of routes available to wheeled vehicles and that the entire area would remain open to snowmobile use during the winter season. Conflicts between motorized and non-motorized users especially during the hunting season would continue.

Alternative B would reduce wheeled motorized riding opportunities on BLM lands by about 55 percent while snowmobile uses would continue unaffected. These additional travel plan restrictions would help reduce recreation use conflicts and should improve non-motorized opportunities for hunting, horseback riding, mountain biking and hiking. Many of the roads proposed for closure under this alternative are primitive, not maintained, have no legal access through private lands, and are duplicative of other roads left open. Increased trends in resource uses such as greater mining activities and vegetative treatments would increase impacts on the natural qualities of the Recreation Opportunity Spectrum settings which are primarily roaded natural and roaded modified.

Alternative C would promote non-motorized opportunities to the greatest extent of all alternatives given the added road closures from travel management, Recreation Opportunity Spectrum settings, and mineral related stipulations. Big-game hunting opportunities for non-motorized users could be enhanced as conditions would be more favorable for elk retention on public lands.

Alternative D would provide the highest level of motorized wheeled access among the action alternatives. Potential for conflicts between motorized and non-motorized users especially during the hunting season would be higher than under Alternatives B and C.

## TRAVEL MANAGEMENT AND ACCESS

### Effects of Alternative A

Under Alternative A all BLM roads in the Boulder-Jefferson City TPA would continue to be managed as open yearlong (60.5 miles) (**Table 4-85**). This is about 90 percent more routes open yearlong than under the action alternatives and 37 percent more routes open to motorized use when considering both open routes and routes with seasonally restricted access. Non-motorized

trails are not available, which would result in fewer recreation opportunities for non-motorized users.

Snowmobile use would continue to be managed as open to area-wide cross country use as well as use on all existing routes (during the season of use, 12/2-5/15, conditions permitting); providing the greatest opportunity for motorized winter use while providing the fewest opportunities for non-motorized winter recreation of all alternatives.

The extent of management activities and costs under Alternative A would be mixed. Less personnel time would be required to monitor travel compliance than under the action alternatives. However, more effort would be required for initial implementation (signing designated routes, installing bulletin boards) than under the action alternatives. Estimated costs for road/trail maintenance would be highest of all alternatives.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be minimal under this alternative, given the availability of motorized access.

### Effects of Alternative B

Less than half the wheeled motorized routes would be open yearlong or seasonally restricted than are currently available in the Boulder-Jefferson City TPA (Table 4-85). With 31.7 miles of non-motorized trails, Alternative B would provide more opportunities for non-motorized users than Alternative A. The majority of open routes under Alternative B would be seasonally restricted with a 12/2-5/15 closure.

Table 4-85 Boulder-Jefferson City TPA Route Management Summary				
Proposed Management	Total Miles			
	Alt A	Alt B	Alt C	Alt D
<b>Wheeled motorized routes</b>				
Open Yearlong	60.5	3.7	3.0	5.3
Seasonally Restricted	0	25.1	20.5	32.8
Closed	0	29.0	34.2	20.6
Decommissioned	0	2.7	2.7	2.7
Non-motorized trails <sup>1</sup>	0	31.7	36.9	2.4

<sup>1</sup> Non-motorized trails include all existing trails, closed roads, and decommissioned roads.

Area-wide cross-country snowmobile use, as well as travel on all existing routes during the season of use (12/2-5/15), conditions permitting would continue to be allowed in all the action alternatives. Conflicts between non-motorized users (cross-country skiers, snowshoers) and snowmobilers would be expected to continue or increase as a result.

The extent of management activities and costs under Alternative B would be mixed. Less personnel time would be required for initial implementation (signing designated routes, installing bulletin boards) than under Alternative A. However, more effort would be required for public education and compliance than under Alternative A. Estimated costs for road/trail maintenance would be less than under Alternative A.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would increase under Alternative B compared to Alternative A.

### Effects of Alternative C

Alternative C would have the least number of wheeled motorized routes open yearlong or seasonally restricted of all alternatives in the Boulder-Jefferson City TPA (Table 4-85) which would result in fewer opportunities for motorized users. Alternative C would have 61 percent fewer motorized miles than Alternative A, and 18 percent fewer miles than Alternative B.

Snowmobile use would be restricted to designated routes only, during the season of use (12/2-5/15), snow conditions permitting. This would likely reduce conflicts with non-motorized winter users (cross-country skiing, snowshoeing).

Closure and decommissioning of routes in the southwest corner of the Boulder-Jefferson City TPA would result in an increase in non-motorized opportunities under Alternative C. Alternative C would have 12 percent more miles of non-motorized trails than Alternative B. No non-motorized trails would exist under Alternative A.

The extent of management activities and costs under Alternative C would be mixed. Less personnel time would be required for initial implementation (signing designated routes, installing bulletin boards) than under any other alternative. However, more effort would be required for public education and compliance than under the other alternatives. Estimated costs for road/trail maintenance would be the lowest of the alternatives.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be the greatest under Alternative C of all the alternatives.

### Effects of Alternative D

Alternative D would provide the highest level of motorized access of the action alternatives with 38.1 miles of open and seasonally restricted routes (Table 4-85). This would be 61 percent less than under Alternative A, but 24 and 38 percent more than under Alternatives B and C, respectively. Opportunities for motorized users in the Boulder-Jefferson City TPA would be greater under Alternative D than under Alternatives B and C, but less than under Alternative A.

Area-wide cross-country snowmobile use would continue to be allowed, as well as travel on all existing routes during the season of use (12/2-5/15) conditions permitting.

The extent of management activities and costs under Alternative D would be mixed. Less personnel time would be required to monitor travel compliance than under Alternatives B and D, but more would be needed than under Alternative A. However, more effort would be required for initial implementation (signing designated routes, installing bulletin boards) than under Alternatives B and D, but less effort would be needed than under Alternative A. Estimated costs for road/trail maintenance would be higher than under the other action alternatives, but less than under Alternative A.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be greater under Alternative D than under Alternative A, but less than under Alternatives B and C.

## Cumulative Effects on Travel Management and Access

Under all alternatives, there are a number of past, present, and reasonably foreseeable future BLM and non-BLM actions that could affect travel management and access in the Boulder/Jefferson City TPA.

The Boulder-Jefferson City TPA is located adjacent to the upper Boulder Valley. Human population growth for the upper Boulder Valley (Boulder town statistics) is approximately 2 percent per year. This rate of growth is expected to continue, along with increased recreational use from local residents as well as area users (residents of Helena, Townsend, Butte, etc.).

The small towns of Boulder (population 1,436) and Jefferson City (population 295) are located adjacent to the TPA. Although the rate of growth is low, increased urbanization and recreational use could lead to increased social conflict; between area residents and recreation users, and among recreational users themselves (motorized/non-motorized). These factors could lead to increased public demands to alter travel management to accommodate more, or less motorized use.

Recreational activities for this TPA include big game hunting, motorized OHV travel (motorcycles, ATVs, snowmobiles), and to a lesser extent, non-motorized uses (hiking, horseback riding, and mountain biking). Conflicts between non-motorized and motorized users could lead to increased public demands for either more, or less motorized use.

The TPA mainly provides habitat for big game. The entire area is considered winter range for elk while the lower elevations along the eastern half of the travel plan are winter range for mule deer. Concerns could lead to the need to restrict motorized use.

In some site specific cases, visual resource management may affect or restrict new road/trail construction.

Applications for right-of-way permits to access private property or for commercial development are likely to increase in the future. As a result, public access to BLM lands, via the rights-of-way, could increase as well.

Limits or reductions in the BLM's funding and ability to maintain designated routes could lead to an overall reduction in maintained open road miles.

A variety of resource management projects, such as BLM initiated vegetation treatments, or wildland fire fuels reduction projects, could affect travel management. BLM forest management activities from 1984 to present include 690 acres of fire replanting, 559 acres of timber salvage, and 266 acres of timber harvest. Future activities may include approximately 650 acres of forest and woodland treatment (thinning, selective harvest). There are no wildland fire fuels reduction activities planned for this area at this time. Depending on the type and scope of project, effects could vary from temporary, short-term area/route closures, to new opportunities (new routes) for motorized or non-motorized access.

The TPA has a rich history of mining for lead, zinc, gold, copper, and silver. With the exception of the Montana Tunnels Mine, the remaining mines are no longer active. The Montana Tunnels Mine (located near Jefferson City) continues to produce lead and zinc with associated gold and silver from an open pit. Increases in mineral prices could lead to additional increased or renewed mining activity. Depending on the type and scope of mining activity, effects could vary from temporary, short-term area/route closures, to increased opportunities (new routes) for motorized or non-motorized access.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the TPA. Motorized activities play a large role in the distribution of noxious weeds. Concerns over the spread of noxious weeds may lead to public demands to impose motorized travel restrictions.

Motorized use on dirt roads and trails is a major contributor to soil erosion and stream sedimentation. These concerns may influence travel management, and result in fewer motorized opportunities.

Most illegal activities (trash dumping, drug use, underage alcohol use, unattended camp fires, vandalism, etc.) are directly associated with motorized use. Increases in illegal activity may lead to public demands to alter travel management and impose motorized travel or other restrictions (site specific management).

For perspective, BLM managed lands represent approximately 24 percent of the total travel planning area (60,418 total acres, 14,487 BLM acres); while BLM managed routes represent approximately 15.4 percent of the total routes available (392 total miles, 60.5 miles BLM roads/trails under Alternative A). Future travel

management (for all agencies, nationwide) is likely to lead to fewer opportunities for motorized recreational use than under current management (particularly for OHV use). As a result, BLM routes available to motorized use in this TPA could experience increased use from displaced users, eventually leading to more concentrated use, increased resource impacts, and user conflicts. These impacts could lead to demands from motorized users for additional routes, and conversely, demands from non-motorized users for fewer routes.

Under all alternatives, increases in human population, urbanization, recreation use, user conflicts; and concerns for wildlife, noxious weed spread, soil erosion/water quality, and illegal activities may lead to increased demands to restrict motorized travel, particularly in the areas adjacent to Boulder and Jefferson City. Under Alternative A, these conflicts would likely increase. Under Alternative B these pressures would have less impact on travel management than under Alternatives A and D, due to the overall reduction in motorized opportunities and separation of motorized and non-motorized uses. Under Alternative C these pressures would have the least impact on travel management than under the other alternatives, due to the reduction in motorized opportunities. Alternative D would lessen conflicts associated with these pressures compared to Alternative A, but not as much as Alternatives B and C.

**TRANSPORTATION FACILITIES**

For the sake of this discussion, “open” roads include roads that are open yearlong as well as those that are open with seasonal restrictions.

**Effects of Alternative A**

Under Alternative A, the Boulder/Jefferson City TPA would have 60.5 miles of open roads and no motorized trails (see **Table 4-86** on page 624).

Estimated costs for annual maintenance and stabilization of roads under Alternative A would be higher than under the action alternatives because of the increased number of roads. Estimated annual costs for monitoring and compliance, and weed control would also be higher under Alternative A than under the action alternatives.

**Effects of Alternative B**

Under Alternative B, the Boulder/Jefferson City TPA would have 28.5 miles of open roads and no motorized trails (**Table 4-86**). Estimated costs for annual maintenance and stabilization of roads under Alternative B would be less than under Alternatives A and D and more than under Alternative C due to the reduction in motorized access. Estimated annual costs for monitoring, compliance, and weed control would also be less than under Alternative A, and similar to Alternatives C and D.

<b>Table 4-86 Boulder-Jefferson City TPA Route/Trail/Maintenance Costs</b>				
<b>Classification/ Cost</b>	<b>Alt A</b>	<b>Alt B</b>	<b>Alt C</b>	<b>Alt D</b>
Miles of Open/ Restricted Roads	60.5	28.5	23.5	38.1
Motorized Trails	0	0	0	0
Annual Roads Maintenance	\$4,840	\$2,184	\$1,880	\$3,048
Annual Trails Maintenance	\$0	\$0	\$0	\$0
Periodic Road Stabilization	\$1,936	\$874	\$752	\$1,219
Periodic Trails Stabilization	\$0	\$0	\$0	\$0
Monitoring/ Compliance	\$3,025	\$1,365	\$1,175	\$1,905
Weed Control	\$908	\$410	\$353	\$572

**Effects of Alternative C**

Under Alternative C, the Boulder/Jefferson City TPA would have 23.5 miles of open roads and no motorized trails (**Table 4-86**). Estimated costs for annual maintenance and stabilization of roads under Alternative C would be the least of all the alternatives due to the least number of motorized routes. Estimated annual costs for monitoring, compliance, and weed control would also be less than under the other alternatives.

Closing the southwest corner of the Boulder/Jefferson City TPA to motorized use and the entire TPA to cross-country snowmobile travel would result in an increase in transportation facility costs for additional signage and sign maintenance.

**Effects of Alternative D**

Under Alternative D, the Boulder/Jefferson City TPA would have 38.1 miles of open roads and no motorized trails (**Table 4-86**). Estimated costs for annual maintenance and periodic stabilization of roads under Alternative D would be greater than under Alternatives B and C, but less than under Alternative A. Estimated annual costs for monitoring, compliance and weed control would also be less under Alternative D than under Alternative A and more than under Alternatives B and C.

**LANDS AND REALTY**

**Effects Common to All Alternatives**

The Butte Field Office administers approximately 62 rights-of-way (ROW), and one Recreation and Public Purpose (R&PP) Lease within the boundaries of the Boulder/Jefferson City TPA, which encumber approximately 2,036 acres of BLM land (**Table 4-87**). Various types of road rights-of-way are the most common type of grant, accounting for 42 percent, or just under half of the

total. Other types of authorized uses include: oil and gas pipelines, lines for electrical distribution and telephone facilities, communication sites, ditches, railroads, and mineral material sites.

Type	Approximate Number	Approximate Acres
Roads	26	1,256
Power	11	682
Telephone	9	40
O&G Pipelines	2	7
Comm. Sites	7	5
R&PP Lease	1	39
Other	7	7
<b>Totals</b>	<b>63</b>	<b>2,036</b>

Approximately three right-of-way applications for new facilities as well as amendments, assignments, renewals, or relinquishments of existing right-of-way grants are processed annually in the TPA. This would not vary by alternative.

The general trend of granting rights-of-way is expected to increase through the planning period as a result of increasing public demands. From a cumulative effects standpoint, development of adjacent federal, state and private land, increased recreational use and the trend of homeownership away from urban areas, coupled with traditional on-going uses, are all expected to require more guaranteed access involving public land, including BLM lands.

## SPECIAL DESIGNATIONS

There would be no effects to any special designation areas such as Wild and Scenic Rivers, Wilderness Study Areas, or Areas of Critical Environmental Concern under any of the travel plan alternatives for the Boulder/Jefferson TPA.

## UPPER BIG HOLE RIVER TPA

The Upper Big Hole River TPA is a relatively long, narrow shaped area (approximately 60 by 18 miles) located in the southwest portion of the Butte Field Office. This 357,275-acre TPA contains approximately 63,108 acres of BLM land. It includes BLM lands located along the north and south banks of the Upper Big Hole River as well as a large contiguous section located east of Interstate-15, near the town of Divide. A large contiguous section extends south from Divide to the town of Melrose and includes the Humbug Spires Primitive Area. There are approximately 165 miles of BLM roads, making up about 12.6 percent of the approximate total of 1,309 road miles in the TPA. The majority of roads lie on private (540 miles) and Forest Service (459 miles) lands.

## AIR QUALITY

### Effects Common to All Alternatives

Motorized recreation use is expected to continue to increase, resulting in higher levels of vehicle emissions.

Motorized travel across dry unpaved routes or trails would continue to produce airborne dust.

There could be areas with localized air pollution as a result of higher use numbers, and more concentrated use on fewer miles of available routes.

Drier climate conditions could make soils more susceptible to the effects of motorized travel, resulting in higher levels of airborne dust.

Impacts to air quality vary by alternative and travel plan area. In general, alternatives that reduce the level of motorized use (have fewer available miles) could have a positive impact on air quality; while alternatives that maintain or increase the level of motorized use, could lead to increased air quality impacts. This would not necessarily be a direct relationship, however, because reduction in available road miles for motorized use could redistribute use or focus more use on remaining open routes.

Under all alternatives, impacts from airborne dust could be reduced through mitigation such as hardening native surface roads with gravel or periodically spraying them with water trucks during the dry season. During BLM project work, in addition to watering native surface roadbeds, speed limits could be reduced to further minimize dust emissions.

### Effects of the Alternatives

Under Alternative A (present management), adverse impacts to air quality would be expected to continue, and likely increase, concurrent with higher levels of motorized recreational use. Each of the action alternatives, however, would provide fewer available motorized routes. Alternatives B and C would provide 47 percent and 62 percent fewer motorized routes, respectively, than Alternative A, while Alternative D would provide 39 percent fewer routes than Alternative A. As a result, airborne dust and vehicle emissions would be taking place on fewer BLM routes and could be reduced.

It should be noted that even without motorized use, airborne dust, resulting from wind erosion of exposed dirt surface roads will continue. Therefore, travel plans with more miles of native surface roads will result in more airborne dust.

Under all alternatives, mitigation measures, such as graveling and/or watering native surface roads, could reduce dust emissions even further, and/or help offset the effects of increased or concentrated use on the remaining open routes.

## Cumulative Effects on Air Quality

Under all alternatives, the cumulative effects to air quality from travel management in the Upper Big Hole TPA would arise from a number of past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands.

For perspective, BLM managed lands in the Upper Big Hole TPA area represent approximately 17.7 percent of the total travel planning area (357,275 total acres; 63,108 BLM acres). Under present management (Alternative A) BLM managed routes represent approximately 17.7 percent, of the total routes available (1,309 total miles; 165 miles of BLM roads/trails). Potential air quality impacts associated with activities on non-BLM lands and roads would be a greater contributor to cumulative effects to air quality than activities on BLM lands and roads.

In the past, prior to the 2003 Statewide OHV ROD, BLM management allowed unrestricted cross country travel by all forms of wheeled motorized use. Under present management, in the absence of other existing travel plan direction, all motorized wheeled travel is restricted to existing roads and trails. Under current management, approximately 158 miles of the existing BLM routes are available for motorized use. This mileage available for use would be reduced under the action alternatives as described above with associated potential differences in effects to air quality.

Under all alternatives, cumulative increases in human population, urbanization, recreation use, user conflicts; and concerns for wildlife, noxious weed spread, soil erosion, air/water quality, and illegal activities may lead to increased demands to restrict motorized travel.

## SOILS

### Effects Common to All Alternatives

Road construction, use, and maintenance affect soils in a number of ways. Soils are often compacted by these activities. Soil compaction can lessen the amount of precipitation that can infiltrate into soil and increase runoff, erosion, and sedimentation – in turn decreasing soil/site stability and hydrologic function, as well as soil productivity and plant vigor and diversity.

Ground disturbance associated with road construction, use, and maintenance can result in erosion. Erosion affects soil/site stability and hydrologic function. Erosion and sedimentation can destabilize the surface and sub-surface cohesion of the soil, resulting in soil loss from erosion sites. Loss of soil can impede or prevent establishment and development of vegetation communities.

Closing or decommissioning roads often leads to beneficial effects to soils through decreased site disturbance and re-establishment of vegetative cover on road surfaces. This tends to reduce soil erosion and stabilize soils.

Decommissioning roads may in some cases entail ripping road surfaces to de-compact them, thus improving water infiltration, hydrologic function, and the ability of the treated area to revegetate more successfully.

Impacts to soils associated with site-specific travel plan alternatives were assessed based on the potential for soil erosion using the following erosion risk criteria:

- High – the area a route travels through has slopes greater than 30 percent gradient.
- Moderate – the area a route travels through has slopes ranging from 15 to 30 percent gradient; or, for granitic soils, slopes ranging from 0 to 30 percent gradient.
- Low – the area a route travels through has slopes ranging from zero to 15 percent gradient and soils are not granitic in origin.
- Unrated – road mapping not available at time of erosion impact rating.

### Effects of the Alternatives

The distribution of road miles by erosion risk category and by proposed road management category for all the alternatives is shown for the Upper Big Hole River TPA in **Table 4-88**. Roads in the “unrated” category were excluded from detailed consideration and are shown for the purpose of displaying the extent of lacking information.

Because much of the terrain in this TPA is gentle to moderate in slope, most of the BLM roads are in either the low or moderate erosion categories. Under current conditions (Alternative A) approximately 5.6 miles of open BLM roads are located in areas with high erosion risk, and 60.7 miles are in moderate erosion areas. Soil erosion would be reduced under Alternative B because this alternative would reduce those mileages in the high and moderate erosion categories to 2.4 miles and 25.2 miles, respectively. Approximately 26.7 miles of road in the high and moderate classes combined would be closed under Alternative B with an additional 14.4 miles in these categories being decommissioned. Vegetative recovery should occur to varying degrees on closed and decommissioned roads, with a beneficial effect on soils of reducing erosion from these areas.

Soil erosion would be reduced under Alternative C more than under any other alternative because the lowest mileage of roads in the high and moderate erosion categories would be left open (17.0 miles combined), while the greatest mileage in these categories would be closed (32.9 miles combined) of all alternatives. An additional 16.9 miles in these categories would be decommissioned under Alternative C, more than under any other alternative.

Soil erosion associated with roads would be reduced under Alternative D compared to Alternative A, but

**Table 4-88**  
**BLM Road Miles in Soil Erosion Impact Categories by Alternative for the Upper Big Hole River TPA**  
(mileages are GIS-generated estimates)

Proposed Road Management	Erosion Risk Category	Alternative A	Alternative B	Alternative C	Alternative D
Open Road Miles (incl. Open w/restrictions)	High	5.6	2.4	2.4	2.4
	Moderate	60.7	25.2	14.6	38.1
	Low	81.4	50.2	40.8	60.3
	Other	10.2	3.1	3.2	3.0
Closed Road Miles	High	0	2.9	2.9	2.9
	Moderate	3.3	23.8	30.0	13.0
	Low	1.2	14.9	25.7	7.5
	Other	2.9	9.9	10.6	9.8
Decommissioned Road Miles	High	0	0.2	0.2	0.2
	Moderate	0	14.2	16.7	12.9
	Low	0	14.0	16.5	12.4
	Other	0	0.1	0.1	0.1

Note: Open roads include seasonally open roads as well as roads open yearlong.

would still be higher than under either Alternative B or C. Approximately 40.5 miles of BLM road in the moderate and high erosion categories combined would remain open under Alternative D, while about 15.9 miles in these categories would be closed and 13.1 miles would be decommissioned under this alternative.

### Cumulative Effects on Soils

Cumulative effects to soils in the Upper Big Hole River TPA would arise from a number of past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands. Within this 357,275-acre TPA, BLM lands comprise about 63,108 acres or 18 percent of total lands. The approximately 165 miles of BLM roads make up about 13 percent of the approximately 1,309 road miles in the TPA. Therefore road-related effects to soils described by alternative for BLM roads would affect about 13 percent of all roads in the TPA. The majority of lands (and roads) within the TPA boundary are either private property or public lands administered by the Forest Service. Non-BLM roads are managed by the county, Forest Service, state, and private landowners.

Approximately 6,805 BLM acres are permitted for various rights-of-way and leases. About 2,907 of these acres are for specific road rights-of-way primarily to private landowners. An additional 2,986 acres are associated with railroads and road rights-of-way to the Forest Service. The remainders are associated with powerlines, waterlines, communication sites, oil and gas pipelines, and other utility facilities. Impacts to soils range from compaction and occupation of ground with buildings, roadbeds, and other facilities, to revegetation and ground cover being re-established to stabilize soils.

From 1984 to 1995, timber harvest occurred on approximately 57 acres of BLM lands in this TPA. An addition

189 BLM acres have undergone timber harvest from 1995 to the present. Most of this activity has been selective harvest. Adverse effects on soils from these treatments were generally minor with treated areas having undergone revegetation and soil stabilization since treatment.

Approximately 430 acres of selective timber harvest is foreseeable on BLM lands over the next several years. This harvest would be located in Wildland Urban Interface areas where a mountain pine beetle epidemic is killing many lodgepole pine trees. Effects to soils from this project would likely be minor, possibly with localized areas of erosion or compaction. Timber harvest has also occurred on private and Forest Service lands and will likely continue for the foreseeable future, having localized compaction and erosion effects on soils.

From 1981 to 2004, wildland fire has burned across approximately 230 acres in the Upper Big Hole River TPA, having a range of soil effects with more severely burned areas experiencing localized erosion while less severely burned areas underwent relatively little effect to soils.

Over the past 10 years, approximately 474 acres of BLM land have undergone prescribed fire treatments while an additional 141 acres have undergone mechanical treatments. These treatments occurred in the Jerry Creek and Dickie Hills areas. Overall these projects generally had minor adverse effects on soils as treatment areas have revegetated and soils have stabilized. Within the next several years, BLM plans to implement 2,087 acres of mechanical treatment and 2,659 acres of prescribed fire with the Highland Mountain project in this TPA. BLM is currently planning an additional project to reduce fuels and restore vegetation communities on 500 to 2,000 acres with a combination of mechanical treatments and

prescribed fire. These treatments would generally have minor adverse effects on soils. Prescribed burning would occur under conditions where fire severity and intensity would be low, thereby minimizing adverse effects to soils. All treatments would minimize compaction so as to promote vegetative recovery. Fuels treatments conducted on private and Forest Service lands will likely occur for the foreseeable future with variable effects to soils. Reducing fuels under the controlled conditions of deliberate treatments may benefit soils in the long-term by reducing the risk of high severity fires in treated areas.

Livestock grazing on public and private lands throughout much of the TPA has created areas of localized soil erosion and compaction, particularly in grassland and shrubland areas. This will continue to occur for the foreseeable future.

Increasing residential development will likely continue for the foreseeable future to variable degrees within the TPA. Erosion, compaction, and covering of soils would occur due to additional road construction, clearing/leveling for home sites, and establishment of utility infrastructure for residential developments.

Under Alternative A, the contribution to cumulative effects on soils from BLM road management would continue as it occurs today. Retaining approximately 70 miles of road open yearlong and an additional 88 miles open with various seasonal restrictions would allow for the same level of compaction and erosion impacts that currently exist.

From a BLM road management perspective, all action alternatives would benefit soil resources compared to Alternative A. Alternative B would benefit soils by providing for a reduced contribution to adverse cumulative effects than would Alternative A because about 48 percent of BLM roads would be closed or decommissioned under Alternative B (compared to about 4 percent under Alternative A). Erosion should be reduced on these closed/decommissioned roads as disturbance is eliminated and soils stabilize.

Alternative C would benefit soils the most and provide for the least contribution to adverse cumulative effects on soils of all alternatives. This alternative would provide for closure or decommissioning of about 62 percent of BLM roads in the TPA, thus allowing these areas to vegetatively recover and stabilize soils.

Alternative D would provide for the greatest contribution to adverse cumulative effects on soils of the action alternatives, but would still provide for greater long-term benefits to soils than Alternative A. Alternative D would provide for closure or decommissioning (and therefore vegetative recovery and soil stabilization) of about 36 percent of BLM roads in the TPA, compared to 4 percent for Alternative A, 48 percent for Alternative B, and 62 percent for Alternative C.

Overall, due to the scattered distribution and relatively small proportion of BLM lands (18 percent) and roads (13 percent) relative to the total quantities of lands and roads in the TPA, none of the BLM alternatives would substantially contribute to cumulative effects on soils at the scale of the Upper Big Hole River TPA.

## WATER RESOURCES

### Effects Common to All Alternatives

There are a number of key concepts that are critical to understanding road effects to water resources.

Hydrologic function is an interaction between soil, water, and vegetation, and reflects the capacity of a site to:

- Capture, store, and safely release water from rainfall, runoff, and snowmelt;
- Resist a reduction in this capacity; and
- Recover this capacity following degradation.

Interception of precipitation results when precipitation falls on vegetation. When vegetation is removed, precipitation falls directly on the soil. This can increase surface erosion and sedimentation, and decrease the amount of time between initial precipitation arrival and peak surface runoff – in turn decreasing soil/site stability and hydrologic function. Roads remove vegetation and therefore decrease interception of precipitation.

Infiltration is the process of precipitation entering and traveling through soil. Infiltration reduces the peak runoff during precipitation events by extending the period of runoff after a precipitation event. Infiltration also filters precipitation and reduces erosion and sedimentation. If infiltration is reduced, runoff and erosion will increase and hydrologic function will decrease. Generally, roads are compacted surfaces that have decreased infiltration, thus increasing runoff and potentially increasing erosion.

Runoff can affect the amount of erosion and sedimentation, as well as flooding – both onsite and offsite. If runoff is increased, all of these effects can increase with a result that water quality and hydrologic function will decrease.

Increased sediment entering waterbodies increases turbidity, increases width-to-depth ratios, and consequently increases temperature and dissolved oxygen saturation levels, and creates adverse habitat for aquatic animals and plants.

Alteration of flow routing can also affect water resources. For example, roadcuts into areas with relatively shallow groundwater can intercept groundwater, bring it to the surface, and transport it some distance (i.e. in a roadside ditch) before delivering it to a stream. This can lead to erosion of road ditchlines and subsequent sedimentation of streams during runoff periods, or increased thermal loading of water before delivery to streams during summer periods.

Closure and decommissioning of roads tend to reduce erosion and sedimentation effects stemming from roads on water quality. During road decommissioning, items such as compaction, drainage, stream crossing culverts, and ground cover are often addressed in a manner that markedly improves hydrologic function. These features are not fully addressed on roads that are merely “closed”, but closed roads often gradually revegetate so as to reduce erosion and sedimentation effects to water quality.

### Effects of the Alternatives

Generally, road density is an indicator of overall watershed health and function. Watersheds with higher road densities tend to have lower water quality due to greater disruption of hydrologic function (described above), and potential for erosion and subsequent sedimentation. Road density also is related to the distribution and spread of noxious weeds. **Table 4-89** shows acres of BLM land in three road density categories by alternative for the Upper Big Hole River TPA.

TPA Alternative	Road Density Category		
	Low (<1 mi/mi <sup>2</sup> )	Moderate (1 - 2 mi/mi <sup>2</sup> )	High (> 2 mi/mi <sup>2</sup> )
Alternative A	19,646	18,204	25,357
Alternative B	20,592	19,534	23,080
Alternative C	21,461	19,506	22,245
Alternative D	20,579	19,353	23,276

These data reflect any differences between alternatives based on roads proposed for “decommissioning” by alternative. While many “closed” roads would gradually contribute to increased hydrologic function over time, decommissioned roads would more directly contribute to hydrologic function because measures aimed at restoring hydrologic function would likely be part of the treatment during decommissioning. Alternative A would have the greatest amount of BLM land (25,357 acres) with “high” road densities of greater than 2 mi/mi<sup>2</sup>. Alternative C

would provide for the lowest acreage in the “high” category and the highest acreage in the “low” category of all alternatives. By this measure, Alternative C would benefit hydrologic function more than any other alternative, followed in sequence by Alternative B, then Alternative D. All action alternatives would improve hydrologic function compared to Alternative A.

Motorized routes within 300 feet of streams generally have greater potential to directly impact water quality through erosion and sedimentation, increased water temperatures (due to loss of shading vegetation), and direct alteration of stream channel morphology than those farther away. **Table 4-90** shows the miles of open and closed roads on BLM lands within 300 feet of streams by alternative. Under Alternative A there are about 7.9 miles of open road within 300 feet of fish bearing streams and 29.6 road miles within 300 feet of perennial non-fish bearing streams. Alternative C would provide for the greatest number of closed or decommissioned roads within 300 feet of streams of all the alternatives (total of 10.7 miles). Alternative B would provide for the next greatest mileage (8.5 miles), followed by Alternative D (6.7 miles). By this measure, Alternative C would provide the greatest benefit to water resources of all the alternatives followed by Alternative B, then Alternative D. Each action alternative would reduce effects from roads in close proximity to streams and improve water resources compared to Alternative A.

There is a specific route that fords the Big Hole River to access the Sawlog Gulch area. Under Alternative A, continual unrestricted year-long motorized use of this route would cause the most water quality impacts of erosion and disturbance to the river bed at this site relative to any other alternative. These effects would be localized to tens to feet of river length. Under Alternative B this route would only be open for game retrieval during hunting season. This would reduce its usage and would reduce water quality and river bed disturbance effects at that site. Under Alternative C, this route would be closed yearlong thus eliminating water resource effects altogether. Under Alternative D the route would be closed from 12/2 to 7/15 to avoid use during winter and subsequent spring runoff periods. Alternative D would pose the greatest effects to water resources at this site of any of the action alternatives.

	Perennial Fish-Bearing Streams		Perennial Non-Fish-Bearing Streams	
	Number of Open Road Miles	Number of Closed Road Miles	Number of Open Road Miles	Number of Closed Road Miles
Alternative A	7.9	0.1	29.6	0.8
Alternative B	7.6	0.4	21.6	8.1
Alternative C	6.7	1.3	21.0	9.4
Alternative D	7.6	0.4	24.1	6.3

Note: Open roads include seasonally open roads as well as roads open yearlong. Closed roads include decommissioned roads.

## Cumulative Effects on Water Resources

Cumulative effects to soils in the Upper Big Hole River TPA would arise from a number of past, present, and reasonably foreseeable future actions on BLM lands as well as non-BLM lands. Within this 357,275-acre TPA, BLM lands comprise about 63,108 acres or 18 percent of total lands. The approximately 165 miles of BLM roads make up about 13 percent of the approximately 1,309 road miles in the TPA. Therefore road-related effects to water resources described by alternative for BLM roads would relate to effects associated with about 13 percent of all roads in the TPA. There are approximately 276 miles of fish bearing stream and an additional 223 miles of perennial non-fish bearing stream in the TPA. On BLM lands there are about 19 miles of fish bearing stream and 41 miles of perennial non-fish bearing stream. The majority of lands (and roads) within the TPA boundary are either private property or public lands administered by the Forest Service. Non-BLM roads are managed by the county, Forest Service, state, and private landowners.

A number of the main access roads (non-BLM) in the TPA follow valley bottoms and parallel streams. State Highway 43 along the Big Hole River proper is among these valley bottom roads. Many of these roads are directly affecting stream channel or floodplain function by filling or impinging on stream channels or floodplains, precluding the presence of riparian vegetation (including large woody material in forested locations), producing sedimentation in streams (from road surfaces, ditchlines, winter "road sanding" operations) and potentially increasing thermal loading by lessening streamside shade. In smaller streams these effects are dominant in shaping stream channel and water quality conditions in many areas and will continue into the foreseeable future. Effects of Highway 43 on the Big Hole River are more localized and generally less severe than effects of valley bottom roads on smaller streams.

Approximately 6,805 BLM acres are permitted for various rights-of-way and leases. About 2,907 of these acres are for specific road rights-of-way primarily to private landowners. An additional 2,986 acres are associated with railroads and road rights-of-way to the Forest Service. The remainders are associated with powerlines, waterlines, communication sites, oil and gas pipelines, and other utility facilities. Impacts to water resources are generally minor with some localized erosion and sedimentation and some contribution to decreased hydrologic function (decreased infiltration, increased runoff) due to compaction.

From 1984 to 1995, timber harvest occurred on approximately 57 acres of BLM lands in this TPA. An additional 189 BLM acres have undergone timber harvest from 1995 to the present. Most of this activity has been selective harvest. Adverse effects on water resources were minor from this activity. Approximately 430 acres of selective timber harvest is foreseeable on BLM lands

over the next several years. This harvest would be located in Wildland Urban Interface areas where a mountain pine beetle epidemic is killing many lodgepole pine trees. Effects to water resources from this project would likely be minor, possibly with localized areas of erosion and sedimentation.

Timber harvest has also occurred on private and Forest Service lands and will likely continue to have variable effects on water resources for the foreseeable future. Ground disturbance from these activities will have localized impacts to water resources including some sedimentation, loss of woody material recruitment for streams, and potential water temperature increases due to riparian shade loss.

From 1981 to 2004, wildland fire has burned across approximately 230 acres in the Upper Big Hole River TPA, having minor sedimentation effects on water resources.

Over the past 10 years, approximately 474 acres of BLM land have undergone prescribed fire treatments while an additional 141 acres have undergone mechanical treatments. These treatments occurred in the Jerry Creek and Dickie Hills areas. Overall these projects generally had minor adverse effects (erosion/sedimentation) on water resources. Within the next several years, BLM plans to implement 2,087 acres of mechanical treatment and 2,659 acres of prescribed fire with the Highland Mountain project in this TPA. BLM is currently planning an additional project to reduce fuels and restore vegetation communities on 500 to 2,000 acres with a combination of mechanical treatments and prescribed fire. These treatments would likely have minor adverse effects on water resources. Prescribed burning would occur under conditions where fire severity and intensity would be low so as to prevent scorching of soils and mortality of desirable vegetation. This should minimize erosion and sedimentation of water resources. All treatments would minimize compaction so as to retain hydrologic function. Fuels treatments conducted on private and Forest Service lands will also likely occur for the foreseeable future with variable effects to water resources. Effects of these treatments could be similar to timber harvest effects on these lands. Reducing fuels under the controlled conditions of deliberate treatments may benefit water resources in the long-term by reducing the risk of high severity fires that could have severe adverse water quality effects.

Increasing residential development will likely continue for the foreseeable future to some degree within the TPA, most notably in the Big Hole River valley bottom. Erosion, soil compaction, and runoff would likely increase due to additional road construction, clearing/leveling for home sites, and establishment of utility infrastructure for residential developments. Nutrient, chemical pollutant, and pathogen inputs to streams would also likely increase due to leaching from septic

systems, urban runoff (fertilizer, chemicals, and petroleum pollutants), and waste from livestock.

Livestock grazing on public and private lands throughout much of the Upper Big Hole River TPA has created areas of localized streambank trampling, soil erosion and compaction, and nutrient inputs to streams. In severe cases stream channel morphology may be altered due to severe loss of riparian vegetation, loss of streambank integrity, channel widening and shallowing, and substantial sediment inputs. These effects to water quality will continue to occur for the foreseeable future. Agricultural water withdrawals are a substantial impact to water resources in the Big Hole River itself. Government agencies and local entities regularly work with ranchers to minimize their agricultural withdrawals during summer low flow periods so as to minimize low flow effects on fish populations in the Big Hole River.

There are a number of streams identified as impaired on the MDEQ 303(d) list in the Upper Big Hole TPA. The Big Hole River itself (6.5 miles on BLM) is listed as impaired for heavy metal contamination, low flow alterations, physical habitat alterations, water temperature, and riparian vegetation alteration. Probable sources of impairment include irrigated crop production, mine tailings, abandoned mine lands, acid mine drainage, highways, channelization, riparian grazing, and streambank modification. These impacts will continue for the foreseeable future regardless of BLM road management in this TPA.

Camp Creek (1.8 miles on BLM) is listed as impaired for heavy metal contamination, sedimentation, low flow alterations and nutrient inputs with probable sources being riparian grazing, irrigated crop production, roads (valley bottom non-BLM road), and abandoned mine lands. Soap Gulch (5 miles on BLM) is impaired due to nutrient inputs, sedimentation, alteration of riparian vegetation with probable causes listed as riparian grazing, roads (valley bottom non-BLM road), and irrigated crop production. Though BLM does not manage the most impactive (valley bottom) road along Camp Creek, BLM does manage a considerable portion of the watersheds of both Soap Gulch and Camp Creek. BLM road management could make a considerable contribution to water resource conditions in these two streams. All three action alternatives (B, C, and D) would provide for the closure or decommissioning of some roads in each of these two drainages that would benefit water resources primarily by reducing sediment inputs. Alternative C would provide the most benefit, followed in sequence by Alternative B, then Alternative D.

Charcoal Gulch (1.3 miles on BLM) is impaired for nutrients and sedimentation with probable causes listed as riparian grazing and roads. Moose Creek (6 miles on BLM) is listed as impaired for low flow alterations due to irrigated crop production. Jerry Creek (0.4 mile on BLM) is impaired for alteration of riparian vegetation, excess algal growth, heavy metals, low flow alterations,

and physical habitat alterations. Probable causes of impairment are listed as riparian grazing, abandoned mine lands, timber harvest, agriculture, irrigated crop production, septic systems, and site clearance for land development. Deep Creek (0.9 mile on BLM) is listed as impaired for alteration of riparian vegetation, low flow alterations, and sedimentation. Probable causes are listed as streambank modification, irrigated crop production, and rangeland grazing. These impacts will continue for the foreseeable future. Impacts in these streams (except for Charcoal Gulch which has a valley bottom BLM road maintained in all alternatives), will continue for the foreseeable future regardless of BLM road management.

Overall, due to the scattered distribution and relatively small proportion of BLM lands (18 percent) and roads (13 percent) relative to the total quantities of lands and roads in the TPA, none of the BLM alternatives would substantially contribute to cumulative effects on water resources at the scale of the Upper Big Hole River TPA.

## **VEGETATIVE COMMUNITIES – FOREST RESOURCES AND FOREST AND WOODLAND PRODUCTS**

### **Effects of the Alternatives**

Under all alternatives, existing roads and roads built to access timber and forest product sales on BLM lands may encourage timber harvest and forest product sales on adjacent lands, particularly where landowners and other agencies looking to improve economic efficiency or opportunities in the management on their lands.

In general, vegetative treatment contractors tend to bid more readily on projects in areas with vehicle access or valuable products. BLM often prioritizes forest vegetation management activities such as forest products and forest protection actions (e.g. wildfire suppression and forest insect and disease control) in similar areas.

Rehabilitation of roads (decommissioning and in some cases road closure) would revegetate currently unvegetated roadbeds, which would increase vegetation biomass production on the landscape through colonization of sites with grasses, forbs, shrubs, and trees. Increases in revegetated area would occur at a rate of approximately 1.5 to 3 acres per mile of rehabilitated road. Eventually rehabilitated roads would support plant communities consistent with site potentials which would help resist weed invasions. However, road closures and removals (decommissioning) could make vegetation management treatments more difficult and costly, thereby inhibiting proposed treatments, reducing public access for product use and removal, and potentially slowing fire detection and suppression.

Under Alternative A there would be no increase in project analysis and implementation costs. However, under Alternative B approximately 48 percent (79.9 miles) of BLM roads would be closed or decommis-

sioned. Under Alternative C about 62 percent (102.8 miles) of roads would be closed or decommissioned, while under Alternative D about 36 percent (58.9 miles) of these roads would be closed or decommissioned. These closures would result in commensurate potential increases in vegetative analysis and treatment costs by alternative. These potential cost increases would be considered on a case by case basis by the BLM during project feasibility determinations, and additional funding may be needed to analyze and implement the projects that would remain feasible. Road closures could also result in potential decreases in quantities of forest products removed. Lack of road access could make small projects cost-prohibitive. Although temporary road building is still an option for access, slopes are generally steeper in the Upper Big Hole TPA as compared to other TPAs and may preclude road building. These limitations may increase the occurrence of helicopter logging and other non-traditional forms of product removal. Helicopters are a feasible access alternative in the Upper Big Hole TPA because forest products generally have higher value in this watershed and could absorb the increased cost of access. The extent of the road-related effects described above would be minimized because BLM would likely still be able to plan and implement projects in many areas on closed roads through the variance process for temporary road use. Road-related effects would be greatest under Alternative C, followed in sequence of decreasing effects by Alternative B, then Alternative D.

Roaded access to forested areas would also affect the gathering of firewood and other forest products by the general public. Most public parties prefer to drive close to areas of product removal so they do not have to carry products over long distances to their vehicles. Alternative A would have the greatest opportunity for firewood and other product removal with 70.6 miles of BLM road open yearlong and 88 additional miles open during summer. Alternative B would provide fewer opportunities than Alternative A with 26.9 miles of road open yearlong and 57.9 additional miles open during summer. Alternative C would provide the fewest opportunities of all alternatives with 19.2 miles of road open yearlong and an additional 40.8 miles open during summer. Alternative D (26.8 miles open yearlong, additional 70.6 miles open during summer) would provide more opportunities than Alternatives B and C, but fewer opportunities than Alternative A.

## Cumulative Effects on Forest and Woodland Resources and Products

Forested vegetation in the Upper Big Hole TPA has been affected by past management on all land ownerships. Of the 63,108 acres of BLM owned land in the TPA, 246 were harvested since 1984. One hundred and twenty-six acres were also reforested. Currently, 430 acres are scheduled for insect control harvest in the Upper Big Hole TPA. Planning is also occurring on an additional approximately 1,000 BLM acres to implement forest

restoration harvests and burning. Treatments will result in more open, healthier forest stands. Some temporary roads and travel variances (to temporarily use closed roads) could be associated with these projects.

The Forest Service, with 143,778 acres in the TPA, also manages its forested resources through restoration projects including product removal and prescribed burning. These activities will likely continue in the future and promote healthier forest ecosystems in the planning area. Timber harvest will also continue on state and private ownerships, totaling 149,516 acres in the TPA.

The action alternatives could increase potential forested acreage by decommissioning roads and reclaiming approximately 64 acres under Alternative B, 75 acres under Alternative C, and 58 acres under Alternative D.

Although miles of access would be decreased with road decommissioning, trees have the potential to colonize these areas and provide for forest products in the future.

Currently western spruce budworm, mountain pine beetle, and Douglas-fir Beetle are present in forests within the Upper Big Hole TPA. These species are currently present at higher levels than experienced in the last twenty years and are resulting in widespread tree mortality. Endemic insect levels are expected to remain high in the future, with the bark beetle (mountain pine beetle and Douglas-fir Beetle) infestations peaking in the next several years. Even at lower population levels, these species can reduce forest health and individual tree vigor, sometimes resulting in tree mortality.

Forested vegetation in the Upper Big Hole TPA will also be affected by approximately 6,805 acres of rights-of-way and leases on BLM land. Forested vegetation located in these areas usually is harvested to accommodate the necessary access or facilities. Forest vegetation removal would occur on new authorizations in the future as necessary to maintain sight distances and safety clearances associated with roads and facilities.

Urbanization is expected to continue on the 115,567 acres of private land (28 percent of total acres) within the Upper Big Hole TPA. Forest products are commonly removed from these areas prior to permanent construction. Urbanization is likely to continue in the future and will affect forested vegetation at an unknown rate. As private construction increases, miles of road on private will most likely increase from the current 540 miles (41 percent of total in TPA).

Risk to forests from human-caused wildfires is commonly associated with open roads. Risk to forests from wildfire is greatest under Alternative A with 159 miles of BLM road open during the summer. Alternative B would have less risk of human-caused fire starts with about 81 miles of road open during summer. Alternative C would have the least risk to public forests with only 60 miles of road open during summer months. Alternative D (about 97 miles of road open during summer) would have more

risk than either Alternatives B or C, but less risk than Alternative A. Given that the majority of roads in the TPA (87.4 percent) are non-BLM roads, this contribution to reduced fire risk from BLM roads under the action alternatives is relatively small in the context of the entire TPA.

Since BLM roads constitute only 12.6 percent of all roads in this TPA, and BLM lands make up only 17.7 percent of all lands in the TPA, urbanization and activities on open non-BLM roads in the vicinity may have more cumulative effects on forested vegetation in the TPA than BLM decisions regarding miles of open and closed road.

## VEGETATIVE COMMUNITIES – NOXIOUS WEEDS

Under all alternatives, any snowmobile use would have negligible effects on noxious weed spread and populations. Invasive noxious weeds and non-native species are degrading wildland health. These are aggressive plants that can outcompete many native plants, as they have few natural enemies to keep them from dominating an ecosystem. These plant species are spread by many means. However, any land disturbing activity in the TPA has the most potential to introduce and spread weed species. Motorized vehicles are one vector for noxious weed spread as weed seed becomes attached to vehicles and their tires, and are transported from one area to another where seeds become detached and germinate to inhabit new areas.

### Effects of Alternative A

Under Alternative A, all BLM routes located within the TPA would continue to be managed as indicated on the Southwest Montana Interagency Visitor/Travel Map (interagency cooperative mapping effort, 1996 revision). Alternative A would provide 158.6 miles of routes open to wheeled motorized use (70.6 miles open yearlong, 88.0 miles seasonally restricted and 7.4 miles closed). Where allowed, snowmobile use would continue to be open to area-wide cross-country use as well as use on existing routes, during the season of use, 12/2-5/15, conditions permitting. Alternative A would have the most roads open and in turn would promote the greatest amount of weeds and other undesirable plant spread and production. More herbicide control would be needed to control weeds under Alternative A than under the other alternatives. Under Alternative A the open BLM road miles would make up about 12.6 percent of all open roads in the Upper Big Hole River TPA.

### Effects of Alternative B

Under Alternative B, 84.8 miles of routes would be available for wheeled motorized use (26.9 miles open yearlong, 57.9 miles seasonally restricted). Snowmobile management would continue to remain substantially in effect as represented by the 1996 Southwest Interagency

Visitor/Travel Map. This alternative would close 49.2 miles of road leaving 26.9 miles open yearlong as compared to 69.9 miles of road open yearlong for Alternative A. This would prevent weed spread caused by motorized vehicles on these closed routes, but would increase spread on the open routes because of more concentrated use of these routes. Overall Alternative B would reduce weed spread, but would increase weed treatment costs per road mile on the remaining open roads compared to Alternative A. Under Alternative B, the 84.8 miles of open BLM road would make up about 6.5 percent of all open roads in the TPA.

### Effects of Alternative C

Under Alternative C, 60.0 miles of routes would be available for wheeled motorized use (19.2 miles open yearlong, 40.8 miles seasonally restricted). This alternative would close 69.3 miles of road leaving 19.2 miles open yearlong as compared to 69.9 miles of road open yearlong for Alternative A. This would prevent weed spread caused by motorized vehicles on the closed routes, but would increase spread on the open routes because of more concentrated use of these routes. Overall Alternative C would reduce weed spread more than any other alternative, but would increase weed treatment costs per road mile on the remaining open road miles compared to Alternative A. Under Alternative C, the 60 miles of open BLM road would make up about 4.6 percent of all open roads in the Upper Big Hole River TPA.

### Effects of Alternative D

Under Alternative D, 97.4 miles of routes would be available for wheeled motorized use (26.8 miles open yearlong, 70.6 miles seasonally restricted). This alternative would close 33.2 miles of road leaving 26.8 miles open yearlong as compared to 69.9 miles of road open yearlong for Alternative A. This would prevent weed spread caused by motorized vehicles on the closed routes, but would increase weed spread on the open routes because of more concentrated use of these routes. Overall Alternative D would reduce weed spread more than Alternative A but less than Alternatives B or C, but would increase weed treatment costs per road mile on the remaining open road miles compared to Alternative A. Under Alternative D, the 97.4 miles of open BLM road would make up about 7.4 percent of all open road miles in the TPA.

## Cumulative Effects on Noxious Weeds

Under all alternatives, other past, present, and reasonably foreseeable future actions on BLM and non-BLM lands will affect noxious weeds.

Recreation use is well established in the TPA, with fishing and big game hunting topping the list. The Big Hole River has a national reputation as a premiere fly fishing destination. Big game hunting attracts regional and national attention as well. Motorized recreation uses are

one of the leading causes of introduction and spread of noxious weeds and non native species. Weed seeds are transported by many recreational vectors i.e. water recreation uses, motorized vehicles including their tires, non-motorized vehicles including their tires, pack animals, and humans.

Applications for right-of-way permits on public lands to access private property or for commercial development are likely to increase in the future. As a result, soil disturbing activities (i.e. roads, powerlines, telephone lines, etc.), will likely increase, causing weeds to increase.

A variety of resource management projects, such as BLM initiated vegetation treatments, or wildland fire fuels reduction projects, could affect noxious weed management. There have been multiple fuels treatments in this area in the last 10 years. Treatments consisted of 474 acres of prescribed burning and 141 acres of mechanical treatments primarily in the Jerry Creek and Dickie Hills areas. There are fuels treatments planned by the BLM for this area, mainly in the general area south of Wise River and in the Highland Mountains area. The Highland Mountain project will consist of approximately 2,087 acres of mechanical treatment and 2,659 acres of prescribed fire treatment, implemented in 2007 through 2012. The Wise River project would consist of mechanical and/or prescribed burning treatments from 500 to 2,000 acres focused on the urban interface areas having the objective to restore ecosystem health and reduce fuels. Prescribed burning projects give the ground surface a fertilization effect and eliminate some plant competition for weedy species giving them a niche for establishment and expansion in some areas. Ground disturbing equipment could also transport noxious weed seed to these project sites. BLM implements weed control measures in the aftermath of such ground-disturbing activities so as to minimize noxious weed spread.

Wildland fires create good seed beds and supply nutrients for weed species introduction and production. From 1981 to 2004 there have been 18 wildland fires that burned approximately 230 acres. As with mechanical vegetation treatment projects, BLM implements weed control measures in the aftermath of wildland fires to minimize weed spread.

A portion of the TPA (especially the Soap Gulch and Camp Creek areas) is strongly mineralized and has undergone considerable mining in the past. Current activity is low. However, increases in mineral prices could lead to additional increased or renewed mining activity. Mining is a land disturbing activity and the activity itself and weed seed contaminated equipment that is used could promote weeds in the area. Reclamation of abandoned mine sites can disturb ground and promote weed spread as well. BLM implements weed control measures associated with this reclamation work to minimize weed spread.

Noxious weeds and non-native invasive species are well established and spreading in the area. Weed control activities by BLM and other entities, while often effective at reducing or minimizing weed spread and weed populations, can also lead to some weed spread. Herbicide spray equipment is driven through weed infestations and weed seeds as well as other weed vegetative parts are spread to other lands during and following treatment. This TPA has received about 150 to 200 acres of treatment over the last 6 years on BLM lands. Treatment has primarily been by herbicide. These weed treatments have varying success in killing undesirable plants, depending on many environmental parameters.

Timber sales have built-in stipulations for mitigating weed production and spread. However, with ground disturbance the potential exists for weed introduction to occur on these sites. Since 1995 there has been 189 acres of timber harvest and 126 acres of forest planting (replanted in 1998). Vehicular use associated with tree plantings could contribute to the spread of existing weeds on site. Herbicide treatment of existing weeds is coordinated with tree seedling planting locations and timing, so as to minimize the spread of noxious weeds. .

Future travel management (for all agencies, nationwide) is likely to lead to fewer opportunities for motorized recreational use than under current management (particularly for OHV use). As a result, BLM routes available to motorized use could experience increased use from displaced users, leading to more concentrated use and potentially increased weed spread.

The TPA includes important habitat for big game (elk, bighorn sheep). Noxious weed seeds are transported and spread by wildlife through their digestive system and by attaching to the animals themselves and then being released at a later time.

Livestock grazing on and off BLM lands also contributes to weed spread either through seed being spread or introduced by livestock themselves, or through vehicular uses needed to manage grazing operations.

The majority of the Upper Big Hole River TPA is characterized by undeveloped land (private homes/ranches; BLM, State, and USFS lands). Only about 2,000 people live in the area, many of them making their living by ranching and hay farming. Human population growth for the TPA is expected to remain relatively low. However, the area is experiencing some residential growth on land subdivided near the Big Hole River and as family ranches are sold to out-of-state investors/seasonal residents. Population growth and use of the TPA from the population centers of Butte and Dillon will in turn lead to more opportunities for weed spread and production.

The TPA is largely undeveloped. Several small communities (Divide, Dewey, and Wise River) are located within the TPA; while the communities of Melrose and Wisdom lie just outside. Urbanization is unlikely to become a major issue for many years. However, use of the

TPA by the residents living adjacent to or within this area is increasing and leads to an increase in weed spread and propagation.

About 12.6 percent of all the travel routes in the Upper Big Hole River TPA are located on BLM managed lands (under Alternative A). Because the majority of roads (87.4 percent) and lands (82.3 percent) in the TPA are non-BLM, activities in these areas play a stronger role than activities on BLM lands in determining the status of weed spread and weed populations overall.

## VEGETATIVE COMMUNITIES – RIPARIAN VEGETATION

### Effects Common to All Alternatives

This section focuses on effects to riparian vegetation. For additional discussion of effects to water quality and stream channels, see the Water Resources and Fish sections.

Roads in riparian areas constitute ground disturbance that can eliminate or preclude presence of native riparian vegetation. This ground disturbance and loss of riparian vegetation may facilitate erosion and sedimentation of streams. Roads may also interfere with natural stream channel functions by occupying floodplains or active stream channel margins (see Water Resources section for more discussion). Noxious weeds may dominate riparian vegetation communities after some type of disturbance (such as roads, livestock grazing, mining, etc.) has reduced native vegetation. Noxious weed seed can be spread into riparian areas by motor vehicles via open roads. Closure of roads and trails can improve or maintain riparian condition by reducing avenues of noxious weed spread, as well as allowing for bare area revegetation which filters sediment in addition to stabilizing banks in some areas. Road and trail restrictions have the same effects but to a lesser degree, because some traffic will inhibit vegetation growth and recovery.

As a means of comparing alternatives, **Table 4-91** depicts the miles of wheeled motorized routes that cross or are within 300 feet of streams or wet areas on BLM lands in the Upper Big Hole River TPA.

Under Alternative A, 38.6 miles of BLM roads and trails

would remain open that cross or are within 300 feet of riparian areas, 29.7 miles of roads and trails would have seasonal restrictions, and 3.3 miles would be closed. The noxious weed spread, streambank, and sediment delivery effects would continue as described in the Effects Common to All Alternatives section for the open roads. The BLM roads and trails most affecting riparian conditions are along Soap Gulch, McLean Creek, Moose Creek, Bear Creek, Sawlog Gulch and Charcoal Gulch and all would remain open, although McLean Creek and Charcoal Gulch are open with seasonal travel restrictions.

Under Alternative B, 25.9 miles of roads and trails would remain open that cross or are within 300 feet of riparian areas, 21.1 miles of roads and trails would have restrictions, and 23.7 miles would be closed. The noxious weed spread, streambank, and sediment delivery effects would continue as described in the Effects Common to All Alternatives section for the open roads. The BLM roads and trails most affecting riparian conditions are along Soap Gulch, McLean Creek, Moose Creek, Bear Creek, and Charcoal Gulch and all would remain open, although McLean Creek and Charcoal Gulch are open with seasonal travel restrictions. Sawlog Gulch travel use would be restricted by game retrieval rules, reducing the number of vehicular crossings of the Big Hole River at this location compared to Alternative A. A number of other streams would benefit from road and trail closures posed by this alternative. Alternative B would provide benefits to riparian vegetation compared to Alternative A.

Under Alternative C, 25.9 miles of BLM roads and trails would remain open that cross or are within 300 feet of streams or wet areas, 15.4 miles of roads and trails would have seasonal restrictions, and 29.4 miles would be closed. Effects would be similar to Alternative B with regard to the roads and trails most affecting riparian conditions in Soap Gulch, McLean Creek, Moose Creek, Bear Creek, and Charcoal Gulch. However the Sawlog Gulch and Big Hole River crossing would be closed under this alternative. Riparian condition would improve most under this alternative compared to all other alternatives.

Under Alternative D, 28.8 miles of roads and trails would remain open that cross or are within 300 feet of streams or wet areas, 23.8 miles of roads and trails would have seasonal restrictions, and 18.1 miles would be closed. Effects would be similar to Alternatives B and C with regard to roads along Soap Gulch, McLean Creek, Moose Creek, Bear Creek, and Charcoal Gulch. Travel use along Sawlog Gulch and the Big Hole River crossing would be seasonally restricted under this alternative. Under Alternative D, riparian condition would experience fewer road and trail effects than under Alternative A, but more than under Alternatives B or C.

<b>Miles of Wheeled Motorized Routes</b>	<b>ALT A</b>	<b>ALT B</b>	<b>ALT C</b>	<b>ALT D</b>
Open	38.6	25.9	25.9	28.8
Restricted	29.7	21.1	15.4	23.8
Closed	3.3	23.7	29.4	18.1

## Cumulative Effects on Riparian Vegetation

Noxious weed spread, mining, roads and trails, logging operations, and livestock grazing have affected riparian resource conditions in all TPAs, including the Upper Big Hole River TPA. Some of these factors continue to cause riparian area degradation primarily through direct disturbance or loss of riparian vegetation. Ground disturbance and loss of riparian vegetation facilitate erosion and sedimentation of streams. In the case of noxious weeds, they usually dominate riparian vegetation communities after some type of disturbance (such as roads, livestock grazing, mining, etc.) has reduced native vegetation.

Anticipated subdivision growth on private lands, though anticipated to occur at a lower rate in the Upper Big Hole River TPA than in other TPAs, will lead to more road construction and maintenance. More roads and development will increase severity of runoff events which in turn will cause more sediment delivery to creeks and streams. The additional sediment is likely to affect the functioning condition of some riparian areas by causing streambeds to aggrade at unnatural rates. Streambanks may also be affected if road placements do not allow for natural stream movements or meanders.

Logging and forestry practices on public and private lands are subject to streamside management zone (SMZ) requirements designed to maintain water quality and riparian vegetation. The proposed Riparian Management Zones under Butte RMP Alternatives B and C would be wider than SMZs and activities in these areas would be designed to benefit riparian resources, thus providing more riparian protection and more targeted management of riparian vegetation in both forested and non-forested areas than under RMP Alternatives A and D. The disturbance associated with timber activities does have the potential to increase noxious weed spread which degrades riparian area function and health. On public lands noxious weed control is a standard feature of any ground disturbing activities whereas on private lands noxious weed control is variable.

Livestock grazing will continue in the area and has the potential to impact riparian resource conditions. On BLM lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain riparian vegetation health and vigor. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided. Riparian conditions may improve or degrade as management changes.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, riparian conditions would improve because of the streambank protection gained from shrubby root systems and filtering capability of native riparian sedge and rush species.

In recent years, mitigation work has been completed to harden crossings and reduce sediment production on the roads along Camp Creek, Soap Gulch, McLean Creek, Moose Creek, Sawlog Gulch, and Charcoal Gulch.

The LaMarche Creek fluvial Arctic grayling habitat enhancement project improved riparian condition along this stream by stabilizing banks and creating lateral bars.

The Big Hole Watershed group has completed a number of projects to improve livestock grazing, weed control, and irrigation practices on private land. Riparian conditions along the river have improved in a number of places as a result of increased flows later in the season.

A number of privately owned blocks of land were logged within the past 20 years. Riparian vegetation was removed at the time but has recovered to some degree since then.

Cumulative effects under all the action alternatives would be similar to Alternative A at the scale of the entire TPA. The additional road and trail closures and seasonal restrictions on BLM roads in the action alternatives may slightly offset the cumulative road and trail impacts associated with subdivision development and other lands uses taking place in the TPA as compared to Alternative A. Alternative D would contribute less to riparian vegetation benefits than Alternatives B and C, but would contribute more benefits than Alternative A. Alternative C would contribute the most benefits of all alternatives while Alternative B would contribute more benefits than either Alternatives A or B.

Overall, because BLM roads make up only 12.6 percent of all roads in the TPA (under Alternative A), and BLM lands make up 17.7 percent of all lands in the TPA, the contributions to riparian vegetation benefits associated with closing riparian roads on BLM lands under the action alternatives would be dominated by activities on other lands at the scale of the entire Upper Big Hole River TPA. Activities on private lands (32 percent of total acreage in TPA) and USFS lands (40 percent of total acreage in TPA) would play a substantial role in determining riparian conditions at the scale of the entire TPA.

## WILDLIFE

### Effects of Alternative A

Under Alternative A, the Upper Big Hole River TPA would have considerably more open roads (158 miles) compared to the action alternatives. Under Alternative A, elk winter range on BLM lands in the Upper Big Hole TPA would have a low road density (1.0 mi/mi<sup>2</sup>), but this would still be the highest actual road density compared to the action alternatives (**Table 4-92**). Roads can cause direct mortality to wildlife through road kill, prevent wildlife movement, create disturbance, cause the spread of noxious weeds, reduce habitat and cause habitat fragmentation on the landscape (Joslin et al. 1999).

	<b>Actual Road Density</b>	<b>Acres of Low Road Density</b>	<b>Acres of Moderate Road Density</b>	<b>Acres of High Road Density</b>
<b>Alt. A</b>	1.0	28,511	10,886	11,128
<b>Alt. B</b>	0.3	35,033	10,068	5,423
<b>Alt. C</b>	0.3	35,618	9,876	5,082
<b>Alt. D</b>	0.4	32,875	11,844	5,804

Low Density = 0-1 mi/mi<sup>2</sup>, Moderate Density = 1-2 mi/mi<sup>2</sup>, High Density = >2 mi/mi<sup>2</sup>

Open roads typically increase the level of recreation adjacent to roads which can result in additional disturbance and displacement of wildlife species. Roads can also encourage the public to recreate in areas that had formerly been secluded. Open road miles that are 1 mi/mi<sup>2</sup> have been found to provide roughly 60 percent of functional habitat for elk (Christensen et al. 1993). Permanent and temporary roads could negatively impact wildlife, including special status species, particularly if roads are open during critical periods such as in lynx winter habitat and during the summer months within grizzly bear habitat.

Wildlife, including special status species, that are especially sensitive to roads in the TPA include (but are not limited to) elk, grizzly bear, lynx, wolverine and some raptors. The detrimental effects of open roads to wildlife under Alternative A would be greater than under any of the action alternatives. Under Alternative A, this TPA would have fewer acres of functional winter range (28,511 acres in low road density areas) compared to the action alternatives (Table 4-92). Alternative B would provide 35,033 acres of functional winter range, Alternative C would provide 35,618 acres, and Alternative D would provide 32,875 acres.

Under Alternatives A and D, approximately 31,607 acres of the Upper Big Hole TPA would be closed to snowmobiles with the remaining 31,600 acres open for cross country snowmobile use. Snowmobiling occurs in both the Decision and Planning Areas and the use of snowmobiles could have substantial negative effects to wintering big game and other wildlife species. Cross-country snowmobile use could lead to harassment of wildlife during the high stress winter season (Joslin et al. 1999). This could cause individuals to leave an area (temporarily or permanently) and/or cause an increase in stress that could lead to mortality. Alternatives A and D would have more detrimental effects to wildlife from cross-country snowmobile use than Alternatives B and C.

In evaluating impacts of travel planning on elk and other big game species, it is important to consider impacts on security habitat. Elk security is the inherent protection allowing elk to remain in an area despite increases in stress or disturbance associated with the hunting season or other human activities. Security habitat includes

blocks of nonlinear forested habitats greater than 250 acres in size that are at least 0.5 mile from an open road (Hillis et al. 1991). Security habitat should also consist of larger trees (greater than 8 inches DBH) with vegetation dense enough to hide an adult elk (Thomas et al. 2002). Under Alternative A, there would be approximately 4,665 acres of functional security habitat for big game species. This is the fewest acres of security habitat of all alternatives. Alternative C would have the greatest acres of security habitat (6,813 acres) (Table 4-93).

	<b>ALT A</b>	<b>ALT B</b>	<b>ALT C</b>	<b>ALT D</b>
<b>Upper Big Hole River TPA</b>	4,665	5,296	6,813	5,258

Core areas are areas large enough for wildlife (especially animals with large home ranges such as carnivores and big game) to forage and reproduce. Subcore areas are areas that could act as stepping stones for wildlife as they move through the region (Craighead et al. 2002). Nearly all lands in the TPA are within core or subcore habitat (254,176 acres). Under Alternative A, there would be 79,300 acres with low road density, 60,765 with moderate road density, and 114,111 with high road density in the TPA for all land ownerships. Alternatives A and D would have fewer acres with low road densities in core and subcore habitat at the landscape level compared to Alternatives B and C.

There are also a substantial number of acres on BLM lands that are considered core/subcore habitat, approximately 42,250 acres. Under Alternative A, there would be 22,784 acres with low road density and 8,124 with moderate road density but the majority of acres would have high road density, 11,342 acres, for core and subcore habitat on BLM lands. Alternatives A and D would have considerable fewer acres with low road densities in core and subcore habitat on BLM lands compared to Alternatives B and C.

Wildlife corridors are areas of predicted movement within or between core and subcore areas. The Big Hole Valley provides a critical corridor link from north to south

and the east half of the TPA provides a corridor from the Highland Mountains to the Pintler/Pioneer Mountains. This corridor also provides local daily movements and seasonal movements between higher elevation summer range along the Continental Divide and lower elevation winter range.

Within the Upper Big Hole TPA there are approximately 16,803 acres identified as “high quality” wildlife movement corridors under all land ownerships. In high quality movement corridors under all alternatives there would be 4,981 acres with low road density, 5,009 acres with moderate road density and 6,813 acres of high road densities.

On BLM lands in the TPA there are 3,205 acres mapped as high quality movement corridors. BLM lands in high quality movement corridors under all alternatives would have 2,714 acres with low road density, 480 acres with moderate road density and only 11 acres with high road density.

Riparian areas provide crucial habitat and critical travel corridors for wildlife including special status species. Riparian areas also provide a refuge for native plants and animals in times of stress such as drought or fire. Roads in riparian areas can prevent use of these crucial areas by wildlife, limit use, or cause loss of habitat. Under Alternative A there would be 32 miles of open roads in riparian areas.

## Effects of Alternative B

Under Alternative B, the Upper Big Hole River TPA would have substantially fewer open roads (84.8 miles) compared to Alternative A (158 miles). Of the 84.8 miles of open roads, only 26.9 miles would be open year-round and the remaining 57.9 miles would be seasonally restricted. Alternative B would have more open roads than Alternative C (60 miles) but less than Alternative D (97 miles). Alternative B would decrease harassment to wildlife during all seasons of use, especially during the winter and spring, more than Alternatives A and D. This alternative would also improve habitat and reduce fragmentation more than Alternatives A and D but less than Alternative C.

Under Alternative B, the actual road density in elk winter range in the Upper Big Hole TPA would be 0.3 mi/mi<sup>2</sup>, below the maximum of 1 mi/mi<sup>2</sup> recommended by MFWP in big game winter range. This is lower than the road density under Alternative A (1.0 mi/mi<sup>2</sup>), the same as Alternative C, and slightly lower than Alternative D (0.4 mi/mi<sup>2</sup>) (Table 4-92). Open road miles that are < 0.5 mi/mi<sup>2</sup> have been found to provide greater than 70 percent of functional habitat for elk (Christensen et al. 1993).

Under Alternative B, this TPA would have more acres of functional winter range (35,033 acres with low road density) compared to Alternative A (28,511 acres), a similar amount to Alternative C (35,681 acres), and more acres

than Alternative D (32,875 acres) (Table 4-92). Alternative B would improve the quality and quantity of winter range in the Upper Big Hole TPA compared to Alternatives A and D but would have slightly fewer beneficial effects to winter range than Alternative C.

Alternative B would reduce the acres open to cross country snowmobile use to 13,240 compared to 31,600 acres under Alternatives A and D. Alternative B would have the most acres closed to cross country snowmobile use (46,930 acres) and would have more acres limited to snowmobile use on existing roads (3,030 acres) than Alternatives A and D (0 acres). Alternative B would have fewer negative effects to big game and other wildlife species than Alternatives A and D but could have considerably more effects than Alternative C since all snowmobile use under Alternative C would be limited to open roads.

The amount of big game security habitat would be greater under all action alternatives compared to Alternative A, which would have 4,665 acres. Alternatives B and D would be nearly identical with 5,296 acres and 5,258 acres, respectively. Alternatives B and D would have fewer acres of functional security habitat compared to Alternative C (6,813 acres) (Table 4-93).

For all land ownerships, Alternative B would increase the acreage of core and subcore habitat with low road density to 84,430 acres, compared to 79,300 acres under Alternative A. Alternative B would also increase the acreage with moderate road density to 63,221 acres over Alternative A (60,765 acres), and would decrease the acreage with high road density to 106,524 acres compared to the 114,111 acres under Alternative A. Alternative B would improve core and subcore habitat across the landscape more than Alternatives A and D but less than Alternative C.

On BLM lands acres in core/subcore habitat, Alternative B would increase the acreage with low road density to 26,759 acres compared to the 22,784 acres under Alternative A. Alternative B would also increase acreage with moderate road density to 9,140 acres compared to Alternative A (8,124 acres), and would substantially reduce the acreage in high road density to 6,351 acres compared to the 11,342 acres under Alternative A. Alternative B would improve core and subcore habitat on BLM lands more than Alternatives A and D but less than Alternative C.

Effects associated with high quality wildlife movement corridors under Alternative B would be the same as under Alternative A.

Alternatives B and C would protect and restore substantially more riparian habitat than Alternative A by reducing the miles of open roads in riparian areas to 19.3 miles (from 32 under Alternative A). Alternatives B and C would also have fewer open roads in riparian habitats than Alternative D (22.2 miles). Alternatives B and C would allow for more breeding, foraging and hiding

habitat as well as improve more movement corridors for a wide variety of species than Alternatives A and D.

### Effects of Alternative C

Under Alternative C, the Upper Big Hole River TPA would have substantially fewer open roads (60 miles) compared to Alternative A (158 miles). Of the 60 miles of open roads, only 19.2 miles would be open year-round and the remaining 40.8 miles would be seasonally restricted. Alternative C would also have fewer open roads than Alternative B (81 miles) and considerably less than Alternative D (97 miles). Alternative C would decrease harassment to wildlife during all seasons of use, especially during the winter and spring, more than all other alternatives. This alternative would also improve habitat and reduce fragmentation more than all other alternatives.

Effects associated with open road density in elk winter range under Alternative C would be the same as under Alternative B (**Table 4-92**). Under Alternative C, this TPA would have more acres of functional winter range (36,618 acres with low road density) compared to Alternative A (28,511 acres), a similar amount to Alternative B (35,033 acres), and more acres than Alternative D (32,875 acres) (**Table 4-92**). Alternative C would improve the quality and quantity of winter range in the Upper Big Hole TPA more than Alternatives A and D and would have slightly more beneficial effects to winter range than Alternative B.

Alternative C would have the fewest negative effects to big game and other wildlife species by closing the entire TPA to cross country snowmobile use. Snowmobile use on approximately 31,600 acres would be limited to use on open routes (14 miles).

The amount of big game security habitat would be greater under all action alternatives compared to Alternative A which would have 4,665 acres. Alternative C would have 6,813 acres of security habitat, more acres than any other alternative. Alternatives B and D would be nearly identical with 5,296 and 5,258 acres of security habitat, respectively (**Table 4-93**).

For all land ownerships, Alternative C would increase the acreage of core and subcore habitat with low road density to 85,004 acres, compared to 84,430 acres under Alternative B and 79,300 acres under Alternative A. Alternatives C and B would have similar acreage with moderate road density (63,030 acres and 63,221 acres, respectively), which would be an increase in acreage compared to Alternative A (60,765 acres). Alternative C would decrease the acreage with high road density to 106,142 acres, which would be slightly less than Alternative B (106,524 acres) and substantially less than Alternative A (114,111 acres). Alternative C would improve core and subcore habitat across the landscape more than all other alternatives.

In core and subcore habitat on BLM lands, Alternative C would increase the acreage with low road density to 27,302 acres compared to Alternative B (26,759 acres) and Alternative A (22,784 acres). Alternative C would decrease acreage with moderate road density to 8,947 acres compared to Alternative B (9,140 acres) but would slightly increase acreage with moderate road density compared to Alternative A (8,124 acres). Alternative C would substantially reduce the acreage in high road density to 6,000 acres, compared to the 11,342 acres found under Alternative A. Alternative C would improve core and subcore habitat on BLM lands more than all other alternatives.

Effects associated with high quality wildlife movement corridors would be the same under Alternative C as under Alternative B.

Effects associated with roads in riparian areas under Alternative C would be the same as under Alternative B.

### Effects of Alternative D

Under Alternative D, the Upper Big Hole River TPA would have substantially fewer open roads (97 miles) compared to Alternative A (158 miles). Of the 97 miles of open roads, 26.8 miles would be open year-round and the remaining 70.6 miles would be seasonally restricted. Alternative D would have substantially more open roads than Alternative B (81 miles) and Alternative C (60 miles). Alternative D would allow more harassment to wildlife during all seasons of use, especially during the winter and spring, than Alternative B and, especially, Alternative C. This alternative would also restore less habitat and allow more fragmentation than Alternatives B and C but would improve habitat and lessen fragmentation compared to Alternative A.

Under Alternative D, the actual road density in elk winter range in the Upper Big Hole TPA would be 0.4 mi/mi<sup>2</sup>, below the maximum of 1 mi/mi<sup>2</sup> recommended by FWP in big game winter range (**Table 4-92**). This is lower than the road density under Alternative A (1.0 mi/mi<sup>2</sup>) but slightly more than Alternatives B and C (0.3 mi/mi<sup>2</sup>).

Under Alternative D, this TPA would have more acres of functional winter range (32,875 acres with low road density) compared to Alternative A (28,511 acres) but less than Alternative B (35,033 acres) and Alternative C (35,618 acres) (**Table 4-92**). Alternative D would improve the quality and quantity of winter range in the Upper Big Hole TPA compared to Alternative but would have fewer beneficial effects to winter range than Alternatives B and C.

Under Alternatives D and A, approximately 31,607 acres of the Upper Big Hole TPA would be closed to snowmobile use with the remaining 31,600 acres open for cross country snowmobile use. Alternatives D and A would have **substantially** more detrimental effects to

wildlife from cross-country snowmobile use than Alternatives B and C.

The amount of big game security habitat would be greater under all action alternatives compared to Alternative A, which would have 4,665 acres. With 5,258 acres of security habitat, Alternative D would have fewer acres than Alternative C (6,813) and slightly fewer acres than Alternative B (5,296 acres) (**Table 4-93**).

For all land ownerships, Alternative D would increase the acreage of core and subcore habitat with low road density to 82,317 acres compared to Alternative A (79,300 acres). This alternative would have fewer acres with low road density compared to Alternative B (84,430 acres) and Alternative C (85,004 acres). All action alternatives would increase acreage with moderate road density compared to Alternative A. Alternative D would have 64,613 acres with moderate road density while Alternative A would have 60,765 acres. Alternative D would reduce the acreage with high road density to 107,246 acres compared to Alternative A (114,111 acres), but would have more acres with high road density compared to Alternative B (106,524 acres) and Alternative C (106,142 acres). Alternative D would improve core and subcore habitat across the landscape more than Alternative A but less than Alternatives B and C.

In core and subcore habitat on BLM lands, Alternative D would increase the acreage with low road density to 24,812 acres compared to Alternative A (22,784 acres), but would have fewer acres with low road density compared to Alternative B (26,759 acres) and Alternative C (27,302 acres). Alternative D would increase the acreage with moderate road density (10,587 acres) over Alternative A (8,124 acres) and would also increase the number of these acres compared to Alternative B (9,140 acres) and Alternative C (8,947 acres). Alternative D would reduce the acreage with high road density to 6,850 acres compared to Alternative A (11,342), but would have slightly more acres with high road density compared to Alternative B (6,351 acres) and Alternative C (6,000 acres). Alternative D would improve core and subcore habitat on BLM lands more than Alternative A but considerably less than Alternatives B and C.

Effects associated with high quality wildlife movement corridors would be the same under Alternative D as under the other alternatives.

Alternative D would protect and restore substantially more riparian habitat than Alternative A by reducing the miles of open roads in riparian areas to 22.2 miles (from 32 under Alternative A). Alternative D would have more open roads in riparian habitats than Alternatives B and C (19.3 miles). Alternative D would allow for more breeding, foraging and hiding habitat as well as improve more movement corridors for a wide variety of species than Alternative A but less than Alternatives B and C.

## Cumulative Effects on Wildlife

Wildlife habitat in the Upper Big Hole TPA has been affected by roads, historic and current mining, timber harvest, weed infestations, recreation, powerline corridor development, and communication sites.

The majority of the Upper Big Hole River TPA is characterized by undeveloped land (private homes/ranches, BLM, state, and USFS lands). Only about 2,000 people live in the area, many of them making their living by ranching and hay farming. Population growth for the TPA is expected to remain low. Several small communities (Divide, Dewey, and Wise River) are located within the TPA.

Recreation use is well established in the TPA, with fishing and big game hunting being the dominant recreational activities. The Big Hole River has a national reputation as a premiere fly fishing destination. Big game hunting attracts regional and national attention, as well.

The amount of historic mining varies throughout the TPA. From Divide to the northwest, there is little mineralization and minimal impacts from historic mining. From Divide to the southeast through the Soap Gulch and Camp Creek drainages, there is a substantial amount of mineralization and historic mining. Current activity, however, is low but increases in mineral prices could lead to renewed mining activity.

In the TPA, there are 20 powerlines and one pipeline. There are no existing communication sites in the TPA and, in the future, communication sites on BLM lands would be restricted to existing sites. No future communication sites are expected in the TPA on BLM lands but they could occur on other public or private lands. There is the potential for future powerlines and pipelines to be built in this TPA.

There are approximately 70 rights-of-way (ROW) in the TPA and applications for ROW permits to access private property or for commercial development are likely to increase in the future. As a result, public access to BLM lands could increase. Fewer ROWs would be expected under Alternative A because more BLM roads would remain open under this alternative. Alternative B would be expected to have fewer ROWs than Alternative C but more than Alternatives A and D. Alternative C would be expected to have the most ROWs and, of the action alternatives, Alternative D would have the fewest.

Approximately 63 bighorn sheep were relocated to the Camp Creek and Soap Gulch drainages between 2000 and 2004. These efforts have increased sheep populations in these areas.

From 1981-2004 there have been 18 wildland fires that burned 230 acres of BLM lands (it is unknown how many acres burned in the entire TPA). Nine of the fires were identified as human-caused and these fires burned the majority of the BLM acres (229). There have been several vegetative treatments in the TPA in the last 10

years. On BLM lands, approximately 474 acres were burned with prescribed fire and another 141 acres were mechanically treated in the Jerry Creek and Dickie Hills areas to remove conifer encroachment into meadow habitat. Timber was harvested on approximately 60 acres of BLM land between 1984 and 1995 and from 1995 to present there has been timber harvest on approximately 200 acres of BLM lands. Timber harvest has also occurred on private and Forest Service lands.

Additional vegetative treatments on BLM lands, consisting of thinning dry Douglas fir and removing conifer encroachment from sagebrush and grasslands, are planned for the Highlands and Wise River areas. Approximately 2,660 acres are planned for prescribed fire in the Highlands and approximately 500-2,000 acres of mechanical and prescribed fire are planned in the Wise River area. These projects would likely improve wildlife habitat by restoring grassland, shrubland, and forest habitat conditions.

Vegetative treatments on BLM lands have had moderate effects to wildlife habitat in the TPA. While most vegetative treatments have improved habitat for wildlife, some old timber sale units have not recovered. Timber harvest on private lands and other public lands has also had minor to moderate effects to wildlife habitat in the TPA. Past mining activities on public and private lands in the Soap Gulch and Camp Creek areas has altered some areas of the landscape, although high quality habitat is still available for wildlife. Roads constructed to access mining claims, timber harvest and recreation activities are, most likely, having the most direct impact on wildlife in the TPA.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the TPA. Motorized activities play a large role in the distribution of noxious weeds. The cumulative effects of the spread of noxious weeds from open roads would be greater under Alternative A than all other alternatives. Alternative A would result in more wildlife habitat being lost or degraded due to noxious weed infestations compared to the action alternatives. Alternative B would have fewer open roads than Alternatives A and D resulting in fewer infestations of noxious weeds. Alternative C would close the most roads and would have the fewest cumulative effects from loss of habitat due to noxious weeds of all alternatives. Open roads and development adjacent to BLM lands and the substantial amount of public use this area receives would still allow for the spread of noxious weeds.

Public lands make up 58 percent of the TPA and provide large blocks of habitat. However, open roads on BLM lands as well as on private lands (about 570 miles) and other public lands (about 574 miles) have reduced the quality of wildlife habitat within the TPA. Open roads in the TPA cause disturbance and harassment to wildlife during the breeding and wintering seasons along with fragmentation and loss of habitat. Open roads in the

Planning Area would likely increase due to development and management of private lands, especially in the Big Hole Valley. Alternative A would have the greatest negative cumulative effects to wildlife and wildlife habitat from open roads with 158 miles of open roads. Alternative B would have fewer negative cumulative effects with 81 miles of open road than Alternatives A and D (97.4 miles), but more than Alternative C (60 miles).

Of the action alternatives, Alternative C would have the most beneficial cumulative effects by reducing habitat fragmentation, restoring habitat, and reducing disturbance during all seasons of use. Alternative B would be more beneficial than Alternatives A and D but less than Alternative C.

Historic and recent timber cutting, past mining activity and firewood gathering along open roads in the TPA may have reduced the amount of suitable snag habitat for cavity nesting species. Alternative A would allow a substantial amount of access to the area for firewood cutting that would continue to prevent snag recruitment for snag dependant species and minimize the amount of down woody material along open roads. Alternative B would protect more snag and down woody habitat from loss due to firewood cutting than Alternatives A and D but would protect less of this habitat type than Alternative C.

The Upper Big Hole TPA provides the most functional big game security habitat of the five TPAs being analyzed in this EIS. The large amount of public land allows for larger blocks of habitat away from roads. However, there would be less security habitat under Alternative A due to higher open road densities than under other alternatives. Alternatives B and C would provide the most security habitat for big game (5,296 and 6,813 acres, respectively) and Alternative D would provide a similar amount to Alternative B (5,258 acres). Security habitat would still be limited on private (unless closed to hunting) and other public lands. Under the action alternatives, the reduction of open roads during the hunting season would help mitigate for the loss of security habitat on adjacent lands.

Approximately 71 percent of the TPA is mapped as core and subcore habitat that is predominately Forest Service and BLM lands. Open roads has had some impact on the quality of core/subcore habitat and wildlife movement corridors in the TPA.

Habitat mapped as core and subcore habitat and wildlife movement corridors having high road densities would continue to be of lower value to wildlife under Alternative A. An increase in open roads in both the Decision and Planning Areas could result in a loss of core and subcore habitat under all alternatives but, especially, Alternative A. Although core/subcore habitat and wildlife movement corridors would continue to be impacted by development on private lands in the Big Hole Valley, Alternatives B and C would allow more BLM lands to

function as core/subcore habitat and wildlife movement corridors. Alternatives B and C would have fewer negative cumulative effects to core/subcore and wildlife habitat than Alternatives A and D.

The cumulative effects of high road densities would continue to negatively affect wildlife species during the breeding season more under Alternative A than under the action alternatives. Alternatives B and C would have the most beneficial cumulative effects to wildlife during the breeding season compared to Alternative D and, especially, Alternative A.

## FISH

For the sake of this discussion, “open” roads include roads that are open with seasonal restrictions as well as roads that are open yearlong. Roads identified as “closed” within 300 feet of streams also include roads that would be “decommissioned” in these areas by alternative. Effects to water quality described in the Water Resources section would affect fish populations and fish habitat quality. Analyses described and tabulated in the Water Resources section are referred to in the context of effects to fish in the discussion below.

### Effects of Alternative A

Under Alternative A, the Upper Big Hole TPA would have substantially more open roads (158 miles) compared to the action alternatives. Roads can have a wide range of effects on fish and fish habitat. These effects would include, but are not limited to, increased sedimentation from road construction and vehicle use, increased runoff, changes in surface water and drainage patterns from stream crossings, conduits for noxious weeds, loss of riparian vegetation, potential decreases in stream shading that could lead to water temperature increases, loss of instream habitats, and changes in local fish populations when culverts are impassable and limit fish migration.

Watershed (or hydrologic) function can be used as an indicator of relative risk or impacts to fish habitat. To determine the effects on watershed functions, a moving windows analysis was conducted on BLM lands to look at the miles of roads that would be decommissioned and removed from the landscape for each alternative. During this analysis, it was assumed that even though closing roads would improve watershed function, closed roads would remain on the landscape and could still have negative impacts to water quality and prevent or impede the restoration of riparian vegetation. Under Alternative A, there would be 19,646 acres with low road density, 18,204 acres with moderate road density and 25,357 acres with high road density on BLM lands in this TPA (**Table 4-89**). Alternative A would have fewer acres with low road density and more acres with high road density than the action alternatives and this alternative would be expected to have more overall negative effects

to watershed function and fish habitat due to roads than the other alternatives.

For this discussion, road miles within 300 feet of fish bearing streams would be considered an indicator of direct effects to fish habitat and fish populations. Under Alternative A, there would be 0.1 miles of closed road and 7.9 miles of open road within 300 feet of fish bearing streams on BLM lands. Alternative A would have 0.3-1.2 fewer miles of closed roads than the action alternatives and 0.3-1.3 more miles of open roads adjacent to fish bearing streams than the action alternatives. Of the 8 miles of open road adjacent to fish bearing streams under Alternative A, 4.3 miles are along streams with BLM special status species (westslope cutthroat trout and Arctic grayling). Alternative A would have more long-term negative impacts to westslope cutthroat trout as well as to other fish species compared to the action alternatives.

Perennial non-fish bearing streams contribute to fish habitat indirectly by serving as conduits for watershed products (water, sediment, nutrients, contaminants, and in some cases woody material) to fish bearing streams. Under Alternative A, there would be 0.8 miles of closed road and 23 miles of open road within 300 feet of non-fish bearing streams on BLM lands in the TPA. Alternative A would have substantially more miles of open road adjacent to perennial streams than the action alternatives.

This alternative would have the greatest negative impacts to fish and aquatic resources from open roads of all the alternatives.

### Effects of Alternative B

Under Alternative B, the Upper Big Hole TPA would have substantially fewer open roads (81 miles) compared to Alternative A (158 miles). Alternative B would have more open roads than Alternative C (60 open miles) but less than Alternative D (97 open miles).

In the context of watershed function, Alternative B would have approximately 946 more BLM acres in the low road density category, 1,330 more BLM acres in the moderate road density category, and 2,257 fewer BLM acres in the high road density category than Alternative A (**Table 4-89**).

Alternative B would contribute to improved hydrologic function more than Alternative A. This analysis does consider “decommissioned” roads, but does not consider “closed” roads as contributing to watershed function. Even though closed roads could still have adverse effects to aquatic habitats, these roads have more potential to become revegetated and lessen sedimentation and runoff, and restore riparian vegetation (thus contributing to improved fish habitat conditions) than open roads. Under Alternative B, there would be approximately 44 more miles of closed roads than under Alternative A, an additional indication that Alternative B would pose less impact to fish habitat than Alternative A. Alternative B

would have 0.4 miles of closed road and 7.6 miles of open road within 300 feet of fish bearing streams on BLM lands. Of the 7.6 miles of open roads, 4 miles would be adjacent to streams with special status species (westslope cutthroat trout and/or Arctic grayling). Alternative B would slightly reduce direct effects fish bearing streams (including streams with special status species) compared to Alternative A.

Alternative B would contribute fewer indirect effects to fish habitat associated with roads within 300 feet of perennial non-fish bearing streams than Alternative A. Under Alternative B there would be 8.1 miles of closed road and 15.7 miles of open road within 300 feet of perennial non-fish bearing streams on BLM lands in the TPA. This would be approximately 7.3 more miles of closed roads in these areas than under Alternative A. Alternative B would have fewer road-related adverse effects to fish and aquatic habitats than Alternative A and would contribute to aquatic habitat improvement compared to the current condition.

### Effects of Alternative C

Under Alternative C, the Upper Big Hole TPA would have substantially fewer open roads (60 miles) compared to Alternative A (158 miles). Alternative C would also have fewer open roads than Alternative B (81 miles) and Alternative D (97 miles).

In the context of watershed function, Alternative C would have 1,815 more BLM acres in the low road density category, 1,302 more BLM acres in the moderate road density category, and 3,112 fewer acres in the high road density category than Alternative A (**Table 4-89**). This alternative would have 869 more BLM acres in the low road density category, 28 fewer acres in the moderate road density category, and 835 fewer acres in the high road density category than Alternative B. This analysis does consider “decommissioned” roads, but does not consider “closed” roads as contributing to watershed function. Even though closed roads could still have adverse effects to aquatic habitats, these roads have more potential to become revegetated and lessen sedimentation and runoff, and restore riparian vegetation (thus contributing to improved fish habitat conditions) than open roads. Under Alternative C there would be approximately 62 more miles of closed roads than under Alternative A, and approximately 19 more miles of closed road than under Alternative B. From the standpoint of watershed function, Alternative C would pose less impact to fish habitat than Alternative B, and would provide the greatest improvement to watershed function of all the alternatives.

Alternative C would have more miles of closed roads (1.3) and fewer miles of open roads (6.7) within 300 feet of fish bearing streams on BLM lands than all other alternatives. Of the 6.7 miles of open road, 4.0 miles would be adjacent to streams with special status species (westslope cutthroat trout and/or Arctic

grayling). Alternative C would reduce direct effects to fish bearing streams from roads more than all other alternatives.

Alternative C would contribute fewer indirect effects to fish habitat associated with roads within 300 feet of perennial non-fish bearing streams on BLM lands compared to all other alternatives. Under Alternative C there would be 9.4 miles of closed road and 14.4 miles of open road within 300 feet of perennial non-fish bearing streams on BLM lands in the TPA. This would be 8.6 more miles of closed road than Alternative A and 1.3 more miles of closed road than Alternative B in these areas.

Overall Alternative C would have fewer road-related adverse effects to fish and aquatic habitats than any of the alternatives and would contribute the most to aquatic habitat improvement compared to the current conditions.

### Effects of Alternative D

Under Alternative D, the Upper Big Hole TPA would have substantially fewer open roads (97 miles) compared to Alternative A (158 miles). Alternative D would have considerably more open roads than Alternative B (81 miles) and Alternative C (60 miles).

In the context of watershed function, Alternative D would have 933 more acres in the low road density category, 1,149 more acres in the moderate road density category, and 2,081 fewer acres in the high road density category on BLM lands than Alternative A (**Table 4-89**). This alternative would have the second fewest BLM acres in the low and moderate road density categories, and the second most BLM acres in the high road density category of all the alternatives. This analysis does consider “decommissioned” roads, but does not consider “closed” roads as contributing to watershed function. Even though closed roads could still have adverse effects to aquatic habitats, these roads have more potential to become revegetated and lessen sedimentation and runoff, and restore riparian vegetation (thus contributing to improved fish habitat conditions) than open roads. The fewest total road miles would be closed under Alternative D (33 closed miles) of the action alternatives (51 closed miles under Alternative B and 69 closed miles under Alternative C). Alternative D would improve watershed function more than Alternative A, but less than Alternatives B and C.

Effects associated with roads within 300 feet of fish bearing streams on BLM lands under Alternative D would be the same as under Alternative B.

Alternative D would contribute more indirect effects to fish habitat associated with roads within 300 feet of perennial non-fish bearing streams than Alternatives B and C, but less than Alternative A. Under Alternative D there would be 6.3 miles of closed road and 17.5 miles of open road within 300 feet of perennial non-fish bearing streams on BLM lands in the TPA. This would be 5.5

more miles of closed roads than under Alternative A, 1.8 fewer miles of closed roads than Alternative B, and 3.1 fewer miles of closed roads than Alternative C in these areas.

Alternative D would have fewer road-related adverse effects to fish and aquatic habitats than Alternative A, but more than Alternatives B and C, and would contribute to aquatic habitat improvement compared to the current condition.

## Cumulative Effects on Fish

The Upper Big Hole TPA supports a variety of native and introduced fish species. One of the major human influences to fish in the TPA has been the introduction of non-native trout species including rainbow trout, brook trout, and brown trout throughout the TPA as well as Yellowstone cutthroat trout in Moose Creek and Wise River. Rainbow trout have hybridized with the native westslope cutthroat trout in many streams. Brook trout and brown trout have displaced the native cutthroats in other streams, especially those altered by sedimentation and increased water temperatures brought on by human activities. Yellowstone cutthroat trout have also hybridized with westslope cutthroat trout in Moose Creek.

The majority of the Upper Big Hole River TPA is characterized by undeveloped land (private homes/ranches, BLM, State, and USFS lands). Only about 2,000 people live in the area, many of them making their living by ranching and hay farming. Population growth for the TPA is expected to remain low and the area will likely remain predominantly undeveloped for the foreseeable future.

Recreation use is well established in the TPA, with fishing and big game hunting being the dominant recreational activities. The Big Hole River has a national reputation as a premiere fly fishing destination primarily for rainbow and brown trout. Big game hunting attracts regional and national attention, as well.

Agricultural activities from farming and ranching can contribute increases in nutrients, sedimentation and cause the loss or degradation of aquatic habitats. Many streams in the TPA have been impacted by historic and on-going livestock grazing that breaks down streambanks, widens channels, removes vegetative cover, and causes increases in fine sediment and nutrients.

Agricultural water withdrawals are a substantial impact to water resources in the Big Hole River itself. During late summer the Big Hole River typically experiences lower than natural flows, increased water temperatures, and algal blooms. These conditions are exacerbated by agricultural water withdrawals during this period. Government agencies and local entities regularly work with ranchers to minimize their agricultural withdrawals during summer low flow periods to minimize low flow effects on fish populations in the Big Hole River. In particular, concern about the population status of fluvial

Arctic grayling have prompted stakeholders in the Big Hole River to provide greater instream flows during low flow periods to benefit Arctic grayling and prevent a federal listing of this species under the Endangered Species Act.

The amount of historic mining varies throughout the TPA. From Divide to the northwest, there is little mineralization and minimal impacts from historic mining. From Divide to the southeast through the Soap Gulch and Camp Creek drainages, there is a substantial amount of mineralization and historic mining. Current activity, however, is low but increases in mineral prices could lead to renewed mining activity. Increases in mineral prices could lead to increased or renewed mining activity in the Soap Gulch and Camp Creek drainages. The impacts from historic mining on aquatic habitats have been concentrated in the Soap Gulch and Camp Creek areas. See the Cumulative Effects portion of the Water Resources section for a description of streams impacted with heavy metal contamination due to historic mining.

Fires, floods, and drought have historically affected fish habitat in the TPA. These disturbances can cause a pulse of sediment or may temporarily reduce the quality of fish habitat in some watersheds while leaving other streams largely unaffected. Population recovery in disturbed streams may be facilitated by fish immigration from nearby drainages less affected by the catastrophic event. From 1981-2004 there have been 18 wildland fires that burned 230 acres. Nine of the fires were identified as human-caused and these fires burned the majority of the acres (229). There have been several vegetative treatments in the TPA on BLM lands in the last 10 years. Approximately 474 acres were burned with prescribed fire and another 141 acres were mechanically treated in the Jerry Creek and Dickie Hills areas to remove conifer encroachment into meadow habitat. These activities had minimal effects on fish habitat.

Timber harvest can alter the recruitment of large woody material, reduce canopy closures, and result in an increase in fine sediment to streams. Timber harvest along with associated roads can contribute substantially to the overall cumulative effects in forested watersheds. Approximately 60 acres of timber on BLM lands were harvested between 1984 and 1995 and from 1995 to present there have been approximately 200 acres of timber harvest. Adjacent private and Forest Service lands have also had a small amount of timber harvest in the past and additional harvest is expected in the future with a range of effects to fish and aquatic habitat.

Past vegetative treatments on BLM lands may have had minor to moderate effects to aquatic habitat in the TPA. While most vegetative treatments have improved overall watershed functions, some old timber sale units have not recovered and have removed riparian vegetation. Timber harvest on private lands and other public lands may have also had minor to moderate effects to fish and aquatic habitats in the TPA.

Additional vegetation treatments, consisting of thinning dry Douglas fir and removing conifer encroachment from sagebrush and grasslands, are planned for the Highlands and Wise River areas on BLM lands. Approximately 2,660 acres are planned for prescribed fire in the Highlands and approximately 500-2,000 acres of mechanical and prescribed fire are planned in the Wise River area. These treatments will likely have minimal effects to fish and aquatic habitat.

Roads are another major contributor of sediment to streams and a major problem with regards to cumulative watershed effects. Roads and trails can have localized effects on nearby stream segments or at stream crossing sites, especially fords. Cumulatively, roads degrade aquatic habitat due to sedimentation from road construction and vehicle use, increased runoff, changes in surface water and drainage patterns from stream crossings, loss of riparian vegetation, and loss of large woody material. Roads can cause changes in local fish populations when culverts are impassable and limit fish migration. Alternative A would have more negative cumulative effects to watersheds and individual streams due to roads than the action alternatives. Alternative B would have fewer negative cumulative effects than Alternatives A and D but more than Alternative C. Alternative B would improve overall watershed functions as well as improve habitat in individual streams more than Alternatives A and D but less than C. Alternative C would have the greatest beneficial cumulative effects.

## SPECIAL STATUS PLANTS

### Effects Common to All Alternatives

Ground-disturbing activities from road construction and maintenance, as well as road use by vehicles can affect special status plant populations and habitat. These activities can reduce sensitive plant species through disturbance to individual populations, increasing competition from invasive species, and reducing habitat connectivity. Closure of roads and trails can improve or maintain sensitive plant populations or habitat by reducing avenues of noxious weed spread, maintaining habitat connectivity, and improving pollinator habitat. Road and trail restrictions have the same effects but to a lesser degree.

### Effects of the Alternatives

Under Alternative A, 70.6 miles of BLM roads and trails would remain open, 88.0 miles of roads and trails would be open with seasonal restrictions, and 7.4 miles of roads and trails would be closed. On the open roads, effects would continue as described in the Effects Common to All Alternatives section. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. Restricted routes have some positive impact because some possible noxious weed spread is reduced; however the benefit isn't as large as closing or decommissioning a route.

Under Alternative B, 26.9 miles of BLM roads and trails would remain open, 57.9 miles of roads and trails would be open with seasonal restrictions, 49.2 miles of roads and trails would be closed, and 27.7 miles would be decommissioned. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The restricted roads would reduce weed spread a limited amount. Alternative B would benefit and reduce risk to special status plants compared to Alternative A.

Under Alternative C, 19.2 miles of BLM roads and trails would remain open, 40.8 miles of roads and trails would be open with seasonal restrictions, 69.3 miles of roads and trails would be closed, and 33.5 miles would be decommissioned. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The restricted roads would reduce weed spread a limited amount. Alternative C would benefit and reduce risk to special status plants the most of any alternative because it would eliminate disturbance, vehicular use, and spread of noxious weeds on the most road miles.

Under Alternative D, 26.8 miles of BLM roads and trails would remain open, 70.6 miles of roads and trails would be open with seasonal restrictions, 33.2 miles of roads and trails would be closed, and 25.7 miles would be decommissioned. On the open roads, effects would continue as described in the Effects Common to All Alternatives section. On the closed routes, vectors of noxious weed spread would be reduced and habitat connectivity and health would be improved for sensitive plants and their pollinators. The restricted roads would reduce weed spread a limited amount. Alternative D would benefit and reduce risk to special status plants more than Alternative A, but less than Alternatives B and C.

### Cumulative Effects on Special Status Plants

Under all alternatives there are a number of past, present, and reasonably foreseeable future actions that affect special status plant populations.

Livestock grazing will continue in the area and has the potential to impact sensitive plant populations and habitat. On public lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain sensitive species populations and habitat. On private lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided. Conditions may improve or degrade as management changes.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, sensitive plants would benefit from the reduced competition. Use of her-

bicides for noxious weed control could cause mortality to special status plants if individual plants are inadvertently sprayed.

Although less residential development is anticipated in the Upper Big Hole River area than in other TPAs, recent and anticipated subdivision growth on private lands will lead to more road construction and maintenance. More roads and development will reduce sensitive plant species habitat and in some cases individual populations. Additionally, subdivisions have the potential to disrupt the connectivity of plant habitat and populations as well as disturbing or eliminating pollinators needed by sensitive species. Some sensitive species that require soil disturbance may benefit.

Timber sale activity disturbance can destroy or degrade sensitive plant habitat. On public lands, projects would be designed to avoid, mitigate, or enhance sensitive plant habitats. The disturbance associated with timber harvest activities does have the potential to increase noxious weed spread which degrades sensitive species habitat and individual plant populations.

Mine closures are planned, and have been completed, in the Soap Gulch and Camp Creek areas where sensitive plant habitat is present. Activities have been planned to minimize or eliminate surface disturbance in sensitive plant habitat, however some plant populations or habitat may be inadvertently disturbed.

The Big Hole Watershed group has completed a number of projects to improve livestock grazing, weed control, and irrigation practices on private land. Riparian conditions along the river have improved in a number of places as a result. Habitat for Idaho sedge would improve as well as it is a riparian species.

The BLM fuels reduction project now being planned for the Wise River area is not anticipated to have any adverse effects on special status plants. Treatments would be designed to minimize surface disturbance in sensitive plant habitat. Additionally, treatment would improve habitat in some areas by opening up parks and edges where trees have expanded into grassland soils and trees have thickened to the point of closing canopies.

At the scale of the entire Upper Big Hole River TPA (all land ownerships), the BLM travel plan alternatives would have slightly variable contributions to cumulative effects on special status plants. Under Alternative A less than 1 percent of all roads in the TPA would be closed. Under Alternative B adverse effects on special status plants would be slightly reduced compared to Alternative A because 6.1 percent of all roads in the TPA would be closed or decommissioned. Alternative C would provide the most benefits of all alternatives as 7.9 percent of all roads in the TPA would be closed or decommissioned. Alternative D would provide slightly more benefits than Alternative A but slightly fewer benefits than either Alternatives B or C as 4.5 percent of all roads in the TPA would be closed or decommissioned. Because

BLM lands make up only 17.7 percent of all lands in the TPA, activities on non-BLM lands would play a dominant role in determining status of special status plants.

## WILDLAND FIRE MANAGEMENT

Travel planning alternatives were analyzed to determine whether they could result in impact on wildland fire management, causing change to any of the following indicators:

- Fire regime condition class (FRCC)
- Firefighter and public safety
- Reducing threat to Wildland Urban Interface (WUI)

## Effects Common to All Alternatives

Public road access during the fire season provides opportunities for human-caused fires either due to catalytic converters on vehicles igniting dry vegetation, or due to some types of human activities. Roads that are closed to public access reduce the risk of human-caused fire starts in those areas.

Decommissioned roads and roads that are closed and not regularly maintained for navigability reduce access for fire suppression. Closed roads may become impassible due to vegetation regrowth, downfall of trees, or severe erosion. Some roads may be closed with earthen berms or fallen trees and would need to be physically manipulated to make them useable for vehicles again. These roads would extend firefighting response time and have negative impacts on efforts to reduce wildland fire threat to WUI areas and firefighter and public safety. In an emergency fire suppression situation, any navigable closed roads needed for fire suppression would be used immediately. Non-navigable closed roads could also be used if deemed to be needed for fire suppression, after needed improvements are made to make those roads useable. Planning and implementation of fuels reduction treatments could occur in association with closed roads if variances for temporary road use were to be allowed. Variances would be subject to internal BLM review.

In the context of fuels reduction projects, availability of open roads is important to facilitating fuels project location as well as increasing project feasibility and decreasing costs. Open roads also facilitate spread of noxious weeds by transporting weed seed on vehicles and their tires. Presence of large noxious weed populations could delay or cause fuels projects to be cost-prohibitive due to the fact that the weeds may have to be treated before and/or after the fuels treatment. Also, some applications of fuel treatments (e.g., prescribed fire) may promote the spread of some weeds. The presence of weeds and non-native species are indicators that FRCC has departed from historical conditions.

Noxious weeds and non-native invasive species are well established and spreading in the Upper Big Hole River TPA.

### Effects of Alternative A

Under Alternative A, all BLM routes located within the TPA would continue to be managed as indicated on the Southwest Montana Interagency Visitor/Travel Map (USDA-FS, USDI-BLM, and State of Montana, 1996). Alternative A provides 157.9 miles of routes open to wheeled motorized use (69.9 miles open yearlong, 88.0 miles seasonally restricted). Alternative A would allow for the greatest flexibility between alternatives for access for suppression purposes. Fuels project feasibility would be highest under this alternative. However, public access during the fire season would be the greatest under this alternative and would provide the most opportunities for human-caused fire starts.

The distribution of noxious weeds could be the greatest under Alternative A with the most open roads and noxious weeds already well established. This would contribute to reduced feasibility of fuels reduction projects more than under any other alternative.

### Effects of Alternative B

Under Alternative B, 80.9 miles of routes would be available for wheeled motorized use (26.9 miles open yearlong, 57.9 miles seasonally restricted). Alternative B would limit the flexibility for access for suppression purposes, and fuels project feasibility would go down compared to Alternative A due to the fact that access would be limited to 84.8 miles of road. Of the 76.9 miles of closed roads, 27.7 miles would be decommissioned and would likely be unusable for fire suppression. The risk of human-caused fires from motorized use would be limited compared to Alternative A, due to a 44 percent decrease in miles of road open to motorized public travel.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because more roads would be closed than under Alternative A, Alternative B should help reduce the spread of noxious weeds, and may make fuels treatment more feasible than Alternative A, reducing FRCC departure.

### Effects of Alternative C

Under Alternative C, 60.0 miles of routes would be available for wheeled motorized use (19.2 miles open yearlong, 40.8 miles seasonally restricted).

Alternative C would limit the flexibility for access for suppression purposes, and fuels project feasibility would go down compared to both Alternatives A and B, due to the fact that access would be limited to 60 miles of road. Of the 102.8 miles of closed roads, 33.5 miles would be decommissioned and would likely be unusable for fire suppression. The risk of human-caused fires associated

with motorized use would be the lowest of all alternatives, due to a 58 percent decrease in miles of road open to motorized public travel. However, this degree of reduced motorized access may promote more non-motorized users to a concentrated area, increasing the odds for a human-caused fire to occur by another ignition source.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because more roads would be closed than under any other alternative, Alternative C should help reduce the spread of noxious weeds more than any other alternative, and may make fuels treatment more feasible, reducing FRCC departure.

### Effects of Alternative D

Under alternative D, 26.8 miles of open routes would be available yearlong for wheeled motorized use and 70.6 miles would be restricted seasonally. Of the 58.9 miles of closed roads, 25.7 miles would be decommissioned and would likely be unusable for fire suppression. Alternative D would be more flexible than Alternatives B and C but would limit flexibility for access for suppression purposes, and fuels project feasibility would go down compared to Alternative A. The risk of human-caused fires associated with motorized vehicle use would be reduced compared to Alternative A, but would be greater than under Alternatives B and C, due to a 31 percent decrease in open roads compared to Alternative A.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the area. Because an intermediate number of road miles would be closed under this alternative, Alternative D should help reduce the spread of noxious weeds and may make fuels treatment more feasible compared to Alternative A, but would promote more weed spread and potentially make projects less feasible than Alternatives B and C.

### Cumulative Effects on Wildland Fire Management

Effects on wildland fire management associated with any of the BLM travel plan alternatives would be overshadowed by reasonably foreseeable uncharacteristic fire, continued fire suppression made necessary by WUI and intermingled landownership, and large-scale forest insect infestations and disease outbreaks that would continue for the planning period. BLM lands make up about 12.6 percent of all lands while BLM roads make up about 17.7 percent of all roads in the Upper Big Hole River TPA.

Revision of the Beaverhead-Deerlodge National Forest Plan could result in more or less treatment of adjacent areas. Because no decision has been made, the effects are not known. Wildland fire management, particularly where wildland fire use (management of naturally ignited wildland fires to achieve resource objectives) may

occur on USFS lands, will be determined in the plan decision. BLM would need to coordinate with USFS on all wildland fire use actions and events. Wildland fire use on USFS lands could affect FRCC on BLM lands. USFS lands make up 40 percent of all lands in the Upper Big Hole River TPA so activities there would likely have more influence on future fire characteristics than activities on BLM lands (17.7 percent of all lands in TPA).

Decisions to increase the level of wildland fire use, prescribed fire, or open burning by the public could impact the BLM's ability to use wildland fire and prescribed fire due to air quality concerns and requirements. This could postpone or eliminate BLM fuel reductions or treatments to improve FRCC.

Access is a critical component of wildland fire suppression. In some cases, access to public lands is being reduced by adjacent landowners gating or closing roads, which could hamper wildland fire suppression efforts and pose a risk to public and firefighter safety. Reducing access would also increase the potential for larger fires to occur due to an increase in time needed to access a fire and control it. Time needed to move in crews would be extended, and the ability to effectively apply and place resources (e.g., engines, water tenders, etc.) would be limited.

Effects on wildland fire management, including FRCC and firefighter and public safety due to management accomplished by other landowners may affect wildland fire management on public lands. When activity fuels (such as logging slash) are not treated adequately, fuel hazard could increase on adjacent lands which could affect fire intensity and severity on public lands. When adjacent owners treat fuels or implement fire mitigation plans in the WUI, fires are easier to suppress and firefighter safety is increased. In the Boulder/Jefferson City TPA, activities on private lands (32 percent of all lands in TPA) would have more influence on future fire characteristics in the area overall than activities on BLM lands (17.7 percent of all lands in TPA).

Human population increases and subsequent residential development are likely to expand the WUI and could alter forest management, taking the emphasis off restoring historic composition and structure and focusing more on fuel reduction.

## CULTURAL AND PALEONTOLOGICAL RESOURCES

### Effects Common to All Alternatives

Alternative-specific risks or impacts to cultural and paleontological resources are difficult to discern due to a lack of extensive site-specific knowledge about the presence of these resources in a given TPA. By designating open routes, limiting open-country travel, and closing some routes, inadvertent discovery of cultural and pa-

leontological resources and vandalism to them is reduced. Higher road densities in a given area would allow greater access to more land on the average, but that does not imply greater amounts of vandalism, since the vehicles would remain on designated routes.

## VISUAL RESOURCES

### Effects Common to All Alternatives

Roads (temporary or permanent) may affect visual quality. Roads that remain open for public use may impact visual qualities where noticeable. The quantity of open roads would also influence sensitivity levels since with more open roads, more areas would generally be viewed by more members of the public. Closing or decommissioning roads would generally reduce effects to visual resources and reduce sensitivity levels because fewer members of the public would generally be accessing and viewing areas with closed roads.

### Effects of the Alternatives

Under Alternative A, approximately 158.6 road miles would remain open (including open with seasonal restrictions), while 7.4 miles would remain closed. This alternative would leave the greatest mileage of open roads and would have the greatest level of impact to visual resources of all alternatives.

Under Alternative B, there would be 84.8 miles of open road (including open with seasonal restrictions), 49.2 miles of closed road, and 27.7 miles of decommissioned road. Road closures and decommissioning under this alternative would reduce effects on visual resources compared to Alternative A.

Under Alternative C, there would be 60 miles of open road (including open with seasonal restrictions), 69.3 miles of closed road, and 33.5 miles of decommissioned road. Alternative C would have fewer adverse effects and would improve visual resources the most of all alternatives.

Under Alternative D, there would be 97.4 miles of open road (including open with seasonal restrictions), 33.2 miles of closed road, and 25.7 miles of decommissioned roads. Alternative D would improve visual resources compared to Alternative A, but would have more adverse effects than Alternatives B and C.

### Cumulative Effects on Visual Resources

Under all alternatives, most activities on BLM lands would generally not adversely affect visual resources to unacceptable degrees because discretionary activities on BLM lands would be required to meet Visual Resource Management objectives within individual project areas.

Activities on non-BLM lands, particularly activities near BLM lands associated with residential development, urbanization, additional mining, or vegetation management, could have adverse cumulative effects on visual

resources on BLM lands because BLM VRM objectives would obviously not apply to non-BLM activities.

## LIVESTOCK GRAZING

### Effects Common to All Alternatives

Roads and trails can potentially affect livestock grazing management. Roads and trails often act as avenues of noxious weed spread. Noxious and invasive weeds can reduce the quantity and quality of forage. Users of roads and trails can cause management problems for livestock permittees when they leave gates open at fences, vandalize range improvements, or harass livestock purposely or unintentionally.

Closure of roads and trails can improve or maintain the forage base by reducing vectors of noxious weed spread. Additionally, road and trail closures can reduce management conflicts. On the other hand, closures may increase permittees' time requirements if and when work has to be conducted with horses or afoot. Permittees could minimize effects of closed roads on grazing management time by seeking variances from the BLM for temporary use of specific closed roads.

### Effects of the Alternatives

Under Alternative A, 158.6 miles of BLM roads and trails would remain open during the grazing season, and 7.4 miles of roads and trails would be closed. The effects would continue as described above. All action alternatives would close or decommission more roads and trails than Alternative A. As more roads and trails are closed, noxious and invasive weed spread along with multiple user conflicts would be reduced. On the other hand, permittee management time may increase. Consequently, more effects as described under the Effects Common to All Alternatives section would occur under Alternative C (60 miles open during grazing season, 102.8 miles closed or decommissioned) than under any other alternative. Alternative B (80.9 miles open during grazing season, 79.9 miles closed or decommissioned) would produce fewer effects than Alternative than C, but more than Alternative A or Alternative D (97.4 miles open during grazing season, 58.9 miles closed or decommissioned). Alternative D would have fewer effects than Alternatives B or C, but more than Alternative A.

### Cumulative Effects on Livestock Grazing

A number of past, present, and reasonably foreseeable future actions affect livestock grazing at the scale of the entire Upper Big Hole River TPA. Livestock grazing will continue in the area and has the potential to impact forage quality and quantity. On public lands, ongoing rangeland health assessments and implementation of livestock grazing guidelines would continue to improve or maintain forage quality and quantity. On private

lands, livestock grazing is expected to decline slowly as more ranch and farmland is subdivided.

Noxious weed control will continue on both public and private lands with varying degrees of success. To the extent that these efforts are successful, forage conditions would benefit.

The Big Hole Watershed group has completed a number of projects to improve livestock grazing, weed control, and irrigation practices on private land. Livestock grazing management would improve correspondingly.

The fuels reduction project scheduled for the Wise River area is not anticipated to have any major effects on livestock grazing. Reduction of conifers in meadows and parks would improve forage production for livestock. Some allotments may require growing season rest for one to two years after treatments are completed.

Because BLM lands make up only 17.7 percent of all lands in the Upper Big Hole River TPA, all of the BLM travel plan alternatives would have a minor contribution to cumulative effects on livestock grazing at the scale of the entire TPA.

## MINERALS

### Effects Common to All Alternatives

Road closures and decommissioning could affect access to locatable minerals in areas of moderate or high mineral potential. Operators would be required to seek travel variances from the BLM to use motor vehicles to conduct mineral exploration on closed roads, or to conduct exploration on seasonally restricted routes during the season of closure. Decommissioned roads could not be used for motorized exploration. Travel management provisions that require a permit or variance could result in reducing access to mining claims or interfere with the ability to conduct exploration work for some operators. Historic knowledge of mineralized areas associated with "closed" roads may be lost after long periods of time if no exploration occurs there. Additional costs and time could be required for exploration and development of mining projects associated with closed or decommissioned roads. Impacts of road closures or decommissioning in areas with low mineral potential would not be substantial to mineral development.

### Effects of the Alternatives

Alternative A for the Upper Big Hole TPA would seasonally restrict access on 18 percent of the roads in areas with high mineral potential and 6 percent of those in moderate mineral potential areas (**Table 4-94**).

Alternative B for the Upper Big Hole TPA would seasonally restrict access on 14 percent, close 8 percent, and decommission 3 percent of the roads in areas with high mineral potential. Additionally this travel plan alternative would seasonally restrict access on 4 percent and

<b>Table 4-94</b>				
<b>Analysis of Access to Mineral Potential Areas</b>				
<b>Upper Big Hole River TPA</b>				
<b>Mineral Potential</b>	<b>Open Miles (%)</b>	<b>Seasonally Restricted Miles (%)</b>	<b>Closed Miles (%)</b>	<b>Decom Miles (%)</b>
<b>Alternative A</b>				
High	17.8 (11%)	29.8 (18%)	0.8 (0%)	0.0 (0%)
Moderate	10.2 (6%)	10.2 (6%)	0.1 (1%)	0.0 (0%)
Low	41.8 (25%)	48.0 (29%)	6.5 (4%)	0.0 (0%)

<b>Alternative D</b>				
High	8.9 (5%)	26.3 (16%)	9.3 (6%)	4.0 (2%)
Moderate	4.2 (3%)	7.9 (5%)	7.5 (4%)	0.9 (1%)
Low to none	12.2 (7%)	47.0 (28%)	16.4 (10%)	20.7 (13%)
Total Miles = 165.3				

Mineral Potential areas have been delineated by the Montana Bureau of Mines and Geology (MBMG)

close 7 percent of roads in areas with moderate mineral potential in this TPA (Table 4-94).

Alternative C for the Upper Big Hole TPA would seasonally restrict access on 7 percent, close 16 percent, and decommission 3 percent of the roads in areas with high mineral potential. Additionally this alternative would seasonally restrict access on 4 percent, close 5 percent, and decommission 3 percent of roads in areas with moderate mineral potential in this TPA (Table 4-94).

Alternative D in the Upper Big Hole TPA would seasonally restrict access on 16 percent, close 6 percent, and decommission 2 percent of the roads in areas with high mineral potential. Additionally this alternative would

seasonally restrict access on 5 percent, close 4 percent, and decommission 1 percent of roads in areas with moderate mineral potential in this TPA (Table 4-94).

## Cumulative Effects on Access to Mineralized Areas

No other past, present, or reasonably foreseeable future actions in the Upper Big Hole River TPA would adversely affect mineral availability or access.

## RECREATION

Effects of travel plan alternatives on Recreation in the Upper Big Hole River TPA are described qualitatively below.

### Effects of the Alternatives

Under Alternative A, all BLM routes located within the TPA would continue to be managed as indicated on the Southwest Montana Interagency Visitor/Travel Map (interagency cooperative mapping effort, 1996 revision). Alternative A provides 158.6 miles of routes open to wheeled motorized use (70.6 miles open yearlong, 88.0 miles seasonally restricted). Where allowed, snowmobile use would continue to be open to area-wide cross-country use as well as use on existing routes, during the season of use, 12/2-5/15, conditions permitting.

Under Alternative B, motorized travel opportunities would be decreased by about 50 percent while non-motorized opportunities would be enhanced and conflicts between users would be reduced. Effects of Alternative C would be similar to Alternative B with the exception that 22 additional miles of roads would be closed and snowmobile use would be limited to designated routes only. This alternative would reduce motorized recreation opportunities while non-motorized opportunities would be most enhanced of all alternatives. Impacts of Alternative D would be similar to those of Alternative A with the exception that fewer secondary roads would be available to motorized travel.

### Cumulative Effects on Recreation

Under Alternative A, motorized travel opportunities would be the greatest under this alternative given the miles of roads available to wheeled vehicles and the acres available to snowmobiles. Big game hunting opportunities and motorized access within the Sawlog Gulch, Jerry Creek-Johnson Creek, Tie Creek, Dickie Hills, Sawmill, Humbug Spires/McClain Creek, and Soap/Camp Creek areas would continue. Existing travel restrictions in these areas would encourage big game retention, quality walk-in hunting and game retrieval challenges as motorized vehicle use would be somewhat limited. During the non-hunting season conflicts between non-motorized and motorized users would remain relatively high within some areas. Public access and management of developed recreation sites along the Big Hole River would continue to provide for a wide spec-

trum of water based opportunities and visitor trends are expected to increase. The Upper Big Hole Special Recreation Area and plan would continue and management priorities would remain high. The state would continue lead management responsibilities for the river and quality fishing and floating opportunities will continue subject to water flow conditions.

Under the action alternatives, big game hunting opportunities within the TPA would continue for both motorized and non-motorized users as the primary access routes would remain. Additional travel restrictions of secondary and primitive roads in numerous areas would promote more big game retention on public lands and better walk-in hunting experiences. Game retrieval challenges would be increased in many portions of the TPA since fewer retrieval roads would be available. Recreation Opportunity Spectrum designations would be established and therefore a range of varied settings would be provided and maintained. Although available travel routes and motorized riding opportunities would be limited, access to higher elevation lands and quality walk-in areas would be retained to help disperse users and ensure natural settings. Cumulative impacts on developed recreation sites and water based activities would be similar to Alternative A.

## TRAVEL MANAGEMENT AND ACCESS

### Effects of Alternative A

BLM routes in the Upper Big Hole River TPA would continue to be managed as both open yearlong (70.6 miles) and open with seasonal restrictions (88 miles) (Table-4-95). Alternative A would provide the greatest amount of motorized use opportunities and the least amount of non-motorized opportunities of all the alternatives.

Proposed Management	Total Miles			
	Alt A	Alt B	Alt C	Alt D
<b>Wheeled motorized routes</b>				
Open Yearlong	69.9	26.9	19.2	26.8
Seasonally Restricted	88.0	57.9	40.8	70.6
Closed	7.4	49.2	69.3	33.2
Decommissioned	-	27.7	33.5	25.7
Non-motorized trails <sup>1</sup>	11.5	81.0	106.9	62.9

<sup>1</sup> Non-motorized trails include all existing trails, closed roads, and decommissioned roads.

Where allowed, snowmobile use would continue to be open to area-wide cross-country use as well as use on existing routes, during the season of use, 12/2-5/15, conditions permitting. Alternative A would provide the most miles of routes available to seasonal snowmobile users and the greatest opportunity for motorized winter use

while providing the fewest opportunities for non-motorized winter recreation of all alternatives.

The extent of management activities and costs under Alternative A would be mixed. Less personnel time would be required to monitor travel compliance than under the action alternatives. However, more effort would be required for initial implementation (signing designated routes, installing bulletin boards) than under the action alternatives. Estimated costs for road/trail maintenance would be highest of all alternatives.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be minimal under this alternative, given the availability of motorized access.

### Effects of Alternative B

Approximately 50 percent fewer route miles would be open to wheeled motorized access yearlong or seasonally restricted than under Alternative A (Table-4-95).

Snowmobile management would continue to remain substantially in effect as represented by the 1996 Southwest Interagency Visitor/Travel Map. However, several additional areas would be closed to cross country travel, and travel in other areas would be restricted to existing designated routes and trails. Proposed cross country closures include the area located between the Soap Gulch and Camp Creek roads, the Goat Mountain/Maiden Rock area, and the Sawmill Gulch/Nez Perce Ridge area. The proposed closures would have little impact on snowmobile use due to the poor snow conditions in these areas.

Route restrictions/closures that would enhance recreational opportunities include: enhancement of high-elevation hunting in the Humbug Spires area; road density reduction in the Nez Perce Creek road area that would enhance non-motorized recreation, as well as provide big game security; and restricting motorized vehicle crossings of the Big Hole River from 12/2-7/15 in the Sawlog Gulch (Fishtrap Creek area). The river crossing restriction would help enhance non-motorized recreational experiences as well as provide improved public safety.

The extent of management activities and costs under Alternative B would be mixed. Less personnel time would be required for initial implementation (signing designated routes, installing bulletin boards) than under Alternative A. However, more effort would be required for public education and compliance than under Alternative A. Estimated costs for road/trail maintenance would be less than under Alternative A.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would increase under Alternative B compared to Alternative A.

## Effects of Alternative C

Alternative C would have the least number of wheeled motorized routes open yearlong or seasonally restricted than all other alternatives in the Upper Big Hole River TPA (**Table-4-95**). This would result in fewer opportunities for motorized users. Alternative C would have 62 percent fewer motorized miles than Alternative A, and 30 percent fewer miles than Alternative B.

For areas open to snowmobile use under the Southwest Montana Interagency Visitor/Travel Map, travel would be restricted to designated routes only. No cross-country travel would be allowed. Alternative C would provide the lowest level of opportunities for snowmobile use.

Route closures that would enhance non-motorized opportunities include: additional yearlong closures between Soap Gulch and Camp Creek travel corridors (Humbug Spires area), additional yearlong closures near Johnson and Jerry Creeks (Jimmie New Creek area), and closure of the Sawlog Gulch route (Fishtrap Creek area).

Closing the Sawlog Gulch route (Fishtrap Creek area) would provide for improved public safety by eliminating fording of the Big Hole River.

Closure and decommissioning of routes in the Upper Big Hole River TPA would result in more non-motorized opportunities under Alternative C than under any other alternative. Alternative C would have 89 percent more miles of non-motorized trails than Alternative A, and 46 percent more than Alternative B.

The extent of management activities and costs under Alternative C would be mixed. Less personnel time would be required for initial implementation (signing designated routes, installing bulletin boards) than under any alternative. However, more effort would be required for public education and compliance than under any other alternative. Estimated costs for road/trail maintenance would be the lowest of the alternatives.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be greater under Alternative C than under any other alternative.

## Effects of Alternative D

Alternative D would offer the highest level of motorized access of the action alternatives with 97.4 miles of open and seasonally restricted routes (**Table-4-95**). This would be 38 percent less than Alternative A, but 13 and 38 percent more than under Alternatives B and C, respectively.

Conversely, Alternative D would provide fewer opportunities for non-motorized use than Alternatives B and C. Route closures under Alternative D that would enhance user opportunities include: additional routes in the Humbug Spires area and adjusting existing seasonal route restrictions to allow for high elevation big game

hunting access; additional routes for the Jimmie New Creek area, including game retrieval routes; and a seasonal closure on Sawlog Gulch (Fishtrap Creek area) that could enhance non-motorized opportunities.

For the Sawlog Gulch/Fishtrap Creek area, motorized access would be managed the same as under Alternative B, with a seasonal closure from December 2 to July 15. This change would provide for improved public safety from fording the Big Hole River during periods of high river flows and enhanced non-motorized opportunities.

The Big Hole watershed would be a priority area for restoration and protection treatments. Vegetation treatments could impact user opportunities and create user conflicts, depending on the timing and duration of the treatments.

Snowmobile management and effects would be the same as under Alternative A.

The extent of management activities and costs under Alternative D would be mixed. Less personnel time would be required to monitor travel compliance than under Alternatives B and C, but more time would be needed than under Alternative A. However, more effort would be required for initial implementation (signing designated routes, installing bulletin boards) than under Alternatives B and C, but less effort would be needed than under Alternative A. Estimated costs for road/trail maintenance would be higher than the other action alternatives, but less than under Alternative A.

The need for the BLM and members of the public to obtain travel variances for temporary specific uses of specific closed roads would be greater under Alternative D than under Alternative A, but less than under Alternatives B and C.

## Cumulative Effects on Travel Management and Access

Under all alternatives there are a number of past, present, and reasonably foreseeable future BLM and non-BLM actions and activities affecting travel management and access in the Upper Big Hole River TPA.

The majority of the Upper Big Hole River TPA is characterized by undeveloped land (cattle ranches; BLM, State, and USFS lands). Only about 2,000 people live in the area, many of them making their living by ranching and hay farming. Human population growth for the TPA is expected to remain low. However, as the area becomes more populated, there could be increased public pressure to alter the travel management to accommodate more or less motorized use.

The TPA is largely undeveloped. Several small communities (Divide, Dewey, and Wise River) are located within the TPA; Melrose and Wisdom lie just outside. The extent of urbanization is low, only about 2,000 people live in the area. Urbanization is unlikely to become an issue for many years in this area.

Recreation use is well established in the TPA, with fishing and big game hunting topping the list. The Big Hole River has a national reputation as a premiere fly fishing destination. Big game hunting attracts regional and national attention as well. As recreation use grows, conflicts between non-motorized and motorized recreation users could lead to increased public demands for either more, or less motorized use.

The TPA includes important habitat for big game (elk, bighorn sheep, mule deer) and fisheries (last wild population of fluvial Arctic grayling). Concerns could lead to demands to restrict motorized use.

The Humbug Spires WSA, Humbug Spires Potential ACEC, and Upper Big Hole River Eligible WSR segment are located within the TPA. These special designations could influence (restrict) travel management for existing roads and trails as well as for new proposed roads and trails.

In some site specific cases, visual resource management may affect or restrict new road construction.

Applications for right-of-way permits to access private property or for commercial development are likely to increase in the future. As a result, public access to BLM lands, via the rights-of-way, could increase as well.

Limits or reductions in the BLM's funding and ability to maintain designated routes could lead to an overall reduction of maintained motorized routes.

A variety of resource management projects, such as BLM initiated vegetation treatments, or wildland fire fuels reduction projects, could affect travel management. BLM forest management activities from 1984 to present include 126 acres of forest planting and 246 acres of timber harvest. Future activities may include approximately 430 acres of forest and woodland treatment (thinning, selective harvest). Past wildland fire management activities include treatments of 474 acres of prescribed fire and 141 acres of mechanical treatments in the Jerry Creek and Dickie Hills areas. Future treatments would include the Highland Mountain and the Wise River projects. The Highland Mountain project will entail 2,087 acres of mechanical treatment and 2,659 acres of prescribed fire treatment starting in 2007 through 2012. The Wise River project (currently being planned) will consist of mechanical and/or prescribed fire treatments ranging from 500-2,000 acres, focused on the urban interface areas. Depending on the type and scope of project, effects could vary from temporary, short-term area/route closures, to new opportunities (new routes) for motorized or non-motorized access.

A portion of this TPA is highly mineralized, particularly in the Soap Gulch/Camp Creek area. Current mining activity is low. Increases in mineral prices, however, could lead to additional increased or renewed mining activity. Depending on the type and scope of mining activity, effects on travel planning could vary from tem-

porary, short-term area/route closures, to increased opportunities (new routes) for motorized or non-motorized access.

Noxious weeds and non-native invasive species are well established and spreading rapidly in the TPA. Motorized activities play a large role in the distribution of noxious weeds. Concerns over the spread of noxious weeds may lead to the need to impose motorized travel restrictions or closures.

Motorized use on dirt roads and trails is a major contributor to soil erosion and stream sedimentation. These concerns may influence travel management, and result in fewer motorized opportunities.

Most illegal activities (trash dumping, drug use, underage alcohol use, unattended camp fires, vandalism, etc.) are directly associated with motorized use. Increases in illegal activity may lead to a need to alter travel management and impose motorized travel or other restrictions (site specific management).

For perspective, BLM managed lands represent approximately 17.7 percent of the total travel planning area (357,275 total acres, 63,108 BLM acres); while BLM managed routes represent approximately 12.6 percent of the total routes available (1,309 total miles, 165 miles of BLM roads/trails). Future travel management (for all agencies, nationwide) is likely to lead to fewer opportunities for motorized recreational use than under current management (particularly for OHV use). As a result, BLM routes available to motorized use in this TPA could experience increased use from displaced users, eventually leading to more concentrated use, increased resource impacts, and user conflicts. These impacts could lead to demands from motorized users for additional routes, and conversely, demands from non-motorized users for fewer routes.

Under all alternatives, increases in human population, recreation use, user conflicts; and concerns for wildlife, fisheries resources, noxious weed spread, soil erosion/water quality, and illegal activities are likely to lead to increased conflicts associated with travel management. Under Alternative A, this may lead to increased demands to restrict motorized travel, particularly in the areas adjacent to Divide, Dewey, and Wise River. Under Alternative B, these pressures would have less impact on travel management than under Alternatives A and D, due to the overall reduction in motorized opportunities and separation of motorized and non-motorized uses. Under Alternative C, these pressures would likely have the least impact on travel management than under the other alternatives, due to the greatest reduction in motorized opportunities and separation of motorized and non-motorized uses of all alternatives. Under Alternative D, these pressures may lead to increased demands to restrict motorized travel, particularly in areas with urban development.

## TRANSPORTATION FACILITIES

For the sake of this discussion, “open” roads include roads that are open yearlong as well as those that are open with seasonal restrictions.

### Effects of Alternative A

Under Alternative A, the Upper Big Hole TPA would have 157.9 miles of open roads and no motorized trails (**Table-4-96**). Estimated costs for annual maintenance and stabilization of roads under Alternative A would be substantially higher than under any other alternative. Estimated annual costs for monitoring and compliance, and weed control would also be more than under the action alternatives.

### Effects of Alternative B

Under Alternative B, the Upper Big Hole TPA would have 80.9 miles of open roads and no motorized trails (**Table-4-96**). Estimated costs for annual maintenance and stabilization of roads under Alternative B would be more than two times less than under Alternative A, more than under Alternative C, and slightly less than under Alternative D due to the reduction in roads from current conditions. Estimated annual costs for monitoring, compliance, and weed control would also be much less than under Alternative A.

Effects to transportation facility management under Alternative B would result in increased costs associated with new signage and sign maintenance due to changing seasonal use restrictions in the Humbug Spires area, the reduction in road density in the Jimmie New Creek area, and restricting motorized access in the Sawlog Gulch area of Fishtrap Creek.

Closing additional portions of the Upper Big Hole TPA to cross-country snowmobile travel would also result in an increase in transportation facility costs for additional signage and sign maintenance.

### Effects of Alternative C

Under Alternative C, the Upper Big Hole TPA would have 60 miles of open roads and no motorized trails (**Table-4-96**). Estimated costs for annual maintenance

and stabilization of roads under Alternative C would be the least of all the alternatives due to the least number of motorized routes. Estimated annual costs for monitoring, compliance, and weed control would also be less than under the other alternatives.

Effects to transportation facility management under Alternative C would result in increased costs associated with new signage and sign maintenance due to route closures and seasonal restriction changes in the Humbug Spires area, route closures to reduce road density in the Jimmie New Creek area, and the year-long closure of the Sawlog Gulch area of Fishtrap Creek.

Changing portions of the TPA from an open designation to a limited designation for snowmobile use would result in increases costs associated with new signage and sign maintenance.

### Effects of Alternative D

Under Alternative D, the Upper Big Hole TPA would have 97.4 miles of open roads and no motorized trails (**Table-4-96**). Estimated costs for annual maintenance and periodic stabilization of roads under Alternative D would be about half the cost as under Alternative A due to a reduction in motorized access. Road maintenance would be higher under Alternative D than under either Alternative B or C. Estimated annual costs for monitoring, compliance and weed control would also be much less under Alternative D than under Alternative A, and more than under Alternatives B and C.

Transportation facility costs under Alternative D would increase due to new signage and sign maintenance required in the Humbug Spires area, Jimmie New Creek area, and the Sawlog Gulch area of Fishtrap Creek.

## LANDS AND REALTY

### Effects Common to All Alternatives

The Butte Field Office administers approximately 122 rights-of-way within the boundaries of the Upper Big Hole TPA, which encumber approximately 6,805 acres of BLM land (**Table 4-97**). Various types of road rights-of-way (ROW) are the most common type of grant, ac-

<b>Classification/Cost</b>	<b>Alt A</b>	<b>Alt B</b>	<b>Alt C</b>	<b>Alt D</b>
Miles of Open/Restricted Roads	158.6	80.9	60	97.4
Motorized Trails	0	0	0	0
Annual Road Maintenance	\$12,632	\$6,472	\$4,800	\$7,792
Annual Trail Maintenance	\$0	\$0	\$0	\$0
Periodic Road Stabilization	\$5,053	\$2,589	\$1,920	\$3,117
Periodic Trail Stabilization	\$0	\$0	\$0	\$0
Monitoring/Compliance	\$7,895	\$4,045	\$3,000	\$4,870
Weed Control	\$2,369	\$1,214	\$900	\$1,461

counting for 57 percent, or over half of the total. Other types of authorized uses include: oil and gas pipelines, lines for electrical distribution and telephone facilities, communication sites, ditches, railroads, and mineral material sites.

Type	Approximate Number	Approximate Acres
Roads	70	2,907
Power	20	865
Telephone	4	45
O&G Pipelines	1	2
Comm. Sites	0	0
2920 Leases	0	0
Other	27	2,986
<b>Totals</b>	<b>122</b>	<b>6,805</b>

Approximately one right-of-way application for new facilities as well as amendments, assignments, renewals, or relinquishments of existing right-of-way grants are processed annually in the TPA. This would not vary by alternative.

The general trend of granting rights-of-way is expected to increase through the planning period as a result of increasing public demands. From a cumulative effects standpoint, development of adjacent federal, state, and private land, increased recreational use and the trend of homeownership away from urban areas, coupled with traditional on-going uses, are all expected to require more guaranteed access involving public land, including BLM lands.

## SPECIAL DESIGNATIONS

There would be no effects to any special designation areas such as Wild and Scenic Rivers, Wilderness Study Areas, or Areas of Critical Environmental Concern under any of the travel plan alternatives for the Upper Big Hole River TPA.

## CUMULATIVE EFFECTS OF TRAVEL PLANS AT THE PLANNING AREA SCALE

This section discusses cumulative effects of the five site-specific travel plans in aggregate at the level of all BLM lands in the Butte Field Office (Decision Area), as well as (to the extent possible) all lands in the entire Planning Area regardless of ownership. Effects of activities on BLM lands must be considered in the context of the fact that the approximately 307,300 acres of BLM surface lands administered by the Butte Field Office make up about 4.2 percent of the approximate total of 7,191,181

acres of land in the Planning Area. For the sake of context, total road miles in the Planning Area have been calculated based on available GIS data as approximately 17,810 miles. This figure is an underestimation of total road miles and should be considered a minimum. Total road mileage on Butte Field Office lands is estimated at 856 miles, or 4.8 percent of all roads in the Planning Area based on the 17,810 mile figure. Private lands make up about 49 percent of all lands and 64 percent of all roads are on private lands in the Planning Area. References to effects in this section tie back to effects described for a particular resource or resource use under the TPA-specific discussions.

No additional cumulative effects to Minerals, Lands and Realty, Cultural and Paleontological Resources, or Special Designations associated with the five site-specific travel plans have been identified at the Decision Area or Planning Area scales beyond those discussed in the cumulative effects section for the RMP.

## AIR QUALITY

Contributions of BLM travel plan management to cumulative effects on air quality would be minor regardless of alternatives selected in final implementation decisions because BLM roads make up only 4.8 percent of all roads in the Planning Area. Alternative A would promote the most widespread contributions to airborne dust due to the greatest (and most dispersed) mileage of open roads. Alternative B would lessen this impact by virtue of closing or decommissioning 199 more road miles than under Alternative A. Alternative C would lessen the distribution of airborne dust the greatest of all alternatives by providing for closure or decommissioning of 253 more road miles than Alternative A. Alternative D would be intermediate between Alternatives A and B by providing for closure or decommissioning of 138 more road miles than Alternative A.

Vehicle emissions may be reduced somewhat accordingly as described above for airborne dust. However, it is unknown whether proposed road closures associated with action alternatives would markedly affect motorized use levels, or whether proposed closures would merely redistribute use to other areas or focus it more intensively on remaining open routes.

## SOILS

Under current conditions (Alternative A), approximately 172 miles of motorized routes mapped on the BLM transportation system would remain closed. Generalized impacts to soil resources described above for each TPA (and in "Effects Common to All Alternatives" sections) would reduce over time on these routes as they revegetate and soils stabilize. These routes represent about 20 percent of the approximately 856 BLM road miles, and 1.0 percent of the at least 17,810 road miles across all ownerships in the entire Planning Area.

Alternative B would close (318 miles) or decommission (53 miles) approximately 371 miles of routes in the Decision Area currently open to use by motorized vehicles, the second most of any alternative. These routes represent about 43 percent of the approximately 856 BLM road miles in the Decision Area, and 2.1 percent of the at least 17,810 road miles across all ownerships in the entire Planning Area. This reduction in ground disturbance should reduce adverse effects on soils more than under Alternatives A and D, but less than under Alternative C.

Alternative C would close (375 miles) or decommission (50 miles) approximately 425 miles of routes currently open to use by motorized vehicles. These routes represent about 50 percent of the approximately 856 BLM road miles in the Decision Area, and 2.4 percent of the at least 17,810 road miles across all ownerships in the entire Planning Area. This reduction in ground disturbance associated with motorized routes would reduce impacts to soils more than under other alternative.

Alternative D would close (266 miles) or decommission (44 miles) approximately 310 miles of routes currently used by motorized vehicles. These routes represent about 36 percent of the approximately 856 BLM road miles in the Decision Area, and 1.7 percent of the at least 17,810 road miles across all ownerships in the entire Planning Area. This reduction in ground disturbance would benefit soils more than in Alternative A, but less than in Alternatives B and C.

## WATER RESOURCES

Under current conditions (Alternative A) approximately 172 miles of motorized routes, mapped on the BLM transportation system for the entire Decision Area, would remain closed. Over time, erosion and sediment delivery would likely be reduced as these closed routes revegetate and soils stabilize.

Alternative B would close (318 miles) or decommission (53 miles) approximately 371 miles of routes in the Decision Area currently open to use by motorized vehicles, the second most of any alternative. This reduction in ground disturbance would reduce soil erosion, promote vegetative recovery, and should produce a moderate to high long-term benefit to water quality (compared to the current conditions).

Alternative C would close (375 miles) or decommission (50 miles) approximately 425 miles of routes in the Decision Area currently open to use by motorized vehicles. This reduction in ground disturbance associated with motorized routes would reduce impacts to water quality (primarily sedimentation) more than with any other alternative.

Alternative D would close (266 miles) or decommission (44 miles) approximately 310 miles of routes in the Decision Area currently used by motorized vehicles. This reduction in ground disturbance would reduce soil ero-

sion and should provide a moderate to high long-term benefit to water quality (compared to current conditions). However, the improvement would be less than under Alternatives B and C.

Generally, road density is an indicator of overall watershed health and function. Watersheds with higher road densities tend to have lower water quality due to greater potential for erosion and subsequent sedimentation. Of all the alternatives, Alternative A maintains the most BLM acres in the entire Decision Area with high road density (107,566 acres with greater than 2 mi/mi<sup>2</sup> road density) and the fewest acres with low road density (116,236 acres with less than 1 mi/mi<sup>2</sup> road density (Table 4-98).

Alternative B would result in more acres with low road density across the Decision Area (131,982 acres with less than 1mi/mi<sup>2</sup> road density) compared to Alternative A (116,236 acres) and Alternative D (123,073 acres), but less than Alternative C (141,264 acres). In the moderate road density category (1 to 2 mi/mi<sup>2</sup> road density), Alternative B would produce over 4,000 more acres of this category compared to Alternative A. Alternative B would result in almost 20,000 acres less in the high road density category (greater than 2 mi/mi<sup>2</sup> road density) than Alternative A. This would represent a reduction in risks and adverse effects to water resources associated with watershed conditions, from the current management situation.

Across all Decision Area lands, Alternative C would provide the most acres with low road density (141,264 acres with less than 1 mi/mi<sup>2</sup> road density) compared to all other alternatives (Table 4-98). This represents 25,000 more acres than currently exists. Alternative C would also produce the fewest acres with high road densities (road density greater than 2 mi/mi<sup>2</sup>) of all alternatives (26,000 fewer acres than current conditions). Of the action alternatives, Alternative C would produce 6,500 fewer acres of high road density compared to Alternative B and 14,300 less than Alternative D. This would indicate a lower risk to water quality under Alternative C than under the other alternatives.

**Table 4-98**  
**Acres of BLM Land in Road Density Categories by Alternative for all Decision Area Lands**

Alternative	Road Density Category		
	Low ( <1 mi/mi <sup>2</sup> )	Moderate ( 1 to 2 mi/mi <sup>2</sup> )	High ( > 2 mi/mi <sup>2</sup> )
<b>Alt. A</b>	116,236	78,175	107,566
<b>Alt. B</b>	131,982	82,267	87,729
<b>Alt. C</b>	141,264	79,516	81,196
<b>Alt. D</b>	123,073	83,424	95,481

Alternative D would result in more areas with low road densities than currently exists (123,073 acres versus 116,236 acres with Alternative A). However, it would have the least among the action alternatives. It would also provide a reduction in the amount of area with high road density (greater than 2 mi/mi<sup>2</sup> road density) from current conditions (95,481 acres versus 107,560 acres for Alternative A). However, this would be the lowest reduction among the action alternatives. These road densities suggest that this alternative would pose a reduced risk (to water quality) from current conditions, but the highest among the action alternatives.

Motorized routes within 300 feet of streams generally have greater potential to impact water quality through erosion and sedimentation, increased water temperatures (due to loss of shading vegetation), and direct alteration of stream channel morphology than those farther away. Under Alternative A, approximately 94.3 miles of motorized routes within 300 feet of streams (including intermittent streams) would remain open to motorized use Decision Area-wide. This is the highest of any alternative and represents the greatest threat to water quality associated with motorized routes of the alternatives.

Under Alternative B, approximately 77.4 miles of motorized routes within 300 feet of streams (including intermittent streams) would remain open to motorized use Decision Area-wide. This is less than with Alternatives A and D (94.3 miles and 81.2 miles, respectively), but more than with Alternative C (73.7 miles). Alternative B would pose the second lowest threat to water quality (associated with roads in and near riparian areas) of all alternatives. It would also represent an improvement over existing conditions.

Under Alternative C, approximately 73.7 miles of motorized routes within 300 feet of streams (including intermittent streams) would remain open to motorized use Decision Area-wide. This is less than with any other alternative and would represent a reduction of 21.6 miles from current conditions. Therefore, Alternative C would pose the lowest threat to water quality associated with roads in and near riparian areas of all alternatives.

Under Alternative D, approximately 81.2 miles of motorized routes within 300 feet of streams (including intermittent streams) would remain open to motorized use Decision Area-wide. This is 13.1 miles less than are currently open but would leave more miles open than under Alternatives B and C. As a result, Alternative D would pose the second greatest threat to water quality related to roads in and near riparian areas of all alternatives (but it would still represent an improvement over current conditions).

Overall, from a roads management standpoint, Alternative C would pose the greatest improvement to water resources (and least contribution to adverse cumulative effects) of all the alternatives. Alternative B would be the next most beneficial, followed by Alternative D, then

Alternative A. At the Planning Area scale, effects to water resources associated with management of the 856 miles of road administered by the Butte Field Office would be minor in the cumulative effects context of the at least 17,810 road miles in the Planning Area overall.

## VEGETATIVE COMMUNITIES – FOREST RESOURCES AND FOREST AND WOODLAND PRODUCTS

Since BLM manages only 4.8 percent of the road miles in the Planning Area on the whole, the extent of cumulative effects from road management on BLM lands at the Planning Area scale is not great. However, federal and state public lands are used more extensively than other lands for firewood and other product gathering by the general public, as permission or a bill of sale is needed from landowners to gather products from private lands.

Effects referenced below tie back to effects of travel plan alternatives on forest resources and forest products described for each TPA-specific discussion above.

### Effects of Alternative A

As compared with the other alternatives, travel management under Alternative A provides the highest level of support for forest/woodland management and timber removal activities. There would be no impact on the forest and woodland treatments or the forest products program from travel management. Alternative A has the most miles of open road for economic efficiency, as well as to provide public access for small sales permits (firewood and Christmas trees in particular).

At the scale of all BLM lands managed by the Butte Field Office, Alternative A would retain closure on approximately 20 percent (172 miles) of the current total of approximately 856 road miles. No additional roads would be decommissioned with this alternative so all 172 miles of closed roads would be subject to potential use for vegetation treatments if travel variances for temporary road use were allowed.

### Effects of Alternative B

Travel management under Alternative B in the five TPAs being analyzed with this RMP revision, would provide an adequate level of support for the proposed forest management activities by maintaining approximately 84 percent of the existing roads in these TPAs shown under Alternative A as available for forest management and timber removal activities. While Alternative B would reduce the amount of open and limited use roads for the public by about 55 percent of the total roads available under Alternative A, travel variances could allow temporary use of “closed” roads for vegetation management projects. Road closures under Alternative B are expected to reduce the economic efficiency of some projects, as well as reduce by approximately one-half, public access for small sales permits (firewood and

Christmas tree) in these five TPAs. The maintenance costs for the closed roads would also be reduced, improving management efficiency in isolated areas which have limited product availability and low priority for vegetative treatment.

At the scale of all BLM lands managed by the Butte Field Office, Alternative B would close or decommission approximately 44 percent (371 miles) of the current total of approximately 856 road miles. Approximately 53 miles (6.2 percent of Field Office total) of the road miles across the Field Office would be decommissioned under this alternative. The remaining 318 miles of closed roads would be subject to potential use for vegetation treatments if travel variances for temporary road use were allowed. Alternative B would contribute to cumulative effects associated with making planning and implementation of vegetation treatment projects more costly and complex, as well as decreasing public access for forest product use more than Alternatives A and D, but less than Alternative C.

### Effects of Alternative C

Effects from proposed travel management under Alternative C in the five Travel Planning Areas (TPAs) being analyzed with this RMP revision, would be reduced when compared to Alternative B in spite of the fact that no construction of new permanent roads would be allowed for purposes of extracting forest products under Alternative C. Alternative C would maintain approximately 87 percent of the existing roads in the five TPAs under Alternative A, as available for forest management and timber removal activities. While Alternative C would reduce the amount of open and limited use roads for the public by about 67 percent of the roads available under Alternative A, travel variances could allow temporary use of “closed” roads for vegetation management projects. Road closures under Alternative C are expected to reduce the economic efficiency of some projects, as well as reduce by approximately two thirds, public access for small sales permits (firewood and Christmas tree) in these five TPAs.

At the scale of all BLM lands managed by the Butte Field Office, Alternative C would close or decommission approximately 49 percent (425 miles) of the current total of approximately 856 BLM road miles. Approximately 50.1 miles (5.8 percent of Field Office total) of the road miles across the Field Office would be decommissioned under this alternative. The remaining 375 miles of closed roads would be subject to potential use for vegetation treatments if travel variances for temporary road use were allowed. Alternative C would contribute the most of all alternatives to cumulative effects associated with making planning and implementation of vegetation treatment projects more costly and complex, as well as decreasing public access for forest product use.

### Effects of Alternative D

Effects from proposed travel management under Alternative D in the five Travel Planning Areas (TPAs) being analyzed with this RMP revision, would be similar to those described for Alternative C. Alternative D would maintain approximately 87 percent of the existing roads in the five TPAs under Alternative A, as available for forest management and timber removal activities. While Alternative D would reduce the amount of open and limited use roads for the public by about 39 percent of the roads available under Alternative A, travel variances could allow temporary use of “closed” roads for vegetation management projects. Road closures under Alternative C are expected to reduce the economic efficiency of some projects, as well as reduce by approximately 39 percent, public access for small sales permits (firewood and Christmas tree) and reduced ability to meet public demand in these five TPAs.

At the scale of all BLM lands managed by the Butte Field Office, Alternative D would close or decommission approximately 36 percent (310 miles) of the current total of approximately 856 road miles. Approximately 43.4 miles (5.1 percent of Field Office total) of the road miles across the Field Office would be decommissioned under this alternative. The remaining 267 miles of closed roads would be subject to potential use for vegetation treatments if travel variances for temporary road use were allowed. Alternative D would contribute to cumulative effects associated with making planning and implementation of vegetation treatment projects more costly and complex, as well as decreasing public access for forest product use, less than Alternatives B and C, but more than Alternative A.

### VEGETATIVE COMMUNITIES -NOXIOUS WEEDS

Effects of the five site-specific travel plans in aggregate at the Field Office scale are discussed below. In this discussion closed or decommissioned roads are considered to reduce impacts to the landscape associated with noxious weeds because they eliminate motorized vehicle use as a vector for increasing spread of noxious weeds.

Since BLM roads make up about 4.8 percent of all roads and BLM lands make up 4.2 percent of all lands in the Planning Area, effects of BLM travel planning alternatives on noxious weeds at the RMP Planning Area scale would be minor. Activities and effects discussed above for each TPA on private lands (49 percent of lands, 63 percent of roads) and other public lands (42 percent of lands, 29 percent of roads) would have a stronger influence on noxious weeds in the Planning Area with activities on private lands likely having the greatest effect overall.

## Effects of Alternative A

At the scale of all BLM lands managed by the Butte Field Office, Alternative A would retain closure on approximately 20 percent (172 miles) of the current total of approximately 856 BLM road miles. No additional roads would be decommissioned with this alternative. Alternative A would have the least positive contribution of all alternatives to cumulative effects on weeds by providing for the largest network of open BLM roads for weed spread. Weed spread would be greatest under this alternative than under all other alternatives.

## Effects of Alternative B

At the scale of all BLM lands managed by the Butte Field Office, Alternative B would close or decommission approximately 44 percent (371 miles) of the current total of approximately 856 BLM road miles. Alternative B would contribute positively to cumulative effects on noxious weeds by reducing open road miles from on which weed spread can occur. Under Alternative B these benefits would be greater than under Alternatives A and D, but less than under Alternative C. Alternative B would have higher weed treatment costs on a per road mile basis than Alternative A due to increased concentration of motorized use on fewer open road miles.

## Effects of Alternative C

At the scale of all BLM lands managed by the Butte Field Office, Alternative C would close or decommission approximately 49 percent (425 miles) of the current total of approximately 856 BLM road miles. Alternative C would contribute positively the most of all alternatives to cumulative effects on noxious weeds by promoting weed spread from fewer open roads than under any other alternative. Like Alternative B, Alternative C would have higher weed treatment costs on a per road mile basis than Alternative A due to increased concentration of motorized use on fewer open road miles.

## Effects of Alternative D

At the scale of all BLM lands managed by the Butte Field Office, Alternative D would close or decommission approximately 36 percent (310 miles) of the current total of approximately 856 BLM road miles. Alternative D would contribute positively to cumulative effects on noxious weeds by promoting less weed spread from roads less than Alternatives B and C, but more than Alternative A. Like Alternatives B and C, Alternative D would have higher weed treatment costs on a per road mile basis than Alternative A due to increased concentration of motorized use on fewer open road miles.

## VEGETATIVE COMMUNITIES – RIPARIAN VEGETATION

The following discussion summarizes contributions to cumulative effects on riparian vegetation associated with

BLM road management at the scale of all BLM lands in the Butte Field Office. Specific mechanisms of effect on riparian vegetation tie back to effects described for TPA-specific discussions above, particularly in the Effects Common to All Alternatives sections of those discussions. Since BLM roads make up about 4.8 percent of all roads and BLM lands make up 4.2 percent of all lands in the Planning Area, effects of BLM travel planning alternatives on riparian vegetation at the RMP Planning Area scale would be minor. Activities and effects discussed above for each TPA on private lands (48 percent of lands, 63 percent of roads in Planning Area) and other public lands (42 percent of lands, 29 percent of roads in Planning Area) would have a stronger influence on riparian vegetation in the Planning Area with activities on private lands likely having the greatest effect overall.

## Effects of Alternative A

Under Alternative A, Decision Area-wide, approximately 94.3 miles of routes within 300 feet of streams and wet areas would remain open to motorized use. While this is not a direct indication of road and trail effects on riparian vegetation, it is a relative indication when compared to the other alternatives. Alternative A would leave the greatest mileage of routes within 300 feet of streams open to motorized use of all alternatives.

## Effects of Alternative B

Under Alternative B, Decision Area-wide, approximately 77.4 miles of routes within 300 feet of streams and wet areas would remain open to motorized use. This would be less than under Alternative A (94.3 miles) and Alternative D (81.2 miles), but more than under Alternative C (73.7 miles), and suggests that Alternative B has the next-to-least amount of road-related impacts to riparian vegetation of the alternatives.

## Effects of Alternative C

Under Alternative C, Decision Area-wide, approximately 73.7 miles of routes within 300 feet of streams and wet areas would remain open to motorized use. This is the least of all alternatives and suggests that Alternative C would have the least road-related impacts (and most benefits) to riparian vegetation of all alternatives.

## Effects of Alternative D

Under Alternative D, approximately 81.2 miles of motorized routes within 300 feet of streams would remain open to motorized use Decision Area-wide. This is less than under Alternative A but more than under Alternatives B and C. This suggests that Alternative D would pose the next greatest amount of impact associated with roads to riparian vegetation of all alternatives.

## WILDLIFE

### Effects of Alternative A

Under Alternative A, there would be approximately 472 miles of open roads in the Decision Area and an additional 157.4 miles with seasonal closures. This is substantially more miles of open roads compared to the action alternatives. Limited road restrictions and road closures under Alternative A would not address the impacts of travel management within important wildlife habitat areas such as big game winter and calving habitat, occupied grizzly bear habitat, and wildlife movement corridors. Roads can result in loss of habitat and approximately 2-5 acres of habitat is permanently lost with every mile of road. Open roads cause disturbance and displacement of wildlife, especially to those species sensitive to disturbance, or during crucial seasons of use (winter or spring). Roads fragment habitat, introduce noxious weeds, and make wildlife susceptible to direct mortality (road kill and hunting).

#### Riparian Habitat

Roads within riparian areas can cause disturbance to wildlife and degradation of habitat. There could be a loss of habitat for resident and migratory birds that use riparian areas for nesting and brood rearing. In addition, habitat would be lost for a wide range of wildlife species that use riparian areas for breeding, denning, foraging, overwintering, or for travel corridors. The more roads within riparian areas, especially open roads, the lower the quality of habitat (through disturbance and loss of vegetation) and less likely the habitat would be used.

Riparian roads were evaluated within a 300-foot area adjacent to streams to compare the effects of roads in riparian areas between alternatives. Across Butte Field Office lands, there would be 94.3 miles of open roads and 17 miles of closed roads within riparian areas under Alternative A. This would be considerably more open

roads and fewer closed roads than under the action alternatives.

#### Elk Winter Range

Roads can impact big game species, especially during critical phases of their life cycle. Disturbance and displacement of big game species can increase stress and energy demands of animals during critical periods such as the winter, breeding or calving seasons, and reduce survival, especially during the winter and spring months. Motorized use of roads can produce disturbance that prevents full utilization of available habitat. The losses in potential use of habitat can exceed 50 percent when open road densities exceed 2 mi/mi<sup>2</sup> (Christensen et al. 1993). During the hunting season, the probability of bull elk survival in areas close to open roads is much lower than in areas away from roads. Road kill causes direct mortality of elk and major interstate freeways may act as movement barriers in some cases.

**Table 4-99** displays road densities in big game winter range by big game analysis areas (distinct geographic locations based on winter range and Elk Management Units) in the entire Decision Area (all Butte Field Office lands).

Alternative A would have the highest road density in comparison to the action alternatives. Of the 11 Big Game Analysis Units, five of them would have more acres with high road density than moderate or low road densities (Big Belts, Blackfoot, Clancy, Granite Butte and Jefferson) (**Table 4-99**). Three Big Game Analysis Units (Clancy, Granite Butte and Jefferson) offer large acres of potential winter range within the Decision Area but the quality of this habitat is low due to high open road densities under Alternative A. Winter range would be greatly improved in these three Big Game Analysis Units with the reduction of road densities under Alternatives B and C and moderately to greatly improved with a reduction of road densities under Alternative D.

<b>Elk Winter Range Analysis Unit</b>	<b>Acres of Low Density (0-1 mi/mi<sup>2</sup>)</b>	<b>Acres of Moderate Density (1-2 mi/mi<sup>2</sup>)</b>	<b>Acres of High Density (&gt;2 mi/mi<sup>2</sup>)</b>
<b>Big Belts</b>	2,193	2,207	2,288
<b>Big Hole</b>	12,958	4,504	5,554
<b>Blackfoot</b>	49	76	320
<b>Clancy</b>	1,547	2,159	7,148
<b>Elkhorns</b>	16,225	8,515	4,631
<b>Granite Butte</b>	1,932	3,886	11,881
<b>Highlands</b>	14,871	6,205	5,333
<b>Jefferson</b>	13,059	7,003	13,317

Low Density - (0-1mi/mi<sup>2</sup>), Moderate Density - (1-2 mi/mi<sup>2</sup>), High Density - (>2 mi/mi<sup>2</sup>)

Source: GIS Analysis

Under Alternative A, the amount of big game security habitat on BLM lands in the Butte Field Office would be 5,846 acres. This is the least amount of security habitat of all alternatives (Table 4-100).

	A	B	C	D
<b>All BLM Lands in Butte Field Office</b>	5,846	8,510	10,946	7,007

### **Core and Subcore Habitat**

Core areas were described as areas large enough for wildlife to forage and reproduce, while subcore areas were areas that could act as stepping stones for wildlife as they moved through the region. Table 4-101 shows the approximate acres by road density categories displayed as “low”, “moderate” and “high” for core and subcore habitat. These acres were based on a Moving Windows Analysis.

Because core and subcore areas were delineated based on existing areas with low road density, these areas have the most acres with low road density in both the Planning and Decision Areas.

At the Planning Area scale, BLM roads can affect the quality of core and subcore habitat on other federal and private lands. BLM roads adjacent to other lands with low road densities can degrade the quality of the adjacent habitat and reduce the use of those areas by wildlife. Alternative A would have substantially fewer acres with low road densities than the action alternatives in core and subcore habitat.

Approximately 24 percent (71,600 acres) of the Decision Area is considered core or subcore habitat. As with the Planning Area, Alternative A would have the fewest

	<b>Low Road Density (0-1)</b>	<b>Moderate Road Density (1-2)</b>	<b>High Road Density (&gt;2)</b>
<b>Planning Area</b>			
Alt. A	2,001,951	515,059	878,065
Alt. B	2,010,928	520,019	864,139
Alt. C	2,012,918	520,146	862,134
Alt. D	2,007,448	522,053	865,577
<b>Decision Area (BLM lands)</b>			
Alt. A	33,406	12,629	25,564
Alt. B	40,458	15,052	16,099
Alt. C	42,043	14,959	14,638
Alt. D	37,442	16,850	17,334

BLM acres with low road density and Alternative C would have the most acres. The amount of BLM acres in low road density would be substantially less under Alternative A than the action alternatives. Alternative A would provide roughly 7,000 fewer BLM acres of low road density than Alternative B and approximately 4,000 fewer acres than Alternative D (Table 4-101). Alternative A would have roughly 8,600 fewer BLM acres of core and subcore habitat in low road density than Alternative C.

### **Wildlife Movement Corridors**

Wildlife travel corridors are a vital component of habitat for a variety of species. Corridors are travel routes used by wildlife to disperse to new core areas and/or for seasonal movements between summer and winter ranges. A corridor may also be used for daily movements from loafing to foraging areas. Habitat fragmentation and isolation of populations as a result of degradation or elimination of corridors can result in small, vulnerable wildlife populations. Disturbance related to high road density within wildlife corridors can degrade the quality of wildlife corridors, eventually making them unavailable to wildlife species that depend on them. Corridors were described as areas of predicted movement between core and subcore areas, where habitat quality is high, but not as high and contiguous as the core and sub-core areas.

Craighead *et al.* (2002) modeled wildlife corridors within the Northern Rocky Mountain Region, delineated core and subcore areas, and described corridors based on their habitat quality. High road densities within wildlife movement corridors can degrade the quality of corridors, eventually making them unavailable to wildlife species that depend on them. Factors considered in the delineation of corridors included topography, road density, presence of riparian areas, human developments and activities, vegetative cover and land ownership patterns (Craighead *et al.* 2002).

High and moderate quality corridors were combined on Table 4-102 to show acres of road density in higher quality movement corridors. As with core and subcore habitat, roads on BLM lands can affect the quality of movement corridors on adjacent lands. At the Planning Area scale, travel management under Alternative A would maintain the fewest acres with low road density in high or moderate quality movement corridors of all the alternatives.

Approximately 28 percent (85,120 acres) of the Decision Area is considered to be in high or moderate quality wildlife corridors. As with the Planning Area, Alternative A would have the fewest BLM acres with low road density and Alternative C would have the most acres. The amount of BLM acres in low road density varies markedly between Alternative A and the action alternatives. Alternative A would have roughly 5,300 fewer BLM acres with low road density (47,226 total acres) than Alternative B and approximately 5,100 fewer acres than Alternative D (Table 4-102). Alternative A would

<b>Table 4-102</b>			
<b>High and Moderate Quality Corridors</b>			
<b>Approximate Acres by Road Density Category</b>			
	<b>Low Road Density</b> (0-1)	<b>Moderate Road Density</b> (1-2)	<b>High Road Density</b> (>2)
<b>Planning Area</b>			
Alt. A	237,630	186,068	339,185
Alt. B	244,114	188,383	330,404
Alt. C	244,413	188,910	329,538
Alt. D	243,738	188,220	330,907
<b>Decision Area</b>			
Alt. A	47,226	17,513	20,386
Alt. B	52,580	18,371	14,163
Alt. C	52,756	18,912	13,447
Alt. D	52,359	18,211	14,533

have over 5,500 fewer BLM acres in low road density than Alternative C.

**Table 4-103** shows the acres of road density in low quality wildlife movement corridors (areas with more roads, less federal or state lands and more potential disturbance).

<b>Table 4-103</b>			
<b>Low Quality Corridors Approximate Acres</b>			
<b>by Road Density Category</b>			
	<b>Low Road Density</b> (0-1)	<b>Moderate Road Density</b> (1-2)	<b>High Road Density</b> (>2)
<b>Planning Area</b>			
Alt. A	323,877	221,390	291,595
Alt. B	326,503	221,534	288,780
Alt. C	329,363	219,489	287,952
Alt. D	325,217	222,315	289,295
<b>Decision Area</b>			
Alt. A	18,505	13,821	14,886
Alt. B	21,048	13,563	12,613
Alt. C	22,670	12,342	12,195
Alt. D	19,995	14,128	13,089

At the Planning Area scale, Alternative A would provide the fewest acres in low road density of all the alternatives.

Approximately 16 percent (47,220 acres) of the Decision Area is considered to be in low quality wildlife corridors. As with the Planning Area scale, Alternative A would have the fewest BLM acres with low road density and Alternative C would have the most acres. Alternative A would have over 2,500 fewer BLM acres with low road density (18,505 total acres) than Alternative B and approximately 1,500 fewer acres than Alternative D (**Table 4-103**). Alternative A would have approximately

4,200 fewer BLM acres with low road density than Alternative C.

## Effects of Alternative B

Less motorized access would occur with Alternative B than Alternatives A or D, but Alternative B would provide more motorized access than Alternative C. Across the Field Office, there would be approximately 263 miles of open roads, 371 miles of closed and decommissioned roads and 154 miles open with seasonal restrictions. Seasonal restrictions would reduce the impacts of roads within important wildlife habitats such as big game winter range and spring habitat.

### Riparian Habitat

Under Alternative B, there would be 77.4 miles of open roads and 34 miles of closed roads within a 300-foot riparian analysis area on BLM lands across the Field Office. Alternative B would have fewer open roads in riparian areas than under Alternative A. This alternative would also have fewer open roads compared to Alternative D but about 4 miles more than Alternative C. Alternative B would provide for more improvement in riparian habitat at the Decision Area scale compared to Alternatives A and D, but would provide for less improvement than Alternative C.

### Elk Winter Range

**Table 4-104** displays road densities within elk winter range by Big Game Analysis Areas in the Decision Area. Alternative B would increase the number of acres with low road density in elk winter range in all Big Game Analysis Areas over Alternative A with the exception of Elkhorns (Alternatives B and A would be similar because a travel plan already exists for this area) and Big Belts. In the Big Belts, some roads that had temporary closures in the Ward Ranch area and in the area of the 2000 fires would be opened under Alternative B (East Helena TPA).

Alternative B would have considerable increases in acres of low road density in the Granite Butte, Highlands, and Jefferson Big Game Analysis Areas over Alternative A. This alternative would have fewer acres in the low road density category in most Big Game Analysis Areas compared to Alternative C, especially in the Big Hole, Granite Butte, and Missouri Big Game Analysis Areas.

Alternative B would have more acres in the low road density category in six Big Game Analysis Areas compared to Alternative D. The Big Game Analysis Areas with the largest differences between Alternatives B and D would be the Big Hole, Granite Butte, Highlands, and the Missouri.

Under Alternative B, the amount of big game security habitat on BLM lands in the Butte Field Office would be 8,510 acres (**Table 4-100**). This is about 2,664 acres more than under Alternative A and is the second highest total of security habitat acres of all four alternatives.

<b>Elk Winter Range Analysis Unit</b>	<b>Acres of Low Density</b>	<b>Acres of Moderate Density</b>	<b>Acres of High Density</b>
<b>Big Belts</b>	1,969	2,295	2,425
<b>Big Hole</b>	14,537	4,872	3,607
<b>Blackfoot</b>	52	81	312
<b>Clancy</b>	1,919	3,321	5,614
<b>Elkhorns</b>	16,092	8,721	4,559
<b>Granite Butte</b>	5,289	4,536	7,875
<b>Highlands</b>	19,797	5,017	1,594
<b>Jefferson</b>	16,294	8,749	8,335
<b>Missouri</b>	20,849	2,250	932

High Density - (>2 mi/mi<sup>2</sup>)

Source: GIS Analysis

### ***Core and Subcore Habitat***

At the Planning Area scale, Alternative B would have approximately 9,000 more acres in low road density than Alternative A in core and subcore habitat (Table 4-101). The majority of core and subcore habitat at the Planning Area scale is predominately found on Forest Service lands. This displays how BLM roads can affect the quality of core and subcore habitat on adjacent federal, state, and private lands. BLM roads adjacent to other federal, state, or private lands with low road densities can degrade the quality of the adjacent habitat and reduce the use of those areas by wildlife. In the low road density category, Alternative B would provide approximately 3,500 more acres than Alternative D, but approximately 2,000 fewer acres than Alternative C.

Approximately 24 percent (71,600 acres) of the Decision Area is considered core or subcore habitat. Alternative B would have over 7,000 more BLM acres with low road density (40,458 total acres) than Alternative A, and 3,000 more acres than Alternative D. Alternative B would have about 1,600 fewer BLM acres in low road density than Alternative C (Table 4-101).

### ***Wildlife Corridors***

At the Planning Area scale, travel management under Alternative B would increase the amount of acres in low road density in high or moderate movement corridors by approximately 6,500 acres over Alternative A (Table 4-102). As a group, the action alternatives vary substantially from Alternative A but vary relatively slightly from each other. Alternative B would have only 300 fewer acres in the low road density category compared to Alternative C and only 400 more acres than Alternative D.

Approximately 28 percent (85,120 acres) of the Decision Area is considered to be in high or moderate quality wildlife corridors. Alternative B would have over 5,000 more BLM acres with low road density (52,580 total acres) than Alternative A and only 220 more acres than Alternative D. Alternative B would have slightly fewer BLM acres in low road density (200 acres) than Alternative C.

In the context of low quality wildlife movement corridors, at the Planning Area scale, travel management under Alternative B would increase the amount of acres with low road density compared to Alternatives A and D but would have fewer acres than Alternative C (Table 4-103). Alternative B would provide approximately 2,600 more acres of low road density than Alternative A, 1,300 more acres than Alternative D and approximately 2,900 acres less than Alternative C.

Within low quality movement corridors in the Decision Area, Alternative B would have over 2,500 more BLM acres with low road density (21,048 total acres) than Alternative A and 1,000 more acres than Alternative D. Alternative B would have approximately 1,600 fewer BLM acres in low road density than Alternative C (Table 4-103).

### **Effects of Alternative C**

Less motorized access would occur with Alternative C than with any of the other alternatives. Across BLM lands in the Butte Field Office, there would be approximately 244 miles of open roads, 425 miles of closed and decommissioned roads and 128 miles open with seasonal restrictions. Alternative C would have the greatest benefits to wildlife species from closed, decommissioned, and seasonally restricted roads of all other alternatives. Alternative C would increase the quality of habitat by reducing disturbance. The quantity of habitat would be increased by reducing fragmentation, allowing roads to become re-vegetated and preventing the spread of noxious weeds. Big game would have additional security habitat during the hunting season and wildlife would have additional refuge during critical seasons of use, such as during the winter or spring months, with Alternative C.

### ***Riparian Habitat***

Under the travel management, Alternative C would have 73.7 miles of open roads and 37.6 miles of closed roads within 300 feet of streams on BLM lands across the Field Office. Alternative C would have fewer miles of open roads and more miles of closed roads in riparian areas compared to the other alternatives; therefore, providing the most protection of riparian habitat.

### ***Elk Winter Range***

Table 4-105 displays the road densities within elk winter range by Big Game Analysis Areas in the Decision Area. Alternative C would increase the number of acres

with low road density in elk winter range in most Big Game Analysis Areas over the other alternatives.

<b>Elk Winter Range Analysis Unit</b>	<b>Acres of Low Density</b>	<b>Acres of Moderate Density</b>	<b>Acres of High Density</b>
<b>Big Belts</b>	2,195	2,088	2,405
<b>Big Hole</b>	15,070	4,680	3,265
<b>Blackfoot</b>	52	81	312
<b>Clancy</b>	1,921	3,322	5,610
<b>Elkhorns</b>	17,072	7,751	4,548
<b>Granite Butte</b>	6,445	4,637	6,617
<b>Highlands</b>	19,797	5,017	1,594
<b>Jefferson</b>	16,345	9,016	8,018
<b>Missouri</b>	21,903	1,969	159

Low Density - (0-1mi/mi<sup>2</sup>), Moderate Density - (1-2 mi/mi<sup>2</sup>), High Density - (>2 mi/mi<sup>2</sup>)  
Source: GIS Analysis

Alternatives C and B would have the same or similar number of acres with low road density in the Blackfoot, Highlands, Jefferson and Clancy Big Game Analysis Areas. Alternative C would have more acres in the low road density category (up to 1,200 acres per Big Game Analysis Area) in the Big Belts, Big Hole, Elkhorns, Granite Butte and Missouri Big Game Analysis Areas compared to Alternative B. Alternative C would have considerable increases in acreage of low road density in the Big Hole, Granite Butte, Highlands, Jefferson and Missouri Big Game Analysis Areas over Alternative A. This alternative would have more acreage of low road density in seven Big Game Analysis Areas compared to Alternative D. The Big Game Analysis Areas with the largest differences between Alternatives C and D would be the Big Hole, Granite Butte, Highlands, and the Missouri.

The actual road density in elk winter range would be the lowest under Alternative C of all alternatives and this alternative would have more acreage of elk winter range in low road density than all other alternatives. Alternative C would do more than any other alternative to protect and restore big game winter range.

Under Alternative C the amount of big game security habitat on BLM lands in the Butte Field Office would be 10,946 acres (Table 4-100). This is 5,100 acres more than under Alternative A and about 2,400 acres more than under Alternative B. Alternative C would provide the highest total of security habitat acres of all four alternatives.

### ***Core and Subcore Habitat***

At the Planning Area scale Alternative C would have approximately 11,000 more acres in the low road density category than Alternative A in core and subcore habitat (Table 4-101). Alternative C would provide more acreage of low road density than all other alternatives and would help to improve the quality and quantity of core and subcore habitat on other federal, state, and private lands more than all other alternatives.

Approximately 24 percent (71,600 acres) of the Decision Area is considered core or subcore habitat. Alternative C would have over 8,600 more BLM acres with low road density (42,043 total acres) than Alternative A, and 4,600 more BLM acres than Alternative D. Alternative C would also have 1,600 more BLM acres with low road density than Alternative B (Table 4-101).

### ***Wildlife Movement Corridors***

As with the core and subcore habitat, roads on BLM lands can affect the quality of movement corridors on adjacent lands. At the Planning Area scale, travel management under Alternative C would increase the amount of acreage with low road densities by approximately 6,780 acres over Alternative A (Table 4-102). Alternative C would have 300 acres more than Alternative B and 700 acres more than Alternative D in the low road density category.

Approximately 28 percent (85,120 acres) of the Decision Area is considered to be in high or moderate quality wildlife corridors. Alternative C would have over 5,500 more BLM acres with low road density (52,756 total acres) than Alternative A but only 400 more BLM acres than Alternative D. Alternative C would have 200 more BLM acres in low road density than Alternative B (Table 4-102).

Table 4-103 shows the acres of road density in low quality wildlife movement corridors. At the Planning Area scale, travel management under Alternative C would have the most acres in low road density of all alternatives. Alternative C would provide approximately 5,500 additional acres of low road density in low quality corridors over Alternative A and approximately 4,100 more than Alternative D. Alternative C would provide about 2,900 more acres in low road density than Alternative B.

Approximately 16 percent (47,220 acres) of the Decision Area is considered to be in low quality wildlife corridors. Alternative C would have over 4,100 more BLM acres with low road density (22,670 total acres) than Alternative A, and 2,700 more acres than Alternative D. Alternative C would have approximately 1,600 more BLM acres in low road density over Alternative B (Table 4-103).

Overall, Alternative C would provide the most suitable core and subcore habitat and wildlife movement corridors in both the Decision and Planning Areas.

## Effects of Alternative D

Alternative D would allow more motorized access than the other action alternatives but less than Alternative A. Across BLM lands in the Butte Field Office there would be approximately 305 miles of open roads, 309.6 miles of closed and decommissioned roads, and 174 miles of seasonally restricted roads. Fewer seasonal restrictions would increase impacts associated with travel and recreation within important wildlife habitat areas. Alternative D would have more open roads than the other action alternatives but fewer open roads than Alternative A.

Alternative D would have more negative and long-term effects on wildlife and wildlife habitat from permanent and open roads than Alternatives B and C but fewer effects than Alternative A.

### *Riparian Habitat*

Under Alternative D, 81.2 miles of open roads and 30.2 miles of closed roads would be located within 300 feet of streams on BLM lands across the Butte Field Office. Alternative D would have more miles of open road in riparian areas compared to the other action alternatives but 13 miles less than Alternative A. Alternative D would have more negative effects from roads in riparian areas such as loss of riparian vegetation and habitat and disturbance than the other action alternatives, but fewer negative effects than Alternative A.

### *Elk Winter Range*

**Table 4-106** displays road densities within elk winter range by Big Game Analysis Areas in the Decision Area. Alternative D would increase the number of acres with low road density in elk winter range in all Big Game Analysis Areas over Alternative A with the exception of Elkhorns (Alternatives D and A would be similar because a travel plan already exists for this area) and Big Belts. In the Big Belts, some roads that had temporary closures in the Ward Ranch area and in the area of the 2000 fires would be opened under Alternative

D (East Helena TPA). Alternative D would increase acres with low road density in the Granite Butte, Highlands and Jefferson Big Game Analysis Areas over Alternative A, but would have fewer acres in low road density in most Big Game Analysis Areas compared to Alternatives B and C. Alternative D would have fewer acres in low road density in six Big Game Analysis Areas compared to Alternative B, and in seven Big Game Analysis Areas compared to Alternative C. The Big Game Analysis Areas with the largest differences between Alternatives D and B would be the Big Hole, Granite Butte, Highlands, and the Missouri. This same relative difference comparison applies between Alternatives D and C.

Approximately 28 percent (85,120 acres) of the Decision Area is considered to be in high or moderate quality wildlife corridors. Alternative D would have over 5,100 more BLM acres with low road density (52,359 total acres) than Alternative A and only 220 fewer acres than Alternative B. Alternative D would have approximately 400 fewer BLM acres in low road density than Alternative C (**Table 4-102**).

**Table 4-103** shows the acres of road density in low quality wildlife movement corridors (areas with more roads, less federal or state lands and more potential disturbance). At the Planning Area scale, travel management under Alternative D would increase the amount of acres with low road density compared to Alternative A but would have fewer acres in this category than Alternatives B and C. Alternative D would provide approximately 1,300 more acres of low road density than Alternative A, but 1,300 less than Alternative B and approximately 4,100 less than Alternative C.

Under Alternative D, the amount of big game security habitat on BLM lands in the Butte Field Office would be 7,007 acres (**Table 4-100**). This is approximately 1,160 acres more than under Alternative A but is the lowest number of security habitat acres of the action alternatives.

Elk Winter Range Analysis Unit	Acres Low Density	Acres Moderate Density	Acres High Density
<b>Big Belts</b>	1,583	2,158	2,947
<b>Big Hole</b>	13,335	5,888	3,793
<b>Blackfoot</b>	52	79	314
<b>Clancy</b>	1,919	3,321	5,614
<b>Elkhorns</b>	16,092	8,720	4,559
<b>Granite Butte</b>	4,287	4,796	8,616
<b>Highlands</b>	18,841	5,778	1,789
<b>Jefferson</b>	16,248	8,412	8,719
<b>Missouri</b>	20,243	2,062	1,726

Source: GIS Analysis

**Core and Subcore Habitat**

At the Planning Area scale, Alternative D would have approximately 5,500 more acres in the low road density category than Alternative A in core and subcore habitat (Table 4-101). Alternative D would provide about 3,500 fewer acres in the low road density category than Alternative B and about 5,500 fewer acres in this category than Alternative C.

Approximately 24 percent (71,600 acres) of the Decision Area is considered core or subcore habitat. Alternative D would have over 4,000 more BLM acres with low road density (37,442 total acres) than Alternative A, and 3,000 fewer acres than Alternative B. Alternative D would have approximately 4,600 fewer BLM acres in low road density than Alternative C (Table 4-101).

**Wildlife Movement Corridors**

At the Planning Area scale, travel management under Alternative D would increase the amount of acres with low road density in high and moderate quality movement corridors by approximately 6,100 acres over Alternative A (Table 4-102). Alternative D would have only 700 fewer acres in low road density compared to Alternative C and only 400 fewer acres than Alternative B.

Approximately 16 percent (47,220 acres) of the Decision Area is considered to be in low quality wildlife corridors. Alternative D would have over 1,500 more BLM acres with low road density (19,995 total acres) than Alternative A and 1,000 fewer acres than Alternatives B and C (Table 4-103).

**FISH**

Watershed function and roads within 300 feet of streams were used as indicators of the cumulative impacts of the five site-specific travel plans for BLM lands within the Butte Field Office. Relative comparisons of alternatives

would apply to effects described for fish habitat in the TPA-specific analyses.

**Effects of Alternative A**

Table 4-107 displays acreage of land by major watersheds in the Decision Area (BLM lands in the Butte Field Office) in different road density classes (low, medium, and high). Alternative A would have the greatest detrimental effects to watershed function and subsequently fish habitat, compared to the other alternatives.

Alternative A would maintain the most BLM acres with high density roads (107,566 acres) and the fewest BLM acres with low density roads (116,236 acres) of all other alternatives (Table 4-107).

Table 4-108 and Table 4-109 display miles of open and closed road within 300 feet of streams. The number of open road miles within 300 feet of streams on BLM lands would be greatest under Alternative A (94.3 miles) of all the alternatives. Alternative A would provide for the greatest mileage of riparian roads by each subcategory as well: 39.9 miles near fish bearing streams, 28.1 miles near perennial non-fish bearing streams, and 26.3 miles near intermittent streams. The miles of closed roads in riparian areas would be the least under Alternative A (17.1 miles) with the same trend being the case where Alternative A would provide for the fewest closed riparian roads by sub-category of all alternatives.

**Effects of Alternative B**

Alternative B would have more acres with low density roads across the Decision Area (131,982 acres) compared to Alternative A (116,236). In the moderate road density category, Alternative B has nearly 4,000 more acres compared to Alternative A and almost 20,000 acres less in the high road density than Alternative A (Table 4-107). The most marked differences between alternatives would be in the Big Hole, Boulder, Jeffer-

**Table 4-107**  
**Decision Area Acres in Road Density Categories by Alternative by Watershed**

Road Density	Low (0-1 mi/mi <sup>2</sup> )				Moderate (1-2 mi/mi <sup>2</sup> )				High (>2 mi/mi <sup>2</sup> )			
	Alternative	A	B	C	D	A	B	C	D	A	B	C

Jefferson	13,763	14,270	14,270	14,194	11,983	11,834	11,834	11,893	14,583	14,224	14,224	14,242
Madison	822	822	822	822	387	387	387	387	189	189	189	189
Upper Clark Fork	0	0	0	0	0	0	0	0	0	0	0	0
Upper Missouri River	58,823	65,729	69,884	61,303	35,783	38,863	37,321	38,354	53,615	43,630	41,017	48,565
Upper Yellowstone	5,749	5,749	5,749	5,749	1,918	1,918	1,918	1,918	635	635	635	635
<b>Total</b>	<b>116,236</b>	<b>131,982</b>	<b>141,264</b>	<b>123,073</b>	<b>78,175</b>	<b>82,267</b>	<b>79,516</b>	<b>83,424</b>	<b>107,566</b>	<b>87,729</b>	<b>81,196</b>	<b>95,481</b>

son, and Upper Missouri watersheds. For the five site-specific travel plans considered in aggregate at the Field Office scale, Alternative B would provide improved watershed function and reduced road-related impacts to fish habitat compared to Alternative A.

Under Alternative B there would be approximately 18 percent fewer open road miles within 300 feet of streams than under Alternative A (Table 4-108). Alternative B would provide for about 16.8 more miles of closed road within 300 feet of streams than Alternative A (Table 4-109). Differences between alternatives would be in the Big Hole, Boulder, and Upper Missouri River watersheds where more riparian roads would be closed under Alternative B than Alternative A in every case and in every subcategory of riparian areas (fish bearing streams, perennial non-fish bearing streams, intermittent streams). Alternative B would have fewer road-related adverse effects to fish and aquatic habitats associated with roads in and near riparian areas than Alternative A.

Overall, at the scale of all BLM lands in the Butte Field Office, Alternative B would pose fewer road-related adverse effects to fish and aquatic habitats than Alternative A, and would actually lessen existing impacts to improve aquatic habitats.

### Effects of Alternative C

Alternative C would have the most BLM acres with low density roads (141,264 acres) compared to all other alternatives. This alternative would have 25,000 acres more in the low road density category and 26,000 fewer acres in the high road density category compared to Alternative A (Table 4-107). This alternative would have 9,282 more BLM acres in the low road density category and 6,500 fewer acres in the high road density category than Alternative B (Table 4-107). Alternative C would have the fewest acres with high road densities of all alternatives with the watersheds seeing the most effects being the Big Hole, Boulder, and Upper Missouri River.

Watershed	Fish-bearing				Perennial				Intermittent				Total Open Roads

<b>Upper Clark Fork</b>	0	0.2	0.6	0.2	0	0	0	0	0	0.3	0.4	0.3	0	0.5	1.0	0.5
<b>Blackfoot</b>	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
<b>Total</b>	<b>6.0</b>	<b>9.0</b>	<b>10.6</b>	<b>8.4</b>	<b>5.8</b>	<b>10.7</b>	<b>11.4</b>	<b>10.0</b>	<b>5.3</b>	<b>14.2</b>	<b>15.6</b>	<b>11.8</b>	<b>17.1</b>	<b>33.9</b>	<b>37.6</b>	<b>30.2</b>

For the five site-specific travel plans considered in aggregate at the Field Office scale, Alternative C would provide the greatest degree of improved watershed function and reduced road-related impacts to fish habitat of all alternatives.

Under Alternative C there would be approximately 22 percent fewer open road miles within 300 feet of streams on BLM lands than under Alternative A (Table 4-108). Alternative C would provide for approximately 20 more miles of closed road within 300 feet of streams than Alternative A and about 3.7 more miles than Alternative B (Table 4-109). Differences between alternatives would be in the Big Hole, Boulder, and Upper Missouri River watersheds where more riparian roads would be closed under Alternative C than any other alternative in all riparian categories. Alternative C would have fewer road-related adverse effects to fish and aquatic habitats associated with roads in and near riparian areas than any other alternative. Overall, at the scale of all BLM lands in the Butte Field Office, Alternative C would pose fewer road-related adverse effects to fish and aquatic habitats than all other alternatives, and would actually lessen existing impacts to improve aquatic habitats more than any other alternative.

### Alternative D

Alternative D would provide fewer acres with low density roads (123,073 acres) across the Decision Area compared to Alternatives B and C, but more acres than Alternative A (116,236 acres). Of the action alternatives, Alternative D would have the most acres with high road density (95,481 acres) but moderate road densities would be similar for both Alternatives D and B (Table 4-107). Alternative D would have roughly 12,000 fewer acres with high road density than Alternative A. For the five site-specific travel plans considered in aggregate at the Field Office scale, Alternative D would provide improved watershed function and reduced road-related impacts to fish habitat compared to Alternative A, but more adverse effects than either Alternatives B or C.

Under Alternative D there would be approximately 14 percent fewer open roads within 300 feet of streams than under Alternative A, 5 percent more than under Alternative B, and 10 percent more than under Alternative C (Table 4-108). Alternative D would provide for approximately 13 more miles of closed road within 300 feet of streams than Alternative A, 3.7 fewer miles than Alternative B, and 7.4 fewer miles than Alternative C (Table 4-109). Alternative D would have fewer road-related adverse effects to fish and aquatic habitats associated with roads in and near riparian areas than Alternative A, but more than Alternatives B and C.

Alternative D would close and decommission fewer roads during travel management than Alternatives B and C but more than Alternative A.

Overall, at the scale of all BLM lands in the Butte Field Office, Alternative D would pose fewer road-related

adverse effects to fish and aquatic habitats than Alternative A, but would pose greater impacts than Alternatives B or C. Alternative D would lessen existing impacts to improve aquatic habitats compared to the current condition of Alternative A.

### SPECIAL STATUS PLANTS

The following discussion summarizes contributions to cumulative effects on special status plants associated with BLM road management at the scale of all BLM lands in the Butte Field Office. Specific mechanisms of effect on special status plants tie back to effects described for TPA-specific discussions above, particularly in the Effects Common to All Alternatives sections of those discussions.

Since BLM roads make up about 4.8 percent of all roads and BLM lands make up 4.2 percent of all lands in the Planning Area, effects of BLM travel planning alternatives on special status plants at the RMP Planning Area scale would be minor. Activities and effects discussed above for each TPA on private lands (48 percent of lands, 63 percent of roads in Planning Area) and other public lands (42 percent of lands, 29 percent of roads in Planning Area) would have a stronger influence on special status plants in the Planning Area with activities on private lands likely having the greatest effect overall.

### Effects of the Alternatives

Under Alternative A the greatest amount of BLM road use (629 open miles or 3.5 percent of all roads in the RMP Planning Area) would be possible, causing the greatest amount of special status plant habitat to be at risk. Habitat would be at risk because of greater ground disturbance and increased weed spread which reduces connectivity between populations, increases competition from invasive species, and increases plant mortality.

Under Alternative B, 417 BLM road miles (2.3 percent of all roads in the RMP Planning Area) would be open, reducing adverse effects to special status plants compared to Alternative A.

Under Alternative C, 372 BLM road miles (2.1 percent of all roads in the RMP Planning Area) would be open. Alternative C would reduce adverse effects to special status plants more than any other alternative.

Under Alternative D, 479 BLM road miles (2.7 percent of all roads in the RMP Planning Area) would be open. Alternative D would reduce adverse effects to special status plants more than Alternative A, but less than Alternatives B and C.

### WILDLAND FIRE MANAGEMENT

Effects referenced below are described in more detail in the Wildland Fire Management sections of each of the five specific TPA discussions above. The contribution of the five site-specific travel plans are discussed in aggregate

gate at the Decision Area (all BLM lands in the Butte Field Office) and Planning Area scales below.

The following conditions would apply to closed BLM roads under all alternatives. Many closed roads would still be available for use in fire suppression as well as fuels reduction treatments. Planning and implementation of fuels reduction treatments could occur in association with closed roads if variances for temporary road use were to be allowed. Variances would be subject to internal BLM review.

### **Effects of Alternative A**

Alternative A would leave the most miles of road (629 miles) available for public use (open yearlong and open with seasonal restrictions) of Butte Field Office BLM lands. Roads open to the public can provide benefits for wildland fire suppression by providing access that is usually passable (not overgrown with vegetation or closed by small rock slides, etc.) and allowing access for fuel reduction treatments. Alternative A would provide the most open road miles in the DA and would therefore provide the most benefits of all alternatives for fire suppression access as well as allowing ready access for fuels reduction projects.

Roads open to the public also provide additional opportunities for human-caused fire ignitions (either accidental or intentional). Human activities are the leading source of wildland fire ignition in the Planning Area. Alternative A would contribute the most open road miles of all alternatives from which these fire starts could occur and would therefore provide the greatest overall risk of human-caused fire starts.

At the Planning Area scale, the 629 miles of open BLM roads would make up about 3.5 percent of the at least 17,810 road miles in the entire Planning Area. The contribution of BLM roads is minor at the Planning Area scale, indicating that road management and activities off BLM lands have much more influence on future wildland fire characteristics at this scale than BLM road management.

### **Effects of Alternative B**

Alternative B would leave 417 miles of BLM road available for public use (open and seasonally restricted), slightly more than Alternative C, but 34 percent less than the 629 miles available under Alternative A. Alternative B would provide fewer open road miles in the DA than Alternative A and would therefore have fewer benefits than Alternative A for fire suppression access as well as allowing ready access for fuels reduction projects.

Roads open to the public also provide additional opportunities for human-caused fire ignitions (either accidental or intentional). Human activities are the leading source of wildland fire ignition in the Planning Area. Alternative A would contribute fewer open road miles

than Alternative A from which these fire starts could occur and would therefore provide less risk of human-caused fire starts than Alternative A.

At the Planning Area scale, the 417 miles of open BLM roads would make up about 3.5 percent of the at least 17,810 road miles in the entire Planning Area. The contribution of BLM roads is minor at the Planning Area scale, indicating that road management and activities off BLM lands have much more influence on future wildland fire characteristics at this scale than BLM road management.

### **Effects of Alternative C**

Alternative C would leave 372 miles of road available for public use (open yearlong and open with restrictions), slightly less than Alternative B, but 41 percent less than the 629 miles available in Alternative A. Alternative C would provide the least open road miles in the DA of any alternative and would therefore provide the least benefit of all alternatives for fire suppression access as well as allowing ready access for fuels reduction projects.

Roads open to the public also provide additional opportunities for human-caused fire ignitions (either accidental or intentional). Human activities are the leading source of wildland fire ignition in the Planning Area. Alternative C would contribute fewer open road miles than any other alternative and would therefore provide the least risk of human-caused fire starts than any other alternative.

At the Planning Area scale, the 372 miles of open BLM roads would make up about 2.1 percent of the at least 17,810 road miles in the entire Planning Area. The contribution of BLM roads is minor at the Planning Area scale, indicating that road management and activities off BLM lands have much more influence on future wildland fire characteristics at this scale than BLM road management.

### **Effects of Alternative D**

Alternative D leaves 479 miles of road available for public use (open yearlong and open with restrictions), slightly more than Alternatives B and C, but 24 percent less than the 629 miles available in Alternative A. Alternative D would provide fewer open road miles in the DA than Alternative A, but more than either Alternatives B or C and would therefore have fewer benefits than Alternative A but more benefits than Alternatives B and C for fire suppression access as well as allowing ready access for fuels reduction projects.

Roads open to the public also provide additional opportunities for human-caused fire ignitions (either accidental or intentional). Human activities are the leading source of wildland fire ignition in the Planning Area. Alternative D would contribute fewer open road miles than Alternative A, but more miles than either Alterna-

tives B or C from which these fire starts could occur. Alternative D would provide less risk of human-caused fire starts than Alternative A, but more risk than Alternatives B and C.

At the Planning Area scale, the 479 miles of open BLM roads would make up about 2.7 percent of the at least 17,810 road miles in the entire Planning Area. The contribution of BLM roads is minor at the Planning Area scale, indicating that road management and activities off BLM lands have much more influence on future wild-land fire characteristics at this scale than BLM road management.

## CULTURAL AND PALEONTOLOGICAL RESOURCES

At the scale of either the RMP Planning Area or the RMP Decision Area, alternative-specific risks or impacts to cultural and paleontological resources are difficult to discern due to a lack of extensive site-specific knowledge about the presence of these resources in a given TPA. By designating open routes, limiting open-country travel, and closing some routes, inadvertent discovery of cultural and paleontological resources and vandalism to them is reduced. Higher road densities in a given area would allow greater access to more land on the average, but that does not imply greater amounts of vandalism, since the vehicles would remain on designated routes.

## VISUAL RESOURCES

The following discussion characterizes effects to visual resources at the scale of all Butte Field Office BLM lands. Road mileages depicted are for all BLM lands in the RMP Decision Area with the alternatives of the five site-specific travel plans incorporated.

### Effects Common to All Alternatives

Roads (temporary or permanent) may affect visual quality. Roads that remain open for public use may impact visual qualities where noticeable. The quantity of open roads would also influence sensitivity levels since with more open roads, more areas would generally be viewed by more members of the public. Closing or decommissioning roads would generally reduce effects to visual resources and reduce sensitivity levels because fewer members of the public would generally be accessing and viewing areas with closed roads.

### Effects of the Alternatives

Alternative A would have the most miles of open road (approximately 629 miles) Butte Field Office-wide. This would create the most adverse effects to visual resources of all alternatives from a standpoint of both direct impacts of roads and creating the most potential for sensitive viewpoints.

Under Alternative B, reducing the mileage of designated open routes Field Office-wide to 417 miles would en-

hance scenic qualities and reduce sensitive viewpoints compared to Alternative A.

Under Alternative C, adverse effects from travel management and transportation would be slightly less than those of Alternative B with respect to impacts from open roads (372 open miles) on the landscape. Alternative C would improve visual resources the most of any alternative.

Under Alternative D, impacts from travel management would be less than with Alternative A, but greater than with Alternatives B and C. Alternative D would have 150 fewer miles of open road (479 open miles) than Alternative A. This reduction would lower sensitive viewpoints and the noticeability of landscape changes. Alternative D would have more adverse impacts to visual resources than Alternatives B and C.

Under all alternatives, most activities on BLM lands would generally not adversely affect visual resources to unacceptable degrees because discretionary activities on BLM lands would be required to meet Visual Resource Management objectives within individual project areas.

Activities on non-BLM lands, particularly activities near BLM lands associated with residential development, urbanization, additional mining, or vegetation management, could have adverse cumulative effects on visual resources on BLM lands because BLM VRM objectives would not apply to non-BLM activities.

## LIVESTOCK GRAZING

At the RMP Planning Area scale, contributions to cumulative effects on livestock grazing from alternatives for the five site-specific travel plans would be similar for all action alternatives. All action alternatives would close and decommission more roads and trails than Alternative A. As more roads and trails are closed, noxious and invasive weed spread along with multiple user conflicts would be reduced. On the other hand, permittee management time on BLM lands may increase. Consequently, more effects associated with closed roads as described under the Effects Common to All Alternatives sections for each TPA above would occur under Alternative C than under any other alternative. Alternative B would produce fewer effects than Alternative than C, but more than Alternatives A and D. A summary of the relative degree of proposed road closures at the RMP Decision Area scale (all BLM Butte Field Office lands) as well as the Planning Area scale by alternative is below.

Under current conditions (Alternative A), approximately 172 miles of motorized routes mapped on the BLM transportation system would remain closed. These routes represent about 20 percent of the approximately 856 BLM road miles, and approximately 1.0 percent of the road miles across all ownerships in the entire Planning Area.

Alternative B would close (318 miles) or decommission (53 miles) approximately 371 miles of routes in the Decision Area currently open to use by motorized vehicles, the second most of any alternative. These routes represent about 43 percent of the approximately 856 BLM road miles in the Decision Area, and approximately 2.1 percent of the road miles across all ownerships in the entire Planning Area.

Alternative C would close (375 miles) or decommission (50 miles) approximately 425 miles of routes currently open to use by motorized vehicles. These routes represent about 50 percent of the approximately 856 BLM road miles in the Decision Area, and approximately 2.4 percent of the road miles across all ownerships in the entire Planning Area.

Alternative D would close (266 miles) or decommission (44 miles) approximately 310 miles of routes currently used by motorized vehicles. These routes represent about 36 percent of the approximately 856 BLM road miles in the Decision Area, and 1.7 percent of the road miles across all ownerships in the entire Planning Area.

## RECREATION

Effects of the alternatives for the five site-specific travel plans on Recreation are discussed at the scale of the Butte Field Office below. The public often targets public lands for various recreational activities. At the scale of the 7.2 million-acre RMP Planning Area, the 302,000 acres of Decision Area lands make up about 4.2 percent of the total. Recreation opportunities on other public lands at the scale of the entire RMP Planning Area exist on approximately 2,803,359 acres of USFS lands (39 percent of all lands), approximately 318,000 acres of state lands (4.4 percent of all lands), approximately 11,466 acres of Bureau of Reclamation lands (0.2 percent of all lands), and approximately 150,000 acres of National Park Service lands (2 percent of all lands). BLM lands make up about 8.4 percent of public lands in the RMP Planning Area available for public recreation.

### Effects of Alternative A

This alternative would maximize motorized recreation opportunities, and minimize non-motorized opportunities within the five Travel Planning Areas (Helena, East Helena, Lewis & Clark-NW, Boulder/Jefferson City and Upper Big Hole) compared to the other alternatives. Approximately 372 miles of open road (including seasonally restricted roads) would be available in the five TPAs analyzed. This would provide approximately 629 miles of open road available across all Butte Field Office BLM lands.

### Effects of Alternative B

Road availability for wheeled motorized travel within the five TPAs being analyzed would be the second lowest of all alternatives (approximately 171 miles open yearlong or open with restrictions, 417 miles Butte Field

Office wide). Under this alternative motorized recreation users would be more affected than under Alternative A while visitors seeking non-motorized opportunities would be benefited with more walk-in areas associated with closed roads or from established trailheads.

### Effects of Alternative C

Road availability for wheeled motorized travel within the five TPAs being analyzed would be the lowest of any of the alternatives (approximately 122 miles open yearlong or open with restrictions, 372 miles Butte Field Office wide). Under this alternative motorized recreation users would be most affected while visitors seeking non-motorized opportunities would be benefited the most.

### Effects of Alternative D

This alternative would provide the second highest mileage of available roads (230 miles in the five TPAs, 479 miles Butte Field Office wide) of all alternatives for wheeled motorized recreation opportunities within the five Travel Plan Areas (Helena, East Helena, Lewis & Clark-NW, Boulder/Jefferson City, and Upper Big Hole) analyzed as part of this planning effort. Motorized recreation users would have more opportunities than under Alternatives B and C, but fewer opportunities than under Alternative A. Non-motorized users would have more opportunities than under Alternative A but fewer than under Alternatives B and C.

## TRAVEL MANAGEMENT AND ACCESS

To understand the entire cumulative effects picture for travel management and access at the Decision Area and Planning Area scales, past travel management actions, recent travel planning decisions and effects of the five site-specific travel plans are important.

### *Past Travel Management Actions*

Beginning in 1946, and continuing up to June 2003, the majority of lands managed by the BLM were managed under the “open” area designation. With some exceptions, under this management, the public was allowed to travel off-road (cross country) on motorized vehicles (both wheeled and snowmobiles) without restriction. During the initial decades under this management (1950-1980), the level of off-road motorized recreation use, adverse resource impacts, and user conflicts were relatively low. In more recent years (1980’s to the present), the Butte Field Office (as well as the rest of the nation) has experienced a dramatic increase in the popularity of Off Highway Vehicle recreation. According to a 1995 U.S. Bureau of Census abstract report for recreational use on public lands (U.S. Census Bureau. 1995), off-highway vehicle travel increased 138 percent between the years of 1982-1992, while other forms of motorized travel increased 186 percent. From 1997 to 2001, the number of ATVs in use increased by almost 40 percent (USDA-FS. 2005b). Nationwide, motorized enthusiasts are buying OHVs at a rate of 1,500 units per day, with

nearly one-third of them doing so as first time buyers. Non-motorized use increased as well. According to the U.S. Bureau of Census report, between the years of 1982-1992, non-motorized travel increased 290 percent. As a result, both nationally and at the scale of the Butte Field Office, user conflicts between motorized and non-motorized users have increased.

In 2003, BLM issued a major travel management document, the *2003 Off-Highway Vehicle Record of Decision* and plan amendment for Montana, North Dakota, and portions of South Dakota. Under this decision, all wheeled motorized use is restricted to existing roads and trails only (no cross country use), including big game retrieval, unless in an area with a site-specific travel plan that manages otherwise.

Prior to the recent Butte RMP revision roads/trails inventory, the total number of roads and trails located within the Butte Field Office was generally considered to be 285 miles. This figure has been used for many years by BLM personnel, and represents the primary roads and trails used by the public and agency over the past 20-30 years. During the comprehensive road and trails inventory conducted for the Butte RMP (2002-2004), a total of approximately 856 miles of roads and trails were documented. There is no data available to analyze when or at what rate this growth of the road network occurred (from 285 to 856 miles), or the numbers of miles of roads/trails that are attributed to agency development, versus public development (user made routes). The current total mileage is a combination of both BLM construction and user made routes that BLM never intended to place on the landscape. In some cases, the locations of existing routes and the (vehicle) type, frequency, and season of use, have resulted in resource impacts. This legacy of past travel management has a direct impact on current as well as future travel management.

### **Recent BLM Travel Plan Decisions**

Recent BLM travel planning decisions for four TPAs in the Butte Field Office reflect a general trend of reduced motorized use with more distinction made in designated uses compared to the past (**Table 4-110**). While mileages of road open year-round have generally decreased, miles of seasonally restricted routes, miles of motorized trail for OHVs and motorcycles, and miles of closed roads have generally increased.

Outside of but adjacent to the Butte RMP Planning Area, the Dillon BLM Resource Management Plan (February 2006) provides another example of a recent travel management decision. Prior to its recent travel management revisions, the Dillon Field Office had 1,860 miles of road open yearlong, 242 miles open with seasonal restrictions, and 822,284 acres of area in the "Open" area designation for snowmobile use. With the travel plan revisions made in the Dillon RMP, there are now 1,183 road miles open yearlong, 159 miles with seasonal restrictions, and 763,057 acres in the "Open" area designation for snowmobile use.

### **Recent USFS Travel Plan Decisions**

There have been two recent travel plan decisions made by the USFS on National Forest lands that are partially located within the Butte RMP Planning Area boundary. The North Belts Travel Plan completed in 2005 on the Helena National Forest applies to lands northeast of Canyon Ferry Reservoir. Some of these lands are within the Butte RMP PA boundary while others are outside the PA boundary. This decision has resulted in fewer combined miles of open motorized routes from 415 miles to 345 miles, and a reduction of open area for cross-country snowmobile use (**Table 4-111**).

<b>Butte Field Office Travel Planning Area; (Plan Date)</b>	<b>Plan Status (Before/ After Plan)</b>	<b>Open Yearlong</b>	<b>Seasonally Restricted</b>	<b>Closed</b>	<b>Motorized trails</b>	<b>Non- motorized trails</b>	<b>Open Area for Wheeled Vehicles</b>	<b>Open Area Designation for Snowmobiles</b>
<b>Whitetail-Pipestone (2002)</b>	Before	99.4	0	1.7	0	0	28,647	28,647
	After	51	22	32	20.2	0	0	0
<b>Clancy-Unionville (2000)</b>	Before	14	0	0	15	0	5,590	5,590
	After	5	4	5	14	0	0	1,350

<b>Elkhorn Mountains<sup>1</sup> (1995)</b>	Before	0	1,036	0	32	-- <sup>2</sup>	125,900	125,900
	After	0	708	328	151	-- <sup>2</sup>	31,400	31,400

<sup>1</sup>The data for the Elkhorn Mountains travel management plan includes both BLM and USFS managed lands.

<sup>2</sup>Data Unavailable

Plan Status	Open Roads, Passenger	Dual Use	Motorcycle Trails	Motorized Trails	Snowmobile Only Trail	Snowmobile Open Area Designation
Before	370	0	2	40	3	113,550
After	160	125	14	43	3	63,686

The Gallatin National Forest travel plan (USDI-FS 2006b), a Forest-wide effort completed in 2006, applies to approximately 2.8 million acres within the Butte RMP Planning Area as well as USFS lands outside the Planning Area. This decision increased the miles of routes available for winter driving, snowmobile use, and cross-country skiing (Table 4-112).

Use Type	Before Plan	After Plan
Pleasure Driving	162	169
Snowmobiling	400	468
Cross-Country Skiing	214	231

### Effects of Five Site-Specific Travel Plans at RMP Decision Area Scale

This section discusses effects of the alternatives of the five site-specific travel plans considered in aggregate at the RMP Decision Area (all Butte Field Office BLM lands) scale as well as the Planning Area scale. Table 4-113 displays RMP Decision Area-wide road mileages by alternative.

For summer use, the total miles of routes available for all motorized uses combined increased slightly from 1,577 miles to 1,588 miles, but included shifts in types of uses with mileage increases for pleasure driving and motorcycle riding, and miles reductions for backcountry

Indicator	Alt A	Alt B	Alt C	Alt D
Miles of open yearlong routes	471.8	263.0	244.3	304.8
Miles of seasonally restricted routes	157.5	153.8	128.1	173.9
Miles of decommissioned routes	0	52.6	50.1	43.4
Miles of closed routes	172.0	317.7	375.2	266.2

Source: BLM Butte Field Office transportation GIS database, 2005.

roads and ATV routes (Table 4-114). Combined totals of routes where non-motorized uses were either emphasized or allowed reduced from 7,509 miles to 5,775 miles with reductions in routes where mountain bike and pack and stock saddle uses were emphasized, and increases in miles where mountain bike use is allowed (but not emphasized).

### Effects of Alternative A

Under Alternative A, approximately 629 miles of roads would be open (471.8 miles open yearlong, 157.5 miles open with seasonal restrictions) Decision Area-wide for motorized use opportunities (Table 4-113). This would be the greatest number of open miles of all the alternatives and would create the most opportunities for motorized users, and the least opportunities for non-motorized users of all alternatives. Approximately 172

Plan Status	Pleasure Driving	Backcountry Roads (4 X 4)	ATV	Motorcycle	Mountain Bike Use emphasized	Mountain Bike Use allowed	Pack and Stock Saddle Use emphasized	Pack and Stock Saddle Use allowed	Hiking Use emphasized
Before Plan	309	417	757	74	2,386	898	2,115	1	2,109
After Plan	402	337	554	295	1,323	1,754	347	347 <sup>1</sup>	2,004 <sup>2</sup>

<sup>1</sup> Use for this activity is prohibited on some trails.

<sup>2</sup> Use for this activity is not prohibited on any trails; use is either emphasized or allowed.

miles of road (approximately 20 percent of Field Office total of 856 miles) would remain closed Field Office-wide under this alternative.

Under Alternative A, user conflicts would be greater and safety would be reduced compared to the action alternatives because motorized and non-motorized users would share more of the same routes, which could lead to accidents and injuries.

Management costs under Alternative A would be mixed. Less personnel time would be required to monitor travel compliance than under the action alternatives. However, more effort would be required for signing designated open routes than under any other alternative (routes open yearlong and open with restrictions would be signed while closed routes would not be signed).

### Effects of Alternative B

Under Alternative B, opportunities for wheeled motorized access would be less, while opportunities for non-motorized user would be greater than under Alternative A (**Table 4-113**). Under Alternative B, approximately 43 percent of the current total of approximately 856 road miles would be closed or decommissioned. Alternative B would provide fewer opportunities for motorized users, but would increase opportunities for non-motorized users compared to Alternative A.

Under Alternative B, wheeled motorized and non-motorized users would have more separate routes than under Alternative A. User conflicts would be reduced compared to Alternative A.

The extent of management activities and costs under Alternative B would be mixed. Less personnel time would be required for initial implementation (signing designated routes, installing bulletin boards) than under Alternative A, but more time would be needed than under Alternative C. However, more effort on the part of the BLM would be required for public education and travel plan compliance than under Alternative A, but less time would be needed for this than under Alternative C.

### Effects of Alternative C

Under Alternative C, opportunities for wheeled motorized access would be less, while opportunities for non-motorized users would be greater than under any other alternative (**Table 4-113**). Under Alternative C approximately 49 percent of all BLM roads in the Decision Area would be closed or decommissioned.

User conflicts may be less under Alternative C than the other alternatives because wheeled motorized and non-motorized users would have a greater number of separate routes, thereby reducing the chances of encounters.

The extent of management activities and costs under Alternative C would be mixed. More personnel time would be required to monitor user compliance than under Alternatives A and B, but signage requirements

would be less than under any other alternative due to Alternative C having the fewest open routes.

Road and trail safety would be greater under Alternative C than under all other alternatives. Increased opportunities for dispersed recreation would result in a reduction in accidents and injuries from motorized and non-motorized recreationists using the same trails.

### Effects of Alternative D

Under Alternative D, opportunities for wheeled motorized access would be less than under Alternative A, but greater than under Alternatives B and C (**Table 4-113**). Opportunities for non-motorized users would be greater than under Alternative A but less than under Alternatives B and C. Under Alternative D approximately 36 percent of all BLM roads in the Decision Area would be closed or decommissioned.

Under Alternative D, user conflicts would be less than under Alternative A, but more than under Alternatives B or C. Due to increased route closures and seasonal restrictions, some dispersed recreation opportunities would be created that allow motorized and non-motorized users to recreate separately compared to the current condition.

The extent of management activities and costs under Alternative D would be mixed. Alternative D would entail additional construction costs compared to the other alternatives due to several new roads that would be constructed to interconnect with existing routes. Increased education and compliance monitoring would result in increased management costs under Alternative D compared to Alternative A, but these costs would be lower than under Alternatives B and C. Signage costs would be less than under Alternative A but greater than under either Alternatives B or C.

### Additional Effects at Decision Area and Planning Area Scales

Decreased opportunities for motorized recreation would help reduce the cumulative effects on natural resources, help provide non-motorized opportunities, and help reduce conflicts between motorized and non-motorized users. Under the action alternatives, motorized users would end up with fewer miles of dispersed roads or trails to recreate upon, and/or be displaced from some site-specific areas. As a result, motorized use would become more concentrated onto a smaller network of roads and trails. With some exceptions, given the combined level of motorized opportunities available across public lands managed by various agencies (USFS, BLM, MFWP, etc.), it should be many years before competition among motorized users for the same space becomes a social issue. Exceptions may include focus areas such as the Whitetail-Pipestone designated OHV trail system. Whitetail-Pipestone has gained rapidly in popularity (and public exposure) since its recent travel plan development in 2002; and receives use by local residents as

well as regional and nationwide visitors. Given the increasing popularity of motorized use, focus areas such as Whitetail-Pipestone would likely become more crowded in the future regardless of future travel management direction.

At the Planning Area scale, there are other key variables affecting travel management. Private lands account for nearly 49 percent of lands in the Planning Area. There is a general trend for private landowners to restrict public access onto or across their lands. This trend may be offset somewhat by the acquisition of additional lands by BLM, access easements, and block hunting agreements. Human population in the Planning Area grew by 40 percent between 1970 and 2002. In some cases, this population influx has led to fragmentation of large tracts of private lands for residential development, further complicating public access issues. This trend will likely continue. These same factors and influences would also affect travel management decisions made by other agencies located within the Planning Area, such as USFS, MFWP, and Bureau of Reclamation. Given that Butte Field Office lands occupy about 4.2 percent of all lands, and BLM roads make up about 4.8 percent of Planning Area total road mileage, the effects of BLM travel plan alternatives on travel management overall would be relatively minor at this scale.

## TRANSPORTATION FACILITIES

Costs associated with travel management for all BLM lands in the Butte Field Office (**Table 4-115**) are based on historical cost figures for road and trail maintenance. Percentage of annual maintenance is also historical, with 20 percent of the total mileage of roads receiving annual maintenance. The remaining 80 percent of roads and trails would receive stabilization work and emergency repairs as needed.

Under Alternative A, the Butte Field Office transportation system would have 629.2 miles of open roads (including open with seasonal restrictions) and 75 miles of motorized trails (**Table 4-115**).

Estimated costs for annual maintenance, periodic stabilization, monitoring of compliance with travel plans, and weed control on roads would be about 30 percent more than any of the action alternatives.

Under Alternative B, the Butte Field Office transportation system would have 416.9 miles of open roads (including open with seasonal restrictions) and 75 miles of motorized trails (**Table 4-115**). Estimated costs for annual maintenance, periodic stabilization, monitoring of compliance with travel plans, and weed control on roads under Alternative B would be slightly higher than under Alternative C and less than under Alternatives A and D.

Under Alternative C the transportation system would have 372.4 miles of open roads (including open with restrictions) and 75 miles of motorized trails (**Table 4-115**). Estimated costs for annual maintenance, periodic stabilization, monitoring of compliance with travel plans, and weed control on roads under Alternative C would be less than under any other alternative.

Under Alternative D, the Butte Field Office transportation system would have 478.6 miles of open roads (including open with restrictions) and 75 miles of motorized trails (**Table 4-115**). Estimated costs for annual maintenance, periodic stabilization, monitoring of compliance with travel plans, and weed control on roads under Alternative D would be greater than under Alternatives B and C, but less than under Alternative A.

<b>Classification/ Cost</b>	<b>Alt A</b>	<b>Alt B</b>	<b>Alt C</b>	<b>Alt D</b>
<b>Miles of Open/ Restricted Roads</b>	629.2	416.8	372.4	478.6
<b>Motorized Trails</b>	75	75	75	75
<b>Annual Road Maintenance</b>	\$50,336	\$33,352	\$29,792	\$38,288
<b>Annual Trail Maintenance</b>	\$3,000	\$3,000	\$3,000	\$3,000
<b>Periodic Road Stabilization</b>	\$33,574	\$22,246	\$19,871	\$25,538
<b>Periodic Trail Stabilization</b>	\$1,200	\$1,200	\$1,200	\$1,200
<b>Monitoring/Compliance</b>	\$31,460	\$20,845	\$18,535	\$23,930
<b>Weed Control</b>	\$9,438	\$6,254	\$5,586	\$7,179

## CHAPTER 5

# CONSULTATION AND COORDINATION

---

### INTRODUCTION

This chapter describes the public participation opportunities made available through the development of the Draft RMP/EIS. This chapter also describes consultation and collaboration efforts conducted by BLM with various entities. A distribution list identifies agencies, congressional staff, businesses, and organizations that were sent a copy of the Draft RMP/EIS.

The Draft RMP/EIS was prepared by an interdisciplinary team of resource specialists from the Butte Field Office, Montana State Office, and Maxim Technologies (RMP contractor).

Members of the planning team have consulted formally and informally with various agencies, local government representatives, groups, and individuals during the preparation of this document. Consultation, coordination, and public involvement occurred as a result of scoping, briefings, informal meetings, and individual contacts.

### SCOPING AND PUBLIC INVOLVEMENT PRIOR TO THE DRAFT RMP/EIS

A number of opportunities were available to the public to educate themselves about the planning process and participate in development of the plan prior to release of the Draft RMP/EIS for public review and comment.

A press release with regional distribution was issued at each major stage of the planning process including scoping, travel management planning, and issuance of the Proposed Planning Scenario. In addition, three planning updates were mailed to the general mailing list to announce the start of the planning process, again to announce the start of the travel planning effort, and again to describe preliminary draft alternatives and request Draft RMP/EIS document preference.

The web site [www.mt.blm.gov/bdo/rmp/index.htm](http://www.mt.blm.gov/bdo/rmp/index.htm) provided information on the resource and travel planning processes.

The Western Montana Resource Advisory Council, a 15 member advisory group appointed by the Secretary of Interior, was briefed at a number of their meetings on the status of the Butte RMP/EIS and given the opportunity to ask questions and provide feedback. The council's role is to provide advice to BLM on a variety of issues associated with public land management.

### TRAVEL MANAGEMENT PLANNING

Five public meetings were held over a two-week period during November and December 2004 on travel plan-

ning. Separate meetings were held specific to five Travel Planning Areas: Upper Big Hole, Boulder/Jefferson City, East Helena (North Hills), Helena (Scratchgravel Hills), and Lewis and Clark NW (Marysville). The overall goals of the meetings were to identify public travel planning issues and concerns for BLM lands, and to identify possible solutions to issues and concerns. Public attendance at these meetings is presented below:

- Upper Big Hole – 4 attendees;
- Boulder/Jefferson City – 7 attendees;
- East Helena (North Hills) – 24 attendees;
- Helena (Scratchgravel Hills) – 101 attendees; and
- Lewis and Clark NW (Marysville) – 16 attendees.

### COLLABORATIVE EFFORTS

A variety of public involvement strategies have been implemented throughout this planning process to improve communication and develop understanding of the issues and the process in development of the RMP/EIS. In addition to the scoping efforts and public meetings described in Chapter 1, various potential cooperators including Tribes, the Governor's Office, state and federal agencies, and local governments within the Planning Area were solicited to become cooperators in summer 2002. No agencies or governments signed on as cooperators for the development of this plan.

### TRAVEL MANAGEMENT WORKING GROUPS

In an effort to help BLM develop site-specific travel management alternatives agreeable to the public as well as the agency, community based collaborative working groups were initiated. Two working groups, representing a wide, "balanced" range of public land users, were recruited and managed under the direct supervision and guidance of the Lewis and Clark County Board of Commissioners. One of the groups was assigned to assist with travel planning for the Helena (Scratchgravel Hills) and East Helena (North Hills) TPAs, and the other for the Lewis and Clark County NW (Marysville) TPA. Membership criteria included: Montana residency, familiarity with the TPAs, and a willingness to work collaboratively with people of differing viewpoints. In order to provide for balanced representation, members were selected from three different interest categories (in accordance with the Western Montana Resource Advisory Council criteria), as described below.

#### Category 1:

Hold federal grazing permits or leases within the Travel Planning Area;

Represent interests associated with transportation or rights-of-way;

Represent developed outdoor recreation, OHV users, or commercial recreation activities;

Represent the commercial timber industry; or

Represent energy or mineral development.

**Category 2:**

Nationally or regionally recognized environmental organization;

Dispersed recreational activities;

Archaeological and historical interests; or

Nationally or regionally recognized wild horse and burro interest groups.

**Category 3:**

Hold state, county, or local elected office;

Are employed by a state agency responsible for the management of natural resources, land, and water;

Represent Indian tribes within or adjacent to the Travel Planning Area;

Are employed as academicians in natural resource management or the natural sciences; or

Represent the public-at-large.

The Working Groups consisted of eight or nine members, representing each of the three interest categories. These individuals included:

Helena-East Helena Working Group

- Cleve Johnson (Category 1)
- R. Allan Payne (Category 1)
- Randy Pearson (Category 1)
- Andy Baur (Category 2)
- Cedron Jones (Category 2)
- Connie Cole (Category 2)
- Rich Moy (Category 3)
- Bonnie Morgan (Category 3)
- Marilyn Pearson (Category 3)

Lewis and Clark County NW Working Group

- Mike Clark (Category 1)
- Eric LeLacheur (Category 1)
- Rudy Strobbe (Category 2)
- Ken Wallace (Category 2)
- Shaheen Siddiqui (Category 2)
- George Marble (Category 3)

- George Bower (Category 3)
- Michael McHugh (Category 3)

Each group held a series of five or six meetings during June and July 2005. The meetings were attended by at least one BLM representative available to answer questions, provide information and feedback from the BLM's interdisciplinary team, and provide written materials and maps as needed. Group recommendations for route-specific management were based on consensus. In the end, the working groups were able to arrive at complete consensus for the Marysville (subset of Lewis and Clark County NW TPA) and North Hills (subset of East Helena TPA) areas, but only partial consensus for the Scratchgravel Hills (subset of Helena TPA) area.

The Working Groups presented their findings to the Lewis and Clark County Commissioners at their regularly scheduled meeting in Helena on September 22, 2005. The Lewis and Clark Commissioners forwarded Working Group recommendations to the BLM soon afterward. BLM incorporated working group recommendations into Alternative B for each of these three Travel Planning Areas.

## RELEASE OF THE DRAFT RMP/EIS

The Draft RMP/EIS was mailed to the public in late May/early June 2007. The Notice of Availability was published in the Federal Register by the Environmental Protection Agency on June 8, 2007, beginning the official 90-day comment period. BLM published a concurrent Notice of Availability containing supplemental information. Written comments on the Draft RMP/EIS were initially slated to be due September 6, 2007. The BLM extended this public comment period to October 9, 2007.

In addition to printed copies or CDs mailed to people who requested them, the Draft RMP/EIS was available for review on the Butte RMP website. Approximately 360 printed copies and 130 CDs were distributed.

Over the period of June 26, 2007, to July 16, 2007, the BLM conducted briefings on key RMP contents for each of the eight county commissions in the Planning Area.

The BLM conducted six open house-style public meetings in the Planning Area in July 2007. Dates, locations, and times of public meetings were publicized through multiple press releases to local and regional press. This information was posted on the Butte RMP website as well.

The public meetings were designed to provide information to the public on the content of the Draft RMP/EIS as well as to provide information on how best to provide substantive comments on the document. Each meeting began with an introductory presentation covering key contents of the Draft RMP/EIS, contact information, and

suggestions on how to comment on the plan. Public members were then encouraged to visit with managers and members of the BLM planning team for the Draft RMP/EIS to discuss any specific questions or concerns. At each open house the public was strongly encouraged to provide any input on the Draft RMP/EIS to the BLM in writing during the comment period.

#### Open House Locations, Dates, and Public Attendance

Helena, Montana	July 17, 2007	12 attendees
Townsend, Montana	July 18, 2007	5 attendees
Butte, Montana	July 19, 2007	12 attendees
Boulder, Montana	July 23, 2007	5 attendees
Divide, Montana	July 24, 2007	11 attendees
Bozeman, Montana	July 25, 2007	5 attendees

## FORMAL CONSULTATION

### FISH AND WILDLIFE SERVICE CONSULTATION

Federal agencies are required to comply with provisions of the Endangered Species Act of 1973, as amended. This includes a requirement to “consult” with the U.S. Fish and Wildlife Service on any action that may affect species listed as threatened and endangered or result in destruction or adverse modification of habitat designated as critical for listed species. In addition, federal agencies must “confer” with USFWS on any action that is likely to jeopardize the continued existence of any species proposed to be listed or any action that may result in the destruction or adverse modification of critical habitat proposed to be designated for listed species.

This RMP/EIS is considered to be a major project and this document describes potential impacts to threatened and endangered species as a result of management actions proposed in the RMP. Contacts were made with the USFWS early in the RMP process, and a representative of the USFWS was on the planning team during development of the plan to adequately address and discuss the effects of management actions on listed and proposed species and their critical habitats. The USFWS also provided guidance to the BLM regarding compliance with Executive Order 13186 for the conservation of migratory birds.

Early drafts of alternative provisions were provided to USFWS staff for discussion and review. An initial list of federally listed threatened or endangered plant, animal, or fish species or habitats present in the Butte Field Office Planning Area was requested on March 23, 2006, with an update received March 29, 2006. Four federally listed threatened wildlife species and one threatened plant species potentially occur, or potential habitat is available in the Planning Area. These include: grizzly bear (*Ursus arctos horribilus*), gray wolf (*Canis lupis*), Canada lynx (*Lynx Canadensis*), bald eagle (*Haliaeetus leucocephalus*), and Ute ladies’ tresses (*Spiranthes diluvialis*).

A biological assessment that evaluates the impacts of the preferred alternative on federal threatened and endangered species was submitted concurrently with public release of the Draft RMP/EIS to the USFWS. The Proposed RMP/Final EIS (**Appendix G – Wildlife**) includes the USFWS biological opinion, received on January 22, 2008.

### STATE HISTORIC PRESERVATION OFFICE CONSULTATION

The BLM cultural resource management program operates in accordance with 36 CFR Part 800, and through the Montana State Protocol, which provide specific procedures for consultation between the BLM and the State Historic Preservation Office (SHPO) to meet BLM responsibilities under the National Historic Preservation Act. The SHPO was consulted during the development of the Draft RMP/EIS concerning cultural resources that may be affected by being included on the RMP mailing list throughout scoping and public involvement. The Proposed Planning Scenario and solicitation for feedback were also sent to SHPO in June 2005. Formal comments on the Draft RMP/EIS were received in August, 2007 and are addressed in the Comment and Response section of this chapter.

### TRIBAL CONSULTATION

In accordance with the National Historic Preservation Act as well as in recognition of the government-to-government relationship between tribes and the federal government, the Butte Field Office has included the business and preservation offices of 11 tribal governments in the development of the EIS. Letters were sent to the Blackfeet, Shoshone, Salish and Kootenai, and Shoshone-Bannock tribal governments and officials on August 13, 2002 to invite them to be cooperating agencies on the Butte RMP. The letters also requested their input on issues and concerns to be considered during the planning process and initiate efforts to identify areas of traditional cultural concern.

In December 2004 BLM invited the following tribes to an agency update briefing on the Butte RMP that was held in Helena on February 15, 2005: Tribal Council of the Confederated Tribes of the Flathead Reservation, Shoshone-Bannock Tribes Business Council, Shoshone Business Council, and the Blackfeet Tribal Business Council.

BLM solicited feedback when the Proposed Planning Scenario was sent to the following tribal governments in June 2005: Turtle Mountain Band of Chippewa Indians, Blackfeet Tribal Business Council, Chippewa Cree Business Committee, Tribal Council of the Confederated Salish-Kootenai Tribes of the Flathead Reservation, Crow Tribal Council, Fort Peck Tribal Executive Board, Northern Cheyenne Tribal Council, Shoshone-Bannock Tribes Business Council, and the Nez Perce Tribes.

Feedback was further solicited in additional mailings of the Proposed Planning Scenario in Spring 2006 to the Tribal Historic Preservation Offices of these tribes: Turtle Mountain Band of Chippewa Indians, Chippewa Cree Business Committee, Tribal Council of the confederated Salish-Kootenai Tribes of the Flathead Reservation, Fort Belknap Community Council, Fort Peck Tribal Executive Board, Northern Cheyenne Tribal Council, Shoshone Business Council, Arapaho Business Council, Shoshone-Bannock Tribes Business Council, Nez Perce Tribal Executive Committee, and Blackfeet Tribal Business Council.

Various levels of interest have been expressed by different tribal offices. Informal coordination as well as two meetings with the Preservation Office and resource specialists have been conducted with the Ft. Hall Shoshone-Bannock Tribes. Informal coordination, Business Council and two Preservation Office meetings have been held with the Confederated Salish and Kootenai Tribes of the Flathead Reservation. One meeting with the Tribal Historic Preservation Officer and one Business Council meeting was held with the Blackfeet Tribes.

## INFORMAL CONSULTATIONS

BLM has conducted less formal coordination and consultation with various entities throughout the development of the Draft RMP/EIS. As directed by the Watershed Protection and Flood Prevention Act and the Clean Water Act, BLM has included the U.S. Environmental Protection Agency, Montana Department of Environmental Quality, and Natural Resource Conservation Service in scoping activities, including the scoping of the Proposed Planning Scenario in June 2005.

Livestock grazing permittees and lessees have been included in public scoping efforts and mailings. Interested permittees were included in the scoping of the Proposed Planning Scenario in June 2005.

## PUBLIC COMMENTS ON THE DRAFT RMP/EIS

A total of 172 separate submissions of comments on the Draft RMP/EIS were received during the comment period. Approximately 20 submissions were duplicated through multiple media (fax, email, and U.S. mail). Unique submissions included 68 letters (including BLM-provided comment forms), 76 emails, and 8 faxes. Several additional verbal comments on site-specific travel plan alternatives were also received at public meetings.

## ADDRESSING PUBLIC COMMENTS

Upon receipt by the BLM, each comment submission was assigned an identification number and logged into a tracking database. Specific comments from each submission

were also entered into a database and coded to appropriate categories based on content of the comment, retaining the link to the original commentor. Comments similar to each other were combined and summarized, and have been responded to once in the Comment and Response section below. Commenters can reference their name (listed alphabetically by last name, or by the name of the organization or government entity represented) to identify the sections that contain responses to their identified concerns. When several submissions identified the same concern, the concern was summarized and may not necessarily appear in this document with wording identical to the commentors' language.

All comments were reviewed and considered, however comments were not counted as "votes". Comments that presented new data or addressed the adequacy of the document, the alternatives, or the analysis are responded to in the Proposed RMP/Final EIS. Changes were made to the Preferred Alternative (Alternative B) presented in the Draft RMP/EIS as a result of comments. Major changes or additions in the Proposed RMP/Final EIS are shaded in light gray, and reflect consideration given to public comment, corrections and rewording for clarification. A list of major changes to the document can be found in Chapter 1 of the Proposed RMP/Final EIS.

Many comments received through the process expressed personal opinions or preferences, had little relevance to the adequacy or accuracy of the Draft RMP/EIS, or represented commentary regarding resource management without real connection to the document being reviewed. These comments did not provide specific information to assist the planning team in making a change to the Preferred Alternative, did not suggest rationale for other alternatives, did not take issue with methods used in the Draft RMP/EIS, and are not addressed further in this document. Examples of these comments include:

- *BLM lands are not just dirt. BLM lands are acreage with resources other than oil, gas, coal, timber. Soils, aquifers, plant communities, and wildlife are resources too. So is silence. Please pay a little more attention to the unpermitted part of your resource management. A place to start is with management plans with extensive biological research as a foundation.*
- *MWF believes the BLM can most responsibly manage the public lands in its charge if it elevates the most protective aspects within the RMP/EIS, hereafter referred to as the Butte RMP, for hunting, fishing, and access to our public lands; the economic importance of outdoor recreation activities that include hunting and fishing to the state of Montana has surpassed agriculture, mining, timber and other extractive activities as per the Montana Department of Commerce.*

- *The needs of all the people are best met by management of public lands and programs for multiple-uses. Motorized roads and trails are a significant source of recreation for all of the public. The public expects decision-makers to adequately protect the existing standards of living and opportunities (human environment) in their decisions. NEPA did not intend for citizens who do not comment on NEPA actions to give up their standard of living to those that do. We ask that public comments not be used as a voting process and that the needs of all citizens be fairly addressed in the document and decision-making.*
- *The Elkhorn Mountains should not be a proposed ACEC site nor a wilderness site or any such thing. Now if the goal of BLM is to work with the FS to eliminate all opportunity to explore and mine in this area, an ACEC process is a great way to go. But if you go this way, then you are discriminating against one segment of taxpaying citizens in favor of other mostly non-taxpaying citizens.*
- *We support the designation of all five potential Areas of Critical Environmental Concern (ACECs, Sleeping Giant, Elkhorn Mountains, Spokane Creek, Ringing Rocks, Humbug Spires, page 66), including the expanded all BLM lands in the Elkhorn Mountains for a total ACEC acreage of 87,893 acres, to apply special management to protect such areas from damage or degradation.*
- *I support the BLM's recommendation to designate 3.1 miles of the Missouri River as a Wild and Scenic River.*
- *It is my opinion, given my history of riding and recreating, that ANY closure of existing used trails is unacceptable.*
- *Of all your Travel Plan alternatives it is obvious that the best and most logical choice is Alternative C. Please choose, implement, and enforce Alternative C for all the Travel Plan areas.*
- *Unfortunately rules often times go to the lowest common denominator, i.e. the guy doing the most irrational things. Agencies are encouraged to keep rules as simple as possible and focused on addressing problems that are common and not the exceptions. Motorized recreationists can be called upon to help address the exceptions.*
- *In your Preferred Alternative B and also Alternatives C and D, I feel you are closing and decommissioning way too many roads for no apparent reason, as far as I can see. I feel both BLM and Forest Service should be opening back up roads already closed, especially for game retrieval.*
- *I am writing to advocate Alternative C for the travel plan for the Scratchgravel Hills Draft Resource Management Plan.*
- *Always preserve biological, cultural, scenic and wilderness resources.*

## COMMENT CATEGORIES AND COMMENTER NAMES

Two lists are provided on the following pages. The first list is an index of codes assigned to the 38 subject categories within which comments were received. The second list alphabetically lists the agencies, organizations, and persons who submitted comments on the Draft RMP/EIS and the codes associated with their comments. Commenters can find their name (or the name of the agency or organization they represented) and the corresponding comment codes, and look up responses to see how their concerns have been addressed.

## INDEX OF COMMENT CODES

<i>Subject</i>	<i>Comment Codes</i>	<i>Page Number</i>
Air Quality, Climate	A1 through A9	692-695
Alternatives	B1 through B6	695-697
Cultural Resources	C1 through C3	697-698
Economics	D1 through D14	698-702
Fire and Fuels	E1 through E14	702-705
Fish and Wildlife	F1 through F43	705-725
Forest and Woodland Vegetation	G1 through G12	725-729
Grassland and Shrubland Habitat	H1 through H12	729-733
Lands and Realty	I1 through I6	733-735
Livestock Grazing	J1 through J25	735-740
Minerals	K1 through K15	740-743
Monitoring, Implementation	L1 through L14	743-745
Noxious Weeds	M1 through M20	745-753
Oil and Gas	N1 through N31	753-766
Out of Scope, Staffing, Budget	O1 through O26	766-771
Process, Public Involvement and Editorial Issues	P1 through P57	771-783
Recreation	Q1 through Q24	783-788
Riparian Habitat	R1 through R8	788-791
Social Conditions	S1 through S17	791-796
Soils	T1 through T3	796-796
Special Designations – Areas of Critical Environmental Concern	U1 through U13	796-801
Special Designations – National Trails/Wild and Scenic Rivers/ Wilderness Study Areas	V1 through V12	801-805
Special Status Species	W1 through W17	805-811
Travel Management – General	X1 through X34	811-819
Travel Management – Multiple Use/Public Access	Y1 through Y50	819-830
Travel Management – Mitigation, Maintenance, Closure Methods	Z1 through Z13	830-833
Travel Management – Resource Impacts	AA1 through AA38	833-846
Travel Management – Travel Plan Implementation	BB1 through BB11	846-849
Travel Management – Travel Planning Process	CC1 through CC33	849-857
Travel Management – User Conflicts	DD1 through DD13	857-860
Travel Management – User Data	EE1 through EE8	860-862
Travel Management – Winter Use/Snowmobiles	FF1 through FF5	862-864
Travel Planning Areas – Boulder/Jefferson TPA	GG1 through GG12	864-867
Travel Planning Areas – East Helena TPA	HH1 through HH7	867-869
Travel Planning Areas – Helena TPA	II1 through II12	869-872
Travel Planning Areas – Lewis and Clark Co. NW TPA	JJ1 through JJ7	872-874
Travel Planning Areas – Upper Big Hole River TPA	KK1 through KK16	874-877
Water	LL1 through LL12	877-883

## LIST OF COMMENTERS/CODES

The following list displays the names of the individuals and organizations who commented on the Draft RMP/EIS and the corresponding comment codes for specific comments made. Organizations and government

entities are listed by the organization or government agency rather than by the signatory to the submission. Commentors can use this cross-reference to review responses to their comments by referencing the appropriate comment sections.

<i>Commenter</i>	<i>Code</i>

## COMMENTS AND RESPONSES

Page numbers references in public comments refer to page numbers in the Draft RMP/EIS. BLM responses refer to document sections, rather than page numbers, because page numbers have changed between the Draft RMP/EIS and the Proposed RMP/Final EIS.

### Air Quality, Climate

#### A1

**Comment:** The RMP should meet potential future Regional Haze requirements established by the State, and EPA. We note that the Montana DEQ has returned the clean air visibility program to EPA (see <http://deq.mt.gov/AirQuality/Visibility.asp>). Please call

Ms. Laurel Dygkowski of EPA in Denver for latest information on visibility issues in Montana at 303-312-6144. See also, <http://www.fs.fed.us/pnw/fera/research/smoke/haze/index.shtml>.

**Response:** As stated in Chapter 2 under Management Concerns, Air Quality, Management Common to All Alternatives, the BLM would comply with local, state, and federal regulatory requirements. This includes all existing and future requirements, including regional haze.

#### A2

**Comment:** The last sentence before the section on Air Quality Monitoring and Standards on page 209 refers to fine particulate matter. The sentence reads, “There are

no non-attainment designations for fine particulate matter (PM<sub>2.5</sub>) because the required monitoring data has not been collected or evaluated.” Please correct this sentence; the Montana Department of Environmental Quality (DEQ) and other state agencies have conducted air monitoring for PM<sub>2.5</sub> and EPA has designated non-attainment areas. See: [www.epa.gov/pmdesignations/](http://www.epa.gov/pmdesignations/).

**Response:** Content has been changed in the Proposed RMP/Final EIS to read: “Currently, there are no non-attainment designations for fine particulate matter (PM<sub>2.5</sub>) within the Planning Area. The closest non-attainment designation is Lincoln County in the far North West portion of the state of Montana.”

### A3

**Comment:** A footnote to Table 3-1 (page 210) states, “Monitoring data are not available through the EPA AirData Database for nitrogen dioxide (NO<sub>2</sub>), sulfur dioxide (SO<sub>2</sub>), and ozone (O<sub>3</sub>) since no counties within the Planning Area have monitoring stations for these pollutants.”

Although air monitoring stations in the planning area do not currently collect data for these pollutants, data are available from past monitoring at least in the case of SO<sub>2</sub> in Lewis & Clark County. We recommend that BLM consult with Montana DEQ regarding data for Table 3-1.

**Response:** Table 3-1 has been modified in the Proposed RMP/Final EIS to reflect any new or existing information that is available. Sulfur Dioxide was monitored until 2001 by East Helena (Lewis and Clark County). All values were well below Air Quality standards.

### A4

**Comment:** The Air Quality portion of the section about cumulative effects on resources (page 481) refers primarily to cumulative effects of smoke. The reasonably foreseeable development scenario for oil and gas exploration assumes 15 exploratory wells, and this development should be considered a part of cumulative effects on air quality. (The DEIS also discloses that up to 40 wells would be drilled for coal bed natural gas, but assumes that none of these wells would be drilled on federal mineral estate.) Other aspects of management, such as transportation, may contribute to cumulative effects. We suggest that the FEIS include at least a qualitative discussion of these potential contributions to cumulative impacts.

**Response:** The Air Quality sub-section of the Cumulative Effects section in Chapter 4 has been modified to include additional general discussion about effects from oil and gas development, motorized vehicle emissions, and other activities in the Planning Area.

### A5

**Comment:** It would be appropriate to reference in the air quality discussions in the draft RMP and EIS that Standard #4 in the Standards for Rangeland Health and Guidelines for Livestock Grazing (Appendix E, page 723) states that “Air Quality meets State Standards.” It is not clear to us why this Air Quality Standard is included in the Livestock Grazing guidance. Such an Air Quality Standard should be applied across all BLM lands, and it would appear appropriate to include this Standard also in the RMP section on Air Quality.

**Response:** The Air Quality section in Chapter 2 of the RMP under Management Common to All Alternatives states: “All resources uses would meet the Land Health Standards for air quality and BLM would comply with local, state, and federal regulatory requirements.”

### A6

**Comment:** Also, it would be appropriate to integrate the recent guidance on the PM-2.5 particulate standard into this RMP Standard. Also Appendix E, Standard #4, lists only Montana Ambient Air Quality Standards (MAAQS) and should also address National Ambient Air Quality Standards (NAAQS) in general. Note that the Montana DEQ’s web site has a table showing both MAAQS and NAAQS, [www.deq.state.mt.us/AirQuality/Planning/AirStandards/AIR\\_STANDARDS.pdf](http://www.deq.state.mt.us/AirQuality/Planning/AirStandards/AIR_STANDARDS.pdf).

Montana does not have a PM-2.5 standard other than the NAAQS. Please contact Joe Delwiche in EPA’s Denver Regional Office if you have any questions on the PM-2.5 particulate standard (telephone number, 303-312-6448).

**Response:** Standard #4 does include National Ambient Air Quality Standards. The last sentence under the Air Quality Standards states that “In no case, however, may pollutant concentrations exceed the National or State ambient air quality standards” (Appendix F of the Proposed RMP/Final EIS). This would include the new PM<sub>2.5</sub> National Standard.

### A7

**Comment:** Air quality concerns can result where concentrated snowmobile use occurs in areas of poor air dispersion (e.g., river valleys where frequent inversion conditions may trap air pollutants). Snowmobiles (and ATV) 2-stroke engines mix the lubricating oil with the fuel and both are expelled as part of the exhaust, and allow up to one third of the fuel delivered to the engine to be passed through the engine and into the environment virtually unburned. As stated in the U.S. Department of the Interior document, “Air Quality Concerns Related to Snowmobile Usage in National Parks”, Feb. 2000, hydrocarbon emission rates from 2-stroke snowmobile engines are about 80 times greater than those found in a 1995-96 automobile engines. A majority of these hydrocarbons are aromatic hydrocarbons, includ-

ing polyaromatic hydrocarbons, which are considered to be the most toxic component of petroleum products, and aromatic hydrocarbons are also associated with chronic and carcinogenic effects. If concentrated snowmobile use occurs in areas of poor air dispersion some restrictions may need to be considered. There are numerous studies underway to further determine environmental effects of these pollutants. The National Park Service Final EIS for Winter Use in Yellowstone and Grand Teton National Parks contains a good summary of the science regarding impacts from snowmobile use. EPA recommends that the Forests monitor the results of these studies and factor the results into travel management and resource planning. We will also try to pass on information emerging out of these studies. The EPA encourages use of the newer less polluting 4-stroke engine snowmobiles.

In 2003, the National Park Service implemented a commendable "best available technology" (BAT) program at Yellowstone National Park to reduce snowmobile emissions and noise that is critical to improving air quality and public health and recreational experience, and reducing wildlife disturbances due to snowmobile use in the Park. This has resulted in improved air quality and soundscapes as well as reduced wildlife disturbance from snowmobile use. The combination of significantly reduced snowmobile numbers and the use of BAT has decreased the predicted maximum carbon monoxide and particulate matter levels by about eighty-five percent.

We encourage the BLM to consider development of a program to manage snowmobile use, emissions, and noise to improve air quality, public health, and recreational experience while reducing wildlife disturbances.

**Response:** Most BLM lands are not within areas of poor air dispersion such as river valleys. There are no known areas of concentrated snowmobile use in the planning area on BLM managed public lands. The BLM manages snowmobile use through its site specific travel planning. See Chapter 2 under Travel Management and Access of the RMP for proposed open and closed areas for snowmobiles by alternative. BLM land use and travel plan decisions focus on designation of open, limited, and closed areas and/or routes and do not specify or limit types of snowmobile engines for use on public land since concentrated use is not an issue in the planning area.

#### A8

**Comment:** It is stated (page 81) under the section on Management Concerns, Air Quality, that, "Air resources would continue to be evaluated on a case-by-case basis as part of project level planning to ensure compliance with local, state, and federal regulatory requirements."

Where proposed projects involve substantial burning, particularly near populated areas or areas with protected visibility, planners should use software to estimate emis-

sions and dispersion of smoke. In addition, please add to this paragraph a statement that project level analyses for oil and gas development projects should also address air quality.

**Response:** In Chapter 2 of the Butte RMP under Management Concerns, in the Air Quality section, under Management Common to All Alternatives, it states: "Air resources would continue to be evaluated on a case-by-case basis as part of project level planning to ensure compliance with local, state, and federal regulatory requirements. Evaluations would consider the significance of the proposed project and the sensitivity of air resources in the effected area. Mitigation measures would be developed as appropriate to ensure compatibility of the projects with air resource management." That statement would ensure that projects involve substantial burning, particularly near populated areas or areas with protected visibility be considered.

BLM currently operates under the Interagency Prescribed Fire Planning and Implementation Procedures Reference Guide which provides for the use of computer modeling. It states that the burn plans need to describe how the project will comply with local community, county, state, tribal and federal air quality regulations and identify smoke sensitive areas including population centers recreation areas, hospitals, airports, transportation corridors, schools, non-attainment areas, Class I airsheds, and restricted areas that may be impacted. If required by state implementation plans and/or state or local regulations, modeling outputs will be included in burn plans as well as mitigation strategies and techniques to reduce the impacts of smoke production.

The Air Quality section of Chapter 2 has been modified to discuss oil and gas development by including the following statement under Management Common to All Alternatives: "Before approval of an application for permit to drill (APD) for oil and gas or a Sundry Notice application that would involve surface disturbance the appropriate level of NEPA analysis, in most cases an EA, is completed. This document would analyze effects on all appropriate resources and resource uses including air quality as identified."

#### A9

**Comment:** CHAPTER 3 AFFECTED ENVIRONMENT: Climate: More analysis of climate change should have been provided (p. 210). Table 3-2 provides averages for seven climatic measurements over a 110 year period from four different weather stations. The analysis should have looked at five or ten year increments in order to assess trends rather than averages. These climatic features may have had an influence that could be changing over time and thus affecting landscape function such as winter range, functional summer range, species distribution.

Scientifically quantified examples are the seriously diminishing habitat for pika, expansion of suitable habitat for noxious weeds, and implications for population and habitat management.

**Response:** Climate data displayed in Table 3-2 was provided to show the average temperatures and precipitation over a period of time and was intended to characterize weather patterns within the Butte Field Office. The data was not intended to display trends or changes in climate.

A section on Global Climate Change has been added to Chapter 3 (under the Air Quality heading, Climate sub-heading) to describe global climate change and its potential effects on resources and resource uses in the Planning Area. A section has also been added to Chapter 4 (after the Cumulative Effects on Social and Economic Conditions section) to discuss potential effects of BLM activities associated with the Butte RMP on global climate change.

Because the assessment of greenhouse gas emissions and climate change is in its formative phase, it is not yet possible to know with confidence the net impacts to climate. The Intergovernmental Panel on Climate Change (IPCC 2007) recently stated that “warming of the climate system is unequivocal...” and that “most of the observed increase in globally average temperatures since the mid-20th century is very likely due to the observed increase in anthropogenic [man-made] greenhouse gas concentrations.”

The lack of scientific tools designed to predict climate change on regional or local scales limits the ability to quantify potential future impacts. If global climate change results in a warmer and drier climate, cool season plant species’ ranges could potentially move north and result in a potential loss of habitat. A warmer, drier climate could also result in competition between plant and/or animal species whose ranges shift. It is also possible that populations of many plant and animal species could decline or be at risk of extinction.

Many of the models needed to make effective decisions at the local and regional levels have not been developed. The Department of the Interior is exploring whether global and regional climate modeling can be scaled to the point that it can be used to manage parks and refuges. When further information on the impacts to climate change is known, it would be considered during site-specific analysis and implementation of the RMP.

## Alternatives

### B1

**Comment:** There is a serious deficiency and conflict built into the “Travel & Transportation Management, Planning and Conducting Route Inventories, Technical

Reference 9113-1” (<http://www.blm.gov/nstc/library/pdf/TR9113-1.pdf>). There are only two references in the entire manual to single-track trails and in both cases the manual describes single-track as being primarily used for hiking (page 38, route type 6.) and in the second instance not used by motorbikes (page 39, use classification 6, Wilderness Area). The motorized single-track definition bound on figure 2.2 on pages 12 and 14 of Chapter 2 in the 3-State OHV EIS and decision (<http://www.mt.blm.gov/ea/chapter2.pdf>) is much better and more acceptable to the motorized community. This definition clearly shows that existing single-track trails used by motorcycles are to be considered as motorized trails/routes. We request that the definition of single-track motorized trails in Technical Reference 9113-1 be modified to reasonably address motorcycle trails which are very popular in the project area.

**Response:** Changing the definition of single-track motorized trails in Technical Reference 9113-1 is outside the scope of the Butte RMP.

### B2

**Comment:** Montana Wildlife Federation strongly supports Alternative C as most fully protecting and enhancing the high wildlife values that sportsmen have labored hard to conserve within the Butte RMP area.

Alternative C is far from being the most extreme management options but represents a realistic, pragmatic choice that will indeed maximize wildlife and hunting/fishing values. Montana Wildlife Federation requests that Alternative C to be chosen as the Preferred Alternative as it represents the highest benefit for resource in regards to hunting and fishing values. The following list of bullets supports our rationale and is quoted directly from the draft Butte RMP Alternative C in various places and paraphrased:

- Alternative C poses the lowest impact to water quality and Wild and Scenic values.
- Alt. C creates the lowest impacts from road construction.
- Alt. C offers the greatest winter range protection
- Alt. C provides the greatest habitat protection
- Alt. C provides for the most protection of all alternatives for fish and other aquatic organisms by only allowing activities within riparian areas that would restore or maintain the riparian zone.
- Alt C provides for the optimum protection while the area sustains a long-term population growth.
- Alt. C contributes the least number of adverse cumulative impacts to fish and wildlife values.

**Response:** The BLM acknowledges the long-term efforts of multiple entities in conserving wildlife values within the Butte Field Office. While Alternative C may

best meet the needs of wildlife in some respects, the BLM continues to believe that the mix of proposed activity and resource protection measures under Alternative B best meet the BLM's multiple use mission. The BLM notes that Alternative B provides improved protection and reduced impacts to wildlife compared to the current condition under Alternative A. Riparian protection measures under Alternative B would require these areas to be managed for site-specific riparian values, including wildlife. Alternative B would improve wildlife habitat as related to road impacts compared to the current condition. The nature and extent of proposed vegetation treatments under Alternative B would improve wildlife habitat more than either Alternative A or C.

### B3

**Comment:** American Wildlands recommends that the BLM reconsider Alternative B as the preferred alternative. If only one alternative had to be chosen at this time, Alternative C would be best for long term wildlife habitat connectivity. However, American Wildlands does not view Alternative C as the best alternative in all cases, and in some specific instances, recommends other alternatives.

**Response:** While wildlife habitat connectivity was considered in the development of RMP alternatives, the BLM still considers Alternative B to provide the best balance of resource protection and resource uses to best meet its multiple-use mission. The BLM believes that the level of active vegetation treatments proposed under Alternative B would benefit wildlife habitat more overall than the reduced levels of proposed treatment under Alternative C.

### B4

**Comment:** I have lived in the Silver Creek Subdivision since 1982 and my land is bordering along 6,679 feet of Scratch Gravel BLM land that is adjacent to Helena Travel Plan Route Map 8. This land is being used heavily by off road vehicles, motorcycles, and ATVs which put people that walk or ride horses there at risk due to the speeders which are tearing up the roads, trails and off road areas. They don't care about the damage they cause or the mess they leave behind - garbage, beer cans, drug stuff.

The BLM needs to have additional enforcement to control and catch these bad guys. This is why I feel that the Helena Travel Plan Route Designations under Alternative C would stop some of the damage but not all.

**Response:** The Preferred Alternative for the Scratch-gravel Hills portion of the Helena Travel Planning Area has been changed from the Draft RMP/EIS to the Proposed RMP/Final EIS. The revised Preferred Alternative would close the Scratchgravel Hills to wheeled public motorized use yearlong, 24 hours/day, with the exception of several routes with rights-of-way to homeowners

as well as a few other known routes needed by local residents to access their homes. This closure should improve the negative conditions described in the comment.

### B5

**Comment:** Areas of Critical Environmental Concern (ACEC): We support the ACEC special designation of the Elkhorns as described in Alternative C. Alternative C designates all of the land as described in the Elkhorns Wildlife Management Unit MOU and as depicted by the BLM portion of the ECMA (approximately 67,665 acres). This alternative would provide the greatest protection for the relevant and important values associated with this ACEC and is most compatible with our Forest Plan goals to manage the Elkhorns as a Wildlife Management Unit.

**Response:** The BLM has modified the boundaries of the Elkhorns potential ACEC in the Preferred Alternative (Alternative B). This boundary now excludes the Graymont Mine permitted area as well as the currently proposed expansion boundaries. Also, the Montana Army National Guard proposed withdrawal area is now fully excluded. The recently acquired Iron Mask property has been included in the Preferred Alternative.

### B6

**Comment:** York Bridge East: This is the BLM land on the east side of the bridge and north of York Road/Trout Creek. These lands, along with the adjoining FS lands that lie west of the road to Nelson and SE of Soup Creek, comprise a mini-wilderness, with rugged, scenic terrain, historic artifacts (aqueducts, some prospecting), goats, arches, the old peregrine hawk site, and a few old tracks to explore and help get around on. It's an area that should be left, and preserved, 'just like it is.' To that end, you should make it an "exclusion" area (towers or utility corridors would be an abomination here), impose NSO stipulations (any leaseholder could drill from the FS ground in the Nelson road corridor), and classify it as semi-primitive non-motorized.

The BLM land south of Trout Creek and north of the old sapphire diggings area, on the flats north of the Ward Ranch (roughly the S2 Sec 13 and N2 Sec 24), is also wild and rugged, and should be managed the same way, i.e., "exclusion" area, NSO stipulations, semi-primitive non-motorized.

**Response:** The BLM notes that under the Preferred Alternative in the RMP, much of the area in question is proposed for No Surface Occupancy stipulations for oil and gas leasing, and much of it is proposed for Recreation Opportunity Spectrum management of semi-primitive non-motorized. The Preferred Alternative in the Draft RMP/EIS proposed the area on the east side of the Missouri down through Ward Ranch as an "avoidance" area for rights-of-way. The BLM believes this

level of protection is adequate for this area and retains the same proposed management in the Proposed RMP/Final EIS.

## Cultural Resources

### C1

**Comment:** We do not agree with prescribed fire effects characterization found on page 417. It is and has been widely documented that prescribed fire has the potential to adversely affect many different cultural resources and we have met with you regarding those findings in the past. The potential for adverse effects varies with a number of variables embedded in the prescription and resources types. We disagree with the summary characterization made in the RMP that the potential for adverse effects is a "minimal threat." That threat level varies with the above variables and should be assessed on a case by case basis. If that is understood it should be made explicit in the RMP. Montana Historical Society is more than willing to consult on specific applications and proposed findings of effect as they are proposed. If, on the other hand, this characterization in the Butte RMP implies that prescribed fire will not be considered an undertaking with the potential to effect historic properties as some sort of categorical exclusion based on generic prescriptions we believe formal consultation on the issue is warranted.

**Response:** It is not the BLM's intention to imply that the phenomenon of fire (prescribed or not) is, in itself, a minimal threat. Nor is it the BLM's intention to imply that prescribed fire projects are not undertakings. Prescribed fires are undertakings that require cultural resource inventories and completion of the section 106 process prior to project implementation. Generally, a carefully conducted prescribed fire will avoid most impacts to all known cultural resources. While each project has the potential to escape, the BLM believes that this threat is minimal when prescribed fire burn windows are properly utilized. This section of text has been changed in the Proposed RMP/Final EIS to clarify the BLM's position.

### C2

**Comment:** We are concerned about the preservation of historic mines, cabins, settlements, railroads, access routes, and other features used by pioneers, homesteaders, loggers, settlers, and miners. These are important cultural resources and should not be removed from the landscape. Western culture and heritage has been characterized by opportunities to work with the land and preservation of all remnants of this culture and heritage is important. Current management practices are not adequately protecting western culture and heritage including the opportunity to work with the land. We request that the ties to the land that are part of our local western culture and heritage be protected and that the

preferred travel management alternative include opportunities to visit these features as part of motorized interpretative spur destinations and loops.

**Response:** The BLM has ongoing programs that identify historic structures suitable for restoration and repair. It is BLM policy to avoid impacts to historic structures and other historic property types through project redesign to reduce or eliminate impacts to these properties from a proposed surface disturbing activity. If impacts are not avoidable the BLM will identify measures that will reduce the impact of a proposed activity on that historic structure. The BLM considers impacts to historic period structures and features consistent with regulations found at 36 CFR Part 800, the implementing regulations for the National Historic Preservation Act.

The BLM does interpret some historic period features and properties on a case-by-case basis. For example, at Ward Ranch there are two historic ranch headquarters that are available for walk-in visitation. However, the BLM believes that linking heritage resources to the proposed travel management alternatives would exceed our available resources to prepare those historic features for public visitation.

### C3

**Comment:** Cultural, Historic, Paleontology: The RMP should explain how the agency will work with tribal governments and comply with the National Historic Preservation Act. Areas being considered for oil and gas drilling should be inventoried prior to leasing to determine whether the area is appropriate for oil and gas drilling. If the BLM has not completed an inventory of historic sites, how will the agency determine whether an area is appropriate to lease for oil and gas drilling? The RMP should include information about what areas have been inventoried and how the BLM plans to expand its inventory of cultural, historic, and prehistoric sites. Importantly, it should address how the BLM will protect these sites once they are identified.

**Response:** The BLM employs a phased approach toward oil and gas leasing, development, and meeting our obligations under section 106 of the National Historic Preservation Act (NHPA). The first phase begins at the initiation of the Resource Management Plan process. It is at this point where we analyze existing inventory data concerning the distribution and significance of cultural resources. It is also at this point where we consult with tribes to identify areas where the tribes have particular concerns should development occur in those areas. Based on available data and the results of the tribal consultation, the BLM then makes decisions in the RMP on which areas should be open or closed to leasing and what stipulations should be applied at lease issuance.

The second phase of the leasing development process is initiated when individual lease parcels are reviewed by the BLM prior to a lease sale. The agency decides if

enough information is available to lease the parcel and properly protect cultural resources or if more information is needed. The cultural resource specialist reviews the cultural resource records to determine whether cultural resources are present in the proposed lease area and also reviews previous information from consultation with the tribes, existing ethnographic data, and the archaeological and historic literature specific to the area under review. This information is then analyzed comprehensively to determine if sensitive cultural resources may be present. If it is determined that the analysis requires more information, the BLM may conduct sample-based cultural resource surveys and/or seek additional tribal information to augment existing data.

The final phase of the compliance process occurs at the Application for Permit to Drill (APD) stage where the location of the proposed drilling program has been fully defined. It is at that point where the BLM will require site-specific cultural resource inventories, gather additional tribal information through consultation, and implement mitigation measures where necessary.

## Economics

### D1

**Comment:** Each route must include a socio-economic analysis that includes the impacts on the public owning OHVs and looking for opportunities to use them and landowners who purchased property with the intent of being able to access and recreate using motor vehicles.

**Response:** The economic analysis in this RMP is based on a set of anticipated levels of activities and reasonably foreseeable development scenarios for each alternative. Travel management of individual routes may be one of several management actions that influence the level and nature of these activities in one or more of the following resource management areas (recreation, fish and wildlife, grazing, timber, minerals, and other). The economic impacts expressed for each alternative reflect the impacts of the set of management actions, including travel management actions, for each alternative.

### D2

**Comment:** The negative social and economic impact experienced by motorized recreationists when motorized recreational opportunities do not exist in nearby public lands must be adequately evaluated and considered in the decision-making. This is especially significant now that fuel is over \$2.00 per gallon. These impacts include the complete loss of recreational opportunities and the cost of having to travel farther and farther in search of fewer and fewer motorized recreational opportunities in times of increasing travel costs. For example, the lack of adequate OHV systems in the Helena National Forest requires us to travel at least 180 miles to adjacent national forests and many more miles to other states including Idaho and Utah. A 180 mile roundtrip costs at

least 3 hours and \$70 and that cost will increase substantially in the future. This added cost is a waste of time and energy resources and has not been adequately considered by the agency.

**Response:** The expected level of recreation use for each alternative considered the travel management prescription for each alternative. The level of motorized vehicle travel currently accounts for an estimated 12 percent of total recreation use (in visits). It is predicted to decline by about 7,700 visits (5 percent) with Alternative B, about 15,400 visits (10 percent) with Alternative C, and about 3,100 visits (2 percent) with Alternative D. The economic analysis of recreation management displayed in Chapter 4 is based on expected levels of recreation use for each alternative. These economic impacts are expressed in terms of employment and labor income, including proprietor's income.

### D3

**Comment:** The different management plans being developed by the BLM and Forest Service are using generated, estimated, and inadequate data to forward an agenda of eliminating access and motorized recreation from public lands. The economic impact of these closures will be devastating to small communities throughout the West. Models can be manipulated to predict any result. Economic models such as IMPLAN should not be used when the input data is estimated and not factual or actual. Adequate effort must be exercised by the agencies to gather true on the ground data from businesses and individuals that use our public lands. We request that the economic analysis use actual local data to determine the true economic and social impact of proposed motorized access and closures on the public.

**Response:** IMPLAN data are drawn from several government sources, the most important of which are the Bureau of Labor Statistics ES202 data, and the Bureau of Economic Analysis REIS and County Business Patterns data. All of these data are "real" and "local" in that they come from censuses of individual firms aggregated to the county level. The IMPLAN Model is the most flexible, detailed, and widely used input-output impact model system in the U.S. Over 1,500 clients across the country use the IMPLAN model. IMPLAN is a professionally accepted, widely used computer model to predict economic impacts of resource management decisions. It is analytical and it provides evidence that the agency used professional integrity, including scientific integrity, concerning economic impact assessments. Resource inputs to the Butte RMP IMPLAN analysis reflect the level of activity anticipated by the local Butte Field Office resource professionals and involved extensive levels of local public participation and consultation.

### D4

**Comment:** A recent study by David Sunding, an associate professor of natural resource economics, David

Zilberman, a UC Berkeley professor of agriculture and resource economics, and graduate student Aaron Swoboda to the California Resource Management Institute found that the economic impacts from designation and preservation of special plant and animal habitat areas continue to cost society hundreds of millions of dollars because of delays, court fees and opportunities forgone. Sunding's report, released Feb. 20, found that agencies had underestimated the actual economic and social impact by seven to 14 times. Certainly, natural resource decisions cannot and should not be made entirely on economic impacts. However, NEPA requires that both economic and environmental facts should be considered in the final land management decisions. The U.C. Berkeley study displays the fact that the full economic and social facts and impacts are not being adequately considered by the federal land management agencies. We request adequate evaluation of the economic and social impacts of this proposed action be considered in the analysis and decision-making. Additionally, we request that the cumulative negative impact resulting from inadequate evaluation of economic and social impacts in past actions are considered in the analysis and decision-making and that an adequate mitigation plan be included as part of this action to compensate for past cumulative negative impacts.

**Response:** To analyze individual national policies is beyond the scope of this analysis. The economic analysis in this RMP is based on a set of anticipated levels of activities and reasonably foreseeable development scenarios for each alternative. The designation and preservation of special plant and animal habitat may be one of several management actions that influence the level and nature of these activities in one or more of the following resource management areas (recreation, fish and wildlife, grazing, timber, minerals, and other). The economic impacts expressed for each alternative reflect the impacts of the set of management actions for each alternative by alternative, not individual actions or national policies.

#### D5

**Comment:** We request that the analysis include an adequate benefit-cost analysis of non-motorized versus motorized trail use. This analysis should include the annual cost of the non-motorized trails per the actual and documented number of non-motorized trail user. The economic analysis should also compare the annual benefit-cost per non-motorized user versus the annual benefit-cost per motorized user if the trails and funding were used as multiple-use/motorized trails. Motorized trail users out-number non-motorized trail users at least 25 to 1 (see summary of local observations). Motorized recreationists need approximately 5 times the miles of trail per day compared to non-motorized recreationists (CBU analysis). Therefore, motorized recreationists need 125 times (25 x 5) the miles of trails as do non-motorized recreationists. However, the current allocation of re-

sources in the forest is significantly weighted towards non-motorized and is no where near this ratio. Additionally, the allocation is moving in the wrong direction towards more non-motorized opportunities with each decision (refer to Table 2 past and current actions). An increased allocation of exclusive non-motorized trails is not a good use of the taxpayer's money. Additionally, non-motorized trails benefit a very limited number of recreationists who already have more than adequate recreational resources when compared to motorized recreationists. It is more reasonable for the decision to focus on multiple-use trail projects and invest our limited financial resources in those types of projects. The benefit-cost analysis should also recognize the significant economic benefit associated with motorized recreation. Motorized economic benefit far exceeds the economic benefit of non-motorized recreation because there are more motorized recreationists and they have a considerable investment in their recreation. Economic benefits to the local economy associated with motorized recreation include sale of OHVs, parts and service; sale of tow vehicles, parts and service; sale of camping units, parts and service; fuel; meals; motels, etc.

**Response:** There is no requirement under the National Environmental Policy Act to conduct a benefit-cost analysis, nor is it appropriate to conduct a benefit-cost analysis considering the social and economic goals summarized in Table 2-23 under Management Concern: Social and Economic Environment. Benefit-cost analysis is only one of several economic analysis methods that can be used to help make public decisions about the natural environment. Benefit-cost analysis focuses only on benefits and costs and therefore economic efficiency. This may not be the most socially acceptable option or the most environmentally beneficial option.

The economic analysis summarized in Chapter 4 addresses the changes in local employment and income attributable to the various resource management program decisions. These impacts caused by recreation management, including travel management, reflect the anticipated changes in recreation use and related local expenditures. The level of motorized vehicle travel currently accounts for an estimated 12 percent of total recreation use (in visits). It is predicted to decline by about 7,700 visits (5 percent) with Alternative B, about 15,400 visits (10 percent) with Alternative C, and about 3,100 visits (2 percent) with Alternative D. The economic analysis of recreation management displayed in Chapter 4 is based on expected levels of recreation use for each alternative. These economic impacts are expressed in terms of employment and labor income, including proprietors' income.

#### D6

**Comment:** The positive economic impact on the economy of the area must be adequately considered in the decision-making. Arizona State Parks has prepared a

good example of an economic analysis of OHV recreation for Coconino County, AZ [http://www.gf.state.az.us/pdfs/w\\_c/OHV%20Report.pdf](http://www.gf.state.az.us/pdfs/w_c/OHV%20Report.pdf).

**Response:** The Butte RMP contains information in Chapter 4 on the economic impacts resulting from each of the alternatives. BLM believes this analysis is adequate to make the decisions covered in the Butte RMP.

#### D7

**Comment:** A common theme with the public and local and state governments has been the need for more economic development in the area and they are searching for ways to expand and enhance the local economy. OHV recreation is a significant part of the existing economy. Any reduction in OHV recreational opportunities will hurt the local economy. Additionally, the enhancement of OHV recreational opportunities in the project area will provide a badly needed enhancement of the overall local economy as well.

**Response:** The expected level of recreation use for each alternative considered the travel management prescription for each alternative. The level of motorized vehicle travel currently accounts for an estimated 12 percent of total recreation use (in visits). It is predicted to decline by about 7,700 visits (5 percent) with Alternative B, about 15,400 visits (10 percent) with Alternative C, and about 3,100 visits (2 percent) with Alternative D. The economic analysis of recreation management displayed in Chapter 4 is based on expected levels of recreation use for each alternative. These economic impacts are expressed in terms of employment and labor income, including proprietor's income.

#### D8

**Comment:** Agency staff has told us that they intend to focus on resource management issues. Issues related to the management of natural resources have received most of the attention during the evaluation while socio-economic issues surrounding motorized access and recreation are largely ignored. This lack of adequate recognition has led to the creation of significant socio-economic issues affecting the quality of the human environment for motorized recreationists. Land management agencies must acknowledge that public land has significant meaning and socio-economic value to the public. We request that all significant issues involving the human environment for motorized recreationists be adequately considered during the evaluation and decision-making process.

**Response:** The expected level of recreation use for each alternative considered the travel management prescription for each alternative. The level of motorized vehicle travel currently accounts for an estimated 12 percent of total recreation use (in visits). It is predicted to decline by about 7,700 visits (5 percent) with Alternative B, about 15,400 visits (10 percent) with Alternative C, and

about 3,100 visits (2 percent) with Alternative D. The economic analysis of recreation management displayed in Chapter 4 is based on expected levels of recreation use for each alternative. These economic impacts are expressed in terms of employment and labor income, including proprietor's income.

#### D9

**Comment:** The environmental document should be an issue driven document as required under NEPA and the Council on Environmental Quality guidelines. The driving issue is the development of a reasonable travel management alternative that addresses the needs of the public. NEPA requires that agencies "Rigorously explore and objectively evaluate all reasonable alternatives, and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated" [40 CFR 1502.14(a)]. We request that the environmental document adequately addresses the social, economic, and environmental justice issues associated with multiple-use access and motorized recreation. We request that the environmental document include a travel management alternative for the project area that adequately responds to these issues and the needs for multiple-use access and recreation.

**Response:** The expected level of recreation use for each alternative considered the travel management prescription for each alternative. The level of motorized vehicle travel currently accounts for an estimated 12 percent of total recreation use (in visits). It is predicted to decline by about 7,700 visits (5 percent) with Alternative B, about 15,400 visits (10 percent) with Alternative C, and about 3,100 visits (2 percent) with Alternative D. The economic analysis of recreation management displayed in Chapter 4 is based on expected levels of recreation use for each alternative. These economic impacts are expressed in terms of employment and labor income, including proprietor's income.

The discussion that motorized recreationists should be identified as an environmental justice-covered population is not valid. Order 12898 specifically deals with low-income and minority populations as the subject of this order. The Social Conditions sections of the Butte RMP/EIS address the social issues related to access and recreation uses.

#### D10

**Comment:** Page 204 - Under the heading "Mining and Mineral" it does not appear that the economic impact with respect to the implementation of the four alternatives is accurately described. Specifically, under Alternative C it would appear that more than "20 local jobs and \$0.73 Million in annual labor income" would be the result of the production numbers shown under that alternative. These numbers should be reevaluated.

**Response:** The text in the Proposed RMP/Final EIS has been revised to address this comment.

**D11**

**Comment:** Page 305 - The statistics utilized on pages 305 and 306 including those contained in Table 3-40, do not appear to correspond with the numbers shown on Table 2-24 at page 204.

**Response:** The data on page 305 and 306 of the Draft RMP/EIS describe total employment and income from resource uses on all lands within the planning area whereas the data displayed in Table 2-24 summarize the impacts expected to occur from BLM management decisions and land uses on BLM administered lands and resources only.

**D12**

**Comment:** Our list of concerns has grown considerably as we review the proposed project such as the reduction in organized group activities, reduction in trail miles available throughout the project and the lack of economic review that these reductions would mean for the surrounding communities.

**Response:** The expected level of recreation use for each alternative considered the travel management prescription for each alternative. The level of motorized vehicle travel currently accounts for an estimated 12 percent of total recreation use (in visits). It is predicted to decline by about 7,700 visits (5 percent) with Alternative B, about 15,400 visits (10 percent) with Alternative C, and about 3,100 visits (2 percent) with Alternative D. The economic analysis of recreation management displayed in Chapter 4 is based on expected levels of recreation use for each alternative. These economic impacts are expressed in terms of employment and labor income, including proprietor's income.

**D13**

**Comment:** The Draft Butte RMP has a mere 12 pages dedicated to the economic and social impact of this plan. Again CBU would raise the requirement of the Presidents Council of Environmental Quality which requires agencies to attempt to engage local residents and businesses in the process of gathering true local economic impacts to communities. We find no attempt through the Butte RMP that would satisfy this requirement. CBU requests that the Butte RMP provide this information.

**Response:** Efforts by the BLM to identify issues, gather data, and receive input from the public on how BLM lands should be managed are summarized in Chapter 1 and Chapter 5, Consultation and Coordination. These sections describe the public notification, initial scoping, additional scoping specific to travel planning, additional RMP scoping associated with the Proposed Planning Scenario, public meetings, and presentations to county commissioners, congressional delegations, and other

entities. Economists associated with this RMP worked closely with other resource specialists, local residents, and businesses to identify economic issues and gather appropriate local data for the economic analysis. Other efforts to meet with local publics and businesses include attending the Economic Outlook Seminar in Butte, holding six public meetings upon release of the Draft RMP/EIS throughout the planning area, and briefing all eight county commissions in the planning area on the contents of the Draft RMP/EIS. Various businesses and organizations have been on the Butte RMP mailing list throughout the planning process. The BLM believes that it has gone to considerable efforts to collect local input and information on the Butte RMP, and that the Effects on Social and Economic Conditions section in Chapter 4 of the RMP is adequate.

**D14**

**Comment:** In surveys conducted in 2003 and 2004 by CBU, we found significant expenditures by multiple use visitors. Summer motorized users were on the average spending 100 dollars per visitor day and winter use by motorized reflected an average approaching 300 dollars per visitor day. With these expenditures coupled with the visitor use days that the Butte RMP acknowledges occurs within the planning area, we feel your team has missed the mark on the negative economic impact that the proposed closures will have on the surrounding small communities. CBU requests that the BLM make at least an attempt to gather true economic data from affected communities and take a hard look at the results of this data prior to making any Butte RMP decisions.

**Response:** The level of motorized vehicle travel currently accounts for an estimated 12 percent of total recreation use (in visits). Compared to current management (Alternative A), it is predicted to decline by about 7,700 visits (5 percent) with Alternative B, about 15,400 visits (10 percent) with Alternative C, and about 3,100 visits (2 percent) with Alternative D. However, these impacts are expected to be offset by increases in other areas such as foot travel, biking, and horseback riding. The net effect is expected to be a 1.3 percent decline in recreation use with Alternative B, a 2.5 percent decline with Alternative C, and a 0.5 percent decline with Alternative D. The economic impacts of each alternative that are presented in Chapter 4 are based on the expected level of recreation use and average daily expenditures per visit. The average daily expenditures per visit are based on Spending Profiles of National Forest Visitors, NVUM Four Year Report, May 2005 by Daniel Stynes and Eric White. Based on input-output analysis of anticipated net changes in recreation use it is estimated that local employment supported by recreation use would, compared to current management, decline by about 5 jobs with Alternative B, 10 jobs with Alternative C, and 2 jobs with Alternative D. Annual local income supported by recreation use would decline by an estimated

\$130,000 for Alternative B, \$250,000 with Alternative C, and \$40,000 with Alternative D.

## Fire and Fuels

### E1

**Comment:** As you know, fire suppression over the last 100 years has changed the structure and composition of forest ecosystems, and it is recognized that fire is a necessary disturbance phenomena to keep fuel density in check and to maintain healthy forest ecosystems. The RMP offers opportunities to address the past heavy reliance on fire suppression by restoring more natural fire disturbance regimes to forest ecosystems, and treating unwanted competing vegetation, fuel loads, fire risk, and forest health with prescribed fire.

Although increasing development on private lands interface areas adjacent to public lands may make restoration of natural fire disturbance regimes in private lands interface areas more difficult.

EPA supports the BLM's wildland fire management goals to restore and maintain desired ecological conditions consistent with appropriate fire regimes; and minimize the adverse effects of fire on resources, resource uses and Wildland Urban Interface areas; and control wildland fire safely, efficiently and with minimal impact to resource values while minimizing the risk of catastrophic fire within the BFO lands and adjacent communities, while maintaining and reestablishing the natural influence of fire on vegetation (Table 1-5, page 9).

We especially support the prioritization of fire and fuels management activities in areas within or near the wildland urban interface (WUI) areas and areas of high or severe fire risk, and risk of damage to life and property. The RMP should reflect national fire management strategies and policies such as the 1995 Federal Wildland Fire Management Policy and Program Review (USDA and USDI 1995), that directs integration of fire into land management planning, working with landowners and stakeholders, and directing landscape level analysis; and the National Fire Plan directing full range of fire management activities linked to RMPs.

The risks of uncharacteristic disturbances such as catastrophic wildfire should be evaluated versus the effects of fuels management actions designed to reduce those risks (i.e., water quality, fisheries, and wildlife effects). Methods to address competing and unwanted vegetation and fuel loads and fire risk need to be evaluated vs. water quality, fisheries, and wildlife effects from fuel and vegetation treatments. We note that thresholds for acceptable environmental impacts for fuel treatments around WUIs and areas of severe fire risk may be higher.

**Response:** The SIMPPLLE model was used to: (a) simulate future vegetation changes caused by various disturbance processes at multiple landscape scales, (b)

show trends in vegetative communities over the next 50 years as a result of fire suppression, (c) simulate historic vegetative conditions by running the model over 500 years with variables such as fire, insect and disease activity, (d) simulate management treatment alternatives for their impact on disturbance processes and the attainment of desired conditions defined at the landscape scale, and (e) provide a basis for identifying the probability of disturbance processes and vegetation conditions. Use of the model is described in **Appendix D** of the Proposed RMP/Final EIS. The effects of the risk of wildfire vs. the effects of fuels treatments on resources are analyzed at the site-specific project level. However, Chapter 4 of the RMP (Effects on Resources, Wildlife Fire Management section) does contain generalized discussion on the effects that management proposed under each alternative would have on the potential for wildland fire.

### E2

**Comment:** Table 2-23 (page 115) under Fire Management Response shows the acreage that BLM would manage in various fire management unit (FMU) designations under the four alternatives. The table shows that alternative A (i.e. current management practice) would have approximately 7,300 acres designated as A FMU, 29,590 acres designated as B FMU, and 258,200 acres designated as C FMU, for a total of 295,090 acres. This is 8,910 acres less than the area shown as total managed land under the other three alternatives (304,000 acres). Please explain the difference in total area.

**Response:** All acres in the Butte RMP are approximate acres. It does appear that errors in the acres for Alternative A have occurred in the Draft RMP/EIS. Changes have been made in the Proposed RMP/Final EIS to show the appropriate acres for each FMU under each alternative.

### E3

**Comment:** Also, the data shown under the four FMU designations contrasts with maps 2, 3, 4, and 5, which depict fire management. These maps cover the entire planning area with color coding for the FMU designations even though BLM-managed lands are only a fraction of the planning area. For example, current management (alternative A) has no land under D FMU according to the text, but Map 2 shows areas with this designation. Most BLM land would be under C FMU under Alternative C, but Map 4 shows large areas of Gallatin, Park, and Lewis & Clark Counties under A FMU and B FMU. Only 42,000 acres would be under B FMU in Alternative D, but Map 5 shows most of Gallatin County and portions of Lewis & Clark, Jefferson, Deer Lodge, and Silver Bow Counties under B FMU. Perhaps the maps would be more easily understood if only the BLM lands showed color coding. Alternatively, the maps

could distinguish BLM lands by superimposed marks such as cross-hatching.

**Response:** The BLM acknowledges that errors were made on Map 2 in the Draft RMP/EIS; there is no FMU D designation in the current condition as expressed by the text. The FMU designation and acres only pertain to those acres administered by the BLM. Maps providing a better representation of the BLM administered ground and the FMU designation have been included in the Proposed RMP/Final EIS.

**E4**

**Comment:** It is stated on page 415 and elsewhere in the DEIS that, “no Fire Management Units (FMUs) would have any Category A designated lands” under Alternative B. Accordingly, BLM’s preferred alternative would remove 7,300 acres from Category A, which emphasizes fire suppression and non-fire fuels treatments. Map 2 shows that most of the areas currently under A FMU lie in Gallatin and Park Counties (see related comment above), which suggests the 7,300 acres proposed to be removed from A FMU are in this portion of the planning area. Please clarify the location of these parcels and why BLM’s preferred alternative would remove them from A FMU.

**Response:** The 7,300 acres in Category A are BLM administered land within Park and Gallatin counties. Maps providing a better representation of the BLM administered ground and the FMU designation have been included in the Proposed RMP/Final EIS. In the Butte RMP in Chapter 4, in the Wildland Fire Management section under Effects of Alternative B, it states that “Fire suppression under this alternative would be similar to Alternative A except it would allow for more flexibility to manage fires with no FMU Category A designations.”

**E5**

**Comment:** Revise map to include Beaverhead County, and update to B designation in Wise River/Dewey/Hwy 43 area (see attached). Coordinate with Beaverhead County Fire Plan for this area, call Scott Marsh.

**Response:** The Preferred Alternative in the Proposed RMP/Final EIS has been modified to include these lands in a FMU B designation.

**E6**

**Comment:** The EPA supports reintroduction of fire into federal land management programs to allow fire to play its natural role and provide resource benefits, consistent with public health and environmental quality considerations. We agree that judicious use of prescribed fire can be used to control forest fuel accumulation and to influence vegetative composition and structure. We are pleased that the RMP acknowledges BLM’s participation in the Montana/Idaho Airshed Group in accordance with

the EPA Interim Air Quality Policy on Wildland and Prescribed Fires (page 210). EPA supports management direction consistent with the EPA Interim Air Quality Policy on Wildland and Prescribed Fires, that was developed with the active involvement of stakeholders, including the U.S. Department of Interior, to integrate the public policy goals of allowing fire to function in its natural role in maintaining healthy ecosystems and protecting public health and welfare by mitigating the impacts of air pollutant emissions on air quality and visibility.

We suggest that RMP Air Quality direction advise that project level NEPA documents for prescribed fire treatments discuss the EPA Interim Air Quality Policy on Wildland and Prescribed Fires and disclose involvement in a certified Smoke Management Program (Montana/Idaho Airshed Group). For example, “Project level NEPA documents involving treatments with prescribed fire should discuss the EPA Interim Air Quality Policy on Wildland and Prescribed Fires, and disclose how the BLM is participating in a EPA certified Smoke Management Program (e.g. Montana/Idaho State Airshed Group), and describe how prescribed burns will be conducted in accordance with the State certified Smoke Management Program.” Also, it may be of interest to the public to display the website for the Montana/Idaho State Airshed Group, <http://www.smokemu.org> in the final RMP/EIS. Similarly it may be of interest to display the website for the Interim Air Quality Policy and a fact sheet on this policy in the FEIS, <http://www.epa.gov/ttn/oarpg/t1/memoranda/firefnl.pdf>, and [www.epa.gov/ttn/oarpg/t1/fact\\_sheets/firefl.pdf](http://www.epa.gov/ttn/oarpg/t1/fact_sheets/firefl.pdf).

**Response:** In Chapter 2 of the RMP, under Management Concerns, in the Air Quality section it states: “Air resources would continue to be evaluated on a case-by-case basis as part of project level planning to ensure compliance with local, state, and federal regulatory requirements.” That statement would ensure that project level NEPA takes into account the EPA Interim Air Quality Policy on Wildland and Prescribed Fire.

**E7**

**Comment:** There is a vast difference between the “natural fires” of a hundred years ago and the all-consuming forest fire we witnessed in the Gates of the Mountains Wilderness this summer. Back then forests were in fire equilibrium, that is, periodically natural forest-cleansing ground fires reduced the combustible fuel load on the forest floor, along with excessive numbers of small trees and brush. The fire seldom reached the lower limbs of big trees which would cause them to ignite and in turn create a fire storm that incinerates everything else in the forest.

Since BLM Wilderness Study lands are included in the FMU2 (Flexible Suppression Response Strategy), The Sleeping Giant (a wilderness study area) could suffer the same devastation as the Gates of the Mountains Wilder-

ness. When fires have been suppressed for many years the enormous buildup of fuel creates “burn intensity” such as that of the Meriwether fire. If the Sleeping Giant should ever be exposed to a lightning caused fire - some 6,000 acres will be toast.

Our public comment for the “Sleeping Giant study area”, will be; Alternative D (which allows the greatest flexibility in fire management. It treats the most acres for fuels reduction and would do the most of any alternative to reduce fire intensity and behavior, improve wild land fire fighter safety, and move toward historic fire regimes).

**Response:** BLM guidance mandates Wildland Fire Use will be based on approved Fire Management Plans and will follow specific prescriptions contained in operational plans. This means that if the RMP identifies areas that Wildland Fire Use can be used, a site-specific plan will need to be developed to take into account the specific issues raised in the comment. The BLM notes that the Interim Management Policy and Guidelines for Lands under Wilderness Review limits certain types of fire suppression activities for Wilderness Study Areas, such as Sleeping Giant. In the Butte RMP all BLM administered ground would be put into one of four Fire Management Unit (FMUs) Categories, as discussed in Chapter 2 under Wildland Fire Management in the Management Common to All Alternatives sections. After finalization of the Butte RMP, the Butte Field Office will revise its Fire Management Plan to more specifically address some of these issues.

#### E8

**Comment:** The Wildland Fire Management proposal under Alternative B has no lands designated in the Category A. The rapid growth and development in northern Jefferson County tends to support designation of these lands where fire is not desired.

**Response:** The BLM does not agree that Category A is the best designation for these lands. While Alternative C of the RMP/EIS allocates a portion of northern Jefferson County to Category A, placing these lands in Category B as proposed in the preferred alternative (B) allows for better flexibility for managing fuels in that area.

#### E9

**Comment:** The proposed ACEC designation for the Elkhorn Mountains dictates a more liberal fire management plan for naturally ignited fires. The concern for the large number of trees that are dying due to bug kill makes this large area a potential for being a location where a small fire could quickly grow into a major event that could become a public safety concern. This same concern exists for the proposed Elkhorn WSA tack-on that would further impede firefighting capabilities by restricting heavy equipment use and imposing retardant usage restrictions. The requirement to use 1/8th inch

screens on hoses when removing water from fish bearing streams should not be a restriction on fire management personnel. It appears the wildland fire strategy should include a detailed analysis, in conjunction with the Forest Service, of the current bug infestation and the fire risks involved with proposed fire mitigation measures for the most threatened areas. This fire assessment and discussions should include the county leadership along with volunteer fire management personnel.

**Response:** Under Alternative A (current management) the Elkhorn Mountains are in a Fire Management Unit (FMU) Category C (see Chapter 2 Wildland Fire Management), and they would be designated in Category C under Alternatives B and C. Under Alternative D the Elkhorn Mountains would be designated as FMU Category D which provides for the most flexibility in Fire Management. The BLM believes that a good range of fire management options are presented for the Elkhorn Mountains area. BLM guidance mandates Wildland Fire Use will be based on approved Fire Management Plans and will follow specific prescriptions contained in operational plans. This means that if the RMP identifies areas that Wildland Fire Use can be used, a site specific plan will need to be developed to take into account the specific issues raised in the comment. The BLM current standard for hose screen is 1/8<sup>th</sup> inch, therefore the BLM does not see it as a restriction as discussed in the Wildland Fire Management section in Chapter 2 of the Butte RMP. The Collaborative Efforts including outreach to county commissioners for the Butte RMP DEIS are discussed in Chapter 5.

#### E10

**Comment:** We also encourage BLM to conduct improved public education programs to increase public understanding on the need for and value of fire in forest ecosystems. We encourage the BLM to consider issues such as promoting public education and understanding on air quality trade-offs between increased use of prescribed fire vs. wildfire. Increased public understanding of prescribed fire vs. wildfire air quality tradeoffs may promote increased public acceptance of and support for prescribed fire to manage vegetation and fire risk.

**Response:** The BLM agrees that public education programs to increase public understanding on the need for and value of fire in forest ecosystems is important. The National Fire Plan and 2001 Federal Fire Policy, both referenced in Chapter 1 of the RMP/EIS, place an emphasis on fire mitigation, education, and prevention. Discussions on air quality tradeoffs depending on proposed management in the different alternatives are provided in Chapter 4 of the RMP/EIS.

#### E11

**Comment:** BLM management direction should also assure that prescribed fire for fuel management and control or suppression of wildfire be conducted in a

manner that minimizes potential nonpoint source pollution of surface waters. All bladed firelines for prescribed fire and wildfire should be stabilized with water bars and/or other appropriate techniques if needed to control excessive sedimentation or erosion of the fireline.

**Response:** In Chapter 2 of the RMP, under Management Common to All Alternatives (of the Wildland Fire Management section), it states the BLM would use the BLM's Emergency Fire Rehabilitation Handbook (H-1742-2) for implementing fire rehabilitation projects following wildland fire and wildland fire use. It also states in the same section that: "Fire management activities would be designed and implemented in a manner that meets or moves toward meeting Land Health Standards." This should ensure that excessive sedimentation or erosion of the fireline will be considered in the planning and implementation of wildland fire management activities.

**E12**

**Comment:** On page 344 you state the different goals for prescribed burns – 80 percent consumption of above-ground biomass for Alt B, 60 percent for Alt C, 90 percent for Alt D. But so what? - What's the import of those differences, what are the tradeoffs? (The answer may well be buried in there somewhere, but that's part of my point.)

**Response:** The importance of the difference in percent consumption of above ground biomass is the nature of the mosaic of vegetation that will be left after a prescribed fire treatment, to provide desirable vegetation for colonization into the burned area. The tradeoff would be directly proportional to the size of the treatment area, which will have direct effects on wildlife, vegetation, and soils. See the Wildlife section in Chapter 4 of the RMP, Effects of Alternative B for more detail.

**E13**

**Comment:** Programmatic direction should also assure that the effects of burning on the potential stimulation of noxious weeds be evaluated during site-specific project level analysis. Prescribed fire has the potential to stimulate weed growth (e.g., Dalmatian toadflax or leafy spurge), and can destroy insects planted for biological weed control. Burning followed by application of appropriate herbicides can provide effective weed control. We suggest that such considerations be evaluated during development of direction and plans for prescribed burning. Areas should not be prescribed burned for at least 30 days after herbicide treatment.

**Response:** Treatment of weeds in relation to specific proposed prescribed burning would be determined during project specific analysis. The Wildland Fire Management section in Chapter 2 of the RMP/EIS contains goals that assure that noxious weeds will be evaluated at the site-specific level, while the Noxious Weed Man-

agement section outlines the goal to minimize infestations of invasive plants and noxious weeds. Whether burning would occur within 30 days of herbicide treatment would be dependent on site-specific factors and label instructions on herbicides or other known factors. In general, the window for herbicide treatment in the summer and fall and the windows for prescribed burning in the spring and fall would allow for the suggested objective.

**E14**

**Comment:** Is Urban Wildland Interface still alive? Destroy the vegetation on public lands to protect adjoining private landowners?

**Response:** The BLM is operating under laws, regulations and policies, as well as the most current scientific knowledge, in effort to reduce the risk of large-scale, severe wildfires by restoring healthy, viable ecosystems to our public forests and rangelands. These efforts include fuels reduction projects designed to protect communities at risk of wildfire and promote the safety of firefighting personnel. See Chapter 1 of the RMP, Relationship to BLM Policies, Plans and Programs, for reference to the National Fire Plan and 2001 Federal Fire Police.

**Fish and Wildlife**

**F1**

**Comment:** BLM did not even mention wildlife habitat for wild sheep, mule deer, white-tailed deer, pronghorn antelope, very little on elk, nothing about moose, beaver including beaver dams, ruffed grouse, and blue grouse habitat, very little on non game species and nothing on waterfowl/ wetlands habitat. No vegetative maps were shown of plant communities or wildlife habitat by quality and quantity was presented. Where is bighorn sheep habitat on public lands in HD 340 for example?

**Response:** The Wildlife Section in Chapter 3 of the RMP discusses wildlife habitat for a variety of wildlife species including those species that depend on grassland/shrubland, forest, and wetland/riparian habitats. This section also provides specific discussion on species such as elk, bighorn sheep, mule deer, white-tailed deer, pronghorn antelope, moose, and game birds (including grouse and waterfowl). The role of beaver dams is described in the Wetlands and Riparian Communities Section of Chapter 3.

Although suitable habitat for waterfowl is minimal on BLM lands in the Butte Field Office, the Wildlife Section in Chapter 3 of the Proposed RMP/Final EIS has been modified to include discussion of waterfowl species and their associated habitats that may be present in the Planning Area.

Maps displaying vegetation zones are cited under Vegetation Communities in Chapter 3 of the RMP (AMS

Figures 2-9a, 2-9b, and 2-9c) and are located on the supplemental disc provided in the RMP. The supplemental disc also provides maps that display wildlife habitat for wildlife corridors (AMS Figure 2-15), elk winter range (AMS Figure 2-16), mule deer winter range (AMS Figure 2-17), bighorn sheep winter range (AMS Figure 2-18), grizzly bear recovery and distribution zones (AMS Figure 2-19) and sage grouse distribution (AMS Figure 2-20).

Table 3-4 on the Vegetation Section in Chapter 3 of the RMP displays acres of different vegetation communities for the Planning and Decision Areas. Discussion on the quality and quantity of wildlife habitat is also found in the Wildlife section of Chapter 3.

Bighorn sheep habitat in HD 340 is discussed in the Wildlife Section (Bighorn Sheep) of Chapter 3. Bighorn sheep habitat in HD 340 is identified as habitat within the Soap Gulch and Camp Creek areas.

## F2

**Comment:** MWF agrees strongly that fences can be significant barriers and cause unnecessary wildlife deaths if constructed irresponsibly but believes the statement needs much more clarification and emphasis. Too many area fences do not meet the requirements of the Unlawful Enclosures Act. Ensure that new and existing livestock fences comply with legal parameters as directed in BLM Manual H-1741-1 which ensures they do not inhibit free movement of wildlife. Those standards for domestic fence requirements as quoted, "...3-wire, 38-inch height, with bottom wire 16 inches off the ground..." fences constructed as such comply with the Unlawful Enclosures (sic) of Public Lands Act of 1885 (43 USC. 1061-1064; 23 Stat. L. 321. ch.149). MWF requests that these specifics be stated clearly within the RMP so that BLM's intentions to provide for wildlife friendly fences are more than just empty promises, it complies with the law.

**Response:** In Chapter 2 of the Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section (Management Common to All Alternatives) of the Proposed RMP/Final EIS cites BLM's Manual H-1741-1 to clarify what fence specifications will be used. The BLM also works directly with Montana Fish, Wildlife and Parks to design fences that best allow for wildlife movement.

## F3

**Comment:** No wildlife evaluation was done on any exchange lands.

**Response:** Within the Land Ownership Adjustment Section (Management Common to Action Alternatives) of Chapter 2 in the Draft RMP/EIS, 7,472 acres of BLM lands were identified under the "disposal" category. This figure has been revised to 8,901 acres in the Proposed RMP/Final EIS. Parcels identified for disposal are gen-

erally small (less than 100 acres), isolated parcels and often are surrounded by private lands. The interdisciplinary team reviewed all BLM parcels in the Butte Field Office and determined which parcels could be available for disposal. During this process, no major wildlife issues were identified for any of the parcels. The "disposal" category only determines which parcels would be available for sale or exchanged in the future. Site-specific analysis, however, of each parcel would be required when specific parcels are proposed for sale or exchange. As identified under the Federal Land Policy and Management Act of 1976, parcels can only be sold if important recreation, wildlife, watershed, threatened or endangered species habitat, and/or cultural values are not identified during site-specific analysis. **Appendix L** of the Proposed RMP/Final EIS provides information on land exchanges and sales.

## F4

**Comment:** The document contains generalized statements regarding the potential impacts on wildlife, aquatic, and special status species for all of the proposed alternatives and affected areas. As a result, the reader is left with a limited understanding of the specific impacts on the various species. For instance, the potential effects of Alternative B for the Helena TPA include the following statements (Volume II, page 503, paragraphs 2 and 3): "The amount of big game security habitat would be low, but still more under Alternatives B and C...compared to Alternatives A and D which have no functional security habitat...Alternative B would allow for more breeding, foraging, and hiding habitat as well as improve more movement corridors for a wide variety of species than Alternatives A and D but less than Alternative C." It would greatly benefit the public if more explicit discussions on the potential impacts of the proposed activities on the various species affected could be provided to the extent that the detailed analytical information is available.

**Response:** Many of the types of impacts or effects to wildlife would be the same or similar under the different alternatives. All alternatives propose using the same types of treatments or allow similar management across the Field Office with the major differences being acres treated and road density. Because the type of treatments would be the same, the effects to wildlife species would be similar between alternatives but the degree of those effects would differ. For example, security habitat is defined as blocks of forested habitat greater than 250 acres in size that are non-linear and located further than 0.5 mile from a road that is open during the hunting season. Because of their size and location on the landscape, these areas would provide a refuge to big game during the hunting season. Therefore, the difference between alternatives would be the acres of security habitat available to big game, which are displayed by alternative for each TPA in Chapter 4, Volume II. More acres of security habitat would be better for elk than

fewer acres. This would be similar for wildlife corridors, winter range, and riparian habitat.

The general effects of management actions to wildlife and fish are described in the Wildlife and Fish Sections (Management Common to All Alternatives) of Chapter 4 of the Proposed RMP/Final EIS as well as under alternative-specific discussions in Chapter 4.

Some specific discussion on the effects to wildlife from roads is found within the travel plan sections in Chapter 4 (Volume II) of the RMP and additional analysis on the impacts to big game has been added to these sections in the Proposed RMP/Final EIS.

The Wildlife Section of Chapter 3 (Affected Environment) also provides discussion on the effects of management activities to specific wildlife habitat (such as wildlife corridors) as well as on wildlife species such as elk, black bear, and grizzly bear.

**F5**

**Comment:** It would be of great benefit to the public if the final RMP/EIS included references where statements of fact about species are made and on wildland fire management, especially because the number of references in the draft document are limited. For instance, a reference is needed for statements like (Volume II, page 534, 1st full paragraph), "...perennial non-fish bearing streams contribute to fish habitat indirectly by serving as conduits for watershed products (water, sediment, nutrients, contaminants, and in some cases woody material) to fish bearing streams."

**Response:** The BLM agrees that there was a lack of references in the Draft RMP/EIS. Additional references have been added to the Wildlife and Fish sections of Chapter 4 in the Proposed RMP/Final EIS.

**F6**

**Comment:** There is a big difference in the amount of acres that would be available for oil and gas leasing between alternatives B and C, but it is not clear why B is preferable over C on this point. It would also seem that C would pose far fewer unavoidable adverse impacts due to oil and gas leasing because fewer acres are available, though this is not stated in the plan. For example, an analysis of the impacts identifies benefits to Wildlife for C and to Energy and Minerals for B, while adverse impacts to Energy and Minerals are identified for C. What are the impacts to Wildlife for B? Perhaps the preferred alternative should look more like C when it comes to oil and gas leasing, particularly since the twelve stipulations to lessen the impacts to Special Status Species that are proposed for B (page 400) seem to have been the impetus for identifying much of the additional acres in C as available. At the same time, it is not clear why the same 12 stipulations are necessary for C (page 405), when lands for Special Status Species are specifically unavailable to leasing.

**Response:** The action alternatives represent a range of effects to fish and wildlife from oil and gas leasing. The type of stipulations and acres of leasing under Alternative B were consistent with the other types of management prescriptions proposed under this alternative. Generally, management prescriptions under Alternative B were more restrictive or beneficial to wildlife than Alternative D but less restrictive or less beneficial to wildlife than Alternative C. The comment is correct with the statement that Alternative C does pose fewer adverse impacts to wildlife due to oil and gas leasing. This is consistent with the more "protective" approach under Alternative C. Alternative C however, also effectively prohibits oil and gas leasing from most of the federal mineral estate acres in the Butte Field Office and this is less consistent with the BLM's multiple-use mission than Alternative B.

Impacts to wildlife from oil and gas development under Alternative B are described under the Wildlife and Special Status Species sections of Chapter 4 in the RMP. The BLM believes that the stipulations identified under Alternative B, combined with the relative lack of oil and gas activity in the Decision Area forecast in the Reasonable Foreseeable Development scenario would protect resources while providing for oil and gas development.

The 12 wildlife stipulations for oil and gas leasing found in the Special Status Species section of Chapter 4 of the RMP are necessary to identify the type of stipulation for each species under Alternative C. There are differences between the stipulations under Alternative C including; No Lease, No Surface Occupancy and Timing Restrictions.

**F7**

**Comment:** In the Elkhorn Mountains analyze and map elk security habitat for all elk within Hunting District 380 (using Hillis et al. and in conjunction with information on elk use patterns from Fish, Wildlife and Parks).

**Response:** Acres of elk security habitat were generated for the five site-specific travel plan areas to display differences in acres of security habitat between alternatives. Acres of elk security habitat are also discussed at the Field Office scale to display the cumulative differences of security habitat in the five site-specific travel plan areas by alternative in both the Draft and Final EIS. For those areas that already have travel plans, such as the Elkhorn Mountains, the amount elk security habitat was not specifically displayed because elk security habitat was already mapped and discussed in the Elkhorn Mountains Travel Management Plan (completed in 1995).

Although the BLM agrees that updated mapping should be completed for elk security habitat in the Elkhorn Mountains, it is recognized that this mapping should be done in coordination with the Helena National Forest,

Beaverhead-Deerlodge National Forest and Montana Fish, Wildlife and Parks.

**F8**

**Comment:** In the Elkhorn Mountains thin or reduce conifers in areas where appropriate identified as security habitat in order to reduce risks of catastrophic wildfire, to enhance grasslands, and to maintain security habitat.

**Response:** Although each alternative differs in how aggressive the BLM would be with vegetation treatments to reduce fuel loads and restore grassland/shrubland habitats, all alternatives do propose treatments to meet these objectives. The emphasis for vegetative treatments are found in Chapter 2 of the RMP in Goals Common to All Alternatives for all BLM Activities, General Approach of Vegetation Management Activities, General Summary of Alternative Emphasis for Vegetation Communities as well as within other discussions in the Vegetation Communities main section.

The Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section (Management Common to All Alternatives) in Chapter 2 of the RMP provides direction to consider important blocks of security habitat during project planning.

**F9**

**Comment:** In the Elkhorn Mountains use prescribed fire to reduce or eliminate areas of conifer encroachment. In addition, when prescribed burns are planned to reduce conifer encroachment, the potential of such small patches of hiding cover should be evaluated to determine if some patches might contribute to the landscape pattern of security, and if some, therefore should be retained.

**Response:** The BLM agrees with the comment and the RMP provides for these types of treatments in the Elkhorn Mountains as well as throughout the Butte Field Office. Site-specific analysis (outside the scope of this RMP) of any project that proposes reducing conifer encroachment, or other types of vegetation manipulation, will address the amount and distribution of vegetation that contributes to hiding and security habitat as well as how the project would affect the amount and distribution of hiding and security habitat.

**F10**

**Comment:** We also support management direction that ensures that population strongholds and key refugia for listed or proposed species and narrow endemic populations are protected and restored. More pristine wilderness study areas and less developed areas further from roads often provide the key refuge areas and population strongholds for threatened and endangered and sensitive species. We believe it is important that wilderness study areas and less developed areas further from roads be

protected and maintained in order to protect wildlife resources within the BFO area.

**Response:** The BLM agrees with the comment. The existing six Wilderness Study Areas would continue to be managed under the Interim Management Policy and Guidelines for Lands under Wilderness Review. As stated in the Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section (Management Common to Action Alternatives) in Chapter 2 of the RMP, the BLM would minimize fragmentation in wildlife linkage corridors as well as maintain the function and diversity of habitats within large “patch” sizes. This would be accomplished by protecting areas with low road densities and excluding or minimizing certain types of development in these areas.

The action alternatives also provide additional guidelines to minimize open road densities in important areas such as grizzly bear habitat and big game winter range.

**F11**

**Comment:** Hikers disturb nesting birds (Swarthout, Elliott and Steidl, Robert, Journal of the Society of Conservation Biology, February 2003) yet restrictions on hiking and other non-motorized recreationists to reduce impacts on nesting birds are rarely imposed.

**Response:** The literature referenced by the comment refers to the Mexican spotted owl (Experimental Effects of Hiking on Breeding Mexican Spotted Owls), a species not found in the Butte Field Office.

The BLM, however, is aware that hikers can disturb nesting birds and has taken measures to protect active raptor nests along hiking trails in the past. The BLM will continue to restrict access to areas where hikers or other types of activities could have a substantial negative effect on breeding birds.

**F12**

**Comment:** The encroachment of residences into the forest is often the most significant factor contributing to the loss of summer and/or winter wildlife habitat. First, we request that the impact of these permanent encroachments be quantified and compared to the relatively minor impact that mechanized forest visitors have on wildlife habitat. Secondly, public land visitors should not have to pay the price in the form of motorized closures required to offset the impact of permanent encroachments by private residences. Proper assignment of restrictions would rest on those private individuals who permanently encroached on the natural habitat.

**Response:** The amount of residential development adjacent to BLM lands can not be quantified under this planning effort. However, Chapter 4 of the RMP considers the cumulative effects of residential development and roads in the five travel planning areas (Chapter 4, Wildlife). The Cumulative Effects on Resources sections

(under Vegetation Communities, Wildlife) of the RMP also provide discussion on the effects of residential development adjacent to BLM lands. The amount of residential development adjacent to BLM lands must be analyzed under “Cumulative Effects” because these developments are occurring on private land, not on BLM lands. Roads, however, are located on BLM lands and the effects to wildlife from roads are specifically addressed under all alternatives in the RMP. The alternatives for the five site-specific travel plan areas provide for a range of access into these areas.

The BLM does not have the authorization to assign restrictions to private land owners regarding development of their lands.

### F13

**Comment:** Recreation Management: Executive Order 13443, Facilitation of Hunting Heritage and Wildlife Conservation was enacted on August 17, 2007. The purpose of this order is to “direct Federal agencies that have programs and activities that have a measurable effect on public land management, outdoor recreation, and wildlife management, including the Department of the Interior and the Department of Agriculture, to facilitate the expansion and enhancement of hunting opportunities and the management of game species and their habitat.”

MWF believes E.O. 13443 has not been sufficiently addressed in the Butte RMP/EIS and suggests that the Butte Office amend the RMP to include an analysis of the alternatives and how they affect hunting opportunities, quality of the hunt, and maximizing habitat protection.

MWF also asks how the Travel Plan ensures habitat security so that fish and wildlife remains on the public estate and if displacement of wildlife towards public land is discouraged. We believe these analyses appropriate in light of the new Executive Order 13443.

**Response:** The BLM acknowledges the importance of meeting the direction of Executive Order 13443. A recent study of Montana’s outfitting industry (Nickerson et. al. 2007) indicated that this industry is a viable sub-component of Montana’s travel industry, and that hunting contributes the largest economic portion to outfitting in Montana (Nickerson et al., 2007).

The BLM believes that many management actions proposed under the Wildlife and Travel Management and Access sections in Chapter 2 of the Butte RMP facilitate the implementation of Executive Order 13443 such as providing for wildlife friendly fences; emphasis on security habitat, hiding habitat and winter range; seasonal timing restrictions in big game habitat; minimizing fragmentation of linkage corridors; habitat restoration; identifying big game species as “priority species”; coordination with federal, state, tribal and private landowners to improve wildlife habitat; and cooperating with Mon-

tana Fish, Wildlife and Parks to adjust seasonal travel restrictions to meet state harvest goals.

Hunting access and quality of hunting experiences were issues that were considered during the development of alternatives and later analyzed in Chapter 4 under Recreation effects. These issues influenced many travel plan decisions with regard to routes available to motorized uses. The primary considerations were seasons of use, elevational access for hunters, hunter disbursement opportunities, game retention on public lands, conflicts between non-motorized and motorized users and game retrieval.

Although the alternatives differ in their degree of habitat restoration, each alternative emphasizes conserving and/or restoring wildlife habitat including habitat for game species. The Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section (Management Common to All Alternatives) in Chapter 2 of the RMP states that all alternatives would emphasize maintaining and supporting healthy, productive and diverse wildlife populations and communities of native plants and animals including big game species. All action alternatives would maintain or restore habitat for game species or minimize the effects to these species.

The Environmental Consequences of Five Site-Specific Travel Plans section (Wildlife subsections) in Chapter 4 provides analysis on the effect from roads to wildlife and compares the impacts from roads by alternative. The Wildlife sections in Chapter 4 include discussion on security habitat, winter range, travel corridors, as well as general effects to wildlife from roads.

The Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section (Management Common to All Alternatives) in Chapter 2 of the Proposed RMP/Final EIS states that the BLM would facilitate the expansion of hunting opportunities and management of game species and their habitats, as per Executive Order 13443.

### F14

**Comment:** Elkhorn ACEC: The protection of wildlife is a priority so in areas where vehicle use is well established, the routes should be monitored and re-evaluated to ensure that quality habitat is provided for a wide range of wildlife, but especially for elk which require good winter range, safe calving grounds, and a high level of security to keep them on public land. On BLM lands where vehicle use has become well established, routes should be monitored and evaluated, and management decisions should be primarily based on the most recent science.

**Response:** The Elkhorn Mountains Travel Management Plan Environmental Assessment was completed for Forest Service and BLM lands in the Elkhorn Mountains in 1995. Big game security habitat and winter range

were two driving issues that resulted in road closures (including seasonal closures) in the Elkhorn Mountains.

Montana Fish, Wildlife and Parks conducts annual surveys for big game in the Elkhorn Mountains. The results of these surveys, along with any recommendations for changes in management or restoration opportunities, are provided to both the BLM and the Forest Service. Future amendments to the Elkhorn Mountains Travel Plan could result from these recommendations.

The BLM, Forest Service and Montana Fish, Wildlife and Parks entered into a cooperative agreement to manage the Elkhorn Mountains consistently across administrative boundaries and to manage public lands for wildlife habitat and recreation in 1992. The agencies currently work together to identify issues in the Elkhorn Mountains as well as with management of wildlife and wildlife habitat.

### F15

**Comment:** Pg.S-2: Habitat: Mt. FWP studies show elk numbers exceed the projected goal in all areas under the RMP. There isn't any data presented to warrant [road] closures for wildlife issues.

**Response:** The BLM manages habitat for wildlife, including big game species, while Montana Fish, Wildlife and Parks regulates harvest of game species. One of the goals of habitat management on BLM lands is to provide habitat for self-sustaining populations of game and non-game species. The number of elk in an area depends on many factors including (but not limited to) weather, forage, predation, disease and hunter success. Although elk populations will fluctuate from year to year, the BLM manages wildlife habitat for the long-term sustainability of many species while providing for recreational activities. Montana Fish, Wildlife and Parks' Statewide Elk Management Plan identifies management goals and objectives for each Elk Management Unit across the state. The BLM took these goals and objectives into consideration when addressing the impacts of roads on elk and elk habitat in the five site-specific travel plan areas. In addition, while elk numbers may be high in some areas at the current time, these numbers could change substantially over time, further reinforcing the need for BLM to manage habitat appropriately.

The Travel Management and Access section (Management Common to Action Alternatives) in Chapter 2 indicates that the BLM will continue to coordinate travel restrictions with Montana Fish, Wildlife and Parks to provide adequate access to meet the harvest goals that they set.

### F16

**Comment:** Some wildlife considerations appear to impose more restrictions on land use that could impact future decision-making based on sound logic. The rec-

ommendation to retain contiguous blocks of dead and dying forests is subjective and may not be in the best interests of healthy forests and public safety. The raptor nest restriction of 0.5 mile noise buffer for active nests and the 0.25 mile noise buffer for five years for unoccupied nests has the potential to negatively impact many other aspects of the proposed RMP since raptor nesting locations could easily be a changing variable.

**Response:** Butte RMP management direction to retain contiguous blocks of dead and dying forests was intentionally left general in nature so as to allow project-level planning teams to identify what would be appropriate on a site-specific basis and provide management flexibility. There are a host of wildlife species, including a number of BLM sensitive species (such as black-backed and three-toed woodpeckers), that require this type of habitat. So from that standpoint, dead and dying forests are a natural and healthy part of ecosystem diversity.

The management prescription for raptor nest sites would not preclude management in these areas. The noise buffer around active nest sites would only be in effect during the breeding season. Noise disturbance buffers around raptor nests would entail seasonal activity restrictions, but would allow noise-producing management activities outside nesting/rearing seasons. Management activities could occur in these areas as well as around unoccupied nest sites providing suitable habitat is maintained around the nest sites. In the case of unoccupied raptor nests, some raptors have a tendency to re-occupy such nests in the future. There would be no noise disturbance seasonal restrictions applied to unoccupied raptor nests. In many cases throughout the Butte Field Office, thinning dense stands of trees around raptor nests would improve the habitat for these species.

### F17

**Comment:** Related Plans (p.14). It is not clear whether plans and management direction by other agencies are considered. Recently issued plans, agency direction, and Executive Orders as listed below are not addressed in the plan but should be considered:

\*Lynx Management Direction, adopted by the Forest Service in July 2007 – the core habitat includes several parcels of BLM lands including Granite Creek (Greenhorn-Skelly Gulch area), Marysville, and Virginia Creek area (Stemple Pass). Additional Core Habitat occurs in the Gallatin and Custer National Forests and virtually all of the remainder of southwest Montana occurs in Secondary Lynx Habitat.

\*Grizzly Bear Recovery Plan Supplement: Habitat Based Recovery Criteria for the Yellowstone Ecosystem (March 2007). This plan calls for enhancing linkage connections between Yellowstone and other ecosystems. BLM lands at the headwaters of Little Prickly Pear Creek and Dog Creek on the Continental Divide are essential to the continuity of linkage connectivity north

to the Northern Continental Divide Ecosystem and the Yellowstone Ecosystem.

\*Department of the Interior, Fish and Wildlife Service, Endangered and Threatened Wildlife and Plants; Final Conservation Strategy for the Grizzly Bear in the Greater Yellowstone Area. Federal Register/Vol. 72, No. 48/Tuesday, March 13, 2007/Notices.

\*Executive Order 13443, Facilitation of Hunting Heritage and Wildlife Conservation, August 17, 2007. Addresses hunting opportunity and wildlife conservation on all federal lands.

**Response:** FLPMA emphasizes the need to ensure coordination and consistency with the plans and policies of other relevant jurisdictions. To the extent practicable, BLM will consider these plans and management direction during site-specific planning. All recovery or conservation plans identified by the U.S. Fish and Wildlife Service would be implemented by the BLM as well as management plans developed by Montana Fish, Wildlife and Park for those species removed from the Endangered Species list (such as the Yellowstone population of the grizzly bear).

The BLM will follow the Lynx Conservation Assessment and Strategy and the BLM has worked closely with the Helena, Beaverhead-Deerlodge, and Gallatin National Forests to provide consistent mapping of lynx habitat between Forest Service and BLM lands. To ensure management consistency in the Butte RMP with other agencies, the BLM worked with adjacent National Forests to integrate lynx habitat on BLM and Forest Service lands into common Lynx Analysis Units. This will improve vegetation management and coordination of projects within lynx habitat between the BLM and adjacent National Forests.

The BLM will continue to use peer reviewed scientific studies along with recommendations from the U.S. Fish and Wildlife Service and Montana Fish, Wildlife and Parks to manage habitat in occupied grizzly bear habitat.

The BLM believes that many management actions proposed under the Wildlife and Travel Management and Access sections in Chapter 2 of the RMP will facilitate the implementation of Executive Order 13443 such as wildlife friendly fences; emphasis on big game security habitat, hiding habitat and winter range; seasonal timing restrictions in big game habitat; minimizing fragmentation of linkage corridors; habitat restoration; identifying big game species as “priority species”; coordination with federal, state, tribal and private landowners to improve wildlife habitat; and cooperating with Montana Fish, Wildlife and Parks to adjust seasonal travel restrictions to meet state harvest goals.

The Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section (Management Common to All Alternatives) of the Proposed RMP/Final EIS states that the BLM would facilitate the

expansion of hunting opportunities and management of game species and their habitats, as per Executive Order 13443.

**Appendix B** of the Proposed RMP/Final EIS provides a list of laws and executive orders that affect BLM planning and management.

## F18

**Comment:** Big game security cover could be more adequately addressed if both security blocks of 250 to 500 acres and the Elk Management Guidelines were applied (p. 122). Currently only Alternative A calls for use of Elk Management Guidelines while Alternative B calls for 250 acres and Alternative C calls for 500 acres of security cover. However, the context and distribution in which these security block acreages would be applied is not described, does this mean 250 or 500 acres in an area of 1,000 acres or in an area of 10,000 acres?

**Response:** The Elk Management Guidelines referenced by the commenter found in Alternative A is The Coordinating Elk and Timber Management Study (1985). This study, along with more recent literature and research, was used to identify appropriate activities within elk habitats as well as to address the effects of management actions in the proposed RMP. For example, The Coordinating Elk and Timber Management Study, along with more recent literature, discusses security habitat, road location, road density and closures, vegetative management and winter range. All aspects of this study and other related research are found throughout the Draft and Final EIS.

Site-specific projects will continue to consider The Coordinating Elk and Timber Management Study along with other relevant research and literature during site specific project analysis.

The BLM agrees with the commenter that security habitat identified in the Wildlife Section of the Draft EIS is confusing and may not meet the intent of BLM’s objectives for providing elk security habitat. The management prescription for elk security habitat under each action alternative has been deleted from the Proposed RMP/Final EIS. A new management prescription has been included in the Proposed RMP/Final EIS under the Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section (Management Common to Action Alternatives) of Chapter 2 that states that functional blocks of security habitat for big game species would be maintained across the landscape. Where minimum-size blocks of security habitat (250 acres), as defined by Hillis et al. (1991), are located, they would be retained in a suitable condition during project implementation. Larger blocks of security habitat would be addressed and analyzed during project or watershed level planning to address the protection of security habitat. Where security habitat is limited or fragmented across the landscape, the BLM would emphasize

improving habitat through vegetation treatments and road closures (including seasonal closures) to increase security habitat for big game species.

### F19

**Comment:** Two attached maps submitted from the Helena Area Resource Office entitled “Wildlife Distribution in Northern BLM RMP” and “North BLM RMP Land Ownership & Wildlife Linkage Zones” display linkage zones through the landscape. The primary one, the Continental Divide, as well as a series of local movement linkages (narrow dashed lines) are depicted. These linkages exist and are defined by a combination of suitable topography and vegetative cover, lower human densities, and appropriate habitats render these public lands crucial in the context of wildlife linkages. The most striking feature of the land ownership map is the critical role the BLM lands play in defining these linkages.

In the majority of cases, BLM lands are being utilized by wildlife to move between local areas and between ecosystems. It is a fact that wildlife will do their best to adapt to changes, but as human density spreads throughout all types of wildlife habitats, the simple presence of lands that are not inhabited by people (public lands) provides the security and thoroughfare necessary to accommodate not only local wildlife movements, but also the larger flow of genetic material through the landscape to help minimize isolation of meta-populations. For these reasons whenever BLM lands are being evaluated for disposal the above factors should be analyzed on both the broad and local scales, and wherever possible be retained and managed to provide for wildlife movements.

**Response:** Parcels identified for disposal are generally small (less than 100 acres), isolated parcels and often are surrounded by private lands. The “disposal” category only determines which parcels would be considered for sale or exchange in the future. Site-specific analysis, including a review for wildlife values such as location of lands relative to linkage corridors, would be required when specific parcels are proposed for sale or exchange.

### F20

**Comment:** The RMP specifically indicates that it would coordinate with MFWP to determine whether habitat conditions exist that would allow for successful reintroduction of locally or regionally absent species and then lists several species. However, mountain goats are notably absent and should be added to the list. The mountain goat population decline began to occur immediately after a joint BLM-MFWP effort to introduce bighorn sheep into the Sleeping Giant.

**Response:** The BLM agrees and mountain goats have been added to the list of species identified for possible re-introduction in the Proposed RMP/Final EIS.

### F21

**Comment:** Wolverines are rarely mentioned in the RMP and in Table 3-15 they are listed as occurring in the Planning Area but not in the Decision Area. It is very possible that wolverine do in fact occur within the decision area, particularly in the Great Divide, Mount Thompson, and Sleeping Giant areas that occur at higher elevations and within linkage areas. A dead wolverine was located by MFWP on the Sheep Mountain ridgeline in the Clancy area, and wolverine tracks and cache was observed by MFWP in the Great Divide area. Wolverines have home ranges as large as grizzly bears and both locations were within 2-4 miles of BLM lands.

**Response:** The BLM appreciates the information provided by the commenters regarding wolverines and has included this information in the Proposed RMP/Final EIS. Additional descriptions on wolverine habitats have also been included in the Wildlife Section of Chapter 3 in the Proposed RMP/Final EIS.

### F22

**Comment:** The Western Association of Fish and Wildlife Agencies (WAFWA) convened a Wild Sheep Working Group (WSWG) consisting of wildlife and animal health specialists to develop recommendations for domestic sheep and goat management in Wild Sheep Habitat in 2007. Those recommendations were finalized this year and adopted by the Directors of the Western Agencies on June 21, 2007. Both the BLM and Forest Service had representatives on the Working Group. Some of the recommendations from the WSWG to WAFWA agencies that are pertinent to the discussion of interface between domestics and wild sheep and should be recognized by the BLM in the RMP revision include:

1. Following completion of site-specific risk assessment, wild sheep transplant, augmentation, restoration, and management strategies should be designed to minimize the likelihood of contact between wild sheep and domestic sheep and goats.

2. Wild sheep managers should coordinate with local Weed & Pest Districts or other appropriate agencies/organizations involved with weed management to preclude the use of domestic sheep and goats for noxious weed control, in areas where contact between wild sheep and domestic sheep and goats is likely to occur. Agencies should provide educational information and offer assistance to Weed & Pest Districts regarding the disease risks associated with domestic sheep and goat use. Specific guidelines have been developed implemented in, British Columbia ([www.for.gov.bc.ca/hfp/publications/00006/](http://www.for.gov.bc.ca/hfp/publications/00006/)).

**Response:** The Wildlife, Fish, Wildlife Habitat and Special Status and Priority Plant and Animal Species section (Management Common to Action Alternatives) in Chapter 2 of the RMP addresses the re-introduction of bighorn sheep. This section of the RMP states that the

BLM would coordinate with Montana Fish, Wildlife and Parks to determine whether habitat or other conditions exist that would allow successful reintroduction of big-horn sheep. Any reintroduction efforts would be subject to site-specific analysis in which strategies would be identified to minimize the likelihood of contact between wild sheep and domestic sheep and goats.

Management direction described for each action alternative under Livestock Management in Chapter 2 provide guidance on when domestic sheep and goats could be allowed for weed control on BLM lands. Site-specific analysis of weed control projects using domestic sheep and goats would continue to address the effects to wild sheep. The BLM will follow the recommendations from the Wild Sheep Working Group to reduce the risk of disease transmission to wild sheep from domestic sheep and goats.

### F23

**Comment:** The opening sentence in Appendix F states: “Grizzly bears, wolves, bald eagles, and lynx are the listed species that occur incidentally throughout the Butte Field Office. “ MFWP firmly believes that these species occur more than just “incidentally” throughout the Butte Field Office. It is our opinion that reports of these and other species of concern such as wolverine should be seriously considered, carefully tracked, and their potential habitat conserved.

**Response:** The BLM agrees with the comment and understands the confusion the word “incidentally” has created. The word “incidentally” has been removed from this appendix (now **Appendix G** in the Proposed RMP/Final EIS).

### F24

**Comment:** Wildlife Screens (p. 732) Part 2 (table of activities). For Item 6, Silviculture Activities, in addition to the criteria that “Chemicals do not affect cutworm moth or habitat” it is recommended that honeybees be included.

**Response:** The BLM agrees with the comment and honeybees have been added to these screening criteria.

### F25

**Comment:** Roads and motorized uses also increase wildlife encounters with humans, which can degrade and fragment wildlife habitat; displace wildlife; change behavior and increase stress; reduce reproductive success; and increase wildlife mortality. The proposed management direction did not appear to say much about promoting a road network or transportation system that reduces wildlife fragmentation and displacement, and that is consistent with maintenance and protection of productive and diverse populations of wildlife species; and reducing impacts to sensitive species and contributing to recovery of listed species. To address these con-

cerns we recommend that BLM consider improving such direction. For example, “The BLM will manage the transportation system to minimize fragmentation of wildlife habitat and to maintain and protect productive and diverse populations of wildlife species, reducing impacts to species of concern and contributing to recovery of threatened and endangered species.”

**Response:** The BLM believes that management prescriptions found in the Butte RMP do relate to minimizing road construction and reducing road densities to promote quality habitats for wildlife. Maintaining suitable habitat conditions and minimizing fragmentation in linkage corridors as well as maintaining or emphasizing large block “patches” of habitats across the landscape would not be possible without reducing road densities or by maintaining areas that currently have low road densities. Management actions identified in the Wildlife sections of Chapter 2 in the RMP also identify minimizing road densities and disturbance to wildlife in critical habitats such as big game winter range, calving habitats, security habitat, and in the distribution of grizzly bear. All alternatives would emphasize maintaining and supporting healthy, productive, and diverse populations of animals including threatened, endangered, and sensitive species. Management of the transportation system would be taken into consideration during travel planning to maintain or improve habitats for a wide variety of wildlife species.

Travel planning under the five site-specific travel plans did address the effects of roads on fragmentation of habitats and disturbance as well as the direct and indirect effects of roads on a variety of wildlife and aquatic species.

### F26

**Comment:** We support the proposed fish and wildlife goals in the RMP (page 40) to conserve, enhance, restore, or minimize impacts to important wildlife habitats, and contribute to the recovery of threatened, endangered, or candidate plant or animal species. We encourage restoration of degraded wildlife habitats, and protection and enhancement of travel and migration corridors for wildlife, including threatened species such as the grizzly bear, lynx, and gray wolf. We recommend your consideration of additional more specific language to strengthen protections to fish and wildlife and their habitat. For example, “BLM will ensure that the structure, composition, and function of aquatic ecosystems is maintained and/or restored to support a diversity of aquatic plant and animal species and ensure that hydrologic connectivity within watersheds is maintained and/or restored to provide for habitat and connectivity needs to maintain populations of aquatic dependent species.”

“BLM will ensure that native wildlife species are provided habitat of sufficient quantity and quality, including connectivity and wildlife movement corridors, habitat

complexity, forest openings, edges, and ecotones, to enhance biological diversity”.

**Response:** The BLM agrees with the comment and has added the following modified suggested wording under Management Common to Action Alternatives in the Wildlife, Fish, Wildlife Habitat, and Special Status and Priority Plant and Animal Species section in Chapter 2:

“The BLM would emphasize maintaining and/or restoring the structure, composition, and function of aquatic ecosystems to support a diversity of aquatic plant and animal species and emphasize hydrologic connectivity within watersheds to maintain and/or restore habitat and connectivity needs for populations of aquatic dependent species.

The BLM would emphasize providing habitat of sufficient quantity and quality, including connectivity and wildlife movement corridors, habitat complexity, forest openings, edges, and ecotones, to enhance biological diversity and provide quality, sustainable habitat for native wildlife species.”

The BLM notes that the scattered nature of Butte Field Office lands in the planning area may limit the BLM’s ability to meet these objectives depending on land ownership patterns.

#### F27

**Comment:** If protection of fish and game species is a significant issue, then a reasonable alternative that would produce far more positive results would be a different management scenario for fishing and hunting in the area rather than the closure of trails to OHV use. OHV recreationists have been the only recreationists to pay the price for improvements to fish and game populations. At the same time the improvements to fish and game populations from motorized closures is miniscule and the cumulative impact on motorized recreationists has been significant and negative. Motorized recreationists have been the first to be eliminated for far too long. The human environment is also important but it has been ignored and not adequately quantified. If there is some over-arching mandate to maximize fish and wildlife populations, then fishing and hunting management scenarios must be developed as reasonable alternatives to be considered. It is time for a reasonable approach to the management of fish and wildlife. If maximizing fish and game populations is that significant, then the opportunities for others besides motorized recreationists (who have paid their dues many times over) should be reduced. This concept is entirely reasonable and particularly when fishing and hunting closures or management would be far more effective in producing the desired outcome. We request consideration of fish and game management alternatives and a more balanced consideration of recreation versus fish and wildlife populations in the decision-making.

**Response:** The BLM is responsible for managing habitat for a variety of fish and wildlife species including game and non-game species. Montana Fish, Wildlife and Parks has the responsibility for managing the population of game species. The BLM believes that the alternatives in the Proposed RMP/Final EIS provide a range of alternatives that address the issues of recreation (including OHV use) and habitat for fish and wildlife.

#### F28

**Comment:** We would encourage the BLM to consider developing a new alternative altogether that would emphasize wildlife population habitat connectivity.

**Response:** Connectivity of wildlife populations can occur at many different scales depending on species and/or season of use. Movement corridors are described as areas of predicted movement between blocks of suitable habitat. Corridors can allow seasonal movements for a species such as elk migration between summer and winter range or provide for dispersing juveniles such as a subadult cougar who has to leave fully occupied habitat of other adult cougars.

Movement corridors may be small, such as in the case of amphibians or small mammals, or large such as with grizzly bear or big game species. If a patch of habitat is too small to support a population over time, corridors connecting patches of habitats can provide a larger habitat structure, and thus support a larger effective population.

Because of the different scales of habitat connectivity, it is difficult for the BLM to know exactly what the commenter would like the BLM to display in a new alternative. The BLM did take into consideration important wildlife movement corridors at different scales (landscape scale for large carnivores as well as riparian corridors) throughout the Butte RMP. The impacts to these corridors from management activities under the different alternatives are discussed in Chapter 4 of the Proposed RMP/Final EIS.

#### F29

**Comment:** On page 72 I read under Wildlife that “BLM would seek opportunities to convert sheep allotments to cattle allotments to protect Bighorn Sheep populations.” This is also for Alternative B, the preferred alternative. I am concerned about the ramifications of this proposal. Can the wording here be altered to reflect that the existing sheep allotments will not be targeted for conversion to cattle allotments without the cooperation and consent of the holder of the sheep allotment?

**Response:** Where bighorn sheep populations are at risk in the proposed Elkhorns ACEC (the context of this comment), the BLM would seek opportunities to convert sheep allotments to cattle allotments at the time an allotment is vacated, sold or transferred. Existing sheep

allotments would remain in effect unless the permittee is interested in working with the BLM to convert to cattle.

**F30**

**Comment:** Mountain goat habitats on BLM lands should receive special attention. Few BLM areas qualify as mountain goat habitat, but where they occur, these lands are crucial to the existence of mountain goats, such as the Sleeping Giant Area. Mountain goat population dynamics are such that every opportunity should be afforded to sustain and enhance their habitat and habitat availability. Mountain goats exist within a narrow range of population tolerances, therefore minimal disturbance or overlap of multiple uses would enhance their well being. The RMP does not address mountain goats except in the No Action Alternative (Alternative A). MFWP requests that seasonal mountain goat habitat requirements be addressed and that timing restrictions be applied in all action alternatives, consistent with the Rocky Mountain Front Interagency Cooperative Guidelines that were adopted in 1987 by the BLM, MFWP, USFS, USFWS, Nature Conservancy, Montana State University, and members of the petroleum industry.

**Response:** The BLM will follow existing policy. The seasonal timing restrictions, however, have been added to Management Common to the All Alternatives in the Proposed RMP/Final EIS. Currently, the Sleeping Giant area represents the only occupied mountain goat habitat on BLM lands in the Field Office. Since the Sleeping Giant area is within a Wilderness Study Area and an Area of Critical Environmental Concern, mountain goats would be provided adequate protection in this area.

The Wildlife section of Chapter 3 provides a description of mountain goat habitat in the Butte Field Office.

**F31**

**Comment:** Some recommendations to BLM and USFS (and other land management agencies) from the WSWG report that are pertinent to proposals being made in this RMP revision in relation to bighorn sheep include:

1. Joint federal land management agency guidelines on management of domestic sheep and goats in wild sheep habitat should be developed and included in both broad agency policy documents (e.g., USFS Manuals) and local Forest Plan/Resource Management Plans. Once guidelines have been approved, there should not be an automatic “sunset” provision or expiration date. If there is a specified longevity required by federal policy, and if appropriate and timely review cannot be completed, the existing guidelines should remain in effect, rather than becoming obsolete.
2. Land management agencies responsible for domestic sheep and goat grazing allotments, trailing routes, vegetation management (e.g., weed control, enhancement of conifer regeneration), use as pack stock, or any other uses involving domestic sheep and goats should only

authorize such use where mechanisms are in place to achieve effective separation with wild sheep.

3. Land Use/Resource Management Plans, where relevant, should specifically address the issue of potential domestic sheep and goat interaction with wild sheep. Land use plans should evaluate the suitability of permitting activities involving domestic sheep and goats. Plans should address this issue and identify general areas of public land where domestic sheep and goats should not be permitted for weed control, commercial grazing, recreational packing, conifer regeneration vegetation management, and other management activities.

4. Where mandatory buffer zones (frequently cited as a minimum of 9 air miles [13.5 km]) between domestic sheep and goats and wild sheep have been used to ensure effective separation, it should be recognized that buffer zones apply to herds or populations of wild sheep, rather than wandering individuals (e.g., most often sub-adult bighorn rams).

5. In some cases, buffer zones have been a very effective strategy to reduce the opportunity for interaction between wild sheep and domestic sheep and goats. However, in continuous wild sheep habitat, where wild sheep movements may eventually exceed prior expectations, buffer zones may not be the most effective or practical tool (Schommer and Woolever 2007).

6. Land management agencies should clearly define the process, protocols, and timelines for short-term or emergency management actions when intervention is needed to minimize or eliminate the risk of interaction between wild sheep and domestic sheep and goats.

Given these recommendations from WAFWA, we support the management practice expressed in Alternative B regarding no new sheep/goat allotments occurring within a five-mile buffer of occupied bighorn sheep habitat. However, we strongly recommend going with the management practice put forth in Alternative C that sheep and goats could not be used for weed control within four miles of occupied native sheep habitat.

In short, FWP recommends against any action that may increase the likelihood of increasing contact between domestic sheep and goats and bighorn sheep.

**Response:** The BLM believes that Alternative B provides adequate protection to bighorn sheep. The management proposed under Alternative B meets or exceeds the protection provided by the direction in the current BLM Instruction Memorandum No. 98-140 Revised Guidelines for Management of Domestic Sheep and Goats in Native Wild Sheep Habitats (1998) under which the BLM currently operates. Should this policy be updated, the Butte Field Office would operate under that updated direction. If domestic sheep or goats are used for weed control, the BLM would undergo considerable coordination and effort during implementation to ensure that wild sheep are safeguarded.

**F32**

**Comment:** East Helena TPA: “Under Alternative C, soil erosion from roads would be reduced more than under any other alternative because the lowest mileage of roads in the high and moderate erosion categories would be left open (4.6 miles combined), while the greatest mileage in these categories combined would be closed (43.9 miles) and decommissioned (4 miles) of all alternatives.

Weeds: Alternatives B and C would have the same effects and both would result in fewer weeds than Alternatives A and D.

Wildlife: Actual road density in elk winter range would be 0.3 mi/mi<sup>2</sup> in Alternative C, far less than other alternatives. Under Alt. C there would be substantially more acres of functional winter range. The quality and quantity of winter range would improve more than all other alternatives, and the amount of big game security habitat would be greater (p. 531). Fragmentation of habitat would be least under Alternative C (p. 533).

Please consider modifying your preferred alternative to provide for conditions more favorable towards wildlife, similar to what is found in your Alternative C.

**Response:** The BLM is already proposing to reduce road densities in this area which should improve wildlife habitats. The Preferred Alternative attempts to balance the needs of providing motorized access while providing for resource protection.

**F33**

**Comment:** Recreation Opportunity Spectrum: Alternative C is the least roaded option and would be consistent with previous concerns for wildlife and their habitat by providing the most natural acreage; but even in Alternative C, 60 percent of the landscape would be roaded and allow for moderate to heavy motorized recreation. So from a wildlife perspective Alternative C generally provides the best scenario for maintaining wildlife habitats and linkages.

**Response:** The BLM agrees that Alternative C provides the best opportunities for improving or maintaining wildlife habitats and linkage corridors. However, Alternative B remains the Preferred Alternative that best meets the BLM’s mission to provide for a range of resource uses and resource protection.

**F34**

**Comment:** The Continental Divide Trail (a Congressional Designation): receives a lesser status than Historic Trails, but because it occurs on the divide and essentially identifies the Continental Divide Wildlife Linkage Zone, it should receive greater consideration for non-motorized use and management (as per Congressional designation) to protect the integrity of its varied habitats. Relatively little BLM lands occur along the Continental Divide, but

with notable and important exceptions including: Trout Creek in the northwest Lewis & Clark Area and Marysville. We believe that these areas are at least as important and should receive status equal to or greater than “Historic Trails.”

**Response:** The BLM acknowledges the importance of the Continental Divide Trail for recreation as well as the importance of the Continental Divide for wildlife. BLM’s section of the Continental Divide Trail follows a utility corridor access road and private lands. Due to this, the BLM cannot viably propose this section of trail as non-motorized. To allow for a non-motorized recreational experience along the Continental Divide Trail in the future, both the BLM and the U.S. Forest Service may pursue moving this section of trail onto Forest Service lands.

**F35**

**Comment:** Finally, FWP would like to propose a possible alternative use for the recently acquired McMaster’s property. A possible use for this property may be as an alternative grazing allotment for domestic sheep where the existing allotment may allow for potential contact between bighorn sheep and domestic sheep. This may be a viable option for the permittee and prevent contact between domestic and wild sheep.

**Response:** The BLM believes that appropriate use of this area is as a forage reserve allotment as described in the RMP. Establishing forage reserves on BLM lands would provide the BLM flexibility in conducting vegetation treatment projects within existing general allotments while providing temporary substitute forage for permittees in forage reserve allotments as vegetation project areas are rested from livestock grazing. The McMasters property is ideal for this because it is newly acquired land and does not have any general allotments established on it at this time. The provisions for grazing forage reserve allotments do not restrict the type of livestock grazed. Criteria have been added to the Proposed RMP/Final EIS to address how BLM would determine priority for applicants applying for temporary grazing on a forage reserve allotment.

**F36**

New scientific information and analysis has emerged on the status of greater sage-grouse (*Centrocercus urophasianus*), the affects of energy development and West Nile virus on sage-grouse (Connelly et al. 2004; Naugle et al. 2006a; Naugle et al. 2006b; Holloran 2005). We provide here excerpts from these studies: Energy development for oil and gas influences sagebrush habitats by physical removal of habitat to construct well pads, roads, and pipelines. Indirect effects include habitat fragmentation and soil disturbance along roads, spread of exotic plants, and increased predation from raptors that have access to new perches for nesting and hunting. Noise disturbance from construction activities and vehicles

also can disrupt sage-grouse breeding and nesting. Development of oil and gas resources will continue to be a significant influence on sagebrush habitats and sage grouse because of advanced technological capability to access and develop reserves, high demand for oil and gas resources, and the large number of applications submitted (4,279 in fiscal year 2002) and approved each year. . . . Sage-grouse are a relatively long-lived species of upland game bird with low reproductive rates. Sage-grouse are entirely dependent on sagebrush habitats for successful reproduction and winter survival. Disease and hunting have generally not been major factors in sage-grouse population change but new information suggests West Nile Virus may pose a significant threat. . . . Approximately 56 percent of the potential pre-settlement distribution of habitat is currently occupied. The area currently occupied by sage-grouse is clearly smaller than was occupied in pre-settlement times. With most of the analysis of sage-grouse numbers, we focused on the 1965-2003 period. Although many states and provinces were collecting data prior to 1965, this 39-year range provided an opportunity to analyze data after a sample of leks had been identified and protocols for data collection had been established and implemented. Eleven of 13 (85 percent) states and provinces showed significant long-term declines in size of active leks. Similarly, eight of 10 states (80 percent) showed population declines over the same time frame. . . . Our analysis of the entire sage-grouse population indicated that sage-grouse declined dramatically from the 1960s to the mid-1980s and then tended to stabilize. This analysis indicated that these changes were often not density-independent. If trends characteristic of the 1960s through the mid-1980s continued, sage-grouse had a relatively high likelihood of being extirpated. However, those trends have not continued. As a result, data suggest sage-grouse populations in most areas have been relatively stable or slightly declining during the last 15-20 years. In many areas numbers increased between 1995 and 2003. Although there are areas that presently could be considered population strongholds, some populations are still declining rather precipitously in various portions of the species range. . . . Annual rates of change suggest a long-term decline for greater sage-grouse in western North America and support the trend information obtained from lek attendance (males/lek) data. Sage-grouse populations declined at an overall rate of 2.0 percent per year from 1965 to 2003. From 1965-85, the population declined at an average rate of 3.5 percent. From 1986 to 2003, the population declined at a lower rate of 0.4 percent and fluctuated around a level that was 5 percent lower than the 2003 population. A total of 50,566 male sage-grouse were counted on leks in 2003 throughout western North America. However, we are not optimistic about the future of sage-grouse because of long-term population declines coupled with continued loss and degradation of habitat and other factors (including West Nile Virus), (Connelly et al. 2004). Knowledge that sage-grouse avoid energy development in breeding (Naugle et al.

2006a) and wintering seasons (Naugle et al. 2006b) shows that conservation strategies to date to protect the species have been largely ineffective. An effective conservation strategy is one that limits the cumulative impact of disturbances across a landscape at all times of the year. . . . Winter habitat is limited for birds along the border of Montana and Wyoming. Movements of radio-marked birds indicate that this non-migratory population remains in small parcels of suitable habitat to breed, raise broods, and spend the winter. The most suitable winter habitat in Montana and northern Wyoming encompasses only 13 percent of total land area and has already been impacted by surface mining activities. Expansion of CBNG development threatens to extirpate birds from otherwise suitable habitats and further isolate remaining populations. Risk of complete loss of this population is high if plans proceed to develop the entire northern study area because their non-migratory status and behavioral avoidance of CBNG will leave these birds with no other options (Naugle et al. 2006b). Comparatively more undeveloped winter habitat exists further south in Wyoming (south and east of the town of Buffalo) than along the border of Montana and Wyoming. Large pieces of undeveloped habitat near Buffalo provide winter habitat for a migratory population that nest up to 28 km to the north where winter habitat is poor. Some of these same good wintering areas also contain resident populations of nesting birds that distribute themselves around active leks with >20 males in attendance. Spatially-explicit planning tools, when coupled with knowledge of bird movements and active lek locations provide a biological basis for decision-makers to formulate an effective conservation strategy for sage grouse have shown that sage-grouse either avoid energy development during the breeding season (Holloran 2005, Naugle et al. 2006) or experience rates of mortality that result in extirpation (Holloran 2005). Avoidance is typically detrimental to populations because individuals are forced into sub-optimal habitats where vital rates decline (i.e. survival and reproduction), which in turn negatively influences population growth rate, size, and persistence, and generally leaves populations with little capacity to respond to new stressors (e.g. West Nile virus). New knowledge that sage-grouse also avoid energy development during winter shows that conservation strategies to date to protect this species have been largely ineffective. Current "Best Management Practices" that place timing stipulations or limit surface occupancy next to leks still result in a human footprint that far exceeds the tolerance limits of sage-grouse. We cannot write a prescription for development for each piece of the landscape because the exact mechanisms for each source of disturbance in a gas field that results in avoidance and/or increased mortality are not known. Rather, effective conservation strategies will be those that limit the cumulative impact of disturbances at all times of the year. Size of a functional conservation area will need to be large because sage-grouse are a landscape species that require contiguous tracts of undis-

turbed habitat that meet all their seasonal life requisites. Holloran et al. (2005) found that nest distributions were spatially related to lek location, and that a 5-km buffer encompassed just 64 percent of nests. This marks a shift in our understanding of the size of area necessary to maintain a viable sage-grouse population. Thus, land managers are encouraged to think in terms of “numerous square miles” of suitable habitat rather than individual parcels of land or even an individual square mile of habitat (Naugle et al. 2006b). Greater sage-grouse in western Wyoming appeared to be excluded from attending leks situated within or near the development boundaries of natural gas fields. Declines in the number of displaying males were positively correlated with decreased distance from leks to gas-field-related sources of disturbance, increased levels of development surrounding leks, increased traffic volumes within 3 km of leks, and increased potential for greater noise intensity at leks. Displacement of adult males and low recruitment of juvenile males contributed to declines in the number of breeding males on impacted leks. Additionally, responses of predatory species to development of gas fields could be responsible for decreased male survival on leks situated near the edges of developing fields and could extend the range-of-influence of gas fields. Generally, nesting females avoided areas with high densities of producing wells, and brooding females avoided producing wells. However, the relationship between selected nesting sites and proximity to gas field infrastructure shifted between 2000 - 2003 and 2004, with females selecting nesting habitat farther from active drilling rigs and producing wells in 2004. This suggests that the long-term response of nesting populations is avoidance of natural gas development. Most of the variability in population growth between populations that were impacted and non-impacted by natural gas development was explained by lower annual survival buffered to some extent by higher productivity in impacted populations. Seasonal survival differences between impacted and non-impacted individuals indicates that a lag period occurs between when an individual is impacted by an anthropogenic disturbance and when survival probabilities are influenced, suggesting negative fitness consequences for females subjected to natural gas development during the breeding or nesting periods. I suggest that currently imposed development stipulations are inadequate to protect greater sage-grouse, and that stipulations need to be modified to maintain populations within natural gas fields. My results support the suggestion that greater sage-grouse leks situated relatively near extractive mineral developments ultimately will become unoccupied. The evidence suggests that natural gas field development within 3-5 km of an active greater sage-grouse lek will lead to dramatic declines in breeding populations. Overall declines in male lek attendance approached 100 percent (i.e., lek inactivity) when distances from leks to drilling rigs, producing wells, and main haul roads decreased, and as the number of quadrants containing wells within 5 km and the total length

of main haul road within 3 km of leks increased. Conversely, as distances from leks to disturbance sources increased and the level of development surrounding leks decreased, male lek attendance remained stable. These observations were similar to 3 lek complexes in southern Canada that were disturbed by oil and gas activities occurring within 200 m between 1983-1985; none of these leks has been active since the disturbance (Braun et al. 2002, Aldridge and Brigham 2003). In northern Colorado, the numbers of males counted on 3 of 4 leks within 2 km of coal mine development declined as mining activity increased (Braun 1986, Remington and Braun 1991). Following the increase in activity, 1 lek became inactive in 3 years, 1 lek became inactive in 5 years, and 1 lek declined by approximately 88 percent in 4 years (Braun 1986 Remington and Braun 1991). Further, 2 of the 3 most heavily impacted leks in my study became essentially inactive over a 3-4 year period (Holloran and Anderson In Press). Greater sage-grouse leks appeared to be negatively influenced if situated within 5 km of a drilling rig that was operating during the breeding season. Male lek attendance declines were not associated with drilling rig visibility, suggesting that something other than the potentially negative effects of structure (Braun 1998) were influencing drill-disturbed leks. (Holloran 2005). We report unexpected impacts of West Nile virus (WNV) on radio-marked greater sage-grouse (*Centrocercus urophasianus*), a species that has declined 45-80 percent and is endangered in Canada and under current consideration for federal listing in the US. We show that WNV reduced late-summer survival an average of 25 percent in four radio-marked populations in the western US and Canada. Serum from 112 sage-grouse collected after the outbreak show that none had antibodies, suggesting that they lack resistance. The spread of WNV represents a significant new stressor on sage-grouse and probably other at-risk species. While managing habitat might lessen its impact on sage-grouse populations, WNV has left wildlife and public health officials scrambling to address surface water and vector control issues in western North America (Naugle 2004). Summaries of significant findings in the-above sage-grouse studies:

#### Breeding Activities:

Holloran (2005 - western WY)

§ Male lek attendance declined as distance from leks to drilling rigs, producing wells and haul roads decreased and as densities of those infrastructure facilities increased. Effects were detectable out to various distances (3 - 6.2 km) depending on the disturbance variable. These observations were similar to that reported for sage-grouse associated with energy development in Alberta (Aldridge and Brigham 2003) and Colorado (Remington and Braun 1991).

§ Well densities exceeding 1 producing well every 283 ha (1 well/699 acres) appeared to negatively influence male lek attendance.

§ Main haul roads within 3 km of leks negatively influenced male lek attendance largely through increased traffic volume.

§ Male attendance decreased with traffic volume of < 12 vehicles per day and leks became inactive when volume exceeded 75 vehicles per day.

Naugle et al. (2006 - northeast WY)

§ Among leks of known status in 2004-2005, only 34 percent remained active within CBNG fields, compared to 83 percent of leks adjacent to or outside CBNG fields.

§ From 2000-2005, leks in CBNG fields had 11-55 percent fewer males per active lek than leks outside CBNG development. All known remaining leks with  $\geq 25$  males occurred outside CBNG fields in 2005.

§ Findings show that CBNG development is having negative effects on sage-grouse populations over and above those of habitat loss caused by wildfire, sagebrush control, or conversion of sagebrush to pasture or cropland. Moreover, the extent of CBNG development explained lek inactivity better than power lines, pre-existing roads, or West Nile virus mortality.

§ Research findings show a lag effect, with leks predicted to disappear, on average, within 4 years of CBNG development. Regardless of other stressors, 22 of 24 lek complexes (92 percent) did not go inactive until after CBNG development came into the landscape.

§ Leks typically remained active when well spacing was  $\geq 500$  acres (1.3 wells per section), whereas leks typically were lost when spacing exceeded 4.2 wells per section.

Summary Statement: During the breeding season, male sage-grouse are sensitive to disturbance during both the exploratory and production phase of oil and gas development. Levels of sensitivity as measured by the distance at which no change in male attendance was detectable, vary by factor, but are significant at distances of less than 3 km. In the Powder River Basin, impacts to lek activity included an observed 50 percent decrease in the number of active leks within developed gas fields as well as a 50 percent reduction in the average number of males present on remaining leks. There was a discernable time lag between development and observed declines. Changes in numbers were likely an artifact of both distribution shifts in attendance as well as changes in survival and recruitment rates. Existing stipulations that restrict surface occupancy within .4 km (.25 mile) of an active lek are insufficient to maintain populations within developed oil and gas fields. Current well-spacing of 32 - 64 ha (80 - 160 acres) appear to be several times greater than breeding sage grouse populations can tolerate. Supports utilizing a minimum 1.6 km (1 mile) buffer of no surface occupancy around existing leks and preferably, utilize a minimum 3 km (1.8 mile) buffer. Recognize that development activities within 3 km will have negative impacts on sage grouse populations.

Nesting and Brood Rearing (Holloran and Anderson 2005), (Holloran 2006):

§ Sage-grouse nest locations are spatially related to lek locations and a 5 km buffer included 64 percent of known nests.

§ The substantial number of females nesting > 5 km from a lek could be important for population viability.

§ Observed lek to nest distances was not related to lek size.

§ Closest known lek to nest distance was greater for successful nests than destroyed nests.

§ Nests located < 1 km from another known nest tended to have lower success probabilities.

§ Nesting females strongly avoided areas with high well densities but adult females can exhibit strong nest site fidelity. Mean annual survival rates for females suggest that 5 to 9 years may be required to realize ultimate nesting population response to development activities.

Lyon and Anderson 2003:

§ Female sage-grouse disturbed by natural gas development during the breeding season had lower nest initiation rates.

Schroeder and Robb 2003:

§ Nest distribution patterns may change as a result of habitat alteration and fragmentation and the 5 km buffer should be considered relevant only for contiguous sagebrush habitats.

Aldridge and Boyce 2007.

§ Sage-grouse chick survival decreased as well densities increased within 1 km of brooding locations. These brood-rearing areas acted as habitat sinks where recruitment was poor.

§ Low nest success (39 percent) and low brood survival (12 percent) characterized sage-grouse vital rates in habitat fragmented by energy development in southern Alberta.

Summary Statement: Female sage-grouse are spatially grouped around a lek or lek complex during the nesting season. Females tend to move away from leks in selecting nest locations and to an extent, those movements appear to improve their rates of nest success. However, females in developed habitat moved twice as far as females in undisturbed habitat and exhibited lower rates of nest initiation. Females also select nest locations that segregate their nests from those of adjacent hens and the probability of successfully hatching those nests increases when that distance is > 1 km. When females have suitable and contiguous nesting habitat to select from, slightly over 60 percent of nests occur within 5 km of the lek. This strategy of mutual avoidance reduces nest densities and therefore reduces probability of detection by nest predators. However, land use practices that fragment sagebrush habitat and reduce the amount of suitable nesting cover may lead to increased densities of nesting birds and lower rates of nest success. Even if 5

km buffers are employed around existing leks, increased development and production activity in the zone beyond that buffer will impact the remaining 40 percent of nesting hens and potentially compromise the success of those birds nesting within that 5 km buffer based on the density dependent factors noted above. Stipulations restricting seasonal surface use within 2 miles of an active lek during the breeding and nesting period (1 March - 15 June) are inadequate to maintain sage-grouse populations within developed habitat.

Supports utilizing a 6.9 km (4 mile) buffer around leks to protect nesting and brood rearing habitat for a minimum of 70 percent of the nesting hens associated with a lek from March 1 through June 30. This protection should apply to both initial development and subsequent annual development and maintenance operations.

Winter Habitat Use (Naugle et al. unpub. report 2006):

§ In NE WY, predictive winter habitat use models based on vegetation and topographic features were strongly correlated with observed sage-grouse locations ( $R^2 = 0.96$ ).

§ Sage-grouse select for large intact and relatively flat expanses of sagebrush as winter habitat and avoid more rugged terrain and conifer habitat. Given that severe winter conditions (deep snow, low temperatures) could force birds into more rugged terrain, topographic variables should be considered in regions outside the PRB.

§ After controlling for vegetation and topography, the addition of a variable quantifying the extent of energy development showed that sage-grouse avoid energy development in otherwise suitable habitat. At 80 acre well-spacing birds were found only in the highest quality winter habitat that may not be available in all wintering locations.

§ Avoidance of CBNG in winter and the high likelihood of lek loss in spring threaten to severely impact populations along the Montana/Wyoming border where models classify only 13 percent of area as high quality winter habitat.

Summary Statement: Sage grouse are sensitive to energy development associated with winter habitat. Recent advances in modeling efficiencies provide a tool to assess important winter habitat and the spatial relationship between known leks and potential winter habitat. Sage grouse in this region can be non-migratory when suitable seasonal habitats occur in reasonable juxtaposition while other population segments must move greater distances (and across jurisdictions) when those habitats are unavailable. In some cases, this dissimilar distribution pattern may involve birds using the same lek complex or a shared winter range. Seasonal restrictions will not be effective at mitigating infrastructure development if the level of development is moderate to intense and overlays important winter habitat.

West Nile Virus (Naugle 2004):

§ West Nile virus (WNV) mortalities in radio-marked sage-grouse each year since 2003 (2-25 percent per yr)

show that disease is a new and likely permanent stressor to sage-grouse populations. Mortality from

WNV may have population-level impacts because female survival plays a vital role in population growth. Mortality events from WNV in 8 of 11 states since 2003 support the need to conserve the sage-grouse across their remaining range to reduce the risk of impacts from disease.

§ Research shows that CBNG ponds pose a threat to sage-grouse because they provide habitat for mosquitoes that spread WNV. Landscapes with the highest mosquito densities also harbor the highest infection rates in *Cx. tarsalis*, the species of mosquito that spreads the disease. Larval *Cx. tarsalis* were produced at similar rates in CBNG and natural sites, whereas CBNG ponds produced *Cx. tarsalis* over a longer time period than agricultural irrigation.

Inference: West Nile Virus should be considered endemic across the northern Great Plains portion of the range of greater sage-grouse. The presence of this disease has added another stressor to sage grouse population dynamics. The prevalence of the disease and associated level of mortality in sage-grouse appears to vary considerably from year to year based on environmental conditions. However, CBNG ponds do provide a much more consistent set of conditions favorable to the spread of WNV even in years of low natural precipitation. Conservation actions need to consider the relationship between CBNG and WNV and attempt to mitigate those conditions favorable to WNV. Supports reducing potential of CBNG ponds to produce late summer mosquito populations that vector WNV. The DSEIS fails to consider groundwater reinjection as an alternative which could limit some sources of West Nile virus infection. New Science on Vulnerability of Shrub-Steppe Habitat and Avifauna Degradation, fragmentation, and loss of native sagebrush (*Artemisia* spp.) landscapes have imperiled these habitats and their associated avifauna. Historically, this vast piece of the Western landscape has been undervalued: even though more than 70 percent of all remaining sagebrush habitat in the United States is publicly owned, only 3 percent of it is protected as federal reserves or national parks. We review the threats facing birds in sagebrush habitats to emphasize the urgency for conservation and research actions, and synthesize existing information that forms the foundation for recommended research directions. This research is essential because we already have seen that sagebrush habitats can be altered by land use, spread of invasive plants, and disrupted disturbance regimes beyond a threshold at which natural recovery is unlikely. Research on these issues should be instituted on lands managed by state or federal agencies because most lands still dominated by sagebrush are owned publicly. In addition to the challenge of understanding shrub steppe bird-habitat dynamics, conservation of sagebrush landscapes depends on our ability to recognize and communicate their intrinsic value and on our resolve to conserve them (Knick, et al. 2003).

Thank you for the opportunity to comment on the draft Butte RMP. We hope these comments and new scientific findings and recommendations will be incorporated into final RMP.

**Response:** The BLM manages very little sage grouse habitat in the Butte Field Office. Approximately 9 percent (2,354,572 acres) of the statewide sage grouse habitat is located within southwestern Montana including lands in the BLM's Butte and Dillon Field Offices. Within the Planning Area boundary of the Butte Field Office, current sage grouse habitat is located on roughly 340,000 acres (including all ownerships). Sage grouse breeding and nesting habitat in the Decision Area is found on approximately 67,000 acres and is predominately in the Big Hole and Yellowstone watersheds. BLM surface acres include approximately 2 percent (1,250 acres) of the breeding and nesting habitat and 6 percent (21,700 acres) of general sage grouse habitats within the Planning Area. While there are several known leks within the Planning Area boundaries, no leks have been documented on BLM lands since 1992.

The BLM has analyzed a range of alternatives that would mitigate impacts to sage grouse in the RMP. Under the Preferred Alternative (Alternative B), the BLM would provide mitigation for sage grouse by applying three different stipulations. Winter/spring range would be protected with a timing limit stipulation which would restrict activity in that range from December 1 through May 15. Leks, if any are ever discovered on BLM land, would be protected with a no surface occupancy stipulation extending ¼-mile out from the lek. Breeding habitat would be protected with a timing limit stipulation extending from March 1 through June 30 with a three mile buffer around leks. Essentially, due to the timing limitation stipulations, activity would be limited within the vicinity of leks from December 1 through June 30, a seven month interval. The most restrictive alternative analyzed in detail in the RMP (Alternative C) would make sage grouse winter/spring range unavailable for lease, and would provide for a ½-mile no lease buffer around leks. A no surface occupancy stipulation would apply to breeding habitat with a three mile buffer zone.

The BLM believes that with the use of the stipulations under consideration in the Butte RMP and best management practices, impacts to sage grouse and their habitat would be minimized. The BLM notes that the reasonably foreseeable development scenario prepared for the Butte RMP forecasts only up to seven producing deep gas wells on federal mineral estate. These wells would be spaced at one well for every 640 acres which is state-wide spacing for gas wells. Development would not be as concentrated as in the study areas described in the scientific studies mentioned in the comment. Any other federal wells would be dry holes that would be reclaimed. The oil production is forecast for state or fee minerals. Because of the small amount of sage grouse

habitat present, lack of known leks, small amount of forecasted oil and gas exploration/development activity foreseen, and protection provided by the proposed stipulations, the magnitude of any potential effects on sage grouse associated with oil and gas development from the Butte RMP would likely be comparatively minor.

### F37

**Comment:** FWP believes that no record of decision should be issued until the following concerns have been addressed satisfactorily in any selected alternative.

- 1) sage grouse strutting grounds (leks) should have a 1 mile NSO or be made unavailable for leasing and should have timing stipulations applied within a 4 mile radius in order to protect nesting areas, all sage grouse wintering areas should have an NSO stipulation attached or be unavailable for leasing;
- 2) all BLM minerals that occur under or adjacent within 1 mile to FWP land interests including state parks, wildlife management areas, fishing access sites, land owner incentive contract areas, fee title land, easements and or leased and FWP recreationally managed areas should have a NSO stipulation attached or be unavailable for leasing,
- 3) all conservation easements (FWP and private organization) especially those where Federal funding has been applied to secure the easement should have an NSO stipulation attached or be unavailable for leasing,
- 4) all flood plains, wetland and riparian areas should have NSO stipulations attached, and
- 5) any river eligible for WSA should have the entire drainage or river corridor designated as NSO.

Likewise, FWP is currently pursuing the development of crucial fish and wildlife areas and migratory corridors throughout Montana. FWP would appreciate the insertion of language into the final ROD that would allow this new information, when available, to be considered and included in the RMP and that at that time these areas would be considered for augmentation of stipulations as designated under the record of decision, including NSO if necessary.

Finally, all of the above recommendations should be given especially close consideration in the areas identified on the map insert page 884 that have moderate to high potential for development of oil and gas resources. It should be noted that areas 2 and 3 on the reference map contains large blocks of surface conservation easements established using Federal Funding. Likewise the BLM should consider language in the Butte RMP that will incorporate the need to recognize the future ROD from the BLM statewide CBM SEIS as it relates to area 5 along the Bozeman Pass.

**Response:** The numbered items from the comment are addressed in sequential order below.

1) The BLM manages very little sage grouse habitat in the Butte Field Office. Approximately 9 percent (2,354,572 acres) of the statewide sage grouse habitat is located within southwestern Montana including lands in the BLM's Butte and Dillon Field Offices. Within the Planning Area boundary of the Butte Field Office, current sage grouse habitat is located on roughly 340,000 acres (including all ownerships). Sage grouse breeding and nesting habitat in the Decision Area is found on approximately 67,000 acres and is predominately in the Big Hole and Yellowstone watersheds. BLM surface acres make up approximately 2 percent (1,250 acres) of the breeding and nesting habitat and 6 percent (21,700 acres) of general sage grouse habitats within the Planning Area. While there are several known leks within the Planning Area boundaries, no leks have been documented on BLM lands since 1992.

The BLM has analyzed a range of alternatives that would mitigate impacts to sage grouse in the draft RMP. Under the Preferred Alternative (Alternative B), the BLM would provide mitigation for sage grouse by applying three different stipulations. Winter/spring range would be protected with a timing stipulation which would restrict activity in that range from December 1 through May 15. Leks, if any are ever discovered on federal mineral estate lands, would be protected with a no surface occupancy stipulation extending ¼-mile out from leks. Breeding habitat would be protected with a timing limit stipulation extending from March 1 through June 30 with a three mile buffer around leks. Essentially, due to the timing limitation stipulations, activity would be limited within the vicinity of leks from December 1 through June 30, a seven month interval. The most restrictive alternative analyzed in detail in the RMP (Alternative C) would make sage grouse winter/spring range unavailable for lease with a ½-mile no lease buffer around leks. A no surface occupancy stipulation would apply to breeding habitat with a three mile buffer zone.

The BLM believes that with the use of the stipulations under consideration in the Butte RMP and best management practices, impacts to sage grouse and their habitat would be minimized. The BLM notes that the reasonably foreseeable development scenario prepared for the Butte RMP forecasts only up to seven producing deep gas wells on federal mineral estate lands. These wells would be spaced at one well for every 640 acres. Compared to other areas with more extensive oil and gas resources, this level of development is sparse and widely spaced, and would have fewer impacts on sage grouse overall than operations in more intensively developed areas.

2) The BLM has changed the existing no surface occupancy stipulation (within ¼-mile of developed recreation sites) in Alternative B to make it apply to "all developed recreations sites" with underlying federal minerals. As revised it would also apply to state and local sites and provide the same level of protection that the BLM pro-

vides to its own sites. Under the Preferred Alternative, wildlife management areas would be protected with a No Surface Occupancy stipulation. For landowner incentive areas, the BLM approach is to stipulate the values needing protection, rather than the geographic areas covered due to the fact that the areas periodically shift location. Therefore, if incentive areas include wildlife habitat, we would apply the appropriate stipulations for sage grouse, crucial winter range, etc. The BLM has been informed by MFWP that if MFWP holds land in fee, it is most likely subject to some stipulated designation and therefore the BLM believes that existing stipulations should be adequate.

3) For conservation easements we will follow our own BLM guidance on the "Acquisition and Stewardship of Conservation Easements" (H-2100-1), which indicates that the impact of mineral development on conservation values will be evaluated on a case-by-case basis. The legal language of each individual conservation easement may have addressed severed mineral estate, if it exists, and set parameters for surface occupancy, extraction and restoration within the extent that mineral laws apply. Additionally, mineral status is typically identified and considered during the easement development and this offers a chance to coordinate for new easements.

4) The Preferred Alternative does apply a no surface occupancy stipulation to floodplains, wetlands, and riparian areas.

5) The comment notes that "any river eligible for WSA should have the entire drainage or river corridor designated as NSO." The BLM believes that the comment was really making a reference to Wild and Scenic River (WSR) designations. The BLM notes that a river segment is identified as eligible based on the river area containing "outstandingly remarkable" values. All values should be clearly river related. That is, they should have the following characteristics:

- Be located in the river or on its immediate shorelands (for the purposes of this study, the preliminary boundary is 0.25 mile on either side of the river);
- Contribute substantially to the functioning of the river ecosystem; or
- Owe their location or existence to the presence of the river.

Under the Preferred Alternative, a corridor ½-mile on either side of the active river channels recommended as suitable (not eligible) river segments for WSR designation are proposed for a No Surface Occupancy stipulation.

After the numbered items, the comment mentioned that FWP is currently developing crucial fish and wildlife areas and migratory corridors throughout Montana, and that FWP would appreciate consideration of this information in the future. The BLM is very interested in this

information and when such information is available, the BLM will assess it and determine whether it necessitates an update to all existing RMPs; given that there would be potential impacts to other allocations, there isn't a way to build that data into the Butte RMP. Of course the stipulations ultimately selected in the Record of Decision for the Butte RMP would be applied to new values (i.e., newly found leks, special status fish populations, etc.).

Concern is expressed in the comment about the areas identified in the RMP as having the highest potential for oil and gas. Management prescriptions identified in the RMP apply to BLM minerals on a Field Office-wide basis and will be given close consideration in all parts of the Field Office. The areas identified on page 884 of the Draft RMP were highlighted to help improve the analysis in the document.

The comment expresses the desire that the Butte RMP recognize any future ROD from the BLM statewide Coal Bed Natural Gas Supplemental EIS as it relates to "Area 5" along the Bozeman Pass. No part of the SEIS planning area lies within the Butte Field Office and as such the BLM will not be carrying out this action. However, the BLM notes that there is no reasonably foreseeable chance for coal bed natural gas from federal leases to be produced in this area because the BLM controls almost no mineral estate in the area, and the Gallatin National Forest would be unable to lease due to the lack of a leasing document.

### F38

**Comment:** I thought it was already well established in the minds of most government employees responsible for managing our public lands, the importance of timber areas adjacent to primary winter-spring foraging areas for elk and mule deer as well as wild sheep. Timber cover is essential to save on energy levels with foraging areas close to cover under extreme temperatures. We also have a 15- year cooperative research project in which BLM participated and final recommendations were published in "Coordinating Elk and Timber Management". This document was signed by the BLM state director as well to be used as a guideline for timber management on public lands in Montana. BLM in Butte considers second growth Douglas fir (COVER) "encroachment" that must be dealt with accordingly. BLM again provided no literature references to support their opinions and wishful thinking. The 15-year cooperative project with recommendations BLM said they would follow is not even mentioned in the 11# document.

**Response:** The Coordinating Elk and Timber Management Study (1985) referenced by the commenter is cited in Chapter 2 of the Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section under Alternative A. This study, along with more recent literature and research, was used to identify appropriate activities within elk habitats as well as to ad-

dress the effects of management actions in the Proposed RMP. For example, The Coordinating Elk and Timber Management Study, along with more recent literature, discusses security habitat, road location, road density and closures, vegetative management and winter range. All aspects of this study and other related research are cited and used throughout the RMP.

Site-specific projects will continue to consider The Coordinating Elk and Timber Management Study along with other relevant research and literature during site specific project analysis.

### F39

**Comment:** We support proposed direction in the Draft RMP/EIS regarding retention of adequate snags for wildlife habitat. The RMP states that snag management would be emphasized (page 27) and that there should be "abundant snags and downed logs" with the preferred alternative (page 29), and that impacts to snags and downed woody material will be minimized (page 40), and that the BLM would follow the Forest Service's Northern Region Snag Management Protocol (page 44).

We are also pleased that the direction for timber salvage indicates that when salvage is proposed in dead and dying forests that, "contiguous acres of undisturbed standing and down woody material would be retained in adequate amounts for those wildlife species that depend on this type of habitat" (page 30). This type of direction for retention of undisturbed standing and downed wood material in adequate amounts for wildlife is good, although it appears that such direction should be applicable to general forest and woodland management as well, and not just timber salvage.

**Response:** Although the management prescription raised by the comment is found under the subheading of "Timber Salvage" it would be applicable to all general forest and woodland management.

### F40

**Comment:** We support protection of old growth habitats that maintain and restore large, native, late-seral overstory trees and forest composition and structure within ranges of historic natural variability (e.g. Ponderosa pine). Old growth tree stands are ecologically diverse and provide good breeding and feeding habitat for many bird and animal species, which have a preference or dependence on old growth (e.g., barred owl, great gray owl, pileated woodpecker). Much old growth habitat has been lost. It is important that management direction prevent continued loss of this habitat and promote long-term sustainability of old growth stands, and restore where possible the geographic extent and connectivity of old growth (e.g., using passive and active management-such as avoiding harvest of large old growth trees, leaving healthy larger and older seral species trees, thinning and underburning to reduce fuel loads and

ladder fuels in old growth while enhancing old growth characteristics). Private lands outside the federal land boundary have often not been managed for the late-seral or old growth component, so federal lands may need to contribute more to the late-seral component to compensate for the loss of this component on other land ownerships within an ecoregion.

The draft RMP states that old forest structures would be managed in a sustainable manner (Table 1-5, page 9), and that old forest structures would be emphasized during forest management, and that old forests would be retained and protected from uncharacteristically severe wildland fires and insect and disease epidemics (page 27). The draft RMP also states that the preferred alternative would provide direction to maintain and promote old forest structure and conditions through active treatments and restoration activities (page 29), and that actions would be designed to develop and maintain stand structures that are relatively complex with highly variable tree densities, healthy and diverse understory composition (page 29).

This language provides a level of protection to old growth habitats, but may be subject to varying interpretations, and does not provide optimally clear direction to protect or restore old growth or late seral stage forest habitats. We encourage the BLM to consider additional direction that would provide clearer direction for protection and/or restoration of old growth or late seral stage habitats within historic ranges of natural variability. For example, “BLM will strive to maintain and/or restore old growth habitat within historic range of variability to maintain and/or enhance habitat for old growth dependent species.”

**Response:** The BLM agrees with the comment and has adopted the following modified wording related to old forest structure in Chapter 2 of the RMP:

“The BLM would strive to maintain and/or restore stands with old forest structure within historic range of variability to maintain and/or enhance habitat for old growth dependent species.”

#### F41

**Comment:** MWF believes that the BLM should establish a minimum 5-10 mile buffer zone around inventoried bighorn sheep core areas and not issue sheep grazing allotments to afford the greatest protection for bighorn sheep against contracting disease from domestic sheep in whichever alternative BLM chooses.

**Response:** BLM Instruction Memorandum No. 98-140 provides guidelines for the management of domestic sheep and goats in native wild sheep habitats. The Instruction Memorandum identifies that native wild sheep and domestic sheep or goats should be spatially separated to reduce the potential of interspecies contact. The Instruction Memorandum also states that when reviewing new domestic sheep or goat grazing permit applica-

tions or proposed conversions of cattle permits to sheep or goat permits in areas with established native wild sheep populations, buffer strips surrounding native wild sheep habitat should be developed, except where topographic features or other barriers minimize physical contact between native wild sheep and domestic sheep and goats. No minimum buffer strip widths are identified in the Instruction Memorandum but buffer strips could range up to 9 miles.

All alternatives would follow the Instruction Memorandum but the Preferred Alternative would provide guaranteed protection to wild sheep with a mandatory 5 mile buffer between wild sheep habitat and new domestic sheep or goat allotments. The distance could be greater if determined necessary during site specific analysis.

#### F42

**Comment:** BLM did not mention rainbow x cutthroat trout and brook trout another important species and habitat. What about the brook trout fisheries in Moose Creek and importance of beaver dams? What about the belt of public land along the Big Hole River in the Maiden Canyon area accessed by the Ponderosa Road? This BLM public land is adjacent to a nationally known blue ribbon trout stream. All fish habitat must be considered not what BLM chooses.

**Response:** All fish habitat was considered in the RMP. The Fish section of Chapter 3 in the RMP provides a description of fish species and habitats within the Butte Field Office. A table from the Analysis of the Management Situation indicating all fish species found in the Butte Field Office and their distributions has been added to the Proposed RMP/Final EIS. The role of beaver dams is described in Wetlands and Riparian Communities section of Chapter 3.

Reference to “blue ribbon” streams is located in the Recreation section of Chapter 3 in the RMP.

#### F43

**Comment:** The final document would be improved by including species-specific impact discussion rather than providing general assumptions, such as (Volume II, page 535, right column, 4th paragraph), “...Natural disturbances are typically followed by periods of stability, during which fish habitats and populations recover. Population recovery in disturbed streams may be facilitated by fish immigration from nearby drainages less affected by the catastrophic event [fires, floods, drought].”

**Response:** Many of the types of impacts or effects to fish species would be the same or similar under the different alternatives. For example, an activity that increases fine sediment to a fish bearing stream would have the same general effect to the majority of fish species common in the Butte Field Office, such as degradation of spawning habitat. Because of this, those effects

that could have a similar impact on many different fish and other aquatic species are discussed under the Fish section (Effects Common to All Alternatives) of Chapter 4 in the RMP.

Some specific impacts and threats to sensitive fish species, however, are described in Chapter 3 under Special Status Species. Some specific discussions related to fish species are also found in Chapter 4 under Special Status Species (within the Fish subsections of the different alternatives).

## Forest and Forest and Woodland Vegetation

### G1

**Comment:** Do the visual change maps also include changes in trees from green evergreens to red and brown evergreens? If change is not allowed or acceptable in some of these areas, then what is BLM doing to implement a program to prevent the changes in tree color that are occurring. Does it mean that BLM will actually start managing the forests in a responsible manner again with timber harvesting, spraying, or some other effective means to prevent the continuing change in tree color, which results in major visual impact?

**Response:** The visual maps depict the proposed Visual Resource Management Classifications for the action alternatives. These classifications establish varying degrees of modification allowed for classified landscapes. The primary focus of this management pertains to minimizing visual impacts from human rather than natural caused actions. BLM will strive to minimize visual resource impacts regardless of cause where feasible opportunities and budgets allow. Priorities for forest treatments will generally be driven by vegetation and fuel treatment objectives rather than visual resources. In Chapter 2, under Vegetation Communities, Management Common to All Alternatives, in the Forests and Woodlands section, the RMP indicates that vegetative treatments will be managed to reduce the occurrence of unnaturally large and severe wildland fires and insect outbreaks. Stands with characteristics indicating a substantial risk for developing epidemic levels of insect and disease would be high priority for treatment. Reducing these types of occurrences would also reduce the acres of dead and dying (red) trees on the landscape.

### G2

**Comment:** In the Elkhorn Mountains promote elk use in forested stands in the late-summer and fall by promoting palatable foraging habitat, where appropriate, through thinning and prescribed fire.

**Response:** At least some portion of the Elkhorn Mountains would be managed as an ACEC under all action alternatives in the RMP. Vegetation treatments would be geared toward improving upland and riparian habitat quality and resiliency. In many cases this would likely

entail reducing stem densities in forested stands which would promote development of palatable foraging species on the forest floor. It would also entail treating grassland and shrubland habitats to reduce conifer encroachment and promote palatable forage species in these habitats as well.

### G3

**Comment:** In the Elkhorn Mountains thin known areas of dense, thick conifer regeneration stands in order to open areas for use by elk and minimize elk use of private land. Known areas include Warm Springs, Upper Crow Creek, Staubach Creek, Sheep Creek, and other areas of prior fire activity.

**Response:** The Preferred Alternative of the RMP allows for conducting vegetation treatments such as those described by the comment. Treatment of specific areas in the Elkhorns would be addressed separately in project level NEPA analyses, outside the scope of the RMP.

### G4

**Comment:** EPA supports the draft RMP Forests and Woodlands goal to restore and/or maintain the health and productivity of public forests to provide a balance of forest and woodland resource benefits, as well as wildlife and watershed needs to present and future generations (page 17). We support management that moves vegetative composition, structure, pattern, and function within historic ranges of variability and toward long-term ecological sustainability, and reduced risk of uncharacteristically large and severe wildland fires.

Management should be based on understanding and consideration of natural disturbance processes (e.g. fire, insects, disease), including the intensity, frequency, and magnitude of disturbance regimes: natural succession and disturbance regimes: and ecosystem processes (such as the flows and cycles of nutrients and water) and their dynamics.

Efforts should be made to bring the intensity, frequency, and magnitude of disturbance regimes for all these natural disturbance processes (e.g. fire, insects, disease) within the range of natural or historic disturbance levels. Among the information to consider and analyze are:

1) Normal fire return intervals and mortality levels from disease or insects:

2) Post-treatment landscape vs. desired forest age class, composition, structure (How far outside the natural range of variability and disturbance regimes are areas to be treated? What forest types (e.g. cold, moist, or dry), stand densities, and species composition are to be treated? Do these vary from similar sites that have experienced natural disturbances? Is vegetation management directed at density management, thinning from below, strategically placed treatment units, etc.?);

3) Funding for vegetation management (Are large trees being cut to fund restoration? Are wildlife or restoration funds available to carry out vegetation management to meet desired future conditions?);

4) Trade-offs of adverse water quality, fisheries, wildlife impacts of vegetation management (Will fuels reduction require new road construction or reconstruction of roads? Will riparian areas, wetlands, and other important habitats be treated differently than the rest of the landscape?)

5) Monitoring (Is pre- and post-project monitoring proposed?)

**Response:** The Purpose and Need for Revising the RMP stated in Chapter 1, explains that the RMP provides goals, objectives, land use allocations and management direction to maintain, improve, or restore resource conditions. The RMP is designed to specify overarching management policies and actions, by providing an overall vision of the future (goals and objectives) which includes measurable steps, management actions, and allowable uses to achieve the vision. The statements and questions posed in the comment are appropriately considered at the project level and beyond the scope of the EIS.

**Appendix C** of the Draft RMP/EIS (**Appendix D** in the Proposed RMP/Final EIS) discusses the application of the SIMPPLLE model to the current vegetative conditions to determine the extent of variation from historic conditions and the landscape level treatment needs for the watersheds found in the Decision Area. Current forest conditions are described in the Vegetative Communities section of Chapter 3, specifically for various forest zones in the Planning Area and summarized on Tables 3-5 and 3-6 by forest type and watershed in the Decision Area. These tables present how far the current vegetative conditions have departed from historic conditions. The SIMPPLLE model aided in determining the amount of forest and woodland area that could effectively be treated under the guidance for each of the action alternatives discussed in Chapter 2.

The Record of Decision will provide for specific plan monitoring processes to assess progress toward meeting goals or objectives. Project monitoring will be guided by BLM protocols and conducted as part of the forest and woodland health assessment process.

#### G5

**Comment:** We also encourage efforts to restore declining tree species such as aspen, Ponderosa pine, whitebark pine, etc, and to address conifer encroachment upon non-forest habitat types. EPA encourages BLM to include management direction that assures that large healthy trees of desired species such as Ponderosa pine and whitebark pine that are decreasing in overall composition be retained during timber harvests and other vegetative treatments.

**Response:** The dry forest zone includes the stands of ponderosa pine found in the Butte Field Office. The treatments proposed for dry forest stands in Chapter 2 under Alternative B (preferred) would be designed to move these stands to fewer trees per acre with a larger average tree diameter. This emphasizes the retention of the large healthy trees which are often ponderosa pine, in order to meet the desired conditions that are based on historic range of variability and would provide for self-renewal of ponderosa pine in treated stands. Whitebark pine is a species that is found in some areas of the subalpine fir zone which is discussed under the vegetative communities in Chapter 3. This species comprises only a small portion of the subalpine zone that amounts to about 1 percent of the forests and woodlands in the Butte Field Office. The vegetative management guidance discussed for cool, moist forest types in Chapter 2, would also apply to subalpine fir stands, with the treatments focusing on maintaining and protecting healthy and diverse forest systems.

#### G6

**Comment:** We also support the proposed direction in the draft RMP/EIS for retention of downed woody material for soil productivity (organic matter-nutrient cycling) as well as wildlife habitat. The draft RMP states in the vegetation section that much of the fine material not utilized would be left scattered on the forest floor to maintain site productivity (page 27), and that levels of downed wood be maintain to contribute to the needs of wildlife, invertebrates, fungi, bryophytes, saprophytes, lichens, other organisms, long term soil productivity, nutrient cycling, carbon cycles and other ecosystem processes (page 44). This evidences good understanding of the need to retain woody debris on the ground, although we encourage identification of particular numerical levels of downed woody material per acre for habitat types to provide greater assurance that adequate downed woody debris would be left on the ground to maintain soil productivity (organic matter, nutrient cycling), wildlife habitat, and other ecosystem processes.

**Response:** Appropriate numerical target levels of downed woody debris would vary greatly by specific habitat types across the Butte Field Office. Target values such as “tons per acre” of downed woody debris would be developed as necessary at the project level and are beyond the scope of the RMP analysis

#### G7

**Comment:** The draft RMP and EIS discuss insects and disease (page 334). We note that bark beetles are natives of the forest ecosystem and local endemic populations of beetles are a normal component of the ecosystem and beetle interaction with weakened trees is a normal ecosystem function. Bark beetles have a role in forest ecosystems of helping to remove older, weakened, less vigorous trees. It is our understanding that even large

populations of bark beetles and resulting tree mortality can be part of normal ecosystem function, although we recognize that much of the public perceives epidemic beetle populations as an unhealthy forest environment. However, beetle populations generally experience “boom and bust cycles, and forests have proven resilient, if not dependent on these cycles. A beetle epidemic may also be part of a natural progression to a new successional sere, thus, beetle attack is a natural disturbance and regeneration agent in the ecosystem. Many forests that have undergone “devastating “infestations are now experiencing regeneration without active management before or prior to the epidemic. While we do not oppose management to address bark beetle outbreaks for silvicultural purposes, we think it is important that the public understand that bark beetle outbreaks are a normal component of a forest ecosystem.

**Response:** The BLM agrees with the comment. More information regarding the level of insect and disease infestation by watershed has been added in the Proposed RMP/Final EIS in Chapter 3 under Vegetative Communities, Process of Vegetation Change, Forests Insects, and Disease.

**G8**

**Comment:** Fish Wildlife and Parks looks forward to working with the BLM on the fuels reduction projects in the Big Hole watershed. Within these projects we believe there is a lot of potential to enhance and restore big game winter range in the vicinity of Divide. We also have some concerns about the size and scope of the projects that were proposed, then ultimately shelved, prior to the initiation of this planning effort. More recently concern over Rocky Mountain Juniper and its perceived lack of value, as wildlife habitat has become a concern.

**Response:** The BLM agrees that the size and scope of individual projects are important concerns to be analyzed under the appropriate level NEPA documentation. However, the RMP deals with land use planning level decisions rather than individual projects. The action alternatives in the RMP are flexible so that treatment projects can be designed at the size and scale that is most efficient and effective in meeting the desired conditions while complying with the appropriate laws, regulations, and BLM policies and protecting important resources that are discussed in the RMP.

With regards to the rocky mountain juniper, the RMP discusses the species in the Vegetative Communities section of Chapter 3. Juniper is discussed as both a problem species involved in conifer encroachment of grasslands, shrublands and riparian areas, which competes directly with a number of priority plant species named in the RMP; and, a natural component of forest and woodland systems. Juniper is not considered to be a special status species nor a priority species that the BLM has determined to be unique or significant. Project consider-

ations on juniper may vary based on specific vegetation conditions, treatment needs, and site characteristics, therefore concerns are most properly analyzed and handled at the project level.

**G9**

**Comment:** Approximately 140,000 acres of the 302,000 acres that the BLM manages from the Butte field office is classified as forest. The highest probable timber harvest sale quantity proposed in any of the BLM’s Resource Management Plans alternatives A, B, C, or D is 10 to 30 MMBF per decade. Assuming a harvest of five MBF per acre, 200 to 600 acres will be treated per year or 2000 to 6000 acres per decade. This harvest level is insignificant considering the number of acres that need to be treated. The Butte RMP does not address the problem but exacerbates the problem. Dealing with the problem generates sufficient volumes of timber to Montana’s milling infrastructure. It also leads to improved forest ecosystems conditions and a healthy attractive natural environment that is important to western Montanans and to the economy.

I propose another Alternative E to address these issues. My proposal is to conduct an accelerated timber management program during the next 10 to 20 years. A strong focus on restoration and fire hazard treatments addresses wildfire, insect and disease problems by dealing with the underlying forest density problem. To protect watersheds and be effective, timber management must be conducted at the landscape level. To protect communities and homes the wild land interface zone must be realistic. Let terrain be the determining factor, not political, 400 foot, predetermined distances. In drainages with north facing wetter slopes, zones may be much narrower. In drainages containing south facing slopes, wild land interface zones may extend several miles. Also, to be effective, timber harvesting must remove a sufficient number of trees to allow a minimum of 20 feet between crowns and must be followed by broadcast under burning. Research conducted by the University of Montana has shown that a comprehensive thinning program is an economically effective method to reduce fuels and improve forest health. I would also like to suggest that sale purchasers have the ability to sell small diameter and other non-merchantable material as pulp logs. The best way to accomplish this is with split pricing between saw logs and pulp logs. With one bid price fits all, the bidder has to estimate the volume of each product and lower the bid on saw logs to where he covers his expenses on pulp logs.

**Response:** The estimate of forested acres to be treated that was given in the comment was developed by using an assumed rate of product removal and provided a considerably lower range of area treated than those that would actually occur under all of the RMP alternatives except Alternative C. The amount of forest and woodland area that would be treated under each of the alterna-

tives is listed in the Comparison of Alternatives found in Table 2-23 under Forest Products. The total amount of area that would be treated under Alternative B (preferred) and Alternative D would be 3 to 4 times that of the comment estimate. This is due in part to the variety of treatments that would occur under each of alternative, which included a number of non-commercial or non-timber producing treatments such as broadcast burns, pre-commercial thinning, and mechanical reductions in areas where the products could not be efficiently removed due to access limitations or unacceptable resource damage.

The full range of available treatment tools under all alternatives as discussed in Chapter 2 under Vegetation Management Tools and commercial uses of materials from vegetation management activities would be considered in all cases where appropriate. Current BLM timber sale policy and practice would be followed in the implementation of the forest and woodland treatments under all of the RMP alternatives, as described under 43 CFR 5400 and the 5400 series of BLM timber sale handbooks. These guides encourage utilization of all available commercial products from forest management activities when it is efficient to do so, including the use of low value materials such as pulp and biomass. The BLM will also utilize recently developed stewardship contracting tools that were authorized under the Omnibus Appropriations Bill of 2003 (P.L.108-7, Section 323), which allows for technical evaluation of bidder proposals and award based on best value to the government rather than the highest return in revenue. The Butte Field Office would tend to give higher weight to proposals from bidders that would utilize more of the available forest products in the technical evaluation process.

There is no guidance or policy requiring the BLM to manage public forest specifically for timber production. The BLM would be unable to consider an alternative that promotes the production of timber over the other resources, as that would conflict with the multiple use mandates of FLPMA.

The four alternatives presented in the RMP provide a reasonable range of forest treatment alternatives, including actions needed to protect forest health and values, and to provide timber outputs. None of the alternatives propose exclusive or primary use, specific target output, or individual resource protection except in specific cases mandated by law. The RMP alternatives are designed to be flexible, being that treatments are proposed in acreage ranges that would allow for increased treatment of larger areas of forests and woodlands as natural resource, silvicultural and/or landscape needs and imbalances become apparent. They can be treated up to the high end of the acreage ranges to meet the goals, prescriptions, and benefits of each alternative. Other demands such as complying with the many environmental laws, policy initiatives, and budget constraints also influence the level of BLM activity at the field office level. However,

each alternative allows for an acceleration of treatments and an opportunity to increase product outputs, when the increased activity would comply with the resource management objectives of that alternative, while avoiding or mitigating damage to important resource values described in the RMP or protected by law.

#### G10

**Comment:** We have diseased trees now on much of our public land. A BLM sage burn could touch off a major uncontrolled fire. It's happened in other states with tort claims under the Tort Claims Act of high proportions. Pipestone now has many dead trees, standing firewood. None of this mentioned in your document. Nothing about BLM allowing these trees to be cut now for firewood.

**Response:** As stated in Chapter 2 of the RMP (under Vegetation Communities, Management Common to All Alternatives, Wildland Fire Management section), fire management activities would be prioritized by their risk to life and property across the Butte Field Office. More information regarding the level of insect and disease infestation by watershed has been added to the Proposed RMP/Final EIS in Chapter 3 (under Vegetative Communities, Processes of Vegetation Change, Forest Insects and Disease section). Firewood removal activities would be permitted under all alternatives as discussed in Chapter 2 (under Vegetation Communities, Management Common to All Alternatives, Forests and Woodlands section). Timber salvage resulting from forest insects and disease would also be considered under all alternatives.

#### G11

**Comment:** Forest products are a renewable resource and objectives should be sustained at levels that ensure healthy forests. The current insect infestations coupled with the prolonged drought have decreased healthy timber stands and should be addressed in more detail. A proactive management plan should be developed and implemented that utilizes this resource and reduces the overall public safety fire hazard. The proposed restriction against cutting dead trees over 24 inches in diameter for firewood doesn't seem like a prudent action considering the large amount of bug killed timber and the many mature timber stands that currently exist.

**Response:** Additional information has been included in the Vegetative Communities section of Chapter 3 in the Proposed RMP/Final EIS regarding insect infestations in the Butte Field Office. Public safety related to beetle killed trees will be addressed on a site-specific basis and site-specific analysis will determine the appropriate course of action in those areas.

The firewood restriction on trees greater than 24 inches in diameter is intended to protect the largest and highest quality snags for avian species as well as wildlife species

that use this type of habitat. Areas traditionally used by firewood cutters often have a deficiency of large, old snags.

Firewood cutting is not necessarily an adequate tool for preventing the spread of mountain pine or Douglas-fir beetle. Firewood cutters only remove the trees closest to the road, leaving infested trees throughout a stand. It is also important to note that by transporting infested logs, firewood cutters can actually promote the spread of beetles into healthy forested habitats.

Site-specific analysis will determine those areas where forest treatments should be done to prevent or slow the spread of beetles. The removal of large, mature trees could be identified at that time.

## G12

**Comment:** I generally support the Alternative A proposals. Some items need to be considered whichever plan is adopted:

The bug infestation is getting ahead of BLM, and their staff is not fully aware of the intensity of this concern. A very active forestry harvesting activity needs to commence immediately in order to reap some economic benefit from affected timber and to assist in reducing massive fire occurrences. Traditional economic benefits of forestry practices would also be enhanced.

**Response:** BLM staff is aware of current insect and disease conditions in the Planning Area. Aerial insect and disease surveys are conducted annually across the Planning Area. More information regarding the level of insect and disease infestation by watershed has been added to the Proposed RMP/Final EIS in Chapter 3 (under Vegetative Communities, Processes of Vegetation Change, Forest Insects and Disease section). Vegetation treatments proposed under Alternatives B and D represent increases from the current level of forestry activities on Butte Field Office lands. These levels of activity are summarized in Table 2-23, Comparison of Alternatives, near the end of Chapter 2 in the RMP.

## Grassland and Shrubland Habitat

### H1

**Comment:** This proposal for burning of sagebrush will be detrimental to the wildlife resource as well as watershed protection. The importance of sagebrush to various species of wildlife is well documented. BLM presented no literature references on sagebrush in Montana and the importance to wildlife and what species.

**Response:** The Vegetation Management Tools Section in Chapter 2 of the RMP outlines the types of activities that could be used to manage shrublands (including sagebrush). Although prescribed burning of sagebrush communities could be used as a management tool, if appropriate, the BLM is not specifically proposing the

burning of sagebrush habitat. Mechanical treatments are identified as an acceptable method to remove conifers from sagebrush communities and would likely be used in most cases.

The Vegetation Communities section in Chapter 2 of the RMP identifies goals for sagebrush habitat as well as management actions. Sagebrush communities are identified as priority habitats based on the conservation status of sage grouse, pygmy rabbit and other species associated with sagebrush and would be managed to protect habitat for these species as well as for other species that use sagebrush for all or part of their lifecycle.

The Wildlife, Fish and Wildlife Habitat, Special Status and Priority Plant and Animal Species section (Management Common to All Alternatives) in Chapter 2 of the RMP identifies that management activities in sagebrush habitat will be consistent with the National and Montana Management Plan and Conservation Strategies as well as current, accepted science for sage grouse. These plans provide direction for sagebrush protection and management. This section of the RMP also identifies the maintenance of sufficient densities and cover of sagebrush for sage grouse. All action alternatives would provide additional protection to sagebrush by maintaining large patches of sagebrush in sage grouse habitat, maintaining connections between sagebrush habitats, and enlarging the size of sagebrush patches within sage grouse habitat.

The Wildlife section in Chapter 3 of the RMP discusses the importance of sagebrush habitat for a variety of wildlife species.

### H2

**Comment:** Page 321, BLM selected Alternative B “Treatment of up to 11,800 acres of grassland habitat up to 3,650 acres of shrubland habitat, up to 14,750 acres of dry forest, up to 3,750 acres of cool, moist forest and up to 700 acres of riparian acres.” The grasslands you are referring to are sagebrush/grasslands and some of our most valuable winter range on public land. Are you aware of the memo of understanding with FWP on land treatment projects? Is BLM aware of the “Guidelines for Maintenance of Sage Grouse Habitats” Jour. of Wildlife Mgt and Western States Sage Grouse Committee “Guidelines for Habitat Protection in Sage Grouse Range?” 1. “The state wildlife agency should be notified of each specific vegetal control proposal a minimum of two years in advance of treatment by means of an Environmental Impact Analysis.” This is also stated in the MOU with FWP.

**Response:** The Vegetation Communities section in Chapter 2 of the RMP discusses the goals for vegetation communities. Goals related to vegetation focus on maintaining sustainable vegetation, maintaining or increasing diversity, managing for healthy forest stands and maintaining or moving communities towards proper function-

ing condition. The General Summary of Alternative Emphasis for Vegetation Communities (subsection of the Vegetation Communities section) in Chapter 2 identifies the major emphasis for Alternative B as fuels reduction in the urban interface, reduction of conifer encroachment in grasslands and shrublands (sagebrush) particularly in big game winter range areas (to restore and protect big game winter range), enhancement of bighorn sheep habitat and restoration of dry forest types. In both the Draft and Proposed RMP, the main emphasis of vegetation management outside the urban interface is to protect and restore vegetation communities and wildlife habitats.

The Vegetation Communities section (Management Common to Action Alternatives) under Chapter 2 of the Draft and Final EIS also discusses the objectives for management of grasslands/shrublands, forests/woodlands and riparian habitats. Vegetative treatments will focus on restoring the distribution and vigor of grassland and shrubland habitats by removing invading conifers. Sagebrush habitat is identified as a “priority” species based on concerns over the conservation status of sage grouse, pygmy rabbit and other species associated with sagebrush and grasslands habitats.

**Appendix D** (Use of the SIMPPLLE Model) of the Proposed RMP/Final EIS provides a discussion on how acres of various vegetation communities were identified for treatments and those considerations that went into identifying vegetation treatments. Some considerations with vegetation treatments included how vegetation has changed over time, fire suppression, past management and wildlife habitats.

Although the BLM acknowledges that there are many good recommendations for the management of sage grouse and sage grouse habitat in the literature, the BLM in Montana follows both the National and Montana Management Plan and Conservation Strategies for Sage Grouse (2005). These plans have taken into consideration much of the available literature on sage grouse and incorporated this literature into goals, objectives, and conservation actions for sage grouse habitats. The use of these plans, as well as the use of acceptable science, is outlined in the Wildlife, Fish and Wildlife Habitat, Special Status and Priority Plant and Animal Species section in Chapter 2 of both the Draft and Proposed RMP/Final EIS.

Although the BLM is unclear on the specific Memorandum of Understanding referenced by the commenter, it is assumed that the Memorandum of Understanding referenced is the “Mechanical and Chemical Alteration of Vegetation” Memorandum of Understanding of 1971. The BLM is aware of this Memorandum of Understanding and believes that the Memorandum of Understanding, although outdated, is still followed. As outlined in the Memorandum of Understanding, the BLM does coordinate with Montana Fish, Wildlife and Parks on all projects (not just vegetation projects) that can affect

wildlife and wildlife habitats. It is important to point out that the Memorandum of Understanding is an agreement between the BLM and Montana Fish, Wildlife and Parks and not a law.

### H3

**Comment:** Page 332 the BLM plan “Mechanical treatments (no fire) would be used in most cases to remove conifer encroachment in shrubland communities”. Conifers provide security cover for big game animals on winter range. “Conifer encroachment” does not exist in ecological nomenclature. Perhaps you mean second growth Douglas fir and plant succession of conifers.

**Response:** The term “conifer encroachment” is a common term used by public agencies, including the BLM, to describe coniferous trees that are now becoming established in grassland and shrubland habitats. The BLM uses the term “second growth” to refer to forested habitats where trees are becoming re-established after a disturbance such as fire, insect, disease, or logging. There are a number of studies and anecdotal accounts that verify the establishment of conifers in grassland and shrubland communities throughout the west.

Conifer encroachment can provide escape cover for big game but can also significantly reduce the amount of forage available to big game on their winter range. As described in the Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section (Management Common to All Alternatives) of Chapter 2 of both the Draft and Proposed RMP/Final EIS, during site-specific project planning, important blocks of hiding, security and thermal cover for big game will be considered and the effects to these habitat types from site-specific projects will be analyzed.

### H4

**Comment:** This next statement on page 333 as well defies all the published scientific literature on the subject: “Sage grouse management activities involving treatments of sagebrush habitats would create mosaics of sagebrush and grassland communities, regenerate decadent sagebrush, and prevent further decline in the health of sagebrush communities and reduction in distribution of favorable sites (BLM statement)”. This statement lacks insight on research in Montana on sage grouse and sage grouse habitat and why it grows on a site not to mention wildlife literature on the subject, all falsehoods not supported with any literature reference. Habitat maintenance and preservation of sagebrush communities on our public land is essential.

**Response:** The statement in Chapter 4 mentioned by the comment contained editorial mistakes in the Draft RMP/EIS. This statement has been corrected in the Proposed RMP/Final EIS to state: “Treatments within sagebrush communities would emphasize improving or maintaining habitats for sage grouse and other sagebrush

dependant species by removing conifer encroachment, creating a mosaic of grassland and sagebrush habitats, regenerating decadent sagebrush and by preventing a decline in the quality and quantity of sagebrush communities.”

As stated in the Wildlife, Fish and Wildlife Habitat, Special Status and Priority Plant and Animal Species section (Management Common to All Alternatives) in Chapter 2 of the RMP, sage grouse management activities would be designed and implemented to be consistent with the National and Montana Management Plan and Conservation Strategies for Sage Grouse (2005) as well as current, accepted science. This section goes on to explain that sufficient sagebrush densities and cover would be retained in sage grouse habitat. The Management Plan and Conservation Strategies for Sage Grouse in Montana (2005) was developed by representatives of the Montana sage grouse work group (SGWG) which was comprised of federal and state agencies, tribal representatives, private organizations, and individuals from the general public, all of whom have an interest in the issue of sage grouse conservation. The plan also considered a large amount of literature and research on sage grouse and sagebrush habitat.

The overall goal of the Management Plan and Conservation Strategies for Sage Grouse in Montana is to “Provide for the long-term conservation and enhancement of the sagebrush steppe/mixed-grass prairie complex within Montana in a manner that supports sage grouse and a healthy diversity and abundance of wildlife species and human uses.” Objectives include maintaining the distribution and integrity of sagebrush steppe communities and maintaining the distribution of sage grouse populations within the mountain foothills and sagebrush ecotypes.

The Management Plan and Conservation Strategies for Sage Grouse in Montana (2005) provides a description of breeding, nesting, brood-rearing and winter habitat for sage grouse. Although sage grouse are obviously sagebrush obligates, their biological needs differ throughout the year based on the season. For example, nesting habitat is often located near lek sites and with sagebrush canopy of 15-31 percent whereas brood rearing habitat tends to be in more open sagebrush stands with canopies 1-25 percent and a broad range of succulent forbs, an important food source for young sage grouse. The plan and other sage grouse literature explains the importance of having diversity of sagebrush habitats to meet the requirement of sage grouse throughout their lifecycle.

The RMP emphasizes restoring or enhancing sagebrush habitat for sage grouse and other sagebrush dependant species. In some cases, it may be appropriate to treat decadent stands of sagebrush or remove conifer encroachment into sagebrush stands to improve breeding, nesting, brood-rearing, or winter habitat for sage grouse. A site-specific analysis will be done to identify the ef-

fects to sage grouse and other sagebrush dependant species at the time of a proposed activity.

#### H5

**Comment:** Is BLM aware of the fact that Idaho fescue (*Festuca idahoensis*) is a key winter forage species for elk and wild sheep? Idaho fescue is also susceptible to burning. In other words BLM burn plans will also destroy this key forage species as well as big sagebrush.

**Response:** As stated in the Wildlife, Fish and Wildlife Habitat, Special Status and Priority Plant and Animal Species section (Management Common to All Alternatives) in Chapter 2 of the RMP, fish and wildlife habitat would be evaluated on a case-by-case basis as part of project level planning. Overall, the RMP spells out more broad-scale goals and objectives that are to be implemented at the project level where objectives are defined much more specifically as related to site-specific conditions during project-level planning and NEPA. Such evaluations would consider the impacts to forage species (including Idaho fescue) and sagebrush. Measures would be taken to reduce the negative impacts to these species, such as early spring burning before green-up or burning when patches of snow are present for a mosaic burn pattern.

The Wildland Fire Management Section in Chapter 2 in the RMP provides a range of different intensity burns allowed under the alternatives to address maintaining a source of unburned vegetation.

#### H6

**Comment:** Here are a few references on Big Sagebrush you should consider: “A Sea Fragmented into Lakes, Ponds, and Puddles” by Welsh, Bruce L. USDA, Forest Service, Gen’l Tech Rpt RMRS-GTR-144, March 2005; Montana Sagebrush Bibliography, Montana FWP, Frisina, M.R. John J. McCarthy December 2001; SAGEBRUSH Ecological Implications of Sagebrush Manipulation, FWP by Peterson, Joel G.1995, Montana Sage Grouse, FWP/BLM 1975 by Wallstad, Richard.

**Response:** Almost all the referenced literature cited by the commenter was considered and used during the development of the National and Montana Management Plan and Conservation Strategies for Sage Grouse (2005). The Management Plan and Conservation Strategies for Sage Grouse in Montana (2005) was developed by representatives of the Montana sage grouse work group (SGWG) which was comprised of federal and state agencies, tribal representatives, private organizations, and individuals from the general public, all of whom have an interest in the issue of sage grouse conservation.

Although the BLM acknowledges that there are many good recommendations for the management of sage grouse and sage grouse habitat in the literature, the BLM in Montana follows both the National and Montana

Management Plan and Conservation Strategies for Sage Grouse.

The use of these plans, as well as the use of acceptable science, is outlined in the Wildlife, Fish and Wildlife Habitat, Special Status and Priority Plant and Animal Species section in Chapter 2 of the RMP.

The Draft and Proposed RMP/Final EIS emphasize restoring or enhancing sagebrush habitat for sage grouse and other sagebrush dependant species.

#### H7

**Comment:** Is BLM familiar with “Steppe Vegetation of Washington” by Dr. R. Daubenmire? On page 79 he lists 12 good reasons why not to manipulate sagebrush. 1. “There is little to indicate the extent to which the grass increase measured shortly after shrub eradication is maintained.” 2. “The protection afforded many grass plants by dense clumps of shrubs is the sole reason why any perennial grass remains on much of the depleted range.” He goes on to discuss the importance of big sagebrush in watershed protection and improving soil profile.

**Response:** The BLM was unable to view a copy of the reference cited by the commenter. However, many studies and peer reviewed journal articles related to sage grouse and sagebrush habitat were considered and used during the development of the National and Montana Management Plan and Conservation Strategies for Sage Grouse (2005). Although the BLM acknowledges that there are many good recommendations for the management of sage grouse and sage grouse habitat in the literature, the BLM in Montana follows both the National and Montana Management Plan and Conservation Strategies for Sage Grouse. The use of these plans, as well as the use of acceptable science, is outlined in the Wildlife, Fish and Wildlife Habitat, Special Status and Priority Plant and Animal Species section in Chapter 2 of the RMP. The reference cited by the commenter was addressed during the response to public comments in the Montana Management Plan and Conservation Strategy for Sage Grouse (2005). The BLM notes that sagebrush has been identified as priority species/habitat in the Butte RMP, and that Goal #6 under Vegetation Communities in Chapter 2 focuses on managing to promote sagebrush and other priority species.

#### H8

**Comment:** In the Elkhorn Mountains, continue ongoing encroachment reduction treatments (i.e. Power Gulch, Kimber, and Crow Creek). Pursue treatments in other known areas of encroachment (i.e. McClellan, Crystal, and Jackson Creeks) through mechanical manipulation (e.g. slashing, masticator) or prescribed fire. Pursue additional treatments in areas identified through mapping. Use existing maps of known encroachment and fill

in missing data through photo interpretation and other tools.

**Response:** The BLM agrees with the commenter that the reduction of conifer encroachment should occur in the Elkhorn Mountains as well as throughout the Field Office. The BLM, however, doesn’t manage any land in Power Gulch, Crystal Creek, or Jackson Creek and the BLM manages very little land in the Crow Creek and McClellan drainages. The BLM does manage land in Kimber Gulch and future site-specific projects to reduce conifer encroachment may be proposed within the Elkhorn Mountains to improve habitat for wildlife. Site-specific analysis will continue to map conifer encroachment.

#### H9

**Comment:** The document states that bitterbrush and mountain mahogany would be protected and restored in Alternatives B and C. It is not clear how this would be accomplished, especially with mountain mahogany. We would not support burning in stands of mountain mahogany as fire kills mountain mahogany and it is very slow to reproduce and it may take many decades before climatic conditions are favorable for its reproduction.

**Response:** Mountain mahogany and bitterbrush would be protected, when possible, from fire, herbicides and, in the case of bitterbrush, from extensive browsing by livestock. The BLM would also minimize the loss of these species from ground clearing activities such as road construction and mineral activity. To promote these species, the BLM would target projects that focus on the use of mechanical treatments to eliminate conifer encroachment. As described in the Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section of Chapter 2, there would be more proactive efforts to restore these species as described under Alternative B, than would be the case under Alternative C where such efforts would be undertaken on an opportunistic basis.

#### H10

**Comment:** Ward Ranch: For now, your Alt B seems a good start, except I don’t see any reason to move the trailhead further west from where it is now. The main thing is to not let ORV use get established in the area. There’s lots of neat hiking and exploring in the wooded sections (the old BLM holdings). And there’s a crying need to restore the grasslands on the old ranch holdings, and to preserve or improve the scenic qualities (as viewed from west of the river.)

**Response:** All action alternatives in the Butte RMP provide for restoring up to 850 acres of grasslands in the Ward Ranch and McMasters Ranch acquisitions (Chapter 2, Vegetation Communities, Management Common to Action Alternatives, Grasslands and Shrublands section). After further consideration of the location of the

Ward Ranch trailhead, the BLM is proposing to change the Preferred Alternative to keep the trailhead in its current location on the ground as under Alternative A. Because the public has grown accustomed to and regularly uses the existing trailhead, the BLM believes it is more desirable overall and is an appropriate blend of uses to maintain the existing motorized access to this trailhead in a predominantly non-motorized area.

**H11**

**Comment:** I strongly believe that only native plant materials (seeds, seedlings, etc.) appropriate to the area should be used for restoration and revegetation projects. Sometimes, non-native materials appear to be cheaper and more abundant in the short term, but in the longer term, the non-native introduction may prove to be noxious and it may take great time, effort, and cost to fix such mistakes.

**Response:** Using native plant materials was analyzed under Alternative C. Under the Preferred Alternative, revegetation seed mixes would usually consist of site-appropriate native species. In some instances such as after an intense fire or in an area infested with noxious weeds, low-impact, non-invasive species or annual cereal crops may be used to stabilize soils or to compete with noxious weeds. Additionally, seed availability of native species can be an issue when time is of the essence to re-establish vegetative ground cover over large areas. The ability to use non-native species in those rare cases, provides the BLM with more management options.

**H12**

**Comment:** We recommend that ecological site descriptions (ESD's) need to be developed for all lands (USFS, BLM, State, DNCR, and private) in the Elkhorns to be used within the State Transition Model.

**Response:** The Natural Resources Conservation Service (NRCS) develops ecological site descriptions which the BLM uses for site specific planning and rangeland health standard evaluation. The NRCS is currently in the process of developing new ecological site descriptions for the entire state of Montana.

**Lands and Realty**

**I1**

**Comment:** The elimination of public access to public lands through private property has also contributed to the loss of motorized access and motorized recreation opportunities. We request that agencies acquire private land and right-of-ways to provide access to public land that is now blocked off to the public. Anytime there is a land exchange between private and public entities, a public access easement or right-of-way should be required. This action is necessary to reverse the prevailing

trend of significantly less public access to public land over the past 35 ± years and the cumulative negative impact of that trend on multiple-use recreationists.

**Response:** The BLM shares the concern about the lack of legal access to certain areas of public lands, and will continue to pursue access easements from willing landowners as funding and staff capabilities allow. The goal statement for Lands and Realty in Chapter 2 indicates that it is our intention to look for opportunities to acquire non-federal land or interest in non-federal land with important resources or resource uses. Under the Management Common to All Alternatives section under the heading of Access, the RMP lists the various means by which the BLM would seek to acquire access, including easement acquisition and several different types of land ownership adjustment. For more specific information please refer to **Appendix L** (Lands and Realty) in the Proposed RMP/Final EIS.

**I2**

**Comment:** I request that my desire to acquire a portion of these lots be included in the new Butte Resource Management Plan. I have attempted to show basis of inclusion from the "Draft" wording. I attach that statement.

I understand that legal description through the Public Land Survey System is required for a property to be listed. The above "Lots 15 and 18, Sec. 16, T.6 N, R.5W, PMM" are specified for that purpose. However, only a small portion of each lot is involved. The boundaries to be specified later. Some 5 to 15 acres of Lot 18 and 2 to 5 acres of lot 15 are desired. Only a portion of the south face of the mountain side is needed. No "island effect" of land boundaries would be created. I would, of course, pay for the cost of the cadastral survey as well as other expenses involved in the sale.

I request this to be a direct sale since the land is so isolated from ease of public access. If any but the adjacent landowner bought it, the right-of-way issue would be very invasive to the surrounding forest. This proposal before you has no more invasion of the BLM land than the transaction itself. And it will open another public access for the surrounding lands.

**Response:** The BLM is unable to add these parcels to the potential disposal list as they are attached to and contiguous with a large block of federal land administered by the BLM. Parcels identified on the disposal list in **Appendix L** (Lands and Realty) of the Proposed RMP/Final EIS are generally scattered parcels that are difficult and/or uneconomical to manage.

**I3**

**Comment:** BLM proposes land sales and land exchanges but where? The BLM land pooling program promoted for years resulted in the loss of valuable wild-

life habitat and public land access in this area. No public lands should be sold and little if any exchanged.

**Response:** The Butte RMP follows national and state-level planning direction by 1) specifically listing legal descriptions of tracts that could potentially be sold pursuant to Section 203 of the Federal Land Policy Management Act (FLPMA) (although land exchange is the preferred means of disposal), and 2) developing land acquisition criteria rather than listing legal descriptions of specific tracts for acquisition.

Land exchange transactions are typically processed under the authority of Section 206 of the FLPMA and involve the discretionary, voluntary exchange of lands or interests in lands between the federal government and a non-federal party. Since most land exchange proposals are initiated by external customers, the Butte Field Office has no way of identifying where land exchanges are likely to occur.

Sales of public lands are authorized under Section 203 of the FLPMA and parcels are offered at not less than fair market value. Public lands determined suitable for sale are offered only on the initiative of the BLM. Approximately 8,901 acres in the Butte FO are potentially suitable for disposal under Section 203 of FLPMA if important recreation, wildlife, watershed, threatened or endangered species habitat, and/or cultural values are not identified during disposal clearance reviews and no viable exchange proposals have been identified.

The Butte FO recently completed the Ward Ranch land exchange and has acquired the McMasters and Iron

Mask properties to promote wildlife habitat and increase public access in this area.

Please refer to **Appendix L** (Lands and Realty) in the Proposed RMP/Final EIS to obtain information pertaining to land ownership adjustments, and the list of potential disposal parcels.

#### I4

**Comment:** In lieu of such a designation [as ACEC], the Limestone Hills area should be identified as an area available for disposal through sale or exchange into private ownership as suggested in Graymont's 2005 comments. [BLM Note: ACEC boundary will likely exclude Graymont's permitted area.]

**Response:** Disposal of the Limestone Hills area is outside of the scope of this planning effort as the area is currently being considered for a legislative withdrawal for military training purposes by the Department of Defense.

#### I5

Appendix K – Lands and Realty - Potential Disposal Parcels (p. 873). Many of these parcels should not be considered for disposal. See table below, describing parcels in Helena-west area that should not be disposed of.

The following table identifies several parcels that the BLM has identified for “disposal” that MFWP does not feel would be in the best interest of the wildlife resource

Potential Disposal Parcels			
T/R/Sec	Acres	Location-HD	Rationale for not disposing the parcel
6N 4W 5	38.54	Amazon-318	Elk winter range
9N 3W 32	1.43	Lump Gulch-335	Deer, moose, elk. Contiguous with other accessible BLM lands
10N 1W 6	3 small parcels	Spokane Bay	This may be a surveying issue, but BLM lands are accessible from Missouri River
10N 1W 32	40	Spokane Creek	No BLM land appears on map
10N 5W 3	38.33	Greenhorn	Elk, deer, bear, Wildlife Linkage on Cont. Divide. Contiguous with accessible public land
10N 5W 4	34.93	Greenhorn	Same as above
10N 5W 13	40.41	Stemwinder Hill	Elk winter range
11N 4W 36	77 (4)	Scratchgravel, adjacent to Green Meadow Dr.	Wildlife Linkage Zone, continuous public land, important buffer to Scratchgravel
11N 5W 15	17.73	Threemile Creek	Adjacent to state section. Accessible. Mule deer, elk, Wildlife Linkage Zone.
11N 5W 16	44.09	Threemile Creek	Same as above
11N 5W 27	43.69	Willet Ridge	Important elk winter range. Wildlife Linkage Zone
11N 5W 34	61.53	Willet Ridge	Important elk winter range. Wildlife Linkage Zone

or the public if they were disposed. Section 203 (a) of FLPMA indicates that if important recreation, wildlife, watershed, threatened or endangered species habitat, and/or cultural values are not identified during the disposal clearance reviews then parcels can be considered for disposal. Only parcels that meet one of these criteria are listed in the following table, and therefore should not be removed from BLM (public land) ownership. Several small isolated segments are valuable wildlife habitat, however they are not mentioned here because they are isolated and inaccessible.

**Response:** The table in **Appendix L** (Lands and Realty) in the Proposed RMP/Final EIS (formerly **Appendix K** in Draft RMP/EIS) depicts the legal descriptions of parcels which are potentially suitable for disposal through sale under section 203(a) of FLPMA if important recreation, wildlife, watershed, threatened or endangered species habitat, and/or cultural values are not identified during disposal clearance reviews and no viable exchange proposals for them can be identified. These lands would also be available for transfer to another agency or to local governments, as needed, to accommodate community expansion and other public purposes. Project level NEPA under which site-specific issues could be identified would be conducted before any such transactions.

The following parcels are generally widely scattered parcels which are difficult and uneconomical to manage due to their size, shape, location, topography, and access constraints. They would remain on the proposed disposal list in the Proposed RMP/Final EIS.

Township	Range	Section
6 North	5 West	5
10 North	5 West	4 and 13
11 North	5 West	15, 16, 27, and 34

In the Proposed RMP/Final EIS, the parcel located in T. 10 N., R. 1 W., Section 32, is land administered by the BLM and this parcel remains on the list due to the same rationale listed above.

The parcels located in 11 N., R. 4 W., Section 36 and T. 9 N., R. 3 W., Section 32 are very small slivers of public land which are either within the boundaries or very close to proposed subdivision developments. These parcels would stay on the disposal list in order to reduce the chance of future trespass issues.

The parcels located in 10 N., R. 1 W., Section 6 are currently authorized as non-commercial occupancy (2920) leases which were issued to resolve un-willful trespass cases that involve permanent residential structures. These parcels would remain on the disposal list.

The parcel located in 10 N., R. 5 W., Section 3 has been removed from the disposal list upon further review by the BLM.

**I6**

**Comment:** On page 479 under "Lands Use Authorizations", the right-of-way agreement between BLM and MTARNG is mentioned. The following sentence is "about 30,000 acres that are currently withdrawn." It is our opinion that it could cause confusion to the reader. MTARNG has proposed a withdrawal of the Limestone Hills Training Area and a reader might think that the decision has already been reached. We suggest that some addition be made to the paragraph to clarify.

**Response:** Language in this Land Use Authorizations section in the Proposed RMP/Final EIS has been changed to correct this error.

**Livestock Grazing**

**J1**

**Comment:** In the livestock section of the document, BLM recommended land treatment over management.

**Response:** Virtually all of the prescriptions for Livestock Grazing described in Chapter 2 for all the alternatives cover various aspects of livestock grazing management. Some prescriptions do address livestock grazing management as it relates to land treatments. The BLM will continue to address livestock management at a site-specific allotment level, outside the scope of this RMP revision.

**J2**

**Comment:** BLM will not mention again Rest Rotation Grazing and applying the principles and concepts of August L. Hormay to manage our public lands.

**Response:** Rest rotation grazing is certainly one of the methodologies employed in grazing management on a number of Butte Field Office allotments; however it will not be the only method applied. The specific method of grazing on an allotment will continue to be determined on a site-specific basis, outside the scope of this RMP.

**J3**

**Comment:** We are concerned that there is no proactive planning to enhance grazing on BLM land. We recommend allotment improvements in planning process.

**Response:** The BLM's goal is to manage for a sustainable level of livestock grazing while maintaining, restoring, or enhancing BLM rangelands to meet the Land Health Standards. Allotment range improvements are tools to help achieve Land Health Standards and are included in the guidelines for livestock grazing management found in **Appendix F** of the Proposed RMP/Final EIS. Additionally, new and existing Allotment Management Plans would continue to be implemented with associated allotment improvement projects under all alternatives as staffing and budgets allow. Proposed vegetation treatments also stand to increase the

amount of forage available that would contribute to enhanced livestock grazing. Any range improvements would require site-specific analysis.

**J4**

**Comment:** Maintain upland utilization monitoring during cattle grazing season.

**Response:** The BLM will continue to collect utilization data on allotments as staffing and budgets allow. Livestock grazing prescriptions in Chapter 2 and guidelines in **Appendix F** of the Proposed RMP/Final EIS both outline the need for utilization monitoring.

**J5**

**Comment:** We recommend that the agencies establish, maintain, and document an annual pre-cattle utilization-monitoring program in all allotments in the Elkhorns.

**Response:** Although beyond the scope of this RMP, the BLM will continue to collect utilization data on allotments as staffing and budgets allow. Livestock grazing prescriptions in Chapter 2 and guidelines in **Appendix F** of the Proposed RMP/Final EIS both outline the need for utilization monitoring. The method and timing of utilization monitoring on each allotment will be determined on an interdisciplinary, site-specific basis, outside the scope of this RMP.

**J6**

**Comment:** Elkhorn Working Group recommends: Re-establish all Parker 3-Step transects, even if permanent are gone.

**Response:** The Butte RMP is a broad-based plan covering the analysis area. The BLM will continue to collect monitoring data on BLM allotments as staffing and budgets allow. The BLM will continue to use BLM approved vegetation monitoring methods which does include the Parker 3-Step method as one of many. However, most of the established Butte Field Office long term trend monitoring studies use Daubenmire or other methodologies. Switching to, or establishing, Parker 3-Step studies would not improve long term trend information and analysis. The method to be used on each allotment will be determined on an interdisciplinary, site-specific basis outside the scope of this RMP.

**J7**

**Comment:** Elkhorn Working Group recommends continuing existing riparian utilization standards and monitoring while rethinking monitoring site selections.

**Response:** Under all alternatives, existing utilization objectives would continue to be implemented under existing Coordinated Resource Management Plans. Lower or higher utilization objectives and changes in monitoring sites may be set through interdisciplinary

planning or project level NEPA processes to achieve resource objectives on a site-specific basis.

**J8**

**Comment:** Elkhorn Working Group recommends future adoption of the State and Transition Model to help better understand and manage rangeland habitats. Elkhorn Working Group believes that state and transition modeling as a measure of range condition or health, and its relation to succession and ecological processes will enhance management of the Elkhorns.

**Response:** Although beyond the scope of the RMP, under all alternatives, existing management for all Elkhorn Mountain allotments would continue to be implemented under existing Coordinated Resource Management Plans. Elements of the State and Transition model are currently applied by the Bureau as rangeland health assessments are conducted. Additionally, the SIMPPLLE analysis process basically uses the state and transition theory of vegetation modeling. The SIMPPLLE analysis was used to complete a portion of the vegetation potential and analysis in the RMP (See **Appendix D** of the Proposed RMP/Final EIS).

**J9**

**Comment:** Elkhorn Working Group recommends that normal precipitation figures be developed and utilized to predict annual production and to plan for reduced forage availability. This precipitation data should be utilized for adaptive monitoring for elk/cattle management purposes.

**Response:** The BLM regularly examines precipitation and climatic data collected and collated by the various branches of the National Oceanic and Atmospheric Administration (NOAA). This data is used to modify annual operating plans of livestock permittees as needed. Although beyond the scope of this RMP, under all alternatives, existing management for all Elkhorn Mountain allotments would continue to be implemented under existing Coordinated Resource Management Plans. Changes to management and/or monitoring plans to include climate and precipitation data collection may be effected through interdisciplinary planning or project level NEPA processes to achieve resource objectives on a site-specific basis.

**J10**

**Comment:** We recommend the US Forest Service and BLM adopt State and Transition Models to manage this species (Kentucky Bluegrass).

**Response:** Elements of the State and Transition model are currently applied by the BLM as rangeland health assessments are conducted, which would be the avenue where issues with Kentucky Bluegrass are identified.

**J11**

**Comment:** In the Elkhorn Mountains management strategies should move away from attempts to resolve cattle vs. wildlife use conflicts and begin to develop long term approaches designed to sustain grassland systems.

**Response:** The BLM believes the prescriptions outlined for the action alternatives in Chapter 2 of the RMP are designed to sustain grassland ecosystems. The BLM's goal is to manage upland vegetation communities to move toward or remain in proper functioning condition, including a full range of herbaceous and shrub species. Grasslands and shrublands would be treated to remove conifer encroachment and move towards a more desired ecological condition of open areas with a low density of tree species. Grasslands and shrublands would also be assessed to ensure that uplands are in properly functioning condition. If these habitat types are not in properly functioning condition due to management activities, management would be modified to improve conditions. Alternatives B, C, and D as described in Chapter 2 outline varying degrees of aggressiveness towards addressing this issue.

**J12**

**Comment:** In the Elkhorn Mountains continue current adaptive allotment systems, rather than strict management plans.

**Response:** Although beyond the scope of this RMP, under all alternatives, existing management for all Elkhorn Mountain allotments would continue to be implemented under existing Coordinated Resource Management Plans. Changes to management may be effected through interdisciplinary planning or project level NEPA processes to achieve resource objectives on a site-specific basis.

**J13**

**Comment:** Elkhorn Working Group recommends maintaining cattle grazing on public land in the Elkhorn Mountains and using cattle as a tool for achieving wildlife management goals.

**Response:** Cattle grazing would be maintained on public lands in the Elkhorn Mountains under all alternatives with one exception. As shown on Table 2-2 in Chapter 2, under alternative B the Indian Creek allotment (Iron Mask property) would be managed as a forage reserve allotment and under Alternative C, this allotment would not be available for livestock grazing.

The Vegetation Management Tools section (under Vegetation Communities) in Chapter 2 of the RMP indicates that livestock grazing management or prescription grazing would be available as a method to treat habitat to achieve wildlife management goals.

**J14**

**Comment:** Clarify if there is adequate monitoring and oversight of implementation of Land Health Standards (Appendix E) and enforcement of grazing permits when State Water Quality Standards are not being met due to grazing. We also recognize that it is important to maintain economically viable ranching/ grazing operations on private lands adjacent to BLM lands to reduce pressure for subdivision and development of such lands.

**Response:** The BLM believes there is adequate monitoring and oversight of implementation of Land Health Standards. As of the end of fiscal year 2006, 229,000 acres (90 percent) of a possible 253,000 acres of currently permitted allotments had been assessed for Land Health Standards. Of the acres assessed, 113,000 acres were meeting standards (49 percent), 80,000 acres were not meeting standards but appropriate action has been taken to ensure significant progress toward meeting standards and livestock is a significant factor (35 percent), 3,000 acres were not meeting standards and appropriate action had not been taken yet to ensure significant progress toward meeting standards and livestock is a significant factor (1 percent), and 34,000 acres were not meeting standards due to causes other than livestock grazing (15 percent). Furthermore, the Bureau continues to monitor allotments to ensure Land Health Standards are being met, or progress is being made toward meeting Land Health Standards. The BLM regularly monitors allotments on a scheduled basis.

**J15**

**Comment:** American Wildlands recognizes that riparian zones are often critical for wildlife movement. Livestock grazing often leads to the degradation of these areas; and therefore AWL recommends the BLM fencing where necessary to prevent unrestricted access to riparian zones.

**Response:** In Chapter 2 of the RMP, under Vegetation Communities, Management Common to All Alternatives, in the Livestock Grazing section there is a management prescription that indicates: "The health and integrity of riparian areas and wetlands would be protected by and improved by using tools such as livestock fencing, alternate upland water sources or livestock grazing adjustments (timing and stocking rates)."

**J16**

**Comment:** American Wildlands recommends that the BLM perform a thorough watershed assessment of all livestock allotments within the BLM's Butte Office lands. AWL was particularly impressed with the series of watershed assessments performed by the BLM's Dillon Field Office (2006-2007) and suggests the Butte Field Office provides a similar assessment. This would give the BLM a strong foundation from which to create and implement changes in allotments, and would pro-

vide the public with technically solid reasoning behind these changes.

**Response:** Given the scattered and fragmented nature of BLM ownership across the planning area, the Butte Field Office has conducted Rangeland Health Assessments on an allotment-by-allotment basis. The Butte Field Office has used the information from these assessments to develop and implement changes on allotments where livestock grazing is a significant factor in not meeting standards.

#### J17

**Comment:** Using domestic sheep to control noxious weeds in Schedule [Alternative] B is interesting. The proposed regulations state that the domestic sheep will be kept 2 miles from the known Bighorn Sheep habitat, with the bed grounds for the domestic sheep being 4 miles from the known Bighorn Sheep habitat. The management provisions that are proposed concerning domestic sheep grazing of noxious weed infestations in areas adjacent to Bighorn Sheep habitat are so restrictive that it is unlikely that any sheep producer will agree to the restrictions. I base this upon my 30 years experience of raising range sheep. Domestic sheep will have a greater impact controlling noxious weeds when they are camped or bedded in the noxious weed infestation. From a livestock producer perspective these proposals effectively preclude the possibility of using domestic sheep to graze noxious weeds in areas adjacent to Bighorn Sheep habitat.

**Response:** Grazing domestic sheep to control noxious weeds is one of many useful management tools for controlling noxious weeds. However, the transmission of disease from domestic sheep to bighorn sheep is a significant concern. Buffer strips of sufficient distance or topographic barriers to keep domestic sheep and bighorn sheep from interacting are the only currently known methods of preventing disease transmission. The proposed management prescription was included to provide the possibility of management flexibility to address some noxious weed infestations near bighorn sheep habitat. Using domestic sheep as a weed control tool under a contract basis rather than under a permit basis would require the sheep owner to use younger sheep which would graze further from camp; in this case the sheep owner would calculate the costs of using younger animals and trailing further as part of his or her bid proposal.

#### J18

**Comment:** On page 33, though, livestock grazing is discussed and it is mentioned that cattle allotments cannot be converted into sheep allotments if they are within 5 miles of known Bighorn Sheep habitat. Is it stated anywhere what will happen if Bighorn Sheep populations shift into an existing domestic sheep allotment? When the Bighorn Sheep were introduced to the Elkhorn

Mountains years ago assurances were given that the Bighorn Sheep would be far from existing domestic sheep allotments. Presently the range of the Bighorn Sheep is different from what was originally thought to be.

**Response:** Current BLM guidance would be followed under all alternatives for the scenario described above. Current BLM guidance outlined in Washington Office Instruction Memorandum 98-140 states that cooperative efforts should be undertaken to notify the permittee and appropriate agency to determine the appropriate action if domestic and wild sheep come in contact. Appropriate action is often removal of stray wild sheep, but could also entail removal of stray domestics if they may contact the wild sheep.

#### J19

**Comment:** Who will perform the maintenance of fences and water development projects and provide weed control of the Forage Reserve Allotments if those allotments are used only on a temporary and nonrenewable basis?

**Response:** The BLM would pursue and establish the infrastructure (i.e. fences, water developments, etc.) and control weeds through the annual work planning for forage reserve allotments. The BLM would assign maintenance to users or perform upkeep as needed to maintain the infrastructure.

#### J20

**Comment:** The livestock grazing analysis needs to clearly specify the anticipated impact on grazing allotments when other conditions presented in the plan such as riparian areas, water quality, wilderness areas, and endangered species plans are overlaid. It appears current grazing allotments may be reduced due to these outside impacts and [the RMP] does not address the potential impacts on the agricultural producers through possible mitigation measures by reallocation of grazing allocations from one area to another.

**Response:** Impacts to livestock grazing are disclosed in Chapter 4 of the RMP under Effects on Resource Uses in the Livestock Grazing section, based on estimates of what could occur with implementation of any given alternative. The impacts described in the Economic and Social sections also estimate impacts to livestock operators and people/groups that value livestock grazing on public lands. Under current regulations and management direction, the BLM is required to manage livestock grazing to meet Rangeland Health Standards for riparian areas, water quality, and endangered species. This will remain the case for all of the alternatives. In most cases when an allotment is not meeting standards, a range improvement project or change in season of use is sufficient to initiate an improving trend. Additionally, the Butte Field Office manages livestock grazing in a num-

ber of Wilderness Study Areas. No significant reduction in the amount of livestock grazing authorized in the BFO is anticipated with adopting any of the alternatives.

**J21**

**Comment:** Range monitoring: “self-monitoring is encouraged” (p.724) Agency monitoring is a must.

**Response:** Under current regulations and management direction, the BLM is required to manage livestock grazing to meet Rangeland Health Standards described in **Appendix F** of the Proposed RMP/Final EIS. This will remain the case under all of the RMP alternatives. As is stated in the appendix, “Self-monitoring by permittee should be encouraged, but with these sideboards:

- permittee's data and BLM's data should be comparable;
- BLM must perform some level of compliance monitoring for each self monitored allotment to ensure the permittee's monitoring is being done and it is valid;
- there should be regular reporting of self-monitoring data; and
- when appropriate, monitoring should include the use of reference sites (such as exclosures).”

The BLM will continue to monitor rangeland and vegetation on a regular basis as time and funding allow.

**J22**

**Comment:** I agree with the grazing level of Alternative B although rotational grazing through quality range review is very important. We need to insure our range conservationists are out in the field reviewing the need for rest rotation of the pastures. Soil and riparian impacts will be decreased with a quality level of on-the-ground management.

**Response:** The BLM agrees that range inspections and monitoring of resources are important. The BLM will continue to inspect allotments and collect data on allotments as staffing and budgets allow. Livestock grazing prescriptions in Chapter 2 and guidelines in **Appendix F** of the Proposed RMP/Final EIS both outline the need for regular range inspections and periodic monitoring.

**J23**

**Comment:** Recommendations for the Elkhorn Mountains, Page 31 and 32 concerning forage reserve allotments:

1. An appropriate infrastructure including boundary and interior fences, water development and weed treatment, will occur before livestock grazing use begins on the forage reserve allotments.
2. The BFO will determine who is responsible for building and maintaining boundary and interior fences and water developments.

3. The Elkhorn coordinator shall track interested applicants for livestock grazing on the forage reserve allotments.
4. Preference shall be given to forest service permittees, BLM permittees or private land owners who are otherwise qualified applicants and involved in or affected by a project, emergency or resource use occurring in the Wildlife Management Area or the lands managed by the BFO in the Elkhorns.
5. The Elkhorn Coordinator shall collaborate with the BLM range specialist, Forest Service Range Specialist, and FWP on a yearly basis as to the rangeland health on the forage reserve allotments.

**RATIONALE:** One of the primary reasons for the acquisition of the lands proposed for the forage reserve allotments was to help resolve wildlife/livestock grazing issues on federal lands under the particular managements as a Wildlife Management Area and a MOU among the Forest Service, Fish Wildlife and Parks, BLM and other state and federal agencies. The success of management practices concerning wildlife within the managed lands is inherently tied to private ranches surrounding the federal lands and the maintenance of that open space landscape. It is therefore important to give preference to those ranches around the Elkhorns who affect and are affected by this unique management situation. As the Ecosystem Research Group noted in its recent study, “The benefit of coordinated public/private land management in the Elkhorns is the leverage it offers our public land resources to produce a far larger accessible wildlife ecosystem than would otherwise be available from public land only.” By giving a preference to those Elkhorn connected ranches that are involved in or affected by projects, emergencies, or wildlife resource use, the BLM will be furthering their goals shared with other agencies in this cooperative management plan. Whether the BLM Elkhorn lands are managed pursuant to an MOU or by an ACEC designation, the preference will facilitate and help achieve those management goals and policies of the federal and state agencies regarding wildlife and the other resources involved.

**Response:** The BLM would pursue and establish the infrastructure (i.e. fences, water developments, etc.) where necessary for forage reserve allotments through the annual work planning process. The Butte Field Office would assign maintenance to users or perform upkeep as needed to maintain the infrastructure. The BLM will determine the amount and timing of use and rest on forage reserve allotments to ensure they are meeting rangeland health standards. The BLM will keep track of interested applicants. As modified in the Proposed RMP/Final EIS for Alternative B in Chapter 2, preference will be given to qualified applicants within the Elkhorn Cooperative Management Area for the Indian Creek forage reserve allotment (Iron Mask acquisition). The Proposed RMP/Final EIS also provides addi-

tional criteria as to how the BFO would select applicants if multiple applications were received.

#### J24

**Comment:** Rework upland use standards for areas in the Elkhorn Mountains that have transitioned to non-native grass communities.

**Response:** Under all RMP alternatives, existing utilization objectives would continue to be implemented under existing Coordinated Resource Management Plans. Lower or higher utilization objectives may be set through interdisciplinary planning or NEPA processes to achieve resource objectives on a site specific basis.

#### J25

**Comment:** Repeat rangeland data collection on the Elkhorn Vegetative Study area using methods similar to those used during the Elkhorn Vegetation Study.

**Response:** Though this comment is outside the scope of the Butte RMP, the BLM will continue to collect monitoring data on BLM allotments within the Elkhorn Vegetative Study area as staffing and budgets allow. The BLM will continue to use BLM approved vegetation monitoring methods which are similar to those used during the Elkhorn Vegetation Study.

### Minerals

#### K1

**Comment:** Page 463 - This page contains Table 4-39. Under the heading "Limestone" the data on that table indicates a consistent output both currently and through all alternatives at a level of 365,000 short tons. Page 466 - Tables 4-41 and 4-42 appear to contain conflicting information when compared to the content of Table 4-39. In Table 4-41 under the heading "Minerals" it is currently stated that there are "16" full and part-time jobs in the minerals industry. Under Alternatives A, B and D the number of full and part-time jobs would be 105 while under Alternative C the number would again be 16. Given the employment at the Graymont facility and the content of Table 4-39 it would appear that these numbers are simply not correct.

**Response:** The Proposed RMP/Final EIS has been adjusted to address this comment. Text revisions address economic impacts related to minerals management in Table 2-24, Chapter 3, and Chapter 4 of the Proposed RMP/Final EIS. Please note that the minerals resources referred to in Tables 4-41 and 4-42 of the RMP include anticipated natural gas activities as well as locatable minerals.

#### K2

**Comment:** On Table 4-42, it is currently estimated in 2006 Dollars that the "average annual labor income"

from the minerals" industry is \$730,000. Under Alternatives A, B and D this average annual income would increase to \$1,087,000 while under Alternative C it would remain at \$730,000. Obviously, these numbers do not reflect Graymont's operations and apparently were based upon the erroneous "Analysis Assumptions and Guidelines" instead of the reality of Graymont's existing operations. Also, Graymont could not find anything in its analysis of the various alternatives that would support the numbers utilized in Alternative C which would appear to indicate that somehow Graymont's operations would cease under Alternative C. If the Draft Plan alternative intends to terminate Graymont's operations it should be more clearly stated.

**Response:** Text revisions that address economic impacts related to minerals management have been made in Table 2-24, Chapter 3, and Chapter 4 of the Proposed RMP/Final EIS. Please note that the minerals resources referred to in Tables 4-41 and 4-42 of the RMP include anticipated natural gas activities as well as locatable minerals.

#### K3

**Comment:** Page 478 - In Table 4-44, the "anticipated operation timeframe" for Graymont's operations run through 2030. As indicated in the Mine Plan Modification submitted to the Butte Field Office in early 2006, Graymont anticipates that its mining operations in the Limestone Hills will run at least 50 additional years. Graymont believes the table should reflect this anticipated life.

**Response:** Text in this table has been corrected in the Proposed RMP/Final EIS to address this comment.

#### K4

**Comment:** The RMP analyzes the impacts on mineral exploration as it relates to wilderness area expansion, Areas of Critical Environmental Concerns (ACEC) and Visual Resource Management (VRM). When all these other proposed conditions are overlaid on the available land there is a significant increase in restricted area available to potential future mining operations in Alternative B. This limitation on possible mineral production has the potential to decrease tax revenues to Jefferson County due to the increased requirements that will be placed on future mineral development. The proposed Muskrat Creek and Elkhorn Tack-on Wilderness Study Area would preclude mineral development in areas of high proven mineral deposits and be a foregone opportunity for future generations. These permanent closures would also generate standard county PILT payments that wouldn't be equitable to the permanent lost potential that mineral development could produce.

**Response:** The RMP provides for mineral development opportunities in both ACECs and areas with high VRM ratings. These areas would likely require additional

measures to mitigate visual impacts or prevent unnecessary or undue degradation, but they are available for mineral development. The Muskrat Creek withdrawal has been dropped from the Preferred Alternative of the Proposed RMP/Final EIS because the BLM believes that aquatic resources there could be protected using the 43 CFR § 3809 regulations. The Elkhorns Tack-On WSA existed before this RMP revision so this RMP revision would not apply any additional restrictions than what already exist for this area. The Preferred Alternative for the Butte RMP does provide for this tack-on WSA being dropped in the event that adjacent Forest Service lands are removed from wilderness consideration.

#### K5

**Comment:** “Map 46: Lands Proposed for Withdrawal from Locatable Mineral Entry under Alternatives B & C” includes several recreation areas and the proposed Muskrat Creek Wilderness Area, but does not include the proposed Wilderness of the Sleeping Giant – it should.

**Response:** One complexity with respect to proposing a withdrawal from locatable mineral entry in the Sleeping Giant Wilderness is that the area does include privately held mineral rights that would not be affected by any withdrawal. The area has low potential for mineral resources other than slate so the likelihood of claims being filed is low. However, on lands for which the BLM holds mineral rights in Wilderness Study Areas (WSAs), locatable mineral entry would be managed in accordance with the Interim Management Plan for Lands under Wilderness Review. If Congress designates WSAs as wilderness, they would then be withdrawn from mineral entry where the BLM holds mineral rights.

#### K6

**Comment:** On page 13 under planning criteria and regulatory requirements BLM indicates that FLPMA and all other applicable laws will be met. Montana Fish, Wildlife, and Parks believes that some of the issues we have related to mineral and energy issues ultimately stems from the vision and management mission statement in Table 1-5. This statement fails to capture the spirit of the Federal Land and Policy Management Act of 1976 that directs the BLM to conduct land use planning, and that management on the basis of multiple use and sustained yield unless otherwise specified by law. The overarching mission and goal statement for minerals and energy that will help frame the selection of an alternative for the record should include a statement to address fish, wildlife, and recreational resources. Specifically, this mission should state that not only geologic features be preserved but that in mineral leasing and development should occur in a manner that protects fish, wildlife and recreational resources, including crucial fish and wildlife habitat and migratory corridors through

appropriate stipulations including No Surface Occupancy where required.

**Response:** The plan does protect fish, wildlife, and recreational resources using appropriate stipulations, including the use of No Surface Occupancy stipulations for oil and gas exploration.

#### K7

**Comment:** The Boulder Batholith has traditionally offered mining opportunities and tremendous local and statewide economic and employment benefits from extractive industries. These opportunities should continue to be made available without undue restrictions.

**Response:** The RMP notes the Boulder Batholith is an area of high mineral potential that has hosted many of Montana’s most historic mining districts. The plan continues to make lands available for mineral development. Any measures required to prevent unnecessary or undue degradation related to mineral development are the result of the BLM’s responsibility to protect a variety of resources as noted in FLPMA.

#### K8

**Comment:** Page 601 Minerals, Effects Common to All Alternatives; Travel management provisions that “could result in reducing access to mining claims or interfere with the ability to conduct exploration work for some operators”, is inconsistent with Locatable Minerals, Management Common to all Alternatives on Page 94 that states, “BLM provide opportunities for mineral exploration an development”, and “BLM will ensure accessibility to mineralized areas for exploration and development”. Any travel provisions in any of the options contrary to those statements on Page 94 need to be removed.

**Response:** The access for mineral development through the travel management plans will restrict access only to those operators who may not be willing to take the time to follow the travel plan variance requirements. Operators following the available provisions for obtaining a travel plan variance will have access to mineralized areas for the purpose of mineral exploration and development. Operators interested in obtaining a travel variance should be aware of additional lead time and potential expense that a travel variance request may involve.

#### K9

**Comment:** It is obvious (clear) that our concern was well founded that BLM is very serious about closing off as much mineralized areas from public access as possible. This is reflected in the pursuit of closing off 20-70 percent of the mineralized areas to public use/prospecting and claim staking. If you say I have it all wrong and BLM is not intentionally locking up minerals by closing and decommissioning key roads, let look at

their conclusions in the EIS/RMP. Helena TPA – BLM wants to lock up 49-72 percent of all known high-mineral potential areas by closing and decommission key roads. East Helena TPA – BLM wants to lock up 9-22 percent of all known high-mineral potential areas by closing and decommission key roads. NW L&C TPA - BLM wants to lock up 32-36 percent of all known high-mineral potential areas by closing and decommission key roads. Boulder/Jefferson City TPS - BLM wants to lock up 38-61 percent of all known high-mineral potential areas by closing and decommission key roads. Upper Big Hole TPA - BLM wants to lock up 8-19 percent of all known high-mineral potential areas by closing and decommission key roads.

**Response:** The areas identified for road closure or decommissioning are not withdrawn from operation of the Mining Law and remain open to the location of mining claims and development of minerals. The travel restrictions would impact the exploration and development by requiring the permitting, either through a travel variance or a Plan of Operations for activities that might otherwise have been Casual Use or Notice level activity under the Bureau's Surface Management Regulations (43 CFR 3809). These requirements may restrict exploration and development activities to those unwilling to pursue the required permits, but these lands do remain open to the Mining Law and are not "locked up".

#### K10

**Comment:** The final RMP/EIS should evaluate and discuss the potential for acid mine drainage and/or metal or nutrient transport or pollution to occur during mineral exploration and development on BLM lands. Impacts to water quality from active and inactive mining on BLM lands within the BFO area should be identified and disclosed. It would also be helpful to identify where active and inactive (abandoned) mines are located on a map, and to identify mine sites where reclamation work is needed for environmental restoration, and the proposed implementation schedule for mine reclamation. There is a need to protect the taxpayer from the potential expense of reclamation and remediation following hard rock mine financial failures or abandonment.

We note that pollutant discharges from mine adits, and mine site surface runoff and ground water seepage are regulated by EPA and/or the States National or Montana Pollutant Discharge Elimination System (NPDES or MPDES) permits under Section 402 of the Clean Water Act.

**Response:** The potential for acid mine drainage (now more commonly referred to as acid rock drainage) and/or metal or nutrient transport or pollution is much too site-specific to be discussed in the RMP, and would be addressed at a project-specific scale. Impacts to water quality from Abandoned Mine Land (AML) sites are also highly site-specific. AML sites proposed for reclamation work are discussed only briefly in the RMP. For

a more detailed discussion of BLM AML sites please visit: [http://www.blm.gov/wo/st/en/prog/more/Abandoned\\_Mine\\_Lands/abandoned\\_mine\\_site.html](http://www.blm.gov/wo/st/en/prog/more/Abandoned_Mine_Lands/abandoned_mine_site.html). Potential impacts associated with these sites are addressed in project level NEPA analyses.

#### K11

**Comment:** Under the heading Resource Assumptions and the subheading "Minerals and Geology" there is a further subheading titled "Locatable" on pages 314 and 315. As we have reviewed this material, while it makes reference to "three currently operating large scale metal mines" and "three currently operating limestone mines located on private land within the initial Planning Area..." we do not find any reference to Graymont's activities on the public lands nor to the significant impacts Graymont's operation has on the economy of Broadwater County. To the extent the text accurately reflects the "analysis assumptions and guidelines actually used in preparing the alternative management actions," it would appear to Graymont that the failure to even consider Graymont's operations as a part of the analysis of the alternative management actions constitutes a significant defect in the preparation of the Draft Plan as it relates to locatable minerals.

**Response:** The text has been changed in the RMP to reflect the fact that the limestone mines are on both private and public lands.

#### K12

**Comment:** Why is White Sandy, Spokane Bay (or Bar?), Muskrat Creek, and French Bar being proposed for mineral withdrawal? This is the first I heard about it, I haven't seen any public notices or anything in the Federal Register that you are planning to withdraw those areas from mineral entry. Isn't this a major process and shouldn't it be done in a separate process, not sneaked in through the backdoor in a RMP? It is fine to note that these areas "may be" considered for withdraw, but I thought there is an actual proper and formal route to take to withdraw minerals from public domain?

**Response:** The proposal to withdraw these areas is initiated through the planning process and the RMP, but the RMP does not actually withdraw these lands. The comment is correct that the "withdrawal" process for withdrawing areas from the operation of the Mining Law is a formal process involving both internal and public review. The areas proposed for withdrawals remain open to the Mining Law until the withdrawal process is formally started. The RMP recommendations are only the first step in this process.

#### K13

**Comment:** Page 87 - The Draft Plan acknowledges the fact that the LEIS is being prepared and that if, and when, legislation is passed by Congress, the legislation

would "subsequently amend the Butte RMP." This text does not appear to reflect the actual circumstance in the Limestone Hills, particularly with regard to the existing emergency closure and the recently published "segregation" for purposes of the proposed withdrawal. The Draft Plan needs to be amended to reflect actual circumstances as they exist on the ground.

**Response:** Text has been added to reference the Federal Register notice which segregated the lands.

#### K14

**Comment:** Table 2-23 on page 141 under the heading "Management Common to All Alternatives" appears to indicate at the third bullet point that the LEIS itself would cause a revision to the Draft Plan. It was our understanding that only the actual legislation would cause the change in the plan. If the mere preparation of the LEIS will change the Draft Plan, then since the draft of the LEIS has already been published, this text should be clarified.

**Response:** The text under the heading Management Common to All Alternatives has been modified to address this comment.

#### K15

**Comment:** Page 263 - On this page in the right hand column under the heading Limestone, the second sentence in the second paragraph should be reconsidered. While this sentence appears to reflect the proposed action as contained in the draft LEIS, it does not refer to the preferred alternative identified in the LEIS. Also, it would appear to indicate the "Army National Guard" is evaluating the withdrawal while in fact it is Congress that is ultimately going to consider the withdrawal on behalf of the Department of the Army, Corps of Engineers.

**Response:** The text has been modified in this location in the RMP to reflect this comment.

## Monitoring, Implementation

### L1

**Comment:** Monitoring and evaluation must be made consistent with and pursuant to the best available scientific information, techniques, and methods, and any conclusions based on these evaluations must be statistically significant.

**Response:** Appendix N of the Proposed RMP/Final EIS describes the implementation, monitoring, and evaluation process that will be used for the Butte RMP. The Approved Plan accompanying the Record of Decision will identify monitoring processes by goal and program area.

### L2

**Comment:** Monitoring and adaptive management programs are necessary and crucial elements in identifying and understanding the impacts of management actions, and should be an integral part of ongoing resource management and RMP implementation. There should be a continuing process of planning, implementing, monitoring, and evaluating effects of management, and adjusting management where effects are not as predicted. It is only through monitoring of actual effects that occur that the BLM will be able to determine whether:

- 1) goals and objectives are being met;
- 2) assumptions/indicators used in developing and implementing the plan are valid; and
- 3) effects are as predicted (i.e. addressing uncertainties); and
- 4) if mitigation is effective or should be increased or decreased or otherwise adjusted to be meet project goals and objectives. A properly designed monitoring plan will quantify how well the preferred alternative resolves the issues and concerns identified during scoping, and provides the flexible program for monitoring and feedback of monitoring results to improve predictive methodology and modify mitigation. Balancing of recreational uses and resource development with ecosystem and environmental protection needs will require careful monitoring of impacts associated with uses and resource development and feedback of monitoring information to BLM management within an adaptive management framework.

We did not see much discussion of the BLM's proposed monitoring and adaptive management program for the BFO area. Additional information on the BFO's monitoring and adaptive management program should be provided in the final RMP/EIS. Programmatic documents provide an ideal mechanism to develop monitoring programs ultimately used through tiered documents to gather data and answer questions raised in scoping. EPA supports linking the approval of projects tiered to the RMP to availability of funding for conducting necessary monitoring and evaluation. We are concerned that monitoring is often under funded in land management agencies. We believe the RMP/EIS should include a strong, explicit commitment to monitoring, especially watershed/water quality monitoring, such as that in the Forest Service Pacific Northwest Region's Forest Monitoring and Evaluation Guide in which the Regional Forester stated, "All programs and projects should contain appropriate levels of monitoring funds in their costs or they should not be undertaken." (USDA FS 1993)

We recommend that an Appendix be devoted to describing the monitoring and adaptive management program that will be used within the BFO to assure that goals and objectives are met. The final RMP/EIS should demonstrate how future decisions will affect monitoring and

evaluation if financial commitments to these programs or the operating budget are reduced.

**Response:** Appendix N of the Proposed RMP/Final EIS describes the implementation, monitoring, and evaluation process that will be used for the Butte RMP. The Approved Plan described in the Record of Decision will identify monitoring processes by goal and program area.

### L3

**Comment:** Does BLM consider the second growth Douglas fir growing on the winter range in Sawmill Gulch a weed, a nuisance species as well as big sagebrush and Idaho fescue? This winter range needs more timber cover not less.

Is BLM again going to try to burn sagebrush on elk/mule deer winter-spring range in the Pole Creek, Whiskey Gulch, and winter range south of Divide using this seriously flawed document?

**Response:** Vegetative conditions and associated potential treatments of specific localities within the Butte Field Office, such as the areas mentioned in the comment, are implementation decisions that will be considered site-specifically outside of the RMP. After finalization of the RMP priority project areas and habitats for vegetative treatments will be tiered to the priorities identified in the RMP.

### L4

**Comment:** BLM also has a memo of understanding with FWP on land treatment projects and it should be in this document. Each land treatment is subject to an EA/EIS with full public involvement as well including field trips. Refer to BLM manual on Environmental Assessments H-1790-1 and National Environmental Policy Act. This document will not give BLM a license to go out and destroy our public land wildlife habitat.

**Response:** The BLM agrees with the commenter that specific treatment projects are subject to site-specific NEPA analysis on a project-level basis outside the context of the Butte RMP. The BLM regularly coordinates these projects and activities to involve Montana Fish, Wildlife and Parks. The BLM has no plans to go out and destroy wildlife habitat.

### L5

**Comment:** We request public meetings on any sagebrush control project and the process followed including Fish Wildlife and Parks involvement.

**Response:** The BLM proposes to promote and enhance sagebrush habitats in the Butte RMP. Specific projects geared toward promoting sagebrush will follow a site-specific NEPA process that may involve public meetings, and will involve coordination with Montana Fish, Wildlife, and Parks. Such project level site-specific NEPA occurs outside the RMP process. Upon finaliza-

tion of the RMP, such projects will employ and tier to management direction described in the RMP.

### L6

**Comment:** The most common maintenance requirement for 4x4 and OHV routes is the construction and maintenance of water bars/dips/mounds to divert runoff from the route. This maintenance could easily be provided by running a SWECO trail machine with a trained operator over each route once every 5 years. OHV trail maintenance and gas tax monies are available to fund this maintenance. AmeriCorps type labor could also be used. The SWECO could not be used on motorcycle single-track trails but they typically require less maintenance and water bars/dips/mounds can usually be constructed on these trails by hand work.

**Response:** As part of travel plan implementation and road/trail maintenance, the BLM routinely physically maintains motorized routes with a SWECO and other machinery.

### L7

**Comment:** Sheep Mountain area outside Clancy near Lump Gulch has been used as a motorized playground in recent history. Other areas would get increased use if the motorized public were aware of them. Montana Wildlife Federation encourages the BLM to concentrate motorized activities to roads in and near Sheep Mountain and offer the most protective measures elsewhere in the Helena TPA.

**Response:** Travel planning for the Sheep Mountain area was completed several years ago in the Clancy-Unionville travel plan. This area is outside the Helena Travel Planning Area (TPA) and is therefore not being re-addressed in this RMP revision. The BLM is addressing travel management in the Helena TPA with the range of alternatives presented in the Butte RMP. The Preferred Alternative (Alternative B) for the Helena TPA would reduce availability of motorized routes overall in that area.

### L8

**Comment:** If criminal or illegal activity in the Scratchgravel Hills is a big concern, the BLM and local authorities need to provide more effective enforcement regardless of the alternative selected. A dusk to dawn curfew could provide this security only if more effective enforcement is provided.

**Response:** Law enforcement issues are outside the scope of the RMP. However, the Preferred Alternative for the Helena Travel Planning Area has been modified in the Proposed RMP/Final EIS so that all interior roads in the Scratchgravel Hills would be closed to public wheeled motorized travel yearlong at the five proposed trailheads, with the exception of a few perimeter right-of-way routes and routes to private residents. This mod-

ification of the Preferred Alternative is due to the high degree of user conflicts and illegal activity taking place in this area. The BLM believes that this closure may reduce criminal/illegal activity in this area but we also acknowledge that this closure will need to be enforced.

#### L9

**Comment:** Northeast of the Wheat Montana Store and west of Three Forks are several BLM sections and a state section (Copper City). This area is becoming important for mountain bikers from the Gallatin Valley in recent years. This area is only used during the shoulder season months of the spring and fall. Bicyclists have expressed a desire to have a couple of loop trail options there. I would like this area identified in the resource management plan as a potential non-motorized recreation area.

**Response:** Decisions suggested by the comment are implementation decisions that will be considered during site-specific travel planning for this area after finalization of the RMP.

#### L10

**Comment:** Recover and restore Cottonwood Creek [in the Sleeping Giant area].

**Response:** After reviewing the location of the Cottonwood Creek in question, the BLM believes the comment is related to Cottonwood Creek on state-owned lands east of Sleeping Giant. There are no BLM lands in the watershed for this creek. Therefore, restoration of this creek is beyond the BLM's control.

#### L11

**Comment:** CBU has been proactive in preventing cross country travel in the B-D National Forest by offering a 250 dollar reward for individuals reporting violators that are convicted. CBU is willing to engage with your agency in a similar program. This type of cooperative effort between user groups and agencies creates an atmosphere of a vested interest in the resource by the public. Responsible use of the resource should be the primary goal of your agency and CBU is willing to assist the BLM in accomplishing this. Closure of trails and roads to multiple use should be a last resort.

**Response:** The BLM appreciates willingness to assist with enforcement of travel plans. While this implementation issue is beyond the scope of the RMP, the BLM will consider this suggestion for implementation of both existing travel plans, as well as those that will be developed and finalized in the future.

#### L12

**Comment:** Fish, Wildlife, and Parks looks forward to working with the BLM on the fuels reduction projects in the Big Hole watershed. Within these projects we be-

lieve there is a lot of potential to enhance and restore big game winter range in the vicinity of Divide. We also have some concerns about the size and scope of the projects that were proposed, then ultimately shelved, prior to the initiation of this planning effort.

**Response:** Implementation of projects is outside the scope of the Butte RMP. However, the BLM looks forward to working with Fish, Wildlife, and Parks on the fuels reduction project in the Big Hole watershed as well as other future projects.

#### L13

**Comment:** Regardless of what Travel Plans get chosen, we are concerned for the successful implementation and enforcement of any travel plan changes that are proposed. Without strong commitment to the financial and personnel resources necessary to affect and maintain on-the-ground change, even the most thoughtfully devised travel management plan will not work.

**Response:** Travel plan implementation is outside the scope of the Butte RMP. However, the BLM agrees that there are considerable financial and personnel investments that need to be made with implementation of site-specific travel plans. The BLM will continue to request funding for workforce and facilities necessary to implement and enforce travel plans upon finalization of travel plan decisions being made with this RMP.

### Noxious Weeds

#### M1

**Comment:** I would prefer to see the greatest effort possible to reduce noxious weeds on BLM lands. Noxious weeds reduce habitat for game animals and other wildlife, crowd out native vegetation, and are an eyesore. Alternative B appears to be acceptable, especially when paired with fewer travel routes. I would like to see weed control activities taking place at trailheads, along travel routes, and in areas where sensitive or "threatened" plant species are threatened by weeds. Also, BLM may consider posting signs with pictures of noxious weeds at trailheads to educate BLM users about the identification of these plants. BLM should encourage recreators to notify BLM of small (more controllable) infestations in otherwise weed-free areas, so that BLM can manage these areas before the infestation spreads. BLM may also consider partnering with researchers, high schools, and groups like the Native Plant Society to conduct weed pulls and other vegetation management activities, especially at areas close to towns.

**Response:** The Noxious Weed section in Chapter 2 of the RMP outlines priority areas for treatment including trailheads and travel routes.

Presently BLM does provide noxious weed education in terms of posting noxious weed signs and conducting direct user communications at recreation sites including

trailheads. Chapter 2 of the RMP under Vegetation Communities, Alternative B – Preferred Alternative, Noxious Weeds section indicates that weed education would be offered to the public at campgrounds and trailheads. The BLM believes that early detection and rapid response is one of the most effective methods of invasive species management, and uses an integrated approach to use all tools to curb the spread of weeds.

The Butte Field Office has several weed partnerships using biological and herbicide weed control. Some of these partnerships include the following: with Montana State University biological weed researchers, the Elkhorn Mountains Implementation Group, the Big Hole Watershed Weed Committee, the Lewis & Clark County Weed District, the Silver Bow County Weed District, the Jefferson County Weed District, the Broadwater County Weed District, the Beaverhead County Weed District, the Gallatin County Weed District, Whitehall High School and the Park County Weed District. Spray treatment days and weed pulls have been completed with many of these groups, often in cooperation with local watershed groups and/or county representatives.

### M2

**Comment:** Page 33 Noxious Weed Management: The BLM needs more aggressive weed management on all BLM land, particularly on McMasters and Iron Mask properties. BLM is responsible for the weeds on their properties and should demand more accountability from contracted services regarding weed control.

**RATIONALE:** Recommendations from the Elkhorn Working Group to the Elkhorn Steering Committee, on July 14, 2007, include monitoring weed treatment effectiveness and mapping weed infestation.

**Response:** The BLM is treating and monitoring noxious weeds and non-native invasive species as aggressively as time and budget allow. Both the Iron Mask and McMasters areas are priority weed treatment areas and received treatment in 2007 by herbicide and biological means. Both monitoring for weed treatment effectiveness and mapping weed infestations are tools used by the BLM in weed management on public lands including lands in the Elkhorn Mountains.

### M3

**Comment:** In the Elkhorn Mountains, conduct a complete weed-mapping program, spray and pull weeds, monitor effectiveness of treatments, prioritize treatment areas. Treat trailheads, roads and other disturbed areas first.

**Response:** The weed-mapping suggestion in the comment is outside the scope of the RMP. The BLM acknowledges that a complete weed mapping program has not been finished in the Elkhorn Mountains. However, many of the public lands in the Elkhorn Mountains managed by the BLM have been inventoried for noxious

weed infestations in Broadwater and Jefferson Counties. Achievement of a complete weed-mapping effort will depend upon future budgets and workforce availability. Herbicide and biological control methods have been used on weed project areas in the Elkhorns. Many areas of public lands in the Elkhorn Mountains are monitored annually for weed treatment effectiveness. All weed infested areas in the Elkhorns aren't treated annually, but treatment is centered around trailheads, travel routes, and recently disturbed sites where weeds exist.

### M4

**Comment:** Plant seeds can be carried from a source area by the wind, wildlife, or pack animals, on equipment tires and tracks, by water, and on the boots of workers, so care should be taken to implement control procedures in all source areas to avoid spread to unaffected areas. For your information, measures we often recommend at the project level for preventing spread from source areas to uninfested areas include:

Ensure that equipment tracks and tires are cleaned prior to transportation to an uninfested site.

Focus control efforts at trail heads and transportation corridors to prevent tracking of seed into uninfested areas.

Attempt to control the spread from one watershed to another to reduce water as a transport vector.

If a localized infestation exists and control is not a viable option, consider rerouting trails or roads around the infestation to reduce available vectors for spread.

Establish an education program for industrial and recreational users and encourage voluntary assistance in weed prevention and control activities.

Reseed disturbed sites as soon as possible following disturbance.

**Response:** Many of these measures are regularly utilized on public lands within the Butte Field Office to help prevent the further spread of weed seed and noxious weed plant parts. The BLM includes requirements to clean mechanical equipment that are authorized to work on public lands. Other public land users including many recreationists clean their vehicles to rid them of as many weed seeds and weed plant parts as possible, but are not regulated to do so.

### M5

**Comment:** Also, if sufficient vegetation is killed during ground disturbing activities (e.g. by prescribed burning) it may warrant revegetation efforts. Revegetation (re-seeding with native grass mix) should be expanded to seed any site within the control area where the vegetation density is low enough to allow reinfestation or introduction of other noxious weeds, or erosion. The goal of the seeding program should be to establish the sustain-

nability of the area. Where no native, rapid cover seed source exists, we recommend using a grass mixture that does not include aggressive grasses such as smooth brome, thereby allowing native species to eventually prevail. Mr. Phil Johnson, Botanist, Montana Dept. of Transportation, in Helena at 406-444-7657, may be able to provide guidance on revegetation with native grasses.

**Response:** It is BLM policy to reseed disturbed areas of ground. Proposed management in the Preferred Alternative of the Butte RMP (Chapter 2, Vegetation Communities, Alternative B – Preferred Alternative, Grasslands and Shrublands section) states that, “native or low impact, non-invasive seed mixtures would be used when restoring vegetation on disturbed ground.” Mr. Phil Johnson may be contacted if guidance is needed on specific projects.

**M6**

**Comment:** Programmatic direction should also assure that the effects of burning on the potential stimulation of noxious weeds be evaluated during site-specific project level analysis. Prescribed fire has the potential to stimulate weed growth (e.g., Dalmatian toadflax or leafy spurge), and can destroy insects planted for biological weed control. Burning followed by application of appropriate herbicides can provide effective weed control.

We suggest that such considerations be evaluated during development of direction and plans for prescribed burning. Areas should not be prescribed burned for at least 30 days after herbicide treatment.

**Response:** Weed presence and weed control is evaluated in every fuels reduction proposal. As a standard operating procedure, if weeds are present in a proposed prescribed burn area, the weeds are generally treated at a minimum one year before and one year following the burn. Weed infestations are treated in following years if needed. Label instructions and manufacturer’s recommendations will be adhered to for any prescribed burning that would occur on an area following herbicide treatment.

**M7**

**Comment:** As a general practice, EPA suggests prioritizing perimeter weed infestations such as around trailheads and roadsides before treating interior weed infestations. Also, in order to prevent the establishment and spread of noxious weeds in recreation areas (trailheads, toilet areas, etc.), it may be helpful to consider the use of mulch where foot traffic is high and revegetation is difficult or impossible. Additionally, we encourage use of aesthetic barriers and posted signs to discourage foot traffic in sensitive areas.

**Response:** The Butte Field Office uses an Integrated Weed Management (IWM) approach in the treatment and control of weeds. This includes a wide range of strategies to prevent and control the spread of noxious

weeds on public lands including those mentioned in the comment. The BLM uses the IWM approach under all alternatives of the Butte Draft RMP/EIS including the “No Action” alternative.

**M8**

**Comment:** Please be aware that certain pest control activities described in the RMP may fall under EPA’s Worker Protection Standard (WPS) if, (1) the BLM is the “employer” in control of the “operation” and the operation involves or is related to commercial production of timber or timber products, (2) the BLM is using WPS-labeled pesticides, and (3) the pesticide applications in question are related to the production of timber/timber products and they are not covered by one of the applicable exceptions or exemptions. If you have any questions regarding the WPS or its applicability please contact Jaslyn Dobrahner in the Denver EPA office at (303) 312-6252.

**Response:** The Butte Field Office applies all herbicides and pesticides, in accordance with product labels, Material Safety Data Sheet (MSDS) instructions, and agency policy. Use of Personal Protective Equipment by all personnel applying herbicides or pesticides will continue to be required in accordance with product labels and agency policy. In our contacts with Ms. Dobrahner, it was determined that few of our pesticide applications fall under the EPA’s Worker Protection Standard (WPS). All herbicide and pesticide applications under the RMP will comply with the guidance provided under the EPA publication titled “How to Comply with the Worker Protection Standard for Agricultural Pesticides” No. EPA 735-B-05-002. The herbicide and pesticide application Risk Assessment, for the Butte Field Office, shall also include WPS considerations for personnel involved in these pesticide activities and personnel shall be appropriately trained and equipped for their application tasks.

**M9**

**Comment:** We also fully support the proposed conduct of monitoring to determine effectiveness of weed treatment strategies at project level and Planning Area and Decision-wide level (page 24). We recommend that all weed treatment methods be tracked to provide a comparison of the effectiveness of control measures, and that all weed infestations and control actions be tracked in a BFO level weed database.

**Response:** All weed treatments are tracked through the BLM’s application record process and the hard copies are kept for a minimum of 10 years. Annual summaries are compiled from these records and submitted to the BLM State Office. Some weed treatments receive more on the ground monitoring than other treatments, depending on the size of the infestation. A large majority of all weed treatments are evaluated for treatment effectiveness, however not every weed infestation acre or pre-

viously treated acre is visited each year due to budget and personal constraints.

### M10

**Comment:** The transport mechanism for noxious weeds includes all visitors and uses of public lands including hikers, equestrians, and cattle grazing in addition to motorized recreationists. Many events including fire, floods, and the importation of invasive species also contribute to noxious weed problems. For the most part, vehicles do not have a surface texture that will pick up and hold noxious weeds seeds. Transport mechanisms based on hair, fur, manure, shoes, and fabrics are more effective than the smooth metal and plastic surfaces found on vehicles. Additionally, motorized recreationists practice the "Wash your Steeds" policy. However, closures due to noxious weed concerns are only placed on motorized recreationists. We have observed an equal amount of noxious weeds in non-motorized areas as there are in motorized areas. We request that the document make a fair evaluation of all sources and uses that contribute to the noxious weed problem including hikers, mountain bikers, equestrians (non-use of weed-free hay), etc. The document should also fairly evaluate how natural processes and wildlife spread noxious weeds. The document should include a balanced discussion of the noxious weed problem. The discussions, decisions, and measures used to mitigate noxious weeds should be applied impartially to all visitors and with a realistic representation of noxious weeds natural ability to spread versus a relative magnitude for every activity's contribution.

**Response:** The BLM realizes that all of these mentioned uses transport noxious weed seeds and invasive species plant parts. Weed spread is described in Chapter 3 of the RMP in the Noxious Weeds subsection of the Vegetative Communities section. There are studies that have documented that vehicle travel routes promote a high degree of weed infestation spread. It is true that smooth metal and plastic surfaces on motor vehicles don't hold weed seeds well, however other portions of vehicles do hold them as well, such as the undercarriage and tires, and especially then they are adhered with mud. The Proposed RMP/Final EIS, Chapter 3 has been modified to more deliberately point out that direct human contact, wildlife use, and livestock use contribute to weed spread.

### M11

**Comment:** OHV owners in Montana, as part of their vehicle registration, contribute \$1.50 to a noxious weed abatement program. Non-motorized visitors do not contribute to a weed abatement program. We request that the analysis be based on a balanced discussion of the noxious weed problem. The discussions, decisions, and measures used to mitigate noxious weeds should recognize the relatively minor impact that OHVs have on the

noxious weed problem and credit OHV visitors for contributing to a program to control noxious weeds. Additionally, this is another example of predisposition because motorized recreationists have not been given credit for the positive action that they have taken and we have only been penalized for our past cooperation and the initiative taken to control noxious weeds.

**Response:** All vehicle owners when registering their vehicles pay the \$1.50 for the noxious weed program. This includes non-motorized visitors' vehicles they use to access public lands. There are studies that have documented that vehicle travel routes promote a high degree of weed infestation spread.

### M12

**Comment:** Noxious weeds become more widely distributed each year. Many factors influence the establishment and spread of invasive plant species. The following points should be incorporated into the RMP:

- Give high priority to noxious weed control by aggressively seeking funds to achieve this goal. Use biological controls whenever possible, chemical control when needed to restore natural environments, techniques that fit the "integrated pest management" guidelines. USDA- CSREES (Cooperative State Research Education and Extension Service) defines Integrated Pest Management (IPM) as "a sustainable approach to managing pest species by combining biological, cultural, physical, and chemical tools in a way that minimizes economic, health, and environmental risks". Incorporate some or all of the following techniques.
- Biological controls such as differing various insects are known to control Leafy Spurge, Knapweed, Canada Thistle and Hounds tongue. Leafy spurge flea beetles have proven high success in the Lewistown area as bio-vector of leafy spurge. (Conversation with Craig Roberts, MT DNRC)
- Study the suitability of domestic goats as a bio-agent to control Russian and Spotted knapweed and domestic sheep for leafy spurge. Grazing contracts could concentrate these species, if suitable, in areas of infestation using small enclosures to minimize grazing on desirable species.
- Disturbed ground as will be created if BLM pursues fuel reduction projects is prime substrata for noxious weeds to become established. Plans must emphasize reclamation begin very quickly in those activities that produce this condition: tree and brush removal projects should be reclaimed within 90 days of work completed; Avoid overgrazing by domestic livestock to reduce a disturbed ground situation.

- Minimize use of herbicides in big-sage habitat types to minimize negative impacts to potential sage grouse expansion.

**Response:** The BLM currently uses an Integrated Weed Management approach. The BLM has strategic plans that are being implemented such as Partners against Weeds (PAWS) that parallel this comment. The PAWS plan is referenced in the RMP. These types of weed treatment prescriptions are also discussed in Chapter 2 of the RMP.

Biological controls on noxious weeds have been used in the Butte Field Office since 1992. Various biological control agents have been used in this time on a number of different noxious weeds. The leafy spurge flea beetles (*Apthona species*) and the knapweed root weevil (*Cyphocleonus achates*) have proven the most effective and are readily available.

The Butte Field Office along with the other cooperators including The Sheep Institute and Montana State University are involved in a sheep and goat study to control noxious weeds at present. Noxious weed control using domestic sheep and/or goats in occupied bighorn sheep habitat would be prohibited to prevent any possible disease transmission (from domestic sheep/goats to wild sheep) under the revised RMP.

During implementation of fuels reduction projects, noxious weed infestations are usually treated in those areas before and following completion of each project. BLM would reseed disturbed areas where needed (RMP Chapter 2, Soil Resources, Management Common to Action Alternatives section). Most reclamation is completed sooner than 90 days following any activity that disturbs the ground but this timing would be determined on a case-by-case basis during project implementation. Further reclamation may be completed if monitoring of the site shows it is needed.

Under the Preferred Alternative in the RMP (Chapter 2, Vegetation Communities, Alternative B – Preferred Alternative, Noxious Weed Management section), no herbicide or pesticide which would negatively affect sagebrush would be used aerially in sensitive sagebrush habitats.

### M13

**Comment:** A general comment that applies to alternatives where prescribed burning occurs is the need to ensure adequate noxious weed control prior to and post burning. A viable monitoring and control program needs to be in place to make sure adequate follow up on control of infestations is accomplished.

**Response:** It is a standard practice for the BLM to conduct pre and post weed treatment of fuels reduction treatment areas. Necessary weed treatments are completed a minimum of one year before and one year after the fuels treatments. These areas are monitored both

prior to and following any fuel treatment activity e.g. mechanical or burning. Following the fuels treatment, further weed treatment is completed if needed.

### M14

**Comment:** The remaining or additional recommendations are prioritized and modified by EWG as follows:

1. Fall annual updates on the ‘state of the weeds’ will be provided to the Working Group by all parties engaged in weed management in the Elkhorns.
2. Actively seek funding to pursue weed treatments in areas already identified. Funding would be used to assist agencies and counties in weed treatments.
3. Actively pursue weed control in known locations concentrating efforts along roads and at trailheads (e.g. spray and pull).
4. Mapping of unmapped weed locations can occur simultaneous to treatments.
5. Monitor weed treatment effectiveness. Utilize results to determine need for follow-up treatments and ensure that funding is available for the follow-up treatments.
6. Explore opportunities to develop a permanent fund for long-term weed treatments.
7. Map weed infestations in the Elkhorns. This is a multi-step effort and could utilize ongoing services such as those provided by the Townsend school:
  - a. Elkhorns Coordinator will pull together existing weed maps (B-D, County, Helena, BLM, state, private) and work with Interagency Weed Committee where mapping efforts are already underway;
  - b. Elkhorns Coordinator will work with other agencies, private landowners, and county weed coordinators to develop a collaborative, comprehensive map of Hunting District 380 with the following information: size, location, type of weeds, type of treatment, when treated, and any follow-up treatments. This map will be updated annually;
  - c. Identify where mapping efforts are already planned (e.g. northeast side Elkhorns);
  - d. Prioritize mapping in accessible areas then move towards the interior of the mountain range.

**Response:** BLM responses are indicated by numbered item corresponding to numbered items in the comment.

1. Specific decisions on public outreach to particular groups are beyond the scope of decisions made in the Butte RMP. BLM’s role in working with the Elkhorn Working Group and providing annual weed updates would be determined in the context of the partnership for management of the Elkhorn Mountains.

2. The Butte RMP does not provide direction as to how to use funding. However, the Butte Field Office (BFO) has an active program in weed management as budgets and staffing allow, and will continue to look for funding and grant opportunities to leverage appropriated funds as well as other mechanisms to control and prevent weeds.

3. The RMP outlines priorities for treatment and control efforts across the field office, which would include the BLM portions of the Elkhorn Mountain range, in the Noxious Weed Management section of Chapter 2. Under all alternatives, BLM would focus prevention of weed spread along roads, trails, waterways, and recreations sites, as well as in areas disturbed by project implementation activities. Additional measures would include requiring outfitters to use weed-free hay and to report weed infestations when encountered. The integrated weed management program currently in place and expected to continue after approval of the Butte RMP uses a combination of different methods (e.g. herbicide, pull, biological, etc.).

4. While specifying specific mapping protocols or sequencing of work is beyond the scope of the RMP, the BLM will continue to document weed locations when encountered during treatment activities. The BLM monitors treatment areas at present and requires the counties to do this also, simultaneous to treatment projects on public land. There is Global Positioning System (GPS) mapping and human observation mapping done.

5. The BLM monitors treatment areas at present and requires the counties to do this also, simultaneous to treatment projects on public land. Planning of follow-up treatments is based on results of this monitoring as well as reports of new infestations. This monitoring is used in planning for the method of treatment (e.g. mechanical or herbicide), and the level of intensity of treatment needed for future years. While funding cannot be guaranteed from year to year given the Congressional budget appropriation system, the Butte Field Office actively pursues funding to address identified weed concerns.

6. Specific decisions on developing a permanent fund for work in the Elkhorns are beyond the scope of decisions made in the Butte RMP. The BLM's role in assisting with establishing a permanent fund would be determined in the context of the partnership for management of the Elkhorn Mountains. Currently, the Butte Field Office places priority on the Elkhorn Mountains landscape when asking for funding for weed prevention and control.

7. Specific decisions on mapping weed infestations in the Elkhorns and the role of the Elkhorn Coordinator are outside the scope of decisions made in the Butte RMP. The BLM's role in cooperating with mapping efforts and prioritizing areas would be determined in the context of the partnership for management of the Elkhorn Mountain. In the past, BLM has been active in the Elkhorns Weed Committee and has used resources from Town-

send High School to inventory and map weeds on public lands in the Elkhorns.

### M15

**Comment:** In the Elkhorn Mountains utilize adaptive weed management strategies for ALL areas treated through prescribed burning.

- Inventory - Map the prescribed burn unit and an appropriate buffer around the burn unit to get an accurate inventory of weeds in the area.
- Weed Control Pre Burn - Begin active weed control at a minimum of one year before the unit is burned.
- Revegetation - The unit should be inspected to determine if seeding following the burn will increase competition with weed species, decrease re-invasion of weeds, or establish desired plants that help meet the land use objectives.
- Weed Control - Post Burn Monitoring - Following the prescribed burn and associated restoration, sites should be visited yearly for two to three years to monitor and treat weed infestations. The original inventory and treatments, if any, should be used as a baseline to monitor weed activity for increased infestations, control successes, and to map new invaders. This information can then be assessed and used to improve or adapt the current weed management goals and objects to better address the weeds associated with prescribed burns.
- Apply the above strategies to mechanical treatments where applicable.

**Response:** Weed management strategies for areas targeted for prescribed burning or mechanical treatment would be addressed on a case-by-case basis during project level analysis and planning. In general, BLM agrees with the outlined prescriptions suggested by the EWG. BLM continues to inventory, monitor and treat weed infestations both inside and outside of the Elkhorn Mountain range.

### M16

**Comment:** In the Elkhorn Mountains assure elk security levels are adequate. Prescribed burning should be used to reduce or eliminate the areas of encroachment identified in the Elkhorn Vegetation Study. Begin active weed control at a minimum of one year before the unit is burned.

**Response:** Elk security cover is addressed in all fuel reduction projects on public lands in the Elkhorns. Weeds are generally treated prior to burning and following prescribed burning for fuel reduction projects which have been completed to date on BLM managed lands in the Elkhorn Mountains. Weed treatment is continuing on

burned and unburned weed infested areas in the Elk-horns. Weed management strategies for areas targeted for prescribed burning or mechanical treatment would be addressed on a case-by-case basis during project level analysis and planning. Fuel treatments and weed control are discussed in Chapter 2 of the RMP under each alternative.

#### M17

**Comment:** Among the greatest threats to biodiversity is the spread of noxious weeds and invasive (non-indigenous) plants. Many noxious weeds can out-compete native plants and produce a monoculture that has little or no plant species diversity or benefit to wildlife. Noxious weeds tend to gain a foothold where there is disturbance in the ecosystem. We appreciate the discussion of noxious and invasive plants in the draft RMP/EIS, and support integrated weed management (e.g., effective mix of cultural, education and prevention, biological, mechanical, chemical management, page 23). EPA supports BLM's goal to minimize infestations of invasive plant and noxious weeds (Table 1-5, page 9, and page 17). We are pleased that weed seed-free forage would be used on BLM lands, and that weed management prescriptions would be included in all new treatment projects and incorporated where possible in all existing contracts, agreements, and land-use authorizations that would result in ground disturbing activities (page 24), and that all contractor and BLM equipment would be power washed to remove weed seed before entering areas with ground disturbance (page 28). Another option for preventing the introduction of noxious weeds is to require cattle and horses, especially those coming from areas with noxious weeds, to be penned and fed weed free hay for several days prior to being released on public lands.

**Response:** The BLM agrees that requiring weed free hay to be fed to livestock prior to their use of public land could assist in prevention of weed spread onto public land. However, to be effective, this type of requirement would have to be made at the national level. The Butte RMP has not been altered to require this provision.

#### M18

**Comment:** While EPA supports integrated weed management, including use of herbicides where needed, EPA also encourages prioritization of management techniques that focus on non-chemical treatments first, with reliance on chemicals being the last resort, since weed control chemicals can be toxic and have the potential to be transported to surface or ground water following application.

Management direction should assure that public health and water contamination concerns of herbicide usage are fully evaluated and mitigated. Herbicide drift into streams and wetlands could adversely affect aquatic life and wetland functions such as food chain support and

habitat for wetland species. All efforts should be made to avoid movement or transport of herbicides into surface waters that could adversely affect public health, fisheries, or other water uses. Early recognition and control of new infestations is encouraged to stop the spread of the infestation and avoid wider future use of herbicides, which could correspondingly have more adverse impacts on biodiversity, water quality, and fisheries. Herbicides should be applied at the lowest rate effective in meeting project objectives and according to guidelines for protecting public health and the environment. We recommend that the BLM include an objective stating that, "Herbicides, pesticides, and other toxicants and chemicals be used in a safe manner in accordance with Federal label instructions and restrictions that allow protection and maintenance of water quality standards and ecological integrity, and avoid public health and safety problems."

**Response:** The Butte Field Office uses EPA approved herbicides and pesticides in a safe manner in accordance with label and material safety data sheet instructions. Under an integrated approach, the BLM also uses several other means of weed treatment including: cultural, physical control, and biological controls. These methods are used in combination with strategies for weed prevention, education, monitoring, mapping, and coordination. Herbicide use is only one method of treatment used. It is the primary method used and will continue to be as long as it is the most effective method available. The BLM has many standard operating procedures for applying herbicides including, but not limited to the following:

- Selecting herbicide that is least damaging to the environment while providing the desired results.
- Applying the least amount of herbicide needed to achieve the desired result.

The BLM follows product label and material safety data sheet instructions when treating weeds to protect and maintain ecological integrity, including but not limited to water and air quality resources, livestock, wildlife and human health and safety issues.

#### M19

**Comment:** Aerial application of herbicides in some circumstances can provide the most cost effective means of addressing widespread weed infestations. We note, however, that it is very important that adequate mitigation measures are incorporated into aerial applications to reduce risks of adverse health and environmental effects. We are pleased that the RMP indicates that when winds are greater than 6 miles per hour or within a 300 foot RMZ aerial application of herbicides or pesticides would not occur (page 33). Suggested mitigation measures to avoid herbicide drift to streams and wetlands during ground and aerial applications of herbicide that should be considered as RMP guidelines, include:

- Use adequate streamside buffers {-300 feet for aerial applications and 50 feet for ground applications};
- Flag aquatic areas on the ground;
- Use GPS systems in spray helicopters in association with flagging or field marking of treatment areas to ensure accuracy of aerial treatments (i.e., to better assure that only areas marked for treatment are treated);
- Use drift reduction agents and nozzles that create large droplets to reduce drift to nontarget areas during aerial herbicide applications.
- Use photodegradable dyes in herbicides to facilitate identification of sprayed areas;
- Use spray detection cards;
- Monitor wind speeds;
- Maintain close communications between the helicopter pilot and the ground field observers who monitor herbicide drift, deposition and wind speeds during aerial applications of herbicide;
- Release herbicides at lower altitudes to reduce drift.
- Monitor for herbicides in selected waters near herbicide application areas.
- Notify people living within one-fourth mile of an area to be treated aerially during project planning and shortly before weed treatment.
- Do not locate herbicide mixing, loading, or cleaning areas within 200 feet of private land, open water, or wells, or other sensitive areas; etc.
- Ground field observers, who will be present during aerial applications, should be trained and equipped with the appropriate personal protective equipment according to the label.
- Assure that certified pesticide applicators supervise each BLM application crew and trains crew members in personal safety, proper handling and application of herbicides, and proper disposal of empty containers.
- Consider use of a more selective herbicide (such as clopyralid) in aerial spraying, since a more selective herbicide would kill fewer non-target plants.
- In the unlikely event of a spill, the spill is quickly contained and cleaned up, and appropriate agencies and persons should be promptly notified.
- Conduct surveys for sensitive plants by qualified surveyors prior to aerial applications and at all previously unsprayed sites so that sensitive and/or rare plant species may be protected where such plants are found in areas with weed infestations.

**Response:** While there are no BLM requirements to do so, all of this comment's guidelines are incorporated into the aerial treatment program in place in the Butte Field Office at present, with the exception of monitoring for

herbicides in selected waters near herbicide application areas. The BLM has received guidance for aerial treatment included in the recently completed BLM Vegetation Treatments Using Herbicides EIS (finalized after release of the Butte Draft RMP/EIS) and it will be included in the Preferred Alternative of RMP. Many of the guidelines mentioned in the comment are included in this new guidance.

The BLM does not typically test selected waters near herbicide application areas. The existing mitigation measures and standard operating procedures, used by the BLM, for maintaining buffer areas between treatment areas and water bodies should protect water resources from any impact by aerially applied herbicides. Potable water at developed BLM recreation sites is tested on a regular basis, not only for any herbicide impact but for pollutants that could be a public health concern.

The BLM follows product label and material safety data sheet instructions when treating weeds to protect and maintain ecological integrity, including but not limited to water and air quality resources, livestock, wildlife and human health and safety issues.

#### **M20**

**Comment:** We also recommend mechanical weed removal or hand-pulling of weeds adjacent to streams, for weeds that do not contain extensive root systems near surface waters. It may be helpful to add a list of those weed species which can be effectively hand-pulled (i.e. those without large tap roots and spreading rhizomatous root systems). The herbicide application technique of hand or manual wipe-on (especially applicable for contact systemic herbicides such as glyphosate) is not mentioned as an option to control individual weed plants up to the existing water level adjacent to streams or sensitive aquatic sites. As you know, picloram is toxic, mobile, and persistent, and we would be concerned about use of picloram near streams or in areas of high groundwater. For your information, Dow AgroSciences, the manufacturer of Tordon 22K, has recently developed supplemental labeling for Tordon 22K for areas west of the Mississippi River. They have directions for wick or carpet roller applications. Tordon 22K herbicide can be applied using wick or carpet roller equipment where drift presents a hazard to susceptible plants, surface waters, and other sensitive areas.

One part Tordon 22K is mixed with 2 parts water to prepare a 33 percent solution. The wick method of application is more labor intensive but very effective at targeting particular noxious weeds adjacent to surface waters, wetlands, or protected plants.)

**Response:** Wipe on or wick type weed treatment is considered a tool by BLM in its Integrated Weed Management approach. Biological and hand pulling are two important weed treatment techniques used in riparian areas by the Butte Field Office. Insect releases are the

primary biological technique used. Biocontrol insect releases have proven to be very effective in some areas. Their success is probably dependent upon particular environmental factors of each area. The Butte Field Office utilizes an IWM reference of weed management control methods for State of Montana categorized noxious weeds. This reference discusses the effectiveness of many control methods, including hand pulling, on these particular weed species.

The BLM follows product label and material safety data sheet instructions for each herbicide used, including Picloram, when treating weeds to protect and maintain ecological integrity, including but not limited to water and air quality resources, livestock, wildlife and human health and safety issues.

## Oil and Gas

### N1

**Comment:** Energy and Minerals, page 430, BLM forgot to mention that these activities are subject to individual environmental analysis and must involve the public for public input as well as FWP. Recent leasing in Dillon violated the National Environmental Policy Act and a separate EIS draft was not prepared by BLM. That conforms with the federal judges decision for the East Front Leasing. BLM ignored the federal judge's decision that a separate draft EIS must be prepared beyond a land use plan. That is a federal action requiring a comprehensive approach. Is your office following in the same tracks as Dillon and ignoring a federal judge's decision?

**Response:** The Record of Decision for the Butte RMP will make the decisions required for leasing, as was done for the Dillon RMP, based on the analysis found in this EIS. These required decisions are identified in the BLM Handbook, H-1601-1, Land Use Planning Handbook, beginning on page 23 of Appendix C. These requirements were developed in large part due to the decision that the BLM believes is being referenced in the comment (Connor v. Burford, 848 F. 2<sup>nd</sup> 1441, 9<sup>th</sup> Cir., 1988). Further guidance is found in BLM Handbook, H-1624-1, Planning for Fluid Mineral Resources. The purpose of this Handbook is to help ensure compliance with the Federal Land Policy and Management Act and the National Environmental Policy Act. A separate EIS beyond the land use plan is not required for oil and gas leasing.

### N2

**Comment:** This does not seem like the appropriate place/process to determine where to ban oil and gas exploration and production, especially with the uncertainty in the world market and oil pushing \$70/barrel. Until the US becomes independent upon foreign oil, we should keep all the options open here in Montana. Don't close off any areas until that time occurs. I haven't heard that this is an issue and so I am unsure why you have to

propose banning oil and gas exploration in this area. Again, there doesn't seem to be any "real" data to support your wish to close off all of these areas. It seems more like a lot of "office work" and effort to kiss up to various enviro groups. Actual field work is needed in order to support such premature push to close all these areas with (with no real data provided to support the notion).

**Response:** The BLM is required by law (the Federal Land Policy and Management Act) to manage lands for multiple use. This means the public lands are managed so that they are utilized in the combination that will best meet the present and future needs of the American people. The BLM attempts to make the best use of the land for some or all resources or related services over areas large enough to provide for periodic adjustments in use to conform to changing needs and conditions. In some cases the BLM makes use of some land for less than all of the resources. In other cases the BLM manages a combination of balanced and diverse resource uses that takes into account the long-term needs of future generations for renewable and non-renewable resources, including, but not limited to, recreation, range, timber, minerals, watershed, wildlife and fish, and natural scenic, scientific and historical values. The final goal is the harmonious and coordinated management of the various resources without permanent damage to the productivity of the land and the quality of the environment with consideration being given to the relative values of the resources and not necessarily to the combination of uses that will give the greatest economic return.

### N3

**Comment:** Table 2-20 indicates that the preferred alternative, Alternative B, makes the most acres available for oil and gas leasing of any alternative (i.e. 96 percent of the BFO mineral estate lands or 649,367 acres), even more than Alternative D which generally provides for greatest levels of resource development and least environmental protection of the action alternatives. In general, Alternative B provides for moderate levels of resource development in an apparent effort to balance resource development with environmental protection. It is not clear to us why this perspective of moderation and balancing of resource development with environmental protection appears to change when it comes to oil and gas leasing.

**Response:** The BLM would respond to this comment by first pointing out that Alternative B only makes 43 more acres available for leasing than Alternative D. Of the available acreage 45 percent is available subject to major constraints (No Surface Occupancy stipulations). Fifty two percent is available subject to moderate constraints (Controlled Surface Use or Timing Limitation stipulations). The remainder is available under standard lease terms. In comparison, Alternative D makes 16 percent of the available acreage subject to major con-

straints and 72 percent subject to moderate constraints. While Alternative B makes slightly more land available than Alternative D, it is much more restrictive than Alternative D based on the mix of lease stipulations proposed in the RMP. It is also slightly more restrictive in terms of the mix of stipulations proposed in the RMP than Alternative A.

#### N4

**Comment:** We also recommend a stipulation for Alternative B of a 500 foot no surface disturbance buffer distance for protection of wetlands, natural springs and seeps, reservoirs, lakes, ponds, intermittent or small perennial streams, riparian/wetland areas, natural springs and seeps, and within 1,000 feet of perennial streams and rivers. We believe it is important to avoid placement of roads near streams within riparian areas and wetland areas, and that drilling activities should be sited to avoid activities near such sensitive areas. Exceptions to this buffer distance may be considered for pipelines and short segments of roads.

It is also important that wetlands and riparian areas be avoided as much as possible during pipeline routing, and any pipelines unavoidably placed through wetland areas should avoid dewatering of wetlands during trench construction. Trench drainage plugs can be used to minimize this drainage effect. Pipelines through wetlands and other sensitive areas should also use a minimal narrow width for pipeline right-of-ways.

**Response:** The actions proposed in the comment are in line with BLM policy and regulations. Alternative B contains a No Surface Occupancy stipulation for the protection of wetlands, floodplains, and riparian areas. There is no need for a stipulation in Alternative B for a 500 foot no surface disturbance buffer for protection of wetlands, natural springs and seeps, reservoirs, lakes, ponds, intermittent or perennial streams, and riparian/wetland areas. Regulations at 43 CFR § 3101.1-2 allow the BLM to move a location up to 200 meters (656.16 feet) to mitigate impacts to features proposed for no surface occupancy by the comment. The stipulation listed above would protect and mitigate impacts to perennial streams and rivers. We would also use our authority to move locations up to 200 meters to add additional protection on a case-by-case basis. Alternative B also proposes to stipulate municipal watersheds in the Butte Field Office with a No Surface Occupancy stipulation. Other stipulations for fisheries will indirectly help to mitigate impacts in wetlands, riparian areas, around streams, and other areas.

On BLM-administered lands, pipelines on a lease (or within a unitized area), which are constructed and managed by the lease holder or operator are authorized under an application for permit to drill or sundry notice and lease stipulations applied. On or off lease/unit pipelines constructed and managed by someone other than the leaseholder/operator require a BLM right-of-way and

are governed by restrictions found in the applicable right-of-way. On BLM-administered lands pipelines located off the lease or the unitized area require a right-of-way with its own stipulations.

#### N5

**Comment:** We also recommend that the BLM require that oil and gas operators make maximum use of directional drilling to increase protection of sensitive resources (i.e. require use of directional drilling to reduce risks to sensitive resources such as water quality and important aquatic or terrestrial habitats). New roads should be restricted, and maximum use made of directional drilling and cluster development, with wide spacing of well pads, and few exceptions, modifications or waivers of environmentally protective stipulations.

**Response:** Existing BLM policy, Washington Office Instruction Memorandum (IM) No. 2007-021, emphasizes the use of environmental Best Management Practices (BMPs). This IM directs all field offices to incorporate environmental BMPs into proposed Applications for Permits to Drill (APDs), sundry notices, and associated on- and off-lease Rights-of Way approvals after appropriate environmental review. Environmental BMPs to be considered in nearly all circumstances include the following:

- Interim reclamation of well locations and access roads soon after the well is put into production;
- Painting of all new facilities a color that best allows the facility to blend with the background, typically a vegetated background;
- Design and construction of all new roads to a safe and appropriate standard, “no higher than necessary” (see BLM 9113 Roads Manual) to accommodate their intended use; and
- Final reclamation recontouring of all disturbed areas, including access roads, to the original contour or a contour that blends with the surrounding topography.

Other environmental BMPs are more suitable for Field Office consideration on a case-by-case basis, 1) depending on their effectiveness, 2) the balancing of increased operating costs vs. the benefit to the public and resource values, 3) the availability of less restrictive mitigation alternatives that accomplish the same objective, and 4) other site specific factors. Examples of typical, case-by-case BMPs include, but are not limited to, the following:

- Burying of distribution power lines and/or flow lines in or adjacent to access roads;
- Centralizing production facilities;
- Installing submersible pumps;
- Placing wellheads below ground; and

- Drilling multiple wells from a single pad.

What the comment recommends is already BLM policy applied in Montana.

#### N6

**Comment:** We also note that mitigation plans that use enhancement or creation of off-site wildlife habitat to offset loss or destruction of natural habitats often results in development of habitat of lesser quality than natural habitat. We believe caution should be exercised in allowing adverse impacts to natural habitat and using human-created habitats of uncertain quality to offset loss of natural habitats. This often results in loss of natural ecological functions. Avoidance of impacts to natural habitats should be prioritized over efforts to use human created habitats as compensation for loss of natural habitats.

**Response:** Appendix M of the Proposed RMP/Final EIS provides the stipulations that would be required for a range of species during oil and gas exploration. These stipulations range from timing restrictions to no lease and would be required for all oil and gas exploration activities. Off-site mitigation could be authorized, in some cases, but all measures would be taken to protect natural habitats before off-site mitigation would be allowed.

#### N7

**Comment:** We are also concerned that BLM exceptions, modifications, or waivers may be granted that allowed increased surface disturbance and activity timing that may reduce protection of environmentally sensitive areas if operators submit plans that demonstrate that impacts to resources are “acceptable” or can be “adequately mitigated” (per Appendix L). We are particularly concerned if exceptions are granted to the no surface occupancy buffers for important wildlife and fisheries habitats and municipal watersheds.

We believe that the practice and process for removing environmentally protective restrictions on oil and gas development and for demonstrating “acceptable” levels of impacts or “adequate” mitigation should be more fully described in the Final EIS. There should be very careful review of, proposed exceptions, modifications and waivers to protective restrictions, since exceptions, modifications and waivers to protective stipulations may reduce the level of environmental protection.

**Response:** We have added language to RMP at that point in Appendix L, Fluid Minerals, where the leasing process is explained to address these concerns. However, we have also addressed portions of this comment in our response here.

The Great Falls Oil and Gas Field Station is the BLM office with approval authority for oil and gas activities for the Butte Field Office. During the last two fiscal

years, our Great Falls office has not granted any requests for waivers, exception, or modifications for lease stipulations as none have been requested. However, they have granted a total of 51 waivers, exceptions, or modifications to existing conditions of approval attached to APDs. These approvals affected eagle, big game, and sage grouse timing limitation conditions and conditions of approval imposed due to the Migratory Bird Treating Act (MBTA). The MBTA conditions of approval only affected very small areas in and around well sites or other sites disturbed for oil and gas operations. In all of these cases the areas were physically inventoried before approval of any request for a waiver, exception, or modification. In the case of the wildlife conditions of approval the average time granted for an exception was normally less than two weeks long and just involved one well site. Time frames granted for big game conditions of approval were also for very short periods of time.

In regards to the concerns expressed in the comment over public involvement in the process of granting proposed waivers, exceptions, or modifications the BLM will follow requirements found at 43 CFR § 3101.1-4:

“A stipulation included in an oil and gas lease shall be subject to modification or waiver only if the authorized officer determines that the factors leading to its inclusion in the lease have changed sufficiently to make the protection provided by the stipulation no longer justified or if proposed operations would not cause unacceptable impacts. If the authorized officer has determined, prior to lease issuance, that a stipulation involves an issue of major concern to the public, modification or waiver of the stipulation shall be subject to public review for at least a 30-day period. In such cases, the stipulation shall indicate that public review is required before modification or waiver. If subsequent to lease issuance the authorized officer determines that a modification or waiver of a lease term or stipulation is substantial, the modification or waiver shall be subject to public review for at least a 30-day period.”

These provisions provide for appropriate public involvement.

#### N8

**Comment:** Thank you for directing the RMP/EIS reader to the websites for Best Management Practices (BMPs) for oil and gas operations in Appendix D (page 717). It is our understanding that site-specific BMPs may be negotiated with the operator, and it is not clear if site-specific BMPs will be negotiated with operators above and beyond the standard BMPs identified on the BLM websites. The final RMP/EIS should discuss the potential for development of any site-specific BMPs with oil and gas operators.

**Response:** The BLM has changed the RMP in Appendix M of the Proposed RMP/Final EIS (formerly Ap-

**pendix L** in the Draft RMP/EIS) at the subsection labeled “Conditions of Approval” to better explain the use of BMPs and other conditions of approval (COAs). The commenter is correct about the BLM’s use of BMPs in the oil and gas program. The BLM does negotiate site-specific BMPs as appropriate/needed with operators.

#### N9

**Comment:** We did not see much discussion in the draft RMP/EIS of potential for spills or leaks of petroleum products during oil and gas drilling or production activities, or during pipeline transport. We are concerned about the risk and potential for a spill of petroleum product into the environment, and the serious environmental impacts that may accompany such a spill. We note that small leaks to pipelines or other petroleum transport or storage facilities are often difficult to detect and can allow many thousands of barrels of petroleum product to discharge into the environment before a leak is detected. We believe the potential for spills or leaks of petroleum products to the environment should be evaluated and discussed, and management direction and oil and gas leasing plans should provide for use of state-of-the-art leak detection and monitoring equipment, remote control shut off valves, check valves, etc.

We also suggest that RMP management direction should provide for periodic on the ground inspection of facilities that have potential for petroleum product leakages using hydrocarbon monitoring equipment be considered. All possible actions to reduce the probability of a spill/leak occurring, the magnitude of a spill/leak, and to reduce or mitigate the adverse consequences of a spill/leak should be taken. The CEQ regulations require disclosure of the adverse environmental impacts that cannot be avoided should the proposal be implemented and that appropriate mitigation measures be included (40 CFR 1502.16 and 1502.14).

**Response:** The reasonably foreseeable development (RFD) scenario developed for the Butte RMP does not forecast any oil production on federal lands. It forecasts only gas production on federal lands.

Revisions have been made in **Appendix M** in the Proposed RMP/Final EIS (formerly **Appendix L** in Draft RMP/EIS) to include information on how potential spills or leaks of petroleum products during oil and gas drilling or production activities would be addressed. The determination to require state-of-the-art leak detection and monitoring equipment, remote control shut off valves, and check valves is a site-specific decision and would be made if and when an application for permit to is filed for a well in the Butte Field Office.

#### N10

**Comment:** Are Spill Prevention, Control, and Countermeasure (SPCC) Plans with information on spill response procedures and containment and other counter-

measures to prevent and mitigate oil spills within the Monument [Field Office]? A SPCC identifies specific procedures to control and mitigate potential spills and impacts to surface or ground water, including discussion of the location of equipment and expertise available to respond to environmental cleanup, (see EPA website, <http://www.epa.gov/oilspill/spcc.htm>). Special conditions such as weather impaired and cold weather response procedures should be addressed in SPCC Plans. The final RMP/EIS should clarify that adequate SPCC Plans will be prepared for oil and gas activities within the BFO Planning Area.

**Response:** Spill Prevention, Control, and Countermeasure (SPCC) Plans are a requirement of the Environmental Protection Agency. However, by regulation at 43 CFR § 3162.5-1(d) when reasonably required by the authorized officer (AO) of the BLM a contingency plan shall be submitted describing procedures to be implemented to protect life, property, and the environment. Our Notice to Lessees (NTL-MSO-1-92) governs the reporting of undesirable events with Part IV dealing with contingency plans. That section states that “upon request of the AO, a copy of any Spill Prevention Control and Countermeasure Plan required by the Environmental Protection Agency, pursuant to Title 40 CFR 112 or other acceptable contingency plans, must be submitted. All plans shall provide the names, addresses, and telephone numbers (both business and private) of at least two technically competent company or contract personnel authorized to order equipment or supplies and to expend funds necessary to control emergencies.” The BLM will enforce this requirement as appropriate. The RMP has been changed to acknowledge this.

#### N11

**Comment:** It is important that BLM inspect and monitor oil and gas activities to assure that activities are in compliance with stipulations and BMPs. We note that BLM could also write stipulations for oil and gas development that requires operators to monitor for water quality impacts and for impacts to fish and wildlife. We are also enclosing an article entitled “Federal Wildlife Monitors Oversee a Boom in Drilling” from the February 22, 2006 Washington Post. This article describes concerns in BLM’s ability to monitor wildlife effects of oil and gas drilling. The article appears to support concerns that BLM resources for monitoring and mitigating effects of oil and gas development on wildlife, and perhaps other resources, may be inadequate. How can the effects of oil and gas development activities, particularly cumulative effects, be identified and then mitigated if BLM monitoring resources are so limited?

**Response:** The article cited in the comment provides no information supporting the assumption that BLM monitoring resources in Montana and the Dakotas are limited. The BLM carries out an active inspection and enforcement/monitoring program in Montana and the Dakotas

and will ensure that it would be carried over into the Butte Field Office if oil and gas production is ever established on the public lands or on split estate minerals administered by the BLM. Recently, with the passage of the Energy Policy Act of 2005 additional emphasis has been placed at a national and state level on monitoring and mitigating effects of oil and gas on wildlife and other resources. Beginning with this fiscal year (October 2008), the BLM now uses a workload measure/program element to track oil and gas surface and environmental monitoring including conducting baseline and follow-up inventory and monitoring activities. Oil and gas surface and environmental monitoring is performed to ensure:

- oil and gas lease stipulations and application for permit to drill conditions of approval are achieving the desired outcome;
- environmental impacts of fluid mineral development are identified;
- interim and final reclamation trend and success;
- BLM and operator follow-up actions are identified;
- Adaptive changes are implemented; and
- Desired outcome measures are appropriate.

Finally the BLM has also adopted policy directing that all Field Offices incorporate environmental best management practices (BMPs) into proposed applications to drill, sundry notices for surface disturbing activities, and associated on- and off-lease rights-of-way approvals after appropriate environmental reviews. Some, but not all, of the BMPs that can be considered include the following items:

- installing raptor perch avoidance;
- burying of distribution power lines and/or flow lines in or adjacent to access roads;
- monitoring wildlife by the operator;
- placing seasonal restrictions on public vehicular access; and
- using common utility or Right-of-Way corridors.

These BMPs are meant to minimize impacts to wildlife.

#### N12

**Comment:** We appreciate the inclusion of a section in the draft RMP/EIS regarding anticipated cumulative effects of all resource development activities (pages 480-489), and cumulative effects of travel plans (pages 636-656). We are particularly concerned about the cumulative effects associated with oil and gas drilling and production activities. Appendix L indicates that ancillary facilities would be needed to support oil and gas activities, including well sites, access roads, compressors, and pipelines (Table 2, page 887). We anticipate that in addition to these activities production facilities and

equipment, pump stations, sheds, water disposal pits, ground based communication sites, and powerlines feeding pump stations may be needed. There is not much discussion and disclosure of the cumulative effects of oil and gas wells and the ancillary facilities on wildlife and other ecological resources within the BFO Planning Area. The potential cumulative impacts from these wells and ancillary facilities may be significant and should be more fully discussed and disclosed in the final RMP/EIS. We recommend that Table 2 in Appendix L be reviewed to see that it provides full and comprehensive disclosure of all the ancillary facilities and disturbances associated with the drilling of the estimated 15 exploratory oil and gas wildcat wells, with four well having oil and gas discoveries, two of which would become producers, and the 40 coal bed natural gas wells.

**Response:** The BLM has reviewed the material in **Appendix M** of the Proposed RMP/Final EIS (formerly **Appendix L** in Draft RMP/EIS) on the reasonably foreseeable development (RFD) scenario developed for oil and gas for the RMP and also on the forecasted effects for oil and gas. The RFD scenario has been changed to reflect recent drilling activity by the Bill Barrett Corporation in northern Park County in the Butte RMP Planning Area (but not on federal mineral estate lands). The company recently reached total depth in a deep gas well and has announced that they will be testing the well this fall (2007). A second well has been spud in and is drilling. There are two other permitted locations in the same area. In addition after review, we have revised the information in **Appendix M** dealing with the cumulative impacts of oil and gas development to better portray the potential impacts from a RFD scenario showing 29 total wildcat wells, 12 of which would be discovery wells, and 36 step-out wells. As noted in **Appendix M**, 40 of the total wells are forecast to be coal bed methane. The RFD forecasts seven producing federal wells, all of them deep gas wells.

#### N13

**Comment:** An important aspect of mitigating cumulative impacts is the ability to monitor and detect impacts that are occurring, and then to take actions to mitigate impacts (mitigation means avoid and minimize impacts and then rectify or compensate for unavoidable impacts), such as maximizing distance between well pads, phasing development, minimizing new roads and other ancillary facilities, assuring that well sites for non-producing wells are adequately reclaimed and abandoned wells are properly sealed, adequate oversight and follow-up monitoring of exploration and development activities. What procedures are being used to ensure that leases on producing or non-producing sites are properly monitored? How can the public and other agencies review monitoring information for leases within the BFO area?

**Response:** Producing leases or non-producing leases with drilled and abandoned wells will be monitored and compliance with lease stipulations and any conditions of

approval applied to an Application for Permit to Drill ensured in the same way as the BLM does in parts of Montana and the Dakotas where there is existing oil and gas activity. Beginning with this fiscal year (October 2008), the BLM now uses a workload measure/program element to track of oil and gas surface and environmental monitoring including conducting baseline and follow-up inventory and monitoring activities. We also carry out periodic program reviews of all phases to our oil and gas program to identify strengths and potential weaknesses for improvement. In addition, a monitoring plan, similar to the one developed for the Dillon Field Office, for oil and gas leasing and exploration and development in the Butte Field Office will be included in the Record of Decision for this RMP. That information, excluding proprietary or confidential information, would be available for public review upon request.

#### N14

**Comment:** Montana Wildlife Federation was dismayed to find the Sleeping Giant and Canyon Ferry recognized for high Oil and Gas drilling potential. MWF does not believe the O&G values of these areas surpass their wildland value and requests that leases are not given a high priority.

**Response:** The BLM believes that the commenter is referring to the map in **Appendix M**, Fluid Minerals, of the Proposed RMP/Final EIS (formerly **Appendix L** in Draft RMP/EIS) depicting oil and gas occurrence and development potential in the Butte Field Office. That map identified five areas where conventional oil and gas activity was considered most likely in the Field Office and one area of coal bed natural gas. These areas were described in the appendix and in Chapter 3 under the subheading Leasable Fluid Minerals. Sleeping Giant and Canyon Ferry are in two of the areas identified for conventional oil and gas. In no way is the BLM prioritizing these areas for oil and gas leasing. In the case of the Sleeping Giant area we would point out that a major portion of the general area is in within the Sheep Creek and Sleeping Giant Wilderness Study Areas (WSAs) and as such by regulation cannot be leased for oil and gas as long as these areas retain that classification. If the Sleeping Giant area is ever released from WSA status that portion that is included in the Area of Critical Environmental Concern would be managed under the management plan developed when it gained that status. As such it would be managed for its recreational, scenic, and fish and wildlife values. The existing management plan use constraints for oil and gas would apply which do not allow surface occupancy on BLM lands. In the case of Canyon Ferry lake the Bureau of Reclamation manages approximately 1,800 acres of Federal lands surrounding the reservoir. Leasing decisions (applicable constraints) for these lands are being made with this RMP. However, the BLM would still request the Bureau of Reclamation to review any proposed leases.

It is also noteworthy that none of these areas have “high” potential for oil and gas leasing. They are a mix of “low” and “moderate” potential.

#### N15

**Comment:** With this vast amount of public land being leased out for oil and gas exploration and drilling, it is essential that the leasing process be open and that the public be fully informed before any leases are issued. The RMP is unclear about how the public will be adequately informed about new leases.

**Response:** The BLM notifies the public of lands that will be available for leasing and under what terms during the planning process when we make the required site-specific leasing decisions in the Proposed RMP/Final EIS and then the Record of Decision. During that process the public has the right to comment on our proposed decisions found in the Draft RMP/EIS and offer suggested changes to our proposed alternatives and mitigation measures.

The BLM notifies the public of competitive oil and gas lease sales through several different avenues. First, as required by regulations at 43 CFR § 3120.4, a notice of competitive sale containing the a list of the lands available at that sale and a map depicting those lands is posted in a public place in the Montana State Office, BLM Field Offices in Montana and the Dakotas, and offices of other affected surface management agencies at least 45 days prior to the sale date. Second, the BLM Montana State also posts the sale list on the internet site ([www.blm.gov/mt/st/en/prog/energy/oil\\_and\\_gas.html](http://www.blm.gov/mt/st/en/prog/energy/oil_and_gas.html)) at least 45 days before the sale date. Finally, any member of the public may request that the BLM mail them a copy of the sale notice on either an individual sale or by establishing an account with us having all sale notices mailed to them.

In addition to general public outreach described above, it is BLM policy to carry out the following after a land use plan is finalized to better contact surface owners over federal mineral estate when that mineral estate is being offered for lease:

The BLM will use widely available media, such as newspaper, radio, and television, to inform the public of the BLM websites that host lease sale information.

The BLM will work through local forums to maintain a dialogue on local leasing activity. Where practical, the BLM will identify areas of leasing interest.

Oil and Gas Competitive Sale Notices should include links, where available, to sites that offer information regarding surface ownership and leasing information.

#### N16

**Comment:** Sufficient information about proposed energy leases and development must be provided to the pub-

lic and sufficient time for public comment should be allowed based on the complexity of the proposal.

**Response:** The Butte RMP is making those decisions required by the BLM planning handbook, H-1601-1, for oil and gas. These decisions are found in Appendix C of the Handbook beginning at page 23 of the Appendix. The following specific decisions required by this handbook were made for the BLM administered oil and gas estate. The RMP identifies:

1. Areas open to leasing, subject to existing laws, regulations, and formal orders; and the terms and conditions of the standard lease form.
2. Areas open to leasing, subject to moderate constraints such as seasonal and Controlled Surface Use restrictions.
3. Areas open to leasing, subject to major constraints such as No Surface Occupancy stipulations.
4. Areas closed to leasing. Identify whether such closures are discretionary or nondiscretionary; and if discretionary, the rationale.
5. Resource condition objectives and specific lease stipulations and general/typical conditions of approval and best management practices to be employed to accomplish these objectives in areas open to leasing.
6. For each lease stipulation, circumstances for granting an exception, waiver, or modification are identified. The RMP also identifies the general documentation requirements and any public notification associated with granting exceptions, waivers, or modifications.
7. The RMP identifies whether leasing and development decisions also apply to geophysical exploration.
8. Whether constraints identified in the land use plan for new leases also apply to areas currently under lease.
9. Long-term resource condition objectives for areas currently under development to guide reclamation activities prior to abandonment.

The decisions in the Butte RMP to open the lands to leasing represents the BLM's determination, based on the information available that it is appropriate to allow development of the specific BLM lands in the planning area consistent with the terms of the lease, specific stipulations, laws, regulations, and orders, and subject to reasonable conditions of approval.

The Butte RMP meets BLM guidance for oil and gas leasing and development and includes a reasonably foreseeable development scenario for oil and gas, identification of oil and gas potential within the planning area, and the site-specific identification of lease stipulations to be used. It also identified a range of alternatives with varying levels of constraints. Further, the document also identifies a range of conditions of approval to be used to mitigate impacts from oil and gas leasing and development. It also reflects consideration of public, other agency, and interdisciplinary team input.

Opportunity for public input has been ongoing throughout the development process for the Butte RMP beginning with initial scoping for the RMP. Other opportunities for public comment occurred during development of the travel plans described in the RMP. Finally, the Draft RMP/EIS was released to the public for a 90 day public comment period on June 8, 2007, which was extended to 120 days ending on October 9, 2007. During that period the BLM accepted written comments and also held public meeting in six communities within the boundaries of the Field Office.

**N17**

**Comment:** An evaluation of impacts from energy development and a specific "conservation strategy" should be completed for each energy field or project before leases are issued which identifies the wildlife, vegetative, historic, geologic and recreational resources. The conservation strategy should provide specific recommendations for actions to minimize impacts on fish and wildlife, while establishing plans for mitigation and detailed monitoring. Only with a thorough analysis will the right stipulations be attached to the leases which genuinely protect wildlife and other resources and values.

**Response:** The BLM is unsure what the commenter means by the phrase "conservation strategy." However, we believe that the Butte RMP has evaluated the impacts from reasonably foreseeable oil and gas development in the Butte Field Office. The RMP identifies and describes all resources and resource uses in the Butte Field Office including, but not limited to, wildlife, vegetative, historic, geologic, and recreational resources. In the four alternatives the RMP provides specific recommendations for actions to minimize impacts to fish and wildlife through the development of a range of oil and gas lease stipulations. Oil and gas lease stipulations were developed to mitigate impacts to a total of 23 different classes of fish and wildlife habitat. Other stipulations were developed to help mitigate impact to vegetation wetlands, riparian areas, and water quality. In addition to these stipulations a wide range of other stipulations have also been developed to mitigate impacts to other resources in the Butte Field Office. The RMP also identifies potential conditions of approval that may be used on a site-specific basis to mitigate impacts for approved wells or other surface disturbing activities. The BLM has also included information our use of best management practices in the oil and gas program. Information in the Draft RMP has been expanded in **Appendix M** of the Proposed RMP/Final EIS to note that it is the BLM's policy to use best management practices and that we will develop local best management practices as needed.

**N18**

**Comment:** According the map displaying areas of "reasonably foreseeable development" and drilling activity, it appears that the Sleeping Giant ACEC is included

as an area with some potential for exploration and drilling activities. In keeping with the plan for managing ACECs, oil and gas exploration and drilling activities would seem to be incompatible with the values for they are supposed to be managed. Therefore we ask that no new oil and gas leases be issued for exploration and drilling activities, or if they are, that they only be issued with a “no surface” and “no surface disturbance” stipulation.

**Response:** The commenter is correct in noting that the Sleeping Giant ACEC is located in an area of reasonably foreseeable development and drilling activity. This is based on a review of the geology of the area. It is not a determination that drilling and other development will occur in the ACEC. Most of the Sleeping Giant ACEC is located within the boundaries of the Sheep Creek and Sleeping Giant Wilderness Study Areas (WSAs). By regulation any lands within the boundaries of a Wilderness Study Area cannot be leased as long as they are subject to that designation. The small area outside of the two Wilderness Study Areas will be managed under the existing ACEC management plan which would require a No Surface Occupancy stipulation for oil and gas leasing. If Congress removes these two WSAs from wilderness consideration, management of the total area encompassed by the WSAs would revert to the existing management plan for the ACEC. As noted earlier this would mean that any new leases issued for lands within the boundaries of the ACEC would carry a No Surface Occupancy stipulation.

#### N19

**Comment:** Mineral development and utility corridors would be inappropriate 'nuisances' here; so we support making the Scratchgravels a 'no-lease' area and an 'exclusion' area respectively. (The oil & gas potential in the batholith probably insignificant; and with all the surrounding roads, and existing towers in the north hills, Spokane Hills, Boulder Hill, MacDonald Pass, etc., there's no need to trash the Scratchgravels.

**Response:** This comment is stating an opinion and provides no justification for placing the area in a no-lease status. In order to close lands for leasing the BLM has to determine that other land uses or resource values cannot be adequately protected with even the most restrictive lease stipulations; appropriate protection can be ensured only by closing the lands to leasing.

Finally the comment is correct in stating the Scratchgravel Hills are within the boundaries of the Boulder Batholith which is an area of very low potential for oil and gas occurrence. Due to this the BLM forecasts a very low potential for oil and gas development, if any, in the future in this specific area.

#### N20

**Comment:** The No Surface Occupancy (NSO) stipulations in the Final RMP need to specify that NSO in this case means not only that surface occupancy is prohibited, but ground disturbances including road building, stream crossings, and pipeline placement are likewise prohibited through no surface occupancy/no ground disturbance (NSO/NGD) stipulations.

**Response:** A brief description of lease stipulations is given in Chapter 2 of the RMP at the section Leasable Fluid Minerals – Management Common to All Alternatives. That explanation contains a reference to **Appendix M** of the Proposed RMP/Final EIS (formerly **Appendix L** in Draft RMP/EIS) where there is a section titled Lease Stipulations. That section contains further description and definition of No Surface Occupancy stipulations that may be required on leases. As noted in **Appendix M** a No Surface Occupancy (NSO) stipulation means “use or occupancy of the land surface for fluid mineral exploration or development is prohibited to protect identified resource values.”

On BLM-administered lands pipelines, access roads, and utilities located on a lease (or within a unitized area), which are constructed and managed by the lease holder/operator can be authorized under an application for permit to drill or sundry notice. In this case any NSO stipulation part of lease would be applied. On or off lease/unit pipelines, roads and utilities constructed and managed by someone other than the leaseholder/operator require a BLM right-of-way and are governed by other restrictions found in the right-of-way. On BLM-administered lands pipelines, access roads, and utilities located off the lease or the unitized area require a right-of-way with its own stipulations.

#### N21

**Comment:** In the Draft EIS, lands known as split estate - where BLM manages the mineral estate while the surface is under separate ownership – are not identified. A map of these lands needs to be provided in the Final RMP EIS and stipulations developed that would accompany any of these split estate lands should the BLM lease them for oil and gas development. While it is true that the BLM does not have the authority to manage the surface of these lands, as the mineral estate manager, BLM should include as part of any lease contract sold, applicable stipulations identical to those that BLM managed lands are subject to that, if violated, would nullify the contract with the lease holder, voiding the lease. Whereas, a lease for split estate lands is nothing more than a contract between BLM and a lease holder, the BLM has the authority to impose such a provision in split estate leases and Montana Trout Unlimited feels very strongly that it is the BLM's responsibility to manage all mineral estates that BLM controls uniformly for the protection of our public fish, wildlife, and streams.

**Response:** The RMP addresses split estate minerals when talking about oil and gas leasing and development. Within the Decision Area (refer to Decision Area definition in glossary), BLM will make decisions for fluid minerals, oil and gas, and geothermal energy where the surface and minerals are administered by the BLM as well as for federal minerals where the surface owner is a separate entity. This includes lands where the surface is privately owned and approximately 65,000 acres of surface lands administered by the State of Montana. These lands are identified on Maps 42 through 45 in the Draft RMP/EIS.

The lease stipulations developed in the RMP are applicable to both public domain lands and split estate lands as the BLM has legal responsibilities for oil and gas leasing and operations on split estate lands. The BLM has responsibilities under the Federal Land Policy and Management (FLPMA). In the case of FLPMA, the BLM is required to indicate in RMPs how the federal mineral estate would be managed, including identification of lease stipulations. In order to meet the consistency requirements of FLPMA the BLM has applied the same standard of environmental protection to split estate lands as to federal surface. Second, the BLM also has responsibilities under the National Environmental Policy Act because the issuance of a lease and potential approval of applications for permit to drill are federal actions. Third, the BLM has responsibilities under the National Historic Preservation Act (NHPA) on split estate lands. The BLM's responsibilities commence with a proposed action that requires BLM's approval. If activities to be conducted on split estate lands under the terms and conditions of a federal oil and gas lease would result in adverse effects to historic properties, the BLM has the authority to impose appropriate avoidance or mitigation measures. Finally, oil and gas leasing and operations on split estate lands constitute federal actions under the Endangered Species Act (ESA). As such, the requirements and procedures of the ESA apply to split estate lands just as they do to federal lands including, as appropriate, preparation of biological assessments and conduct of consultations.

## N22

**Comment:** The Reasonably Foreseeable Development (RFD) analysis only looks at certain areas (Areas 1, 2, 3, 4, and 5) in which the BLM expects there to be development potential within the planning area. Should leases be nominated by the industry outside of Areas 1, 2, 3, 4, 5, BLM needs to conduct a Supplemental NEPA Analysis to determine if the variables used to determine the RFD have changed, why these parcels have been nominated, and if the RFD - and environmental consequences derived from it in the Final EIS - are still accurate, and if additional stipulations need to accompany the proposed parcels. This should be conducted before proposed parcels outside of the RFD areas are sold to prevent a NEPA violation.

**Response:** The commenter is mistaken in believing that the reasonably foreseeable development RFD scenario only applies to the five numbered areas described in both Chapter 3 and **Appendix M** of the Proposed RMP/Final EIS (formerly Appendix L in Draft RMP/EIS). In Chapter 3, the RMP under "Leasable Fluid Minerals" in a section referred to as "Reasonably Foreseeable Development", the following passage can be found:

"The Reasonably Foreseeable Development (RFD) scenario is an estimate of oil and gas activity expected because of resumed oil and gas leasing in the PA [Planning Area]. The scenario is hypothetical in that drilling may occur anywhere in the PA where an oil and gas lease allowing surface occupancy is issued. Actual drilling proposals that result from leasing, if any, will likely differ in location from those anticipated by this RFD scenario. It is also possible that leasing could result in either more or fewer drilling proposals than presented in the scenario."

The passage above is very specific in noting that the RFD scenario acknowledges that drilling may occur anywhere in the planning area (PA) which consists of the Butte Field Office where surface occupancy is allowed. The RMP also makes it clear that actual drilling proposals, if any, will likely differ from the scenario in the document. The five numbered areas identified in the RMP are strictly the areas that the BLM believes have the highest reasonably foreseeable chance for development in the planning area. They are not the only areas that might see development in the future.

**Appendix M** in the Proposed RMP/Final EIS has a more detailed description of the RFD scenario than that found in Chapter 3. It notes that the RFD scenario is an attempt to portray the most reasonable and likely number of wells expected from a leasing decision on the Butte Field Office Planning Area. It also points out that development potential is not a prediction of precise future drilling locations and should not be used as a gauge of future interest or lack of interest in leasing. **Appendix M** has been clarified to explain that the five numbered areas are those with the highest potential for development. They are not the only areas that may see development.

## N23

**Comment:** In the RFD, BLM believes that coal bed methane (CBM) development may occur in the Livingston and Trail Creek coal fields. The impacts relative to CBM development need to be analyzed and specific stipulations developed to protect fish, wildlife, and hunting and angling opportunities in these areas with potential for CBM exploration and development. Because an EIS is required to disclose for the public baseline conditions and potential impacts of a proposed action, the BLM needs to fully evaluate the potential harm CBM development could impose through a complete, professional, and enumerated inventory of the aquatic com-

munities and wildlife that could be affected by CBM development in the planning area. CBNG development is currently occurring throughout the West, thereby providing BLM plenty of opportunities to study how this development is affecting fish and wildlife and provide a rigorous evaluation of development impacts and potential stipulations and mitigation measures relative to CBM development.

**Response:** In Chapter 3 of the RMP, in the discussion of leasable fluid minerals in the section titled Coal Bed Natural Gas, the RMP notes that the coal fields in question are not located on BLM administered public lands and that there are only isolated tracts of BLM split estate minerals in the area. The narrative further notes that all of the coal bed natural gas wells drilled in the area would likely not be BLM wells based on the small percentage of BLM administered split estate mineral ownership in the area (most of the federal lands in the area are administered by the Gallatin National Forest which cannot lease at this time). The same comments are made in **Appendix M** in the section titled Drilling Activity Forecast. The BLM does not believe that there is a reasonably foreseeable chance at this time that coal bed natural gas development will occur on federal lands in the Bozeman Pass area due to the small amount of split-estate lands and due to the fact that the Gallatin National Forest is not able to authorize oil and gas leases at this time. However, the oil and gas lease stipulations and other mitigation measures developed in the RMP would apply if development did occur in the future on the very small acreage of split estate lands on Bozeman Pass. We have analyzed an extremely low level of development on federal lands in the area.

#### N24

**Comment:** McMaster Hills: It's a small area, surrounded by ever increasing residential development, with some really unique natural features, like Spokane Creek bay and the little drainage in the eastern portion. You should pursue acquisition of as much of the remaining private lands in Sec. 6 as possible, to facilitate hiking in the area and to permit public access to the neat draws in the center of that section. This area should be developed for walking and nature/wildlife appreciation. It's really too small to appeal to mountain bike or stock use. And there's a crying need for restoration - especially around Spokane Creek bay. Like with the Ward Ranch, your Alt. B is a good start. It's very important to keep ORV use, especially by neighborhood kids, from getting started there. And this should be a "no-lease" area - as with the Scratchgravel, any kind of oil & gas exploration or development would be untenable - a gigantic "nuisance" - in such a suburban setting. I'd like to see more in-depth planning done, with a focus on the Bay and on community/neighborhood involvement. For example, should all signs of the old campground be removed or not? Should access to the west side bluffs (i.e., a bridge across the creek) be provided or not?

**Response:** In terms of priorities for future land acquisitions for Butte Field Office lands, under all action alternatives the BLM would place a high priority on areas with special designations such as Areas of Critical Environmental Concern or Wild and Scenic Rivers, or areas with habitat for special status and priority species. However, future acquisition of lands in Section 6 would be dependent on interest on the part of any willing landowners as well as other acquisition priorities within the BFO.

The McMasters Hills property was acquired primarily with Land and Water Conservation Funds. To provide management in keeping with the intent of LWCF acquisitions, in the Preferred Alternative the BLM is proposing that McMasters Hills be a "no lease" area for oil and gas. Additional issues mentioned in the comment relate to site-specific implementation decisions that would be made outside the scope of the RMP. Future implementation decisions would be consistent with the finalized Butte RMP.

#### N25

**Comment:** Table 1-5 in the draft RMP/EIS (page 11) includes a minerals and energy goal stating that exploration and development of mineral resources will be conducted in an "environmentally sound" manner. We note that the mineral and energy resources goal does not mention "environmentally sound" exploration and development of energy resources. It is important that oil and gas exploration and development, as well as mineral exploration and development, occur in a manner that protects the environment. The final RMP/EIS should clarify that oil and gas are included in the mineral resources for which environmentally sound exploration and development would occur. We recommend that BLM make it clear that oil and gas exploration in the BFO Planning Area will be done in an environmentally sound manner that avoids and minimizes adverse environmental impacts. For example, "The BLM's goal is that oil and gas exploration and development will occur in a manner that avoids and minimizes adverse environmental impacts."

**Response:** The BLM believes the goal statement adequately addresses the concerns raised by the comment. As written, the management direction for minerals and energy at "2)" applies to the development of federal minerals for both energy and non-energy uses.

#### N26

**Comment:** We also recommend that BLM write stipulations for oil and gas development that requires operators to monitor for impacts to water quality and fish and wildlife habitat.

**Response:** The BLM normally does not write stipulations that require oil and gas lessees/operators to monitor for impacts to resources or resource uses. Normally, the

BLM conducts all required monitoring for lease activities. However, on a case-by-case basis we have the authority under terms of the lease form at Section 6 to require lessees or operators to complete inventories or special surveys to monitor impacts from their lease operation. These requirements would be incorporated as best management practices/conditions of approval applied to either applications for permit to drill or surface disturbing sundry notices.

#### N27

**Comment:** Minerals (Oil and Gas): Alternative B as shown on Map 43 would be improved with the following amendments. 1. Land in the Boulder Mountains and Elkhorns be rated “No Surface Occupancy”. While AWL prefers no minerals activities be conducted in this area, no surface occupancy restrictions, seasonal closures during fall and spring, and an adaptive management plan are recommended as lease requirements for these areas. 2. AWL suggests removing the term “Standard Lease” from the area Northwest of Helena and restricting the area to sub-surface mining with no additional surface occupancy. While AWL prefers no minerals activities be conducted in this area, no surface occupancy restrictions, seasonal closures during fall and spring, and an adaptive management plan are recommended as lease requirements for these areas. 3. Mining in the area southwest of Butte should be removed, reduced or should at the very least include timing restrictions as this area is an important movement area for wildlife. While AWL would prefer no minerals activities be conducted in this area, no surface occupancy restrictions, seasonal closures during fall and spring, and an adaptive management plan are recommended as lease requirements for these areas.

**Response:** The BLM response is itemized by numbered items corresponding to those in the comment.

1. Under Alternative C, the majority of the Boulder Mountains and Elkhorns administered by the BLM are designated as not available for oil and gas leasing and impacts of making those and other extensive discretionary no lease decisions in the Planning Area were fully analyzed in the RMP. In addition to Alternative C there were three other alternatives analyzed in detail in the RMP for impacts to all resources and resource uses. After review of the impacts it was determined to adopt Alternative B, which uses a combination of controlled surface use and timing limitations with some areas being under no surface occupancy stipulations in the referenced area, as the preferred alternative as it provided the least restrictive mix of constraints that meet resource protection objectives. The Elkhorn Tack-on Wilderness Study Area is not available for lease under any alternative. Only very small areas in the Boulder Mountains and Elkhorns would be leased under standard terms.

2. Under Alternative C, the majority of the BLM administered lands northwest of Helena, except for the

Scratchgravel Hills, are designated as not available for oil and gas leasing and impacts of making those and other extensive discretionary no lease decisions in the Planning Area were fully analyzed in the RMP. The Scratchgravel Hills would be leased with no surface occupancy stipulations. The small area directly northwest of Helena shown in the Draft RMP/EIS as being available for lease under Standard Lease Terms under Alternative C is Fort Harrison. (Between release of the Draft RMP and the Proposed RMP/Final EIS the BLM has determined that this area has been withdrawn and the BLM therefore has no mineral estate there. These lands are not shown as federal mineral estate in the Proposed RMP/Final EIS.) In addition to Alternative C there were three other alternatives analyzed in detail in the RMP for impacts to all resources and resource uses. After review of the impacts it was determined to adopt Alternative B, which uses a combination of controlled surface use and timing limitations with some areas being under no surface occupancy stipulations in the referenced area, as the preferred alternative as it provided the least restrictive mix of constraints that meet resource protection objectives. The lands under withdrawal for Fort Harrison have been deleted from Maps 42 through 44 in the RMP because the RMP does not make leasing decisions for the Department of the Army.

3. Under Alternative C, almost all BLM administered lands southwest of Butte are designated as not available for oil and gas leasing and impacts of making those and other extensive discretionary no lease decisions in the Planning Area were fully analyzed in the RMP. The Humbug Spires Wilderness Study Area is not available for lease under all alternatives in the RMP. In addition to Alternative C there were three other alternatives analyzed in detail in the RMP for impacts to all resources and resource uses. After review of the impacts it was determined to adopt Alternative B, which uses a combination of controlled surface use and timing limitations with some areas being under no surface occupancy stipulations in the referenced area and one area that is closed to lease as the preferred alternative as it provided the least restrictive mix of constraints that meet resource protection objectives while providing for oil and leasing.

#### N28

**Comment:** While it appears that the potential for oil and gas development in the BFO area is somewhat limited, (i.e. the Reasonably Foreseeable Development Scenario (RFD) estimates that 15 exploratory oil and gas wildcat wells will be drilled in the BFO Planning Area in the next 15-20 years, with four wells having oil and gas discoveries, two of which would become producers, and 40 coal bed natural gas wells, Appendix L, page 884), we believe there are additional areas that should be considered for withdrawal from availability for oil and gas leasing in order to protect environmentally sensitive areas (e.g. sage grouse winter/spring range, lands within 0.5 mile of sage grouse leks, municipal watersheds and

source water protection areas, lands within 1 mile of bull trout, Yellowstone cutthroat trout and arctic grayling habitat, and habitat of genetically pure westslope cutthroat trout habitat). We recommend that areas with fragile or environmentally sensitive resources be stipulated as No Lease (NL), or at a minimum at least have "No Surface Occupancy" (NSO) stipulations. Table 2.21 (beginning on page 93) identifies lease stipulations by alternative, and Appendix L (beginning on page 903) describes lease stipulations. As noted above, we recommend that a no lease or at a minimum no surface occupancy stipulation be applied to environmentally sensitive areas such as sage grouse winter/spring range, lands within 0.5 mile of sage grouse leks, bull trout habitat, Yellowstone cutthroat trout habitat, 99-100 percent pure westslope cutthroat trout habitat, Class I fisheries, and municipal watersheds and source water protection areas.

**Response:** The BLM believes that the measures proposed in the Butte RMP will provide adequate protection for the resources listed in the comment without applying a blanket no lease decision or blanket no surface occupancy stipulations to the resources you refer to. Components of the Preferred Alternative in this RMP recognize that with few exceptions, mineral exploration and development (including oil and gas exploration) can occur concurrently or sequentially with other resource uses. The policy of the BLM is to use the least restrictive oil and gas stipulations that effectively accomplish the resource objectives established in the plan.

The BLM believes that we have analyzed a broad array of stipulations and other related mitigation measures in the RMP that would provide the appropriate mitigation to the listed resources. Impacts to winter/spring sage grouse habitat were analyzed with timing limitation stipulations in the Preferred Alternative, and in the most restrictive alternative (Alternative C) there would be a no lease decision. Impacts to leks were analyzed with a range of no surface occupancy stipulations in Alternatives A, B, and D, and in the case of Alternative C a no lease decision was considered within a ½-mile buffer around leks. Municipal watersheds were examined for impacts with standard lease terms, a controlled surface use stipulation, no lease, and no surface occupancy in the Preferred Alternative analyzed as proposed mitigation measures. In the case of bull trout, Yellowstone cutthroat trout, and Arctic grayling the BLM also analyzed mitigation for the three species ranging from a controlled surface use stipulation for bull trout under Alternative A, to a no surface occupancy within a one mile buffer zone under Alternative C, with the Preferred Alternative featuring a no surface occupancy within a ½-mile buffer zone for all three of these species. For genetically pure westslope cutthroat trout habitat, the BLM analyzed stipulations ranging from no surface occupancy within a ¼-mile buffer, to no lease within ½-mile of habitat in the most restrictive alternative, with the Preferred Alternative featuring no surface occupancy within ½-mile. For class one fisheries the Preferred Alternative

entails no surface occupancy within a ½-mile buffer zone. However, in Alternative C the BLM did analyze no surface occupancy within a one mile buffer.

In addition to the lease stipulations analyzed by alternative in the RMP, the BLM has identified in the RMP that environmental best management practices (BMPs) and other site-specific conditions-of-approval (COAs) will be used on a site-specific basis to mitigate potential impacts. **Appendix E** and **Appendix M** of the Proposed RMP/Final EIS provide further information on the BLM's use of BMPs and COAs. Conditions-of-approval and BMPs are mitigation measures that provide for restrictions in light of site-specific conditions. General guidance for conditions of approval and surface operating standards can be found in the fourth addition of "Surface Operating Standards and Guidelines for Oil and Gas Exploration and Development" published by the BLM in 2007.

#### N29

**Comment:** Global Climate Change: The BLM needs to conduct an assessment of vulnerable aquatic game species and natural systems that will be adversely impacted by global climate change. The BLM should manage vulnerable systems and their tributaries to prevent them from experiencing regime shifts brought on by the impacts of climate change and remove other stressors from those systems by thoroughly analyzing cumulative impacts that the RMP may authorize, including leasing for – and in turn development of – oil and gas resources . The impacts of closures to angling, and relationships between land use decisions such as oil and gas leasing by the BLM and the impaired nature of coldwater fisheries leading to closures in the planning area needs to be analyzed. This analysis should culminate in appropriate stipulations, lease terms, and/or decisions not to lease in these vulnerable habitats.

**Response:** This comment raises generalized concerns about climate change and the potential cumulative impacts of oil and gas development on vulnerable aquatic species. While the conditions the comment observes are likely related to the long term drought conditions experienced by the intermountain west, the analysis of direct, indirect, and cumulative impacts to climate change from oil and gas leasing and development in the Butte Field Office would likely be very low based on the low level of activity forecast in the reasonably foreseeable development scenario.

The assessment of greenhouse gas emissions and climate change is in its formative phase; therefore, it is not yet possible to know with confidence the net impacts to climate. However, the Intergovernmental Panel on Climate Change (IPCC 2007) recently stated that "warming of the climate system is unequivocal..." and that "most of the observed increase in globally average temperatures since the mid-20<sup>th</sup> century is very likely due to the

observed increase in anthropogenic [man-made] greenhouse gas concentrations.”

The lack of scientific tools designed to predict climate change on regional or local scales limits the ability to quantify potential future impacts. For example, potential impacts to air quality resulting from climate change are likely to be varied. If global climate change results in a warmer and drier climate, increased particulate matter could occur as a result of increased windblown dust from drier and less stable soils. Cool season plant species’ ranges could potentially move north and due to the potential loss of habitat, or from competition from other species whose ranges shift northward, the population of some animal species could change.

Many of the models needed to make effective decisions at the local and regional levels have not been developed. The Department of the Interior is exploring whether global and regional climate modeling can be scaled to the point that it can be used to manage parks and refuges. When further information on the impacts to climate change is known, such information would be considered in the implementation of this plan as appropriate.

**N30**

**Comment:** All known and future identified drainages containing pure (90-99 percent pure) populations of westslope or Yellowstone cutthroat trout, arctic grayling populations and crucial habitat for bull trout are identified as class 1 fisheries by Montana Department of Fish, Wildlife, and Parks. Under the Preferred Alternative (B), streams harboring conservation populations of westslope cutthroat trout have a ½-mile NSO buffer. Whereas, poor land use management quite literally flows downhill, this NSO stipulation needs to be increased to the entire watershed in order to meet the intent of the Memorandum of Understanding and Conservation Agreement for Westslope Cutthroat Trout and Yellowstone Cutthroat trout in Montana (April, 2007) – (Montana Cutthroat Trout MOU) to which Montana BLM is a party – and lists as Objective 1: “Maintain, secure and/or enhance all cutthroat trout populations designated as conservation populations, especially the genetically pure components.”

For Yellowstone cutthroat trout, streams with genetically pure populations of these native trout are proposed in the Preferred Alternative to receive a ½-mile NSO buffer; as with westslope cutthroat trout, this buffer needs to be extended to the entire watershed and specify that all ground disturbance and occupancy is prohibited through NSO/NGD stipulations. Additionally, it is important to note that all conservation populations (>90 percent pure) need to be granted this stipulation, not just genetically pure populations.

As with Yellowstone and westslope cutthroat trout, oil and gas leasing stipulations meant to protect bull trout and fluvial and adfluvial arctic grayling habitats need to

be expanded to include watershed wide NSO/NGD stipulations.

**Response:** The Preferred Alternative (Alternative B) would only establish a ½-mile no surface occupancy buffer zone along streams for protection of conservation populations of westslope cutthroat trout, Yellowstone cutthroat, fluvial Arctic grayling, and bull trout. The BLM has modified the Yellowstone cutthroat trout stipulation in the Preferred Alternative to include all populations with 90 percent or greater genetic purity. For genetically pure populations of westslope cutthroat trout, and for Yellowstone cutthroat trout, the BLM proposed a no lease zone one-half mile in width from their habitats in the most restrictive alternative (Alternative C) of the RMP. A no surface occupancy stipulation of one mile within bull trout habitat was proposed in this same alternative.

The BLM believes that the no surface occupancy (NSO) stipulations in the Preferred Alternative will provide adequate mitigation for impacts from reasonably foreseeable oil and gas exploration on BLM lands in the Butte Field Office in any area with occupied habitat by any of these species. The NSO stipulations for these species, combined with additional NSO fisheries stipulations for blue ribbon fisheries streams will protect the areas within one-half mile on either side of the center line of important streams in the Decision Area. Additionally, the no surface occupancy stipulations for wetlands, floodplains, and riparian areas; municipal watersheds; and rivers suitable for wild and scenic designation will provide additional protection of all aquatic habitats. Finally, the controlled surface use stipulation for erosive soils will help mitigate potential for sedimentation in important fish habitat. Approximately 181,943 acres (28 percent) of the Decision Area in the Butte Field Office is protected by the overlapping no surface occupancy stipulations mentioned above. The controlled surface use stipulation for steep slopes provides protection from erosion for an additional 195,984 acres (30 percent) of the Decision Area.

In addition to lease stipulations, the BLM will use environmental best management practices on a site-specific basis to mitigate impacts from oil and gas development that might affect important fish habitat. If an application for permit to drill was filed, during processing the BLM would consider BMPs to reduce unnecessary disturbance. Some, but not all, of these BMPs include:

- Avoiding locating well pads, roads, and pipelines on or adjacent to steep slopes;
- Constructing the minimum sized road required;
- Completing interim reclamation;
- Minimizing topsoil removal during operations;
- Using the minimum sized well pad needed;
- Using oak mats for pads and roads; and

- Co-locating wells on one pad.

Environmental BMPs will also be considered for producing locations, if any are developed, on federal lands. Some but not all of these include:

- The use of secondary containment, such as dikes, around locations;
- Good housekeeping on locations; and
- Proper erosion control.

### N31

**Comment:** While stipulations meant to protect existing populations of native trout are included in the Draft RMP EIS, an important issue overlooked is that of streams with restoration potential. Under the guidance of Objective 3 of the Montana Cutthroat Trout MOU “Seek collaborative opportunities to restore and/or expand populations of each cutthroat trout subspecies into selected habitats within their respective historical ranges.” BLM should include in the Final Butte RMP EIS a list of streams with suitable habitats for potential restoration efforts and protect these watersheds with NSO/NGD stipulations.

All areas identified as potential sites for westslope cutthroat trout replication (as indicated in the westslope cutthroat management plan) should have an NSO stipulation attached for the entire drainage (not just ½ mile) or be unavailable for leasing,

**Response:** The BLM agrees with the comment. While there are no streams where additional native trout restoration is currently being planned in the Butte Field Office, an additional stipulation (no surface occupancy within ½-mile) has been added to the Preferred Alternative that calls for protection of streams with restoration potential for all special status fish species as they are identified in the future. Because Butte Field Office lands are highly fragmented, native fish restoration efforts by the BLM are most often done in conjunction with Montana Department of Fish, Wildlife, and Parks (MFWP) based on MFWP priorities. As a result, the BLM has not identified any additional streams with restoration potential at this time, but may do so in the future in conjunction with MFWP.

## Out of Scope, Staffing, Budget

### O1

**Comment:** BLM presented no information on the need for accurate affordable public land recreation maps and proposals for updated the maps we have. BLM must emphasize the importance of accurate recreation maps available to the public.

**Response:** Development of recreation maps is beyond the scope of the Butte RMP. The Record of Decision for

the Butte RMP will indicate decisions that will need to be incorporated into public maps in the future.

### O2

**Comment:** We recommend that the West side of Elkhorns be further investigated, as it has high rates of tree encroachment, forest in-filling, and wildlife affects on private property.

**Response:** Site-specific data collection is an implementation level decision that is beyond the scope of the Butte RMP. The BLM’s potential role in such data collection in the Elkhorn Mountains would be determined within the context of the partnership for management of the Elkhorn Mountains.

### O3

**Comment:** It is recommended a biological study be done to determine if there are reproductive diseases affecting the Elkhorn herd units.

**Response:** The BLM’s role in a potential biological study of elk herds in the Elkhorn Mountains is beyond the scope of the Butte RMP. The BLM’s potential role in such a study would be determined through interactions within the context of the partnership for management of the Elkhorn Mountains.

### O4

**Comment:** Every planning action "re-invents" the line weights, color, and line styles for the different motorized and non-motorized road and trail designations. This is very confusing to the public and, once again, puts motorized recreationists at a disadvantage. A national mapping standard for travel planning actions must be developed starting with proposed action in order to address this inadequacy and the environmental justice issue associated with it.

**Response:** It is beyond the scope of the Butte RMP to establish national mapping standards. The BLM has done its best to provide readable, understandable travel planning alternative maps for the public during the Butte RMP revision process. Both a hard copy option, as well as a more detailed electronic PDF map option were provided to give the public two different means of viewing travel plan alternatives.

### O5

**Comment:** If the loss of motorized routes cannot be mitigated within the project area, then a Motorized Access and Recreation Mitigation Bank must be established. This mitigation bank would keep an overall accounting of the miles and acres of motorized access and recreational opportunities closed and the new motorized access and recreational opportunities created to offset that loss. It would be the responsibility of a cooperative group of public land management agencies to monitor

the balance sheet and work towards no net loss/closure of motorized access and motorized recreation. Similar to other mitigation banks, motorized access and routes closed to motorized use would be replaced with equivalent routes on a one to one basis.

**Response:** Establishment of such a bank is outside the scope of the Butte RMP and would require commitments within the BLM and other agencies at the national level.

**O6**

**Comment:** We request that an adequate number of agency staff be licensed and safety trained to operate OHVs, have an adequate number of OHVs for their use, and spend an adequate amount of time riding OHVs along with OHV recreationists so that they can adequately understand the needs associated with motorized access and motorized recreationists.

**Response:** Many BLM personnel are licensed and safety trained to operate OHVs and do so on a regular basis as part of their jobs. It is not the policy of the BLM to require its employees to spend a specified amount of time riding along with OHV recreationists as part of their jobs.

**O7**

**Comment:** A quantification of the level of public understanding and participation in the NEPA process has never been undertaken. Additionally, a quantification of the level of public acceptance of the NEPA process has never been undertaken. We request that the significant negative impact on the majority of the public resulting from the lack of information, education, training, understanding, and acceptance of the NEPA process be evaluated and that the cumulative negative impacts which have become significant on the public be adequately mitigated.

**Response:** All members of the public have the same access to information on the NEPA process. For the Butte RMP, guidance has been provided to the public via press releases, newspaper articles, the website, presentations at public meetings, and personal communication with BLM staff on how to participate in the NEPA process.

**O8**

**Comment:** We request the significant impact that national foundation funding to environmental groups has on motorized recreationists be adequately evaluated and considered including:

- (1) the impact that foundation funding has on the NEPA process,
- (2) the impact that foundation funding has on the decision-making, and

- (3) the impact that foundation funding has on the NEPA process through significant use of legal challenges to nearly every decision involving multiple-use proposals for public lands. In addition, the document and decision-makers should evaluate the cumulative negative impact national foundation funding has had on all past NEPA actions involving multiple-use and motorized recreation.

**Response:** There is no requirement for the BLM to evaluate the issue identified. Furthermore, the BLM would have no way of acquiring information on funding sources of commenters on the Butte RMP.

**O9**

**Comment:** Note that an OHV Trust Fund should be set up to collect and hold OHV gas tax monies paid by OHV recreationists in the past but not returned to them. This trust fund could also be used in the event of delays in the start-up of OHV Programs and to accommodate the scheduling of NEPA actions for on-the-ground OHV projects.

**Response:** Setting up an OHV Trust Fund is beyond the scope of the Butte RMP

**O10**

**Comment:** Our vision for motorized recreation includes opportunities such as the Great Western Trail and Oregon Back Country Discovery Route, and other regional opportunities that include connections between forests and adjoining states. A system of OHV back country discovery routes and OHV byways could provide loops and interconnecting trails to points of interest including lakes, streams, rivers, ghost towns, and scenic overlooks. This system of OHV routes could also include connections to small towns for access to motels and restaurants and could be a significant source of economic revitalization for the project area. OHV recreation and tourism could be a significant boost to many local economies. This potential has yet to be recognized and tapped. Examples of OHV tourism can be found at:

- [www.visitid.org/Outdoor/ATV.html](http://www.visitid.org/Outdoor/ATV.html)
- [www.marysvale.org](http://www.marysvale.org),
- [www.trailscout.com](http://www.trailscout.com),
- [www.transamtrail.com/main.htm](http://www.transamtrail.com/main.htm),
- [www.motorcycleexplorer.com](http://www.motorcycleexplorer.com), and
- [www.visitnorthidaho.com/wallace.html](http://www.visitnorthidaho.com/wallace.html).

We request that the positive benefits of OHV recreation and tourism be considered as part of the evaluation and implemented for this action.

**Response:** While BLM routes could be incorporated into expansive trail routes described in this comment, such routes are beyond the scope of the Butte RMP itself and would entail cooperative planning between the BLM and many other entities.

**O11**

**Comment:** OHV recreation and tourism has not been promoted or supported by Montana Department of Fish, Wildlife and Parks (MDFWP) as aggressively as recreation and tourism associated with fish and wildlife programs. We request that MDFWP actively promote OHV recreation and OHV tourism. We also request that MDFWP increase the level of OHV management to a level that addresses the needs of motorized recreationists, enthusiastically promote OHV recreation opportunities, and enthusiastically develop OHV tourism.

**Response:** This issue is outside the scope of the Butte RMP. The BLM has no authority over Montana Department of Fish, Wildlife, and Parks priorities.

**O12**

**Comment:** Motorized recreationists are very concerned that a reasonable alternative will not be adequately addressed in the environmental document and decision-making and that the process is predisposed. To prevent this from happening again, we request a Multiple-Use Review Board be established to assure that the decision-making reflects the multiple-use management goals and the needs of the public. We request that a Multiple-Use Review Board look into all past travel management decisions within public lands to determine whether all decisions have adequately considered the needs of multiple-use and motorized recreationists. Where decisions have not adequately considered the needs of multiple-use and motorized recreationists, we request that the reasons be identified and that corrective actions be taken.

**Response:** Development of a Multiple-Use Review Board is beyond the scope of the Butte RMP. The BLM considers the range of multiple uses, including the needs of motorized recreationists as well as the needs of non-motorized recreationists and resource protection, in its decisions.

**O13**

**Comment:** Ruts caused by ATVs in corners are often due to the solid drive axles which do not allow the wheels to turn at different speeds due to the difference in between outside and inside curve radiuses. These ruts could be significantly reduced by encouraging all manufacturers to develop machines with differential axles that allow the outside and inside tires to turn at different speeds.

**Response:** It is outside the scope of the Butte RMP for the BLM to recommend vehicle specifications to manufacturers.

**O14**

**Comment:** Agencies are encouraged to publish all Travel Plan maps in the same format and in an easy to

read format. The Travel Plan map and Visitors map should be the same. All visitors need to clearly understand what areas, roads or trails are open for motorized travel and what areas, trails, or roads are closed to motorized travel. Current maps lead to misunderstandings by both non-motorized and motorized visitors.

Agencies are encouraged to make Travel Plan maps more readily available. Vending machines could be placed in areas that are accessible at any time of the day or week at BLM and FS offices.

**Response:** The format and availability of travel plan maps would be decided upon during the actual implementation of site-specific travel plan decisions described in the Proposed RMP/Final EIS. This issue is outside the scope of the RMP itself.

**O15**

**Comment:** I agree with the proposed designation of "Closed" for the Iron Mask property. My understanding is that this will mean that no motorized use will be allowed.

**Response:** In the Proposed RMP/Final EIS, the Travel Management and Access section of Chapter 2, under Management Common to Action Alternatives, wording has been adjusted to reflect that the newly acquired Iron Mask property is proposed for a "Limited" area designation for travel planning. After finalization of the Butte RMP, site-specific travel planning will be done in this area (as an amendment to the Elkhorns travel plan) to determine route-specific management.

**O16**

**Comment:** The Jimmy Gulch area has very high potential for hosting an economic deposit. Pegasus Gold and FMC had a joint venture in this area about 15-20 years ago, during a period of time when considerable exploration was taking place in Montana. They used the Jimmy Gulch road to access the patented claims sometimes known as the "Satellite" group. I also know that this road is the only practicable access to that property of around 75 acres, owned by a certain individual. Therefore I would urge the BLM and USFS to make access through the Jimmy Gulch road available at least to owner of said property and her designees. I oppose the closure of the Jimmy Gulch Road.

**Response:** This comment is outside the scope of the Butte RMP revision. The area in question is outside the five travel planning areas being addressed within the RMP revision. Site-specific travel planning within the area in question will be addressed in the future after finalization of the Butte RMP. Until that time, the landowner could seek a right-of-way with the BLM for road access to the property in question.

**O17**

**Comment:** I urge the following: Add the Sleeping Giant/Sheep Creek Wilderness Area to the Gates of the Mountains Wilderness Area to include the 3.1 miles of river and lake (Holter) below Hauser.

Add 16,572 acres to the FS 11,009 Gates of the Mountains Wilderness. Designate the Sleeping Giant wilderness - BLM of 36,204 acres.

**Response:** The BLM has no authority to designate wilderness. Only Congress has the authority to designate wilderness areas. The BLM is obligated to manage its Wilderness Study Areas for wilderness values until Congress decides to either designate them as wilderness, or remove them from wilderness consideration. Management direction described in the Butte RMP meets that obligation.

**O18**

**Comment:** The Butte RMP does not adequately address the cumulative effect that the proposed [road] closures will have when added to past closures. The following list clearly shows that over the past few years multiple users are the user group that is continually being locked off of federally managed public land.

List of Current and Immediate Past Actions Affecting Multiple-Use Recreation

The reduction in available multiple use access will have an adverse effect on the remaining resource as more use is concentrated into smaller areas, CBU requests that the BLM take a hard look at the previously listed actions when evaluating cumulative effects on multiple use recreation in the Butte RMP.

**Response:** While there is no requirement for the BLM to consider decisions from all of the management plans and actions listed in the comment, the BLM believes it has adequately considered cumulative effects of local management decisions from various agencies within and adjacent to the Butte RMP planning area as related to travel planning. These effects are described in Chapter 4, Volume II, in the Travel Management and Access subsection of the Cumulative Effects of Travel Plans at the Planning Area Scale section.

## O19

**Comment:** We need more communication and cooperation as far as this draft RMP goes. More accountability on money spent for range improvements, money spent to increase and expand recreational values, wildlife habitats, and fisheries. Also, show where cooperative agreements with FWP, state agencies, DNRC, and the Forest Service are concerned.

**Response:** The BLM has provided multiple opportunities and avenues for communication and cooperation with the public in the context of the Draft RMP/EIS. Accountability on money spent is beyond the scope of the RMP. The RMP does provide for a wide range of recreational values and improvements to wildlife habitats (primarily through vegetation treatments) and fish habitat as described in Chapter 2. Cooperative and coordination efforts with Fish, Wildlife, and Parks, the Forest Service, and other agencies is described in many different locations particularly in Chapter 2 sections on: Noxious Weeds within the Vegetation Communities section; Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species; Travel Management and Access; and Recreation Management.

## O20

**Comment:** I realize money is always a huge factor, but would it be possible to require schooling at the time an off-road vehicle is licensed, similar to hunting? I think a lot of the problem is ignorance.

**Response:** It is beyond the scope of the Butte RMP and beyond the jurisdiction of the BLM to require schooling at the time of off-road vehicle licensing. Such a requirement would be the responsibility of the State of Montana.

## O21

**Comment:** Terminology: We have identified inconsistencies in some of the definitions included in the Butte RMP glossary relative to those defined in the Helena National Forest Plan glossary. We would like the opportunity to work with the Butte Field Office staff between the draft EIS and the final EIS to develop a terminology set that facilitates consistent management between both agencies.

**Response:** The BLM will gladly meet with the Helena National Forest to resolve issues of consistency and common terminology. However, given the scheduled timeframes for completion of the Butte RMP, the BLM is unable to do so before release of the Proposed RMP/EIS, but may be able to do so before finalization of the Butte RMP in the Record of Decision.

## O22

**Comment:** I hope this management assessment reveals the need for more emphasis on the botanical sciences,

wildlife sciences, and environmental studies in the preparation of Bureau of Land Management employees whose job requirements put them in the field.

**Response:** BLM personnel have appropriate formal educational backgrounds and training for the specific positions and job duties for which they are responsible. Upon issuance of the Record of Decision for the Butte RMP, BLM personnel will be required to become familiar with the provisions of the approved RMP as it pertains to how they do their particular jobs.

**O23**

**Comment:** Regardless of what Travel Plans get chosen, we are concerned for the successful implementation and enforcement of any travel plan changes that are proposed. Without strong commitment to the financial and personnel resources necessary to affect and maintain on-the-ground change, even the most thoughtfully devised travel management plan will not work.

**Response:** The BLM agrees that travel plan implementation requires considerable budget and labor expenditures to ensure proper implementation and enforcement. While this issue is beyond the scope of the Butte RMP, the BLM will do its best to receive appropriate funding to properly implement travel plans.

**O24**

**Comment:** What about the fishing access sites developed under the BLM wildlife challenge cost share program with local TU, Skyline Sportsmen, and Anaconda Sportsmen's Club? Not even mentioned by BLM as well as the Wildlife Challenge Cost Share access road in Sawmill Gulch with the Anaconda Job Corps. Boat ramps on the Bighole River were also funded with this program such as by Divide and Jerry Creek and above Dickie Bridge. Does BLM have the Challenge Cost Share program anymore?

**Response:** Site-specific projects such as those mentioned in the comment are implementation level decisions, not RMP decisions, and thus beyond the scope of this land use planning document. The Challenge Cost Share program does still exist and the BLM uses it where possible to implement projects on the ground.

**O25**

**Comment:** We are especially concerned about the lack of accountability for the wildlife and recreation funding that you receive in your annual budgets - we don't feel that this money is being spent to benefit public access and recreational opportunities. BLM has been engaged in pooling these funds and using these funds to support the land exchange program and other programs such as realty. That is not the purpose of earmarked wildlife and recreation money to BLM. We need to have an accounting of all monies received for wildlife and recreation and

how you plan to improve wildlife habitat and recreational opportunities in the final EIS.

**Response:** Specific programs are held accountable for meeting budget-based accomplishment targets within each program annually. The Vegetation Communities and Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species sections of Chapter 2 of the Butte RMP describe activities that would be accomplished to benefit wildlife. The Recreation Management section of Chapter 2 describes activities and management that would benefit recreational opportunities. An accounting of monies for any specific program is outside the scope of the RMP.

**O26**

**Comment:** I hope you will make a strong argument on behalf of BLM staff to increase your budget for additional personnel. To monitor and maintain the acreage under your responsibility, you MUST HAVE THE RESOURCES AND PEOPLE.

**Response:** While this issue is outside the scope of the Butte RMP revision, the BLM continuously works to receive appropriate levels of funding and staffing to ensure quality land use plan implementation. These efforts will continue after finalization of the approved Butte RMP.

**Process, Public Involvement, and Editorial Issues**

**P1**

**Comment:** I do not support most of the alternatives and question why BLM did not consider hardly any the suggestions offered by the public during the group meetings? Also, why does BLM continue to insist on an "All or Nothing" approach and not a combination of the best of all ideas?

**Response:** The BLM believes it has fairly considered public comments received during the scoping process for the Butte RMP by incorporating public comments into RMP or travel plan alternatives where feasible. The BLM believes it has developed alternatives that provide varying degrees of balance between resources and resource uses.

**P2**

**Comment:** For a process that was purported to be for recreational planning, there are sure a lot of non-recreational issues included.

**Response:** The Butte RMP revision has been portrayed by the BLM as an all-encompassing land use planning process since the beginning of the process. Recreation is one of many different resource uses addressed during the RMP revision.

**P3**

**Comment:** NEPA requires adequate disclosure of the potential impacts of a proposed action as stated in CEQ Sec. 1500 .1. “It shall provide full and fair discussion of significant environmental impacts and shall inform decision makers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment.”

**Response:** The BLM acknowledges this requirement of NEPA and believes it has conscientiously met the intent of this regulation in development of the Butte RMP.

**P4**

**Comment:** The Bureau of Land Management (BLM) is commended for using the SIMPPLLE model (state of the art landscape-level planning tool) to aid in their planning efforts to predict change and vegetation dynamics over time. However, the document mainly provides relative comparisons of the alternatives rather than detailed analytical information that would allow the public to make more informed comparisons.

**Response:** One inherent difficulty in being quantitatively specific in describing environmental consequences associated with RMP alternatives is that most proposed activities necessarily lack absolute quantities or site-specificity at the scale of the RMP. These features would be determined at the project level during implementation of projects under the RMP. However, Chapter 4 of the Proposed RMP/Final EIS provides a combination of data comparisons (where feasible) and relative comparisons of alternatives.

**P5**

**Comment:** BLM makes it appear that they are not responsible to the very law BLM must comply with and an accurate description of each. We want to see these laws all listed in the Plan and explained in such a way the OMB will be happy and so that the public can see all the pieces before any 20-year plan is reached. BLM must operate under numerous federal land laws as well as the Freedom of Information Act (FOIA) and Federal Data Quality Act (DQA). BLM is also subject to Title 18, The False Statements Act. BLM must comply completely with the Federal Data Quality Act (FDQA) and Criminal Code title 18, Chapter 47-1001 which is listed even on grazing leases.

**Response:** The Proposed RMP/Final EIS includes an appendix (**Appendix B**) that synthesizes key attributes of pertinent laws.

**P6**

**Comment:** BLM lands typically occur as somewhat discrete blocks of land with isolated parcels of varying sizes, and varying access constraints, around them. It seems to me that an important and legitimate planning

concern relates to the size and access of the individual parcel. For example, should there be any active management of small parcels or of parcels with no public access; and if so, what kinds of management and why?

**Response:** Specific management activities on site-specific parcels are determined in implementation decisions outside the RMP process. Such decisions regularly consider issues such as those raised by the comment in the context of any proposed management for a particular area. After finalization of the RMP, the RMP will be used as guidance on prioritizing types of work and geographic areas for such project level planning.

**P7**

**Comment:** Many of the differences between the current alternatives rest with how much of what kind of management activity is planned to occur. Presumably your budget requests then seek to fund the adopted levels of activity. But if and more likely when your appropriations are too low to completely fund the plan, what then? Where I'm going with this is the idea that your alternatives should talk about priorities - when faced with limited funding, which activities and which specific areas should be funded.

**Response:** RMP decisions will be implemented based on budget and workforce availability in the future. Future BLM budget requests will be based on decisions made with the RMP. For some resource areas, such as vegetation management, Chapter 2 of the Proposed RMP/Final EIS discusses priority vegetation types, geographic locations, and acreages for treatments (Table 2-23). The Travel Management and Access section of Chapter 2 describes priorities for implementing travel plans. Special Recreation Management Areas in the Recreation section of Chapter 2 identify priority areas where recreation funding would be applied.

**P8**

**Comment:** Ward Ranch: This property needs its own in-depth management plan. What's going to happen with the residence? What values & uses should be emphasized? (Historic, recreation, scenic, ecological restoration) I'm not sure myself; but I am sure it needs and deserves more attention than it can get in this RMP.

**Response:** Management issues raised by this comment are implementation decisions that will need to be made in activity plans after finalization of the RMP.

**P9**

**Comment:** The process used puts the average working class citizen at a great disadvantage. The process is inordinately confusing, cumbersome, and intimidating to the members of the public who are not organized or experienced which is the majority of the public. A 300+ page draft environmental document is too much for the general public to understand and participate in. Coupled

with the current number of other ongoing actions the situation is overwhelming. The size of the environmental document is being used as a mechanism to overwhelm the public and allow the agency to effectively ignore the needs of the public for motorized access and motorized recreation. Council on Environmental Quality regulations for the proper implementation of NEPA can be found at [ceq.eh.doe.gov/nepa/regs/ceq/toc\\_ceq.htm](http://ceq.eh.doe.gov/nepa/regs/ceq/toc_ceq.htm). Sec. 1502.7 Page limits. The text of final environmental impact statements (e.g., paragraphs (d) through (g) of Sec. 1502.10) shall normally be less than 150 pages and for proposals of unusual scope or complexity shall normally be less than 300 pages. The agency is ignoring the page limit guidance and the documents produced are way beyond what the public can process.

**Response:** The rigors of producing credible and defensible NEPA documents has increased in recent years such that document lengths have increased to adequately address all issues. For the Butte RMP, efforts to make the process as user-friendly as possible for the public have included RMP and travel plan-specific public scoping meetings with comment forms available to provide written comments; a website for the Butte RMP; readily available contact information for the BLM project manager to allow the public to have personal contact if desired; six public meetings during the comment period for the Draft RMP/EIS; a 30-day extension of the original 90-day public comment period on the Draft RMP/EIS; and opportunities for the public to comment via email, hard copy letters, or fax. The length of the Proposed RMP/EIS is longer than 300 pages due to the fact that in addition to the RMP/EIS for the Butte Field Office, the document also includes the equivalent contents of five separate Environmental Assessments to address site-specific travel planning for five areas.

#### P10

**Comment:** Positive impacts to the environment in areas such as fisheries, wildlife habitat, sediment reduction, and noxious weeds are largely based on personal judgment or predictive models. These models are not calibrated or based on data from the study area. All models are wrong, so honest modelers first report the expected uncertainty of the model and then the predictions. There are no case histories and very little data to back up any of the predictions.

**Response:** Other than the SIMPLLE (Simulative Landscape Patterns and Processes at Landscape Scales) model used to provide general guidance on vegetation management proposals, no predictive models were used in the development or prediction of environmental consequences associated with the Butte RMP.

#### P11

**Comment:** Impacts should be evaluated in a fair and unbiased manner and with a relative sense of magnitude. Natural conditions should be used as the benchmark for

the test of impacts on natural resources. For example, if natural events including floods, wildfires, and their associated impacts are natural and acceptable as stated by some agency personnel and environmental groups, then (in order to be consistent and equitable) impacts from OHV recreation should be compared in relative magnitude to the impacts associated with floods, wildfire, and other natural events.

**Response:** The locations, severities, and magnitudes of impacts from natural events such as floods or wildland fires are not highly predictable and therefore often cannot be accurately depicted. This makes it impossible to credibly describe site-specific impacts from OHV recreation in the context of natural events. Generalized effects of natural events are discussed in the Cumulative Effects sections for each resource in the Environmental Consequences of Five Site-Specific Travel Plans section of Chapter 4 (Volume II of the RMP). In addition, the BLM cannot control effects of natural events. BLM can control effects of human activities and indeed assessing the effects of human activities is the essence of analyzing effects of the BLM's proposed management activities. Relative contributions of human activities to resource impacts can be more credibly described. Introductory information included at the beginning of Chapter 4 in the RMP provides the framework and describes the approach and assumptions used in this planning process to disclose impacts.

#### P12

**Comment:** Presently, very few agency staff members are OHV enthusiasts and can represent OHV recreation interests in day-to-day operations and long-term management decisions. OHV enthusiasts understand how to educate, manage, and meet the needs of OHV recreationists. Agency personnel are not able to relate to the needs and challenges of OHV recreationists because they are not familiar with OHVs nor are they typically OHV recreationists. There is an inherent bias on management teams that do not include OHV enthusiasts. We request that the staff on each project team include an adequate number of OHV enthusiasts in order to adequately represent and address the needs of OHV recreationists. The test for an adequate number of OHV enthusiasts on a team should be based on the percentages of visitors. Information from NVUM, USDA, and CTVA cited earlier document that OHV recreationists represent from 25 to 60 percent of the visitors and the management team should also reflect these percentages.

**Response:** There are no requirements for BLM planning teams to be made up of certain percentages of enthusiasts of any particular interest. Planning teams include a wide range of professionals with training and experience to address their appropriately assigned areas of specialty, including OHV recreation.

**P13**

**Comment:** In the past many of the impacts associated with motorized recreation were based on opinions about the impacts on wildlife. The courts have clearly established the prevailing standard for evaluating scientific evidence in *Daubert vs. Merrell Dow Pharmaceuticals Inc.* (DAUBERT v. MERRELL DOW PHARMACEUTICALS, INC., 509 U.S. 579 (1993)) ([http://caselaw.lp.findlaw.com/scripts/printer\\_friendly.pl?page=us/509/579.html](http://caselaw.lp.findlaw.com/scripts/printer_friendly.pl?page=us/509/579.html)), in which the U.S. Supreme Court ruled that expert testimony must be based on a testable theory or method that has passed peer review, has a known error rate and has reliable results. Peer reviewed reports and recommendations are mandatory in order to protect the public from personal opinion. We request that an adequate peer review plan and process be used for all impact analyses.

**Response:** Many impacts on wildlife described in the Proposed RMP/Final EIS are based on cited, peer-reviewed scientific literature. After being drafted by the interdisciplinary team, the document (including its impact analyses) has been reviewed by BLM specialists in the Montana State Office as well as the Washington Office prior to finalization.

**P14**

**Comment:** Scientists may come from within federal or state agencies, or the general public, and may hold a variety of important and influential positions. The study team should:

- 1) Require minimum standards and criteria for qualifications which must be met before a scientist can be deemed an "expert";
- 2) Provide minimum standards and criteria for determining when a scientist may be deemed "independent"; and
- 3) Provide a minimum amount of public notice and opportunity to object whenever any such scientist is considered for such participation, whether such position is permanent or temporary, full time, or part time, voluntary or compensated. Such notice should include the qualifications of the individual, the role which the individual will have in such participation, and the type and duration of the position. Review and participation by independent scientists is a good thing, provided the process require standards which assure that such scientists are in fact qualified and independent, and provide the public the opportunity to review such factors.

Independent scientists should review and participate in all aspects of planning, broad-based assessments, local analysis, and monitoring.

**Response:** Chapter 5 of the Proposed RMP/Final EIS includes the list of preparers along with their educational qualifications and areas of responsibility for the Butte

RMP. While the planning process includes several opportunities for public involvement (scoping, alternative development, and comments on a draft document) it does not provide for public notice and review of hiring staff positions within the agency. Although the BLM used an independent contractor to assist with preparation of the Butte RMP, there is no requirement for independent scientists to participate in the RMP revision process.

**P15**

**Comment:** Decisions should be based on:

- (1) accurate and unbiased information,
- (2) fairness to all members of the public and their needs,
- (3) the principles of sharing and tolerance, and
- (4) an equitable distribution of benefits to all interests.

**Response:** The BLM considers these factors in the context of its multiple-use mission to provide for the needs of people to use resources, in concert with the need to provide for and protect resources.

**P16**

**Comment:** Collaborative sessions or other types of negotiations often result in undue benefits for environmental groups because they have manipulated the process. The decision-making process should be solidly founded on the principles of unbiased information and public need.

**Response:** Due to the often inherent conflict between public members with differing viewpoints related to resource management, the BLM does value consensus-based recommendations from collaborative working groups made up of a balanced mix of resource user types. The BLM does not believe that consensus-based recommendations derived from such collaborative working groups favor one interest over another, or that environmental groups have manipulated the process associated with the Butte RMP.

**P17**

**Comment:** The current precedent is that legal actions and appeals are the most effective way to influence decisions on how public land is to be managed. Unfortunately, the true public need for management of public lands for multiple-uses is not adequately defended because agencies are so focused on countering the massive legal attack by environmental groups.

**Response:** Legal actions and appeals associated with BLM NEPA documents arise from a wide range of sources. The BLM does its best to stay focused on its multiple-use mission as these processes proceed.

**P18**

**Comment:** Agencies are encouraged to seek outside review and input by OHV recreationists on all proposed management decisions affecting motorized recreation opportunities including closures. Agencies are encouraged to establish greater credibility with motorized recreationists by having motorized recreation planners on the interdisciplinary team and a board of motorized recreationists.

**Response:** OHV recreationists have the same opportunities as everyone else in the general public to participate in and provide input on any proposed management decisions made by the BLM. The BLM does include recreation planners to address motorized recreation on its interdisciplinary teams. While the BLM has sought the assistance of county-sponsored community-based working groups (which included motorized recreation advocates) to provide input on travel plan alternatives for the Butte RMP, the BLM cannot include a board of motorized recreationists on interdisciplinary teams because this would be a violation of the Federal Advisory Committee Act.

**P19**

**Comment:** I do not believe that the preferred alternative identified (B) is in keeping with the concept of multiple use and does not address the need to provide dispersed use of the “Public Lands” which should ultimately help reduce the environmental impact on any one location. If the BLM finds it absolutely necessary to reduce the number of roads in these travel plan areas, implementing Alternative D in each area would provide a realistic gauge as to whether or not more restrictive measures are actually necessary. This approach combined with increased educational programs could actually provide desired results without significantly reducing access to the areas in question.

**Response:** The BLM does believe that Alternative B provides for multiple use of the wide range of resources in the Butte Field Office. Maximizing dispersion of human activity does not necessarily reduce environmental impacts for all resources. For example, maximizing dispersion of human activity would tend to maximize impacts to wildlife species that are prone to abandoning their habitats when disturbed by human activity. Alternative B has been modified in the Proposed RMP/Final EIS for some travel planning areas to increase motorized access based on specific comments provided by the public.

**P20**

**Comment:** A major concern with your proposed alternatives is the lack of an alternative that maintains or increases recreational opportunities for motorized and/or mechanized recreationists. In one breath you recognize the increased use of motorized recreation but in your

alternatives you only show a “major” reduction in recreational opportunities for the majority of recreationists. The alternatives brought forward in this RMP lack any fairness or provide proof that your agency is actually devising a plan that meets the needs of the public that actually use this public land.

**Response:** Alternative A maintains current motorized use for all travel planning areas considered in the RMP. The BLM believes the alternatives presented meet the needs of the public in the context of multiple use management. It is not the BLM’s mission to solely meet the needs of any particular interest or land use preference in the public. Multiple use entails balancing the needs of resource uses along with the needs for resource protection.

**P21**

**Comment:** Many motorized recreationists, who traditionally recreate on public land, may not participate in a formal NEPA process. The process is both time consuming and confusing. Multiple-use interests often times struggle to provide active participants due to many other time commitments. At the same time, non-motorized groups, well funded by foundations, have organized, trained, and experienced paid staffers that are readily available to participate in the NEPA process and collaborative sessions. These groups are able to participate on a wide front of actions from travel management to timber sales to non-motorized designations.

The magnitude of foundation funding available to non-motorized groups tends to amplify their limited-use interests in comparison to the needs of the public. This setting often results in non-motorized interests getting undue benefits by creating and manipulating the process. This setting is not based on the principles of addressing public need and technical merit. We ask that the effectiveness and impact of foundation-funded organizations versus the needs of all citizens be evaluated and factored into the planning process.

**Response:** The BLM provided the same opportunities to everyone in the public to participate and comment during the Butte RMP revision process. The BLM considered all comments received regardless of their source. An evaluation of the source of comments is not required by the NEPA or BLM planning regulations and guidance.

**P22**

**Comment:** We also recommend that direction regarding reduction of road/ transportation system effects on water quality/fisheries/wildlife be included in and/or repeated in the Travel Management section on the RMP, since we are concerned that the BLM staff responsible for managing and maintaining roads may not know, understand and/or follow the management direction in other resource sections of the RMP. Some redundancy in

the RMP may promote improved understanding and implementation of management direction.

**Response:** Final decisions will be described in the Record of Decision which will be accompanied by an Approved Plan. This document will be release following publication of the Proposed RMP/Final EIS and will be the one that BLM employees will regularly use as the RMP. Specific considerations on how to structure the approved RMP will be made in the future.

### P23

**Comment:** Management direction in the draft Butte RMP in general appears to be less prescriptive than many land management plans we review. Management alternatives include general management goals and desired future conditions and guidance for managing land use, travel, recreation, vegetation, grazing, oil and gas leases, etc. However, there appear to be only a few Standards with more binding limitations on land management. The only more binding Standards that we saw were in the Standards for Rangeland Health in Appendix E, along with the oil and gas lease stipulations (Appendix L).

We believe management direction would be more protective of the environment and ecosystems within the BFO Planning and Decision Areas if additional more binding and protective direction were included. We recommend that the BLM consider development of additional limitations on land uses and activities and more protective management direction to provide increased levels of protection, restoration, and enhancement of the environment (see specific comments and recommendations in our subsequent comments).

**Response:** In some cases the BLM has modified proposed management to make it more specific in the Proposed RMP/Final EIS. Overall the BLM believes the level of specificity of proposed management provided in the RMP is appropriate to provide for appropriate levels of resource protection and site-specific project level flexibility to address the wide range of conditions that exist on Butte Field Office lands.

### P24

**Comment:** Nowhere in any of the documents did BLM mention coordination/cooperation with sportsmen's organizations, FWP biologists, youth organizations, and better involvement of BLM with the public including field trips to examine our public land.

**Response:** Chapter 1 describes public scoping efforts including six public scoping meetings, six additional public scoping meetings specifically for site-specific travel planning, two additional public scoping meetings associated with the extended scoping for the Proposed Planning Scenario, and ten briefings provided to organizations and county commissions after solicitation by the BLM. Chapter 5 describes solicitation of various state

and federal agencies, tribal governments, local governments, and the governor's office as cooperating agencies for the Butte RMP. The BLM attempted to specifically engage biologists from Montana Fish, Wildlife, and Parks (MFWP) by specifically soliciting that agency to become a cooperating agency on the Butte RMP. MFWP never chose to become a cooperating agency but informal contact and coordination between the BLM planning team and MFWP biologists occurred throughout the process of preparing the Draft RMP/EIS. With the release of the Draft RMP/EIS, BLM advertised and provided six public open houses that featured presentations on key contents of the RMP and information on how the public could provide input. Also upon release of the Draft RMP/EIS, organized groups were invited via newspaper articles from press releases to have the BLM provide them specific briefings on the Draft RMP/EIS. No organizations responded to the BLM's invitation during the public comment period for the Draft RMP/EIS.

### P25

**Comment:** The environmental document should evaluate how the number of policy proposals over the past several years has overwhelmed the public. There is no way that the public could evaluate and comment on each proposed action. The cumulative negative impact of the overwhelming number of proposals has been decision-making that does not provide for the needs of the public and a significant reduction in multiple-use and motorized access and recreation opportunities. We request that this cumulative negative impact be adequately evaluated and factored into the decision-making for this action. Additionally, we request that an adequate mitigation plan be included as part of this action to compensate for past cumulative negative impacts on the public associated with the overwhelming number of NEPA actions.

**Response:** Evaluation of the impact that the number of policies established over the past several years or the number of different management proposals has had on the ability of the public to respond is beyond the scope of the Butte RMP. There is no requirement for the BLM to evaluate this. However, the public comment period for the Butte RMP was extended from 90 to 120 days, providing the public more time than usual to comment on the management proposed in the Draft RMP/EIS. The BLM believes this is adequate time for the public to comment.

### P26

**Comment:** We are very concerned that motorized recreationists must identify and inventory specific routes that we want to remain open. These resources are there now and they are being used by the public and in almost all cases, it is entirely reasonable type and level of use. Motorized recreationists should not have to identify and inventory motorized routes as part of the process. This is

the work of the agency. No other visitor group is saddled with this requirement. Our concern is that the agency is using public involvement in a discriminatory way to establish which motorized routes will remain open.

**Response:** In developing travel plan alternatives for the Butte RMP, BLM personnel did inventory motorized routes and develop the baseline for each of the five travel plan areas analyzed (as depicted on travel plan area maps in the RMP). The BLM did not ask nor request the motorized recreation community to conduct a road and trail inventory for the project area. The BLM conducted this work on its own, using a combination of professional knowledge, GPS data, and aerial and digital photography interpretation. Prior to the Butte RMP revision, there was no inventory of motorized routes in these areas. Throughout the scoping process and public comment period on the Draft RMP/EIS, the public was welcome to provide input on specific routes not included in BLM's inventory presented, or to provide input on travel route-specific management of routes in the BLM inventory. As a result of public feedback, the BLM was able to correct several minor errors and provide better maps.

**P27**

**Comment:** We have also observed from past NEPA travel management processes that the lack of participation by motorized recreationists has been due to the cumulative effect of confusing and poor documentation of the proposals, which included maps that did not have clearly defined characteristics, landmarks, trails, roads, routes and historical sites that would be removed from communal use by the proposed closure action. We are concerned that this lack of understanding will lead to resentment and poor support of motorized closures by the community. We request that the travel management process seek out and document the needs of all motorized visitors including those who traditionally use the primitive roads and trails, plus the handicapped, elderly, and physically impaired as required under 40 CFR 1506.6.

**Response:** For the Draft RMP/EIS, travel plan alternative maps were provided in two contexts within the Butte RMP in effort to address concerns associated with potentially confusing maps. Hard copy maps were provided to give the opportunity to look at a physical map of the travel plan alternatives. The supplementary CD contained PDF files of more detailed maps with landmarks and route numbers to provide the public opportunities for more detailed viewing and comment on travel plan alternatives. The BLM believes it has conscientiously followed 40 CFR 1506.6 in providing public outreach and soliciting public input on the Butte RMP through various means including public scoping meetings for the RMP, scoping meetings specifically for travel planning, extended public scoping for the Proposed Planning Scenario, and an extended public comment period on the Draft RMP/EIS. In addition, the

Butte RMP website provided opportunities for the public to stay informed and to contact the BLM to provide input.

**P28**

**Comment:** We request that the process adequately meet public involvement requirements with respect to motorized visitors. The process should include methods of public involvement that effectively reach motorized visitors and methods to account for the needs of citizens who may not participate for diverse reasons. Some public involvement methods that would be effective include; (1) the use of trail rangers (who are motorized enthusiasts) to count and interview visitors using the travelways and distribute Travel Management materials to them, (2) publication in the newsletters of motorized association, (3) attendance at motorized club meetings, (4) posting of information packets at motorized trail head areas, and (5) mailing to OHV enthusiasts and owners.

**Response:** All members of the public were provided the same opportunities to participate in the Butte RMP revision through scoping efforts described in Chapters 1 and 5.

**P29**

**Comment:** Clearly, comments under NEPA were intended to bring issues and concerns to the attention of the team preparing the environmental document and the decision-makers. NEPA did not suggest that comments were to be used as a voting process to indicate support of alternatives. Nor did NEPA anticipate that the scoping and citizen input would be dominated by well-funded special interest groups. NEPA did not intend citizens to comment on every possible NEPA as a requirement to protect their interests, needs, and quality of life. This misuse of the comment process has resulted in agencies overlooking the needs of all citizens and decisions have been made that do not adequately address the needs of the public.

NEPA requires decision-making that adequately addresses the needs of all members of the public. This direction was stated in Title 1, Sec. 101 of NEPA Policy Act of 1969 as "achieve a balance between population and resource use which will permit high standards of living and a wide sharing of life's amenities..." Under NEPA, decision-makers have a responsibility to seek out, determine, and make decisions that address the needs of all citizens and not just those that submit comments.

**Response:** The BLM agrees that comments are intended to bring up substantive issues and concerns (regardless of the source and its funding levels) and that the comment process is not a "voting" process. The BLM does not misuse the comment process as a "voting" process. Inherent in the NEPA process however is the

reality that in order to address specific concerns in specific areas, citizens need to comment on proposed activities there. The BLM believes it has met the cited direction from Title 1, Sec. 101 of NEPA. The BLM notes that this section also includes direction other than that cited by the commenter and the BLM believes that its responsibility is to meet all aspects of this section, and that no one item within this section is intended to take precedence over any other.

### P30

**Comment:** The NEPA process is complicated and unapproachable to most of the public yet there has never been a program to inform, educate, and increase the public's awareness and ability to work with the NEPA process. The lack of widespread information, education, awareness, and NEPA skills has contributed to extremely low participation in the NEPA process by some sectors of the public. Public participation for even the most controversial proposed action (roadless rule) has involved less than 1 percent of the affected public. Additionally, the general lack of understanding of the NEPA process has resulted in poor acceptance and opinions of the process by the public.

**Response:** Throughout the Butte RMP revision process, the BLM has attempted to guide the public on how to provide meaningful input to the NEPA process. Chapter 1 of the RMP describes public scoping efforts including six public scoping meetings, six additional public scoping meetings specifically for site-specific travel planning, two additional public scoping meetings associated with the extended scoping for the Proposed Planning Scenario, and ten briefings provided to organizations and county commissions after solicitation by the BLM. With the release of the Draft RMP/EIS, BLM advertised and provided six public open houses that featured presentations on key contents of the RMP and information on the public could provide input. In each case of these public involvement opportunities, BLM personnel provided information on how to provide substantive input on the RMP.

### P31

**Comment:** We have been told that motorized recreationists must participate in the travel management process and/or collaborative sessions in order to realize future motorized recreational opportunities. While we agree that motorized recreationists have the opportunity to participate in the NEPA process, the level and effectiveness of participation should not be the deciding factor when making decisions about who gets what recreational opportunities within public lands. NEPA does not identify the quality and quantity of individual and group participation as a decision-making criterion. The network of influence groups has a significant advantage over common citizens in areas including funding, staffing, training, and advertising through radio, television,

web sites, and newspapers. This setting allows environmental groups to get undue benefits by manipulating the NEPA process. This setting does not address the principles of meeting public need. NEPA and other laws do not intend for independent individuals who are less organized to give up their life's amenities to better-organized and funded groups.

**Response:** The BLM cannot require or control the participation of any group or individual in its planning processes. The BLM agrees that the level and effectiveness of advocacy group participation is not the deciding factor when making decisions about resource management on BLM land. Any group or individual can participate in the process and consideration given to any input is based on the substantiality of the input regardless of the entity and its resources for getting its particular viewpoint heard. The BLM considers public comments based on the extent to which they are substantive and relate to inadequacies or inaccuracies in the analysis or methodologies used; identify new impacts or recommend reasonable new alternatives or mitigation measures; or involve substantive disagreements on interpretations of significance (BLM NEPA Handbook H-1790-1 (USDI-BLM 2008)). However, it should be noted that without participation, any group or organization's concerns or issues may simply not be identified and therefore not considered when making management decisions. Conversely, the redundant raising of issues or preferences does not ensure a particular RMP outcome or land use decision.

### P32

**Comment:** The establishment of recreational opportunities on public lands should be based on public need. Other government entities are directed to address and meet the needs of the public. For example, cities provide water and sewer systems based on public need. Highways are constructed based on public need. The need for these facilities is not based on the level of citizen involvement. The need for these facilities is based on an assessment of need developed by water and sewer usage, traffic counts, etc. The public has a basic expectation that agencies will look out for all of their interests and the best interests of the public are met when agencies respond to the needs of the public in this manner. If members of the public did not comment on the upgrade of a water treatment plant or the construction of a highway does not mean that their water is shut off or that they can't drive to Bozeman. We request that the use of public participation in decision-making for this proposed action be monitored to assure that it does not obscure the needs of all citizens who rely on the project area for their recreation and livelihoods.

**Response:** Chapter 5 of the Proposed RMP/Final EIS documents the consultation and coordination processes used for public participation. The BLM believes it has conscientiously considered public input received on the

Butte RMP. Due to the inherent nature of conflicting input from different members of the public, RMP decisions cannot possibly reflect all management suggestions received from all members of the public.

**P33**

**Comment:** Both sides would be further down the trail towards measurable protection of the human and natural environment if multiple-use, motorized access and motorized recreation were accepted at a reasonable level and we all focused our energy on visitor education, site-specific problems and site specific mitigation measures. Consensus and collaborative processes cannot by nature produce reasonable results and motorized recreationists should not be forced into these processes where they are guaranteed to lose.

**Response:** The BLM believes that the Butte RMP contains alternatives that provide reasonable levels of motorized access. Educational activities and mitigation projects are implemented at the site scale after RMP and travel plan decisions are made. The BLM does not force any entity into participating in any collaborative processes. However, the BLM does value consensus-based recommendations from collaborative working groups made up of public members that represent a balanced mix of perspectives on resource management issues.

**P34**

**Comment:** While collaborative agreement on a travel management plan between two opposing interests is a desirable solution from an Agency's perspective, the reality of the current setting is that collaborative sessions have failed because a reasonable allocation of recreational opportunities that would meet the needs of all citizens never stays on the table. The lack of a reasonable multiple-use alternative combined with the significant cumulative negative effects that motorized recreationists have experienced (loss of over 50 percent of motorized recreational opportunities during the past 35 ± years) precludes motorized recreationists from accepting any additional unbalanced proposals coming out of collaborative sessions. The collaborative approach must produce reasonable multiple-use alternatives for all (100 percent) of the remaining lands intended for multiple-use.

**Response:** The intent of establishing collaborative working groups, such as those used to assist in development of travel plan alternatives for the Butte RMP, is to identify solutions that best strike a balance for the wide range of perspectives that exist throughout the public on how best to manage multiple-use lands. The makeup of the working groups used for site-specific travel planning addressed with the Butte RMP was intentionally set to prevent one particular interest, such as motorized enthusiasts or non-motorized enthusiasts, from dominating the

process and biasing working group recommendations with their own agendas.

**P35**

**Comment:** CBU did not find that your agency engaged the local government in developing the Butte RMP. Federal law does require the BLM to coordinate and cooperate with state and local governments.

**Response:** Chapter 5 of the Butte RMP describes coordination efforts undertaken by the BLM. For the Butte RMP the BLM offered and provided multiple briefings to county commissions within the Planning Area. For the extended scoping associated with the Proposed Planning Scenario, five of the eight county commissions received briefings on initial management proposals (the other three county commissions did not respond to solicitations for briefings). During the public comment period for the Draft RMP/EIS, all eight county commissions received briefings by the BLM. State agencies as well as local governments were solicited for interest in becoming cooperating agencies for the Butte RMP. None of these entities signed on as cooperators.

**P36**

**Comment:** The cover letter for the RMP invites readers to review and comment on the Draft RMP/EIS. It goes on to say that comments will be most helpful if they are specific and address one or more of four criteria. I can see where this is helpful but in my quick review of the travel plans I could not find where the Draft RMP/EIS gives the same specific reason or information for each of the roads that are slated for closure.

**Response:** The direction provided in the cover letter to the Draft RMP/EIS on how best to provide public comments applied to any and all public comments anyone may have wanted to provide on proposed management in the RMP or the site-specific travel plans. The direction was not intended for a particular interest within the public on a particular issue.

**P37**

**Comment:** Maps 26-30 are too large of scale to allow for any meaningful comments.

**Response:** The BLM apologizes for any difficulty encountered while reviewing maps. The dispersed distribution of BLM lands addressed by the Butte RMP made it difficult to select a more user friendly map scale without driving up document printing costs to prohibitive levels. However, all maps were made available in PDF format at BLM's Butte RMP website where reviewers could zoom in on areas of interest.

**P38**

**Comment:** It also would benefit the reader if detailed analytical information could be presented in tables sup-

plemented by a more limited discussion of that information.

**Response:** The Butte RMP employs a combination of tabular display of analytical data as related to various resources and resource uses, in concert with discussion of data presented. Efforts were made to limit discussion of data presented to the extent practicable. The complex nature of proposed RMP management and associated environmental effects require extensive discussion of effects in some cases.

### P39

**Comment:** It would be very helpful if you provided a "table of comparisons" of the amount of Dry Forest treatment per decade of the four alternatives. These forest management activities are major to the health of the forest and a visual presentation of these data would be very helpful.

**Response:** Table 2-23 in Chapter 2 lists ranges of proposed treatment acres by alternative for all major vegetation types, by major watershed, by RMP alternative.

### P40

**Comment:** Who wrote the plan and what are their qualifications?

**Response:** Chapter 5 lists the preparers, their educational backgrounds, years of professional experience, and areas of responsibility in working on the Butte RMP.

### P41

**Comment:** The really meaningful stuff, which I call the 'science', mostly ends up so buried that it's inaccessible to the public (and to decision makers??) So I'd suggest the following: have the section on 'environmental consequences' explain the science behind the various possible and proposed management activities, with no reference to the various alternatives, and organized by management activity rather than by impacted resource. (This seems to me to be the critical decision framework - whether or not to do something proactive, and if so, what & how. That requires comparing the effects, across all resources, of your options (e.g., to burn, to cut, or to leave alone); so organize the discussion by those options.) Then have sections devoted to each planning area that explore the impacts of the various alternatives on them.

**Response:** While the BLM generally followed the format for the environmental consequences section (Chapter 4) outlined in Appendix C of the BLM Land Use Planning Handbook (H-1610-1), careful consideration was given on how Chapter 4 was structured as related to addressing effects of proposed RMP management versus effects of site-specific travel plan alternatives. In effect, this structure led to the portion of Chapter 4 contained in

Volume I of the RMP describing effects of RMP level decisions. The portion of Chapter 4 in Volume II describes effects associated with site-specific travel planning alternatives, organized by each of the five travel planning areas. This structure was followed so as to allow interested members of the public who might be solely interested in one (or more) specific travel planning area to turn to the section for that travel planning area and see all the environmental consequences described in one location for that area.

### P42

**Comment:** It would be very useful to include a map in the document that shows the location of the various planning areas and sub areas, and the names you use for them. (E.g., it's not obvious to me that "Lewis & Clark County NW" means the Marysville area, nor that McMaster Ranch North means the ground east of Spokane Bay.)

**Response:** Within the Travel Management and Access section of Chapter 2, under the subheading Activity Level Planning for Five High Priority Travel Planning Areas, there is a further subheading for each travel planning area (Helena TPA, East Helena TPA, Lewis and Clark County NW TPA, Boulder/Jefferson City TPA, and Upper Big Hole River TPA). Introductory text for each of these travel planning areas describes which hard copy maps in the document correspond to which sub-areas (by sub-area name) on the electronic maps for each travel planning area.

### P43

**Comment:** First, a couple of 'typos': p. 271, the bird list is riddled with repetition, and p. 295, Table 3-30, the data on acres recommended for Wilderness are wrong.

**Response:** In the Proposed RMP/Final EIS, text has been modified to address repetition of bird species names in the areas in question. The acreages reported as being recommended for wilderness vary slightly from acreages used in past documents because during the RMP process GIS calculations were used to characterize these acreages. The BLM believes that the GIS-calculated acreages are more accurate than the original acreages identified for the Wilderness Study Areas being recommended for wilderness designation.

### P44

**Comment:** Site-specific analysis should be provided for every road and trail so that the benefits of keeping each motorized travel way is adequately addressed and accounted for in the decision. Site-specific questions will need to be discussed during the process. We request that the mapping be sufficient to allow site-specific analysis.

**Response:** The process described in **Appendix A** was followed on a route-specific basis to develop travel plan alternatives for each of the five travel planning areas

analyzed in the RMP. Records of how specific routes rated out for various resources and resource uses are part of the administrative record for the Butte RMP. Electronic maps provided in PDF format on the supplementary CD in the RMP provide route numbers and landmarks to allow for site-specific analysis.

**P45**

**Comment:** The Draft EIS and the maps are not user friendly. None of the proposed route changes have any route designation applied to them. They need better identification in order to comment on specific routes and areas. It is very difficult for the public to orient themselves and to interpret the proposed action for each specific road and trail. Therefore, the public cannot adequately evaluate the proposal and cannot develop comments with reference to specific roads and trails.

**Response:** Maps for travel plan alternatives are provided in two formats in the RMP. Hard copy maps are designed to provide the reader with a “big picture” view of each travel plan alternative. These maps lack route numbers out of necessity because they would be virtually unreadable if route numbers were applied. Travel plan maps in PDF files on the supplementary CD provide a finer scale look for each travel plan area, including more site-specific landmarks than are found on the hard copy maps, as well as route numbers used by the BLM during travel planning efforts. The BLM received a number of route-specific comments from the public during the public comment period.

**P46**

**Comment:** The draft has some serious shortcomings and some blatant misprints, for example, what is a “peregrine hawk”?

**Response:** Text has been modified in the Proposed RMP/Final EIS to address this editorial mistake.

**P47**

**Comment:** Page 146 - Table 2-23 under the heading "Management Concerns: Minerals - Locatable Minerals" and the sub-heading "Management Common to All Alternatives" the last bullet point contains the statement "the Elkhorn Mountains ACEC would not be proposed as a withdrawal under any alternative." This statement appears to be inconsistent with the text that immediately follows regarding the same subject but with the additional heading "withdrawals."

**Response:** While the statement in question in Table 2-23 was intended to express that the Elkhorns ACEC on the whole would not be proposed for a mineral withdrawal under any alternative, this statement is confusing because approximately 180 acres within the Elkhorns ACEC (Muskrat Creek) was proposed for withdrawal under Alternatives B and C in the Draft RMP/EIS. In the Proposed RMP/Final EIS, this proposed 180-acre with-

drawal has been eliminated from the Preferred Alternative. Appropriate adjustment to RMP text and Table 2-23 have been made to reflect this change and eliminate confusion about the point made by the comment.

**P48**

**Comment:** Areas that have historically provided OHV opportunities are now proposed for non motorized use. The Scratch Gravel Hills offers opportunities in close proximity to Helena. The map of Alternative B shows the trails closed yearlong while page 62 text states the "entire Scratchgravel Hills area would be closed to motorized vehicle use after dark year long". We recognize the maps state "intended for display purposes" but the general public will obtain most of their information from the maps provided.

Page 52, table 2-9 shows wheeled motorized routes open: 13.6 miles, with 38.6 miles of non-motorized trails. The conflict between the statements and the map should be addressed.

**Response:** The Preferred Alternative for the Scratch-gravel Hills portion of the Helena Travel Planning Area has been changed from the Draft RMP/EIS to the Proposed RMP/Final EIS. The revised Preferred Alternative would close the Scratchgravel Hills to wheeled public motorized use yearlong, 24 hours/day, with the exception of several routes with rights-of-way to homeowners as well as a few other known routes needed by local residents to access their homes. This closure would negate the need for a nighttime closure and should eliminate the confusion expressed by the comment.

**P49**

**Comment:** The areas with current travel plans are described as "limited" (page 268) is misleading. With the exception of the Whitetail-Pipestone that actually provides trail opportunities for the OHV community, the other limited areas would be described as extremely limited.

**Response:** In the context used, the term “limited” means designated areas or trails where the use of off-road vehicles is subject to restrictions, such as limiting the number or types of vehicles allowed, dates and times of use (seasonal restrictions), limiting use to existing roads and trails, or limiting use to designated roads and trails.

**P50**

**Comment:** Omission: Description of Issue 2 in Table 1-5 as well as language about how Issue 2 will be addressed. Earlier text indicates that Issue 2 addresses Wildlife, Wildlife Habitat, Special Status and Priority Plant and Animal Species. This heading should have been written down in Table 1-5.

**Response:** This was a printing error that occurred after the BLM sent the document out for printing. The BLM

has attempted to ensure this error was not repeated in the Proposed RMP/Final EIS.

#### P51

**Comment:** Maps did not have adequate reference such as corner section numbers, which made it difficult to analyze information.

**Response:** The BLM acknowledges the lack of features on RMP maps. Maps were intended to convey various specific information and in their development the BLM was concerned about packing too much information on any given map. In the case of site-specific travel plan maps, more detailed mapping of travel plan alternatives is provided in PDF format on the CD enclosed with Proposed RMP/Final EIS. Township and Range lines have been provided on maps in the Proposed RMP/Final EIS.

#### P52

**Comment:** Recreation Opportunity Spectrum: All the tables in this section (p. 63) indicate that there are 302,000 acres being considered within the RMP. However, Appendix H indicates that 311,000 acres exist within the planning area with respect to surface lands (and 656,000 acres of federal mineral estate). This leaves 9,000 acres unaccounted and will likely lead to misunderstanding. This is an area equal to 14 square miles and should be properly allocated within all tables in the RMP.

**Response:** Due to land ownership changes between the Draft RMP/EIS and Proposed RMP/Final EIS, the surface acreage managed by the Butte Field Office is now approximately 308,000 acres while total area of federal mineral estate is approximately 654,000. These corrections have been made where needed throughout the Proposed RMP/Final EIS.

#### P53

**Comment:** Page ii. TOC is incorrect in designating Appendices H and I.

**Response:** This has been corrected in the Proposed RMP/Final EIS.

#### P54

**Comment:** Page S-11 and supporting locations in document; the management of the Elkhorn Tack-on as an ACEC if it is released from further review by congress as a wilderness area is inconsistent with Appendix H that does not included the Tack-on as an ACEC (See Figure 3 App H), only the original Elkhorn WSA. The continued management as an ACEC statements needs to be removed.

Maps 33 and 34 (p 69 & 73) have ACEC boundaries in the Elkhorns (specifically the Elk Horn Tack-on in Golconda Gulch) inconsistent with Appendix H. The Maps

need to be revised to be consistent with the Figure 3 in 2006 study in Appendix H.

Page 79 Management Common to Action Alternatives (B, C and D); The management of the Elkhorn Tack-on as an ACEC if it is released from further review by congress as a wilderness area is inconsistent with Appendix H that does not include the Tack-on as an ACEC, only the original Elkhorn WSA. The continued management as an ACEC statements need to be removed.

**Response:** The Elkhorns Tack-on Wilderness Study Area (WSA) would be managed as ACEC as indicated on Figure 3 of **Appendix H** of the Draft RMP/EIS (now **Appendix I** of the Proposed RMP/Final EIS). In Figure 3 the potential Elkhorns ACEC is indicated by a cross-hatch pattern on lands potentially included. This figure does indicate inclusion of the Elkhorns Tack-on WSA in that cross-hatch pattern (and did so in the Draft RMP/EIS). Related maps and text referenced in the comment regarding this issue were all correct in the Draft RMP/EIS and have been carried forward into the Proposed RMP/Final EIS.

#### P55

**Comment:** We are concerned about ACEC designations. Manage all non-wilderness land as multiple use.

**Response:** FLPMA requires the BLM to examine its lands for consideration as Areas of Critical Environmental Concern (ACECs) during the land use planning process. Specific management of ACEC lands is described in the Proposed RMP/EIS and varies by ACEC to include a range of multiple uses with limitations applied in some cases.

#### P56

**Comment:** First, and very important, was the mandate to manage lands under the principles of Multiple Use. Second was the preservation of valid existing rights, including grazing rights, mining claims, oil and gas leases, water rights and rights of access. The third element was specific instructions to the Secretary of the Interior to formulate land use plans that are consistent with State and local plans. The fourth element of FLPMA consists of very specific instructions regarding Wilderness. We simply ask that all of the instructions and requirements of the law as agreed to under the Federal Land Policy and Management Act be honored and applied to this project.

**Response:** The BLM believes it is meeting the requirements of FLPMA in the development of the Butte RMP. Throughout the Butte RMP process the BLM has coordinated with state agencies, tribal governments, and local governments to get their input on proposed management. While there is no wilderness within Butte Field Office lands, the BLM is following appropriate procedures in maintaining current management of Wilderness Study Areas until congress makes decisions about them.

The RMP includes proposed “fall back” management of each Wilderness Study Area to be implemented in the event that congress releases them from wilderness consideration.

#### P57

**Comment:** Social issues: There are already huge blocks of the RMP area that are non-motorized, the plan does not have to take away all of the motorized trails. This goes against the objective of multiple use, on public lands.

**Response:** Of the approximately 308,000 acres of BLM lands in the Butte RMP Decision Area, approximately 31,500 acres would be closed to motorized use (10.2 percent), 283 acres (0.1 percent) would be open to on and off-road use, and approximately 276,217 acres (89.7 percent) would be open to motorized use on designated routes under all action alternatives in the Proposed RMP/EIS. None of the alternatives in the Proposed RMP/EIS propose closing all of the motorized routes.

## Recreation

#### Q1

**Comment:** Under Recreation Management Common to All Alternatives (page 60) it is stated that the BLM would solicit, train and support volunteers. Without analysis of the effectiveness of such activities in the plan, the reader is left to assume that volunteers and employees are interchangeable. Yet, organizations, including most, if not all, companies, typically do not rely on unpaid workers to provide service. Thus it is logical to presume that quality would suffer if the public were served by an unpaid BLM workforce, which runs contrary to Recreation Management Goal 2 (page 60). Either this is a discrepancy in information, or this plan should analyze why there is a need for volunteers and whether or not they would be as good as, or better than, BLM employees in enhancing Recreation.

**Response:** The BLM has a long standing volunteer program and encourages field offices to utilize volunteers to carry out numerous supportive tasks where appropriate. The intent of the volunteer program is to supplement the work of the existing professional staff not replace them. The primary use of volunteers in the Butte Field Office is for campground hosts. These volunteers are used to assist with visitor information, light maintenance, and use compliance. They are generally retired, experienced campers that enjoy interacting with visitors. Other uses for volunteers whether groups or individuals have been for small maintenance projects such as fencing, painting, picnic table assembly, trail maintenance, resource inventories and field monitoring.

#### Q2

**Comment:** Allowing travel up to 300 feet off of a designated route, both roads and trails, is an absolutely necessary opportunity for reasonable use of the area by the public. This access is needed for retrieval, woodcutting, and to reach dispersed campsites and the public’s use of the area would be unreasonably compromised without this access. The use of this access can be qualified to restrict it in situations where it results in unreasonable resource damage.

**Response:** The Butte Field Office followed the Record of Decision in the 2003 Statewide Off-Highway EIS/Plan Amendment for addressing motorized uses off existing routes. The decision of Statewide Amendment and this Proposed RMP is to only allow motorized wheeled travel up to 300 feet for the purpose of establishing dispersed campsites. Exceptions for firewood retrieval can be established by creating temporary area designations. Game retrieval can be accomplished with wheeled hand carts or by foot.

#### Q3

**Comment:** Dispersed campsites are very desirable camp sites. Closure of these sorts of dispersed campsites would have a very significant impact on the public and we request that they remain open. If water quality concerns are the basis for these closures, then there are reasonable alternatives to mitigate these concerns, such as allowing only self-contained camping units to use them. Additionally, a sense of magnitude needs to be applied when assessing the water quality impacts from camping. For example, it appears that cattle grazing along the stream have a much greater impact than any camp site that we observed. Now don’t get us wrong, we support all reasonable multiple-uses of the forest including cattle grazing. We are concerned that the incremental impacts on the public of closing dispersed camp sites are relatively significant while the real improvement to the environment will be relatively insignificant. Again, we request that all reasonable camp sites located along water courses remain open.

**Response:** The 300-foot rule provides numerous opportunities for establishing motorized accessible campsites off existing routes. The BLM strongly endorses the Leave No Trace principle of establishing dispersed campsites at least 200-feet from existing streams. However, except for within developed recreation sites and designated closed areas, all BLM land is open to dispersed camping.

#### Q4

**Comment:** If dispersed camp sites are to be closed based on water quality concerns, then we request that the decision include a water quality monitoring program to establish the baseline water quality prior to the closure of dispersed camp sites and continue that program after

the closure to establish whether any significant water quality improvement was realized. The decision should also include a provision to re-open closed camp sites when no significant improvement in water quality was realized by the closure.

**Response:** The BLM does not have funding or work-force available to monitor water quality changes associated specifically with closing dispersed campsites. The BLM notes that many variables contribute to water quality conditions within any particular water body and that in most cases the existing water quality is often a cumulative result of the effects from land uses and management in a watershed. Water quality monitoring in most cases would be providing information on water quality condition and trends in the context of these cumulative effects, rather than the effects of one particular action.

#### Q5

**Comment:** In general there is a very high demand for camp sites and especially dispersed camp sites. If a dispersed camp site is closed, then we request that the closure be mitigated by creation of new camp sites on at least a 1:1 basis in order to avoid a significant cumulative effect on the public of too few camp sites.

**Response:** This concern is compensated by the 300-foot provision that allows users the opportunity to drive off routes in order to establish suitable dispersed campsites.

#### Q6

**Comment:** Hiking, cross-country hiking and wilderness uses also cause trail impacts yet these impacts are seldom acknowledged. For example, the USDA FS Intermountain Research Station Research Paper INT-450 "Changes on Trails in the Selway-Bitterroot Wilderness, Montana, 1978-89" and dated 1991 found that many trail segments changed markedly, depending on site and use.

**Response:** The BLM agrees that non-motorized user trails do create impacts to other resource values. However, the magnitude of impacts is generally lower than motorized trails given the reduced width of the trail bed, amount of soil displaced or channeled, higher life expectancy of water bars, reduced gradients, and the lower overall maintenance costs. In addition, noise-related impacts from non-motorized users are generally lower.

#### Q7

**Comment:** Why are there so many double-standards in the impact analyses and decision-making? If the issues surrounding motorized travel are significant enough to justify closures, then, in order to avoid introducing a bias to the evaluation and process the same issues and restrictions should also be applied to hiking, mountain climbing, cross-country hiking, wilderness users, etc.

**Response:** A primary goal of resource management is to allocate uses that are compatible with landscape set-

tings, public demands, management capabilities and other important resource values and objectives. In some cases impacts associated with motorized travel pose greater resource concerns than non-motorized uses due to resource sensitivity levels such as vegetation, soil stability, water quality, wildlife security areas, riparian areas, route maintenance costs, and public safety.

#### Q8

**Comment:** The Recreation Opportunity Spectrum (ROS) for motorized recreationists should consist of an equivalent number, type and quality of opportunities as compared to non-motorized recreationists including access to backcountry recreation areas, long distance back country discovery routes, back country airstrips and destinations including historic areas, lakes, vistas, streams and rivers.

**Response:** Under the Preferred Alternative, 88 percent of the BLM land within the Butte Field Office is proposed for varying motorized opportunities that range from Semi-Primitive to Rural type settings. This is described in Chapter 2 of the RMP in the Recreation Opportunity Spectrum section for Alternative B.

#### Q9

**Comment:** Issue 4: The vision is to provide a range of quality recreation opportunities. Closures of access to several routes and areas, is not providing a good mixture of quality opportunities.

**Response:** With this RMP revision, intensive trail riding opportunities would be retained for the three primary OHV areas in the Butte Field Office and motorized access is provided to major attraction areas. In some areas route closures (seasonal and yearlong) are proposed to protect resource values; enhance non-motorized opportunities; provide habitat security so big-game populations are more likely to remain on public lands during the hunting season; reduce maintenance costs and improve safety considerations. Given the varying proposed designations/allocations in Recreation Opportunity Spectrum settings, Visual Resource Management classes, Special Recreation Management Areas, developed vs. undeveloped recreation sites, OHV travel areas, route availability and Special Designations, the BLM believes that a broad range of quality opportunities would be provided under the Butte RMP revision.

#### Q10

**Comment:** The directives separating different visitor use referring to "user conflict" is out of touch with reality. Education and a directive to set expectations for multiple uses on the trail systems should a goal. Fair, diverse, and equitable solutions should be a goal. Rather than perpetuate the "user conflict" that the organized quiet trails community has advertised for the past 15 years. Rather than dispel the "conflict" scenario with

workable solutions, the current land management mind set seems to adopt the concept of separating uses, in essence, using area closure as a management technique.

The statement made on page 469; the "overall effect of reducing opportunities available for motorized recreation" would be "The quality of the experience may increase because separating uses would reduce conflicts between user groups" is unacceptable. The documentation showing any increase in quality is totally lacking. Report FHWA-PD-94-031, Conflicts on Multiple-Use Trails, 1994 has many management suggestions. The focus of the document is "how to improve trail sharing by avoiding and resolving conflicts. Quoted from the Executive Summary: "Conflict in outdoor recreation settings (such as trails) can best be defined as "goal interference attributed to another's behavior" (Jacob and Schreyer 1980, 369). As such, trail conflicts can and do occur among different user groups, among different users within the same user group, and as a result of factors not related to users' trail activities at all. In fact, no actual contact among users need occur for conflict to be felt. Conflict has been found to be related to activity style (mode of travel, level of technology, environmental dominance, etc.), focus of trip, expectations, attitudes toward and perceptions of the environment, level of tolerance for others, and different norms held by different users. Conflict is often asymmetrical (i.e., one group resents another, but the reverse is not true)."

**Response:** Conflicts between motorized and non-motorized users have been identified as a major issue of concern by the public via both oral and written comments on the Butte RMP. Conflict concerns raised include noise intrusions, speed of travel, dust, safety, wildlife displacement, etc. These concerns are typically expressed more often by non-motorized users because their sensitivity to noise and higher speed uses is much greater. Multiple use trails do maximize opportunities for all users however; they do not ensure quality recreation experiences for those who seek quiet, natural settings.

In this planning effort, the Butte Field Office is committed to providing a diverse array of both opportunities and quality user experiences. In order to achieve this, allocations with regard to travel management, recreation settings (Recreation Opportunity Spectrum), special recreation management areas (SRMAs) and Visual Resource Management have been made so that visitors can identify areas that will meet their experience expectations.

#### Q11

**Comment:** The "displaced" motorized community is facing a situation of few or no places to go. If every land management plan simply "manages" motorized recreation by closure and displacement, the consequence will be catastrophic. A recently released Forest Service Study states that motorized recreation is increasing, with 29.1% of Montana's general population describing

themselves as OHV enthusiasts and use OHVs for recreation. This is a significant portion of the population whose desires for access to public lands are not being addressed. (See "Off-Highway Vehicle Recreation in the United States, Regions and States: A National Report from the National Survey on Recreation and the Environment (NSRE), June 2005.

**Response:** Under the Butte RMP, intensive trail riding opportunities are retained for the three primary OHV areas in the Butte Field Office and an extensive network of primitive roads is available in the Limestone Hills area. The BLM recognizes the public demand for motorized travel opportunities and considered additional opportunities in this planning process.

#### Q12

##### Comment:

- Elimination of organized, motorized events (page 444) will not correct management problems (existing or perceived). 'Organized' group events have rules and influence over participants.

- Each event, motorized or non-motorized should be evaluated on its own merits with consideration for the location requested and the group/sponsor accountability. Again, multiple use rather than exclusive use.

- Montana Trail Vehicle Riders Association has held the annual State Ride in the Pipestone vicinity on 3 separate occasions. Members attending worked on trail projects, visited, rode, and enjoyed the opportunity. The event in 2006 was held under a USFS permit at \$50. An event request for BLM permit was quoted at \$4.00 per day per rider.

- In the summer of 1985, a National trials event was held in the Whitetail-Pipestone area. The event was a rare chance for Montana people to watch National riders compete. The area lends itself to a trials type of activity, whether on motorcycles or bicycles. Competitive events come in many sizes and types. This type of activity should not be severely limited.

**Response:** The Alternative B (Preferred Alternative) language regarding organized competitive motorized events has been changed in the Proposed RMP/Final EIS. Existing management for the Whitetail-Pipestone travel planning area does allow for consideration (subject to case by case evaluation) for competitive and non-competitive uses in the Pipestone OHV recreation area. In addition to making this correction, the BLM has been modified Alternative B to allow for additional consideration of organized motorized competitive event opportunities outside Pipestone, subject to management restraints.

The BLM notes that BLM's Special Recreation Permit Administration policy and guidelines, including the fee schedule, vary from USFS management.

**Q13**

**Comment:** The Presidents Council on Environmental Quality just issued a statement that hunting opportunities must be increased on federally managed public land. CBU believes that the Butte RMP severely reduces hunting opportunities with the closure of multiple use trails. The closure of trails prevents direct game retrieval of harvested animals and a study conducted in 2004 by CBU showed limits on game retrieval negatively affected 85% of the respondents to the survey. CBU finds this information important when developing travel plans.

**Responses:** Hunting access and the quality of hunting experiences were issues that were considered during the development of alternatives and later analyzed in Chapter 4 under Recreation effects. These issues influenced many travel plan alternatives with regard to routes available to motorized uses. The primary considerations were route availability, seasons of use, elevational access, hunter disbursement opportunities, game retention on public lands, conflicts between non-motorized and motorized users and game retrieval.

**Q14**

**Comment:** One concern that was not expressed was the extended camping requests on a case by case basis in semi developed camping areas on the BLM public lands. Unfortunately, there seems to be no set criteria for issuing these permits and the decision is left up to the area manager.

**Responses:** In Chapter 2, under Recreation Management, Alternative B (Preferred Alternative) has been modified in the Proposed RMP/Final EIS to allow for variance consideration to the 14-day camping rule under stipulated conditions for appropriate uses in low impact locations throughout the Butte Field Office. The 14-day limit also corresponds to what is allowable for commercial outfitters without additional analysis. Preference will be given to developed recreation sites after the high use season (Memorial Day weekend to Labor Day weekend) that provide hardened camping units, toilet facilities and good access for non-commercial, extended hunting camps during the hunting season.

**Q15**

**Comment:** Recreation Management: Executive Order 13443, Facilitation of Hunting Heritage and Wildlife Conservation, was enacted on August 17, 2007. The purpose of this order is to “direct Federal agencies that have programs and activities that have a measurable effect on public land management, outdoor recreation, and wildlife management, including the Department of the Interior and the Department of Agriculture, to facilitate the expansion and enhancement of hunting opportunities and the management of game species and their habitat.” It is our hope that this Order, together with recommendations called for in the Hunter Behavior

Advisory Council Final Recommendations will be addressed within the RMP.

**Responses:** Hunting access and the quality of hunting experiences are issues that were considered during the development of alternatives and later analyzed in Chapter 4 under Recreation effects. These issues influenced many travel plan decisions with regard to routes available to motorized uses. The primary considerations were route availability, seasons of use, elevational access, hunter disbursement opportunities, game retention on public lands, conflicts between non-motorized and motorized users and game retrieval.

**Q16**

**Comment:** Under the discussion of the preferred alternative for Recreation Management you state your intent to issue an Annual Recreation Permit in order to receive a fair economic return from commercial fishing and floating outfitters/guides. Your discussion should mention the possibility of collaborative special recreation permitting as we have initiated on the Madison River with the Dillon Field Office. I would suggest that a collaborative approach would result in benefits that include less duplication of agency effort and one stop shopping for the commercial users. I would further recommend that this section be amended to recognize the value of partnering with FWP on permitting commercial uses, especially on the portion of the Big Hole River that falls within the Butte Resource Area.

**Responses:** The BLM fully agrees with this comment and will coordinate with FWP on all appropriate waterways where public river access sites are located. This management action is described in Chapter 2 of the RMP, in the Recreation Management section under Management Common to Action Alternatives. In addition, the Preferred Alternative has been modified in the Proposed RMP/Final EIS to include the following statement, “BLM would continue to coordinate with MFWP to enhance river/corridor land management and to develop a multi-agency fee system for the commercial uses of river access sites wherever feasible.”

**Q17**

**Comment:** Scratchgravel Hills - The key concerns are public health & safety, limiting public nuisances and maximizing recreational opportunities. Regarding public health & safety, fire is the over-riding concern, followed by shooting (still a problem, but minor compared to what it used to be.) The major 'nuisances' now are ORV use and late night 'parties.' So I strongly urge you to 'close' the entire area to use after dark.

**Response:** The Preferred Alternative for the Helena Travel Planning Area has been modified in the Proposed RMP/Final EIS so that all interior roads in the Scratchgravel Hills would be closed to public motorized travel yearlong at the five proposed trailheads, with the excep-

tion of a few perimeter right-of-way routes and routes to private residents. This change will negate the need for the dusk to dawn closure since the use of motorized vehicles will not be allowed during any time of the day.

**Q18**

**Comment:** We suggest that management direction for recreation include specification that campground facilities and concentrated public recreational uses should be located away from ecologically sensitive areas, such as riparian areas and wetlands or areas with erosive soils as much as possible. We encourage restricting motorized access to camping sites in ecologically sensitive areas, and identifying and designating camping sites to avoid sensitive areas and/or to encourage camping or concentrated public use in areas that are more resilient and can more easily recover from impacts and/or accommodate public use with less impact. We believe recreational uses should be directed and encouraged toward more resilient areas where they would cause the least environmental harm. For example, including management direction language such as, “BLM will avoid locating campground facilities and concentrated public recreational use areas near ecologically sensitive areas, and will strive to locate such facilities in areas that are more resilient and can more easily recover from impacts and/or accommodate public use with less impacts.”

**Response:** The BLM believes that the last two paragraphs in Chapter 2 of the RMP, Recreation Management, under Management Common to Action Alternatives (B, C, and D) addresses these concerns. Some limited flexibility was included so that existing and future fishing access sites (typically located in riparian areas) could continue or be considered, provided a high public need could be demonstrated. Prior to establishing any new site, BLM is required to complete a NEPA document for public review that analyzes all resource impacts including riparian and wetland areas.

**Q19**

**Comment:** AWL recommends the amendments to Alternative C:

- Change roads designated as “natural roads” to “semi-primitive modified” in the Elkhorns.
- Change roads designated as “roaded natural” to “semi-primitive modified” in the area west of Helena.
- Change roads designated as “roaded natural” to “semi-primitive modified” in the Highlands.

Designating these roads “semi-primitive modified” should enhance security and population connectivity.

**Response:** The Recreation Opportunity Spectrum (ROS) system has established criteria for each setting that must be followed in order to maintain national integrity. This system assesses areas, not roads, and there

are size guidelines that must be followed. The BLM believes that the preferred ROS settings are appropriate based on the characteristics of these areas within the Elkhorns.

**Q20**

**Comment:** I am thrilled that you are considering Wild and Scenic River status for the Missouri River 3.1 miles below Holter Dam. This is a very scenic, free flowing stretch of the Missouri and it deserves protection. And please designate it as non-motorized to provide a Quiet Trail on the river.

**Response:** The BLM corridor lands are designated Semi-primitive under the ROS system. No designations have been for the river or the adjacent Forest Service lands at this point for it is beyond the legal scope or decision making authority of this document. The Forest Service will classify its lands when it completes its pending study in their next Land Use Plan. River use issues such as motorized vs. non-motorized travel could be decided by Congress as part of its designation decision or more likely through a specific WSR management plan should the area be designated.

**Q21**

**Comment:** BLM needs to revisit and show valid reasons for the proposed reduction of boat-in camping opportunities. This will create more demand on the few camping areas you are designating. In turn this will create more user conflicts. The plan does not address this subject in detail as it should.

**Response:** The proposed decision is to designate specific sites that may be used for dispersed camping along the Sleeping Giant shoreline of Holter Lake/Missouri River and to evaluate the need to do likewise on Hauser Lake. Established recreation sites on these lakes would not be affected. The Butte Field Office recognizes that there is a high demand for dispersed boat-in camping sites on Holter Lake and that the Beartooth Wildlife Management Area is closed to camping. In addition the Forest Service is considering limiting camping to Coulter Campground only. BLM believes closure of some sites on Butte Field Office lands is necessary in order to protect important wildlife use areas (nesting sites, natural big-game watering sites, etc) cultural resources, riparian areas, etc. Chapter 4 of the RMP does address impacts related to implementing this action.

**Q22**

**Comment:** You do have a recreation plan that includes aircraft don't you? Since we lost the Ming Bar and Ox Bow landing strips along Holter Lake, a suitable replacement should be made available. Such a replacement area is available in Section 23, Township 14 N, Range 3 W. I challenge you to provide the pilots of Montana with the opportunity to create a new airstrip along Holter

Lake in Section 23. It is not wilderness and is surrounded on three sides with recreational activities.

**Responses:** Establishment of aircraft landing strips is beyond the scope of this planning document. Applications for these types of uses are handled through the Lands program. The land identified by the comment in Section 23 is not suitable for such a use since it is within the Sleeping Giant Wilderness Study Area and subject to the non-impairment criteria.

### Q23

**Comment:** MWF supports nighttime travel closures in the Scratchgravel Hills trail system to discourage parties and vandalism. MWF requests some latitude for hunters who may still be afield after dark taking care of downed game or early entry into BLM lands to be afield before the sun rises. Take note that normal hunting hours are ½ hour before sunrise to ½ hour after sunrise and plan closed periods accordingly. Rather than a sunrise opening and sunset closure, perhaps adjust it to 1 hour previous to sunrise and 1 hour after sunset as deadlines which will have the exact same effect at controlling destructive activities.

**Response:** The Preferred Alternative for the Helena Travel Planning Area has been modified in the Proposed RMP/Final EIS so that all interior roads in the Scratchgravel Hills would be closed to public motorized travel yearlong at the five proposed trailheads, with the exception of a few perimeter right-of-way routes and routes to private residents. This modification is due to the high degree of user conflicts and illegal activity taking place in this area. This change will negate the need for the dusk to dawn closure since the use of motorized vehicles will not be allowed during any time of the day.

### Q24

**Comment:** Visual and other impacts associated with motorized trails have been cited as significant negative impacts. Many non-motorized trails have environmental impacts similar to motorized trails. Existing wilderness and non-motorized areas include many trails that are visually and functionally similar to primitive motorized roads and motorized trails. For example, the Mount Helena trails, and the main trails into the Bob Marshall and Scapegoat Wilderness at Benchmark, Holland Lake, and Indian Meadows and the main trails into the Anacoda Pintler Wilderness are similar visually and functionally to many primitive motorized roads and motorized trails. Additionally, trails resulting from activities including wild animals and Native Americans have always been a part of the natural environment. We request that the existence of trails be considered part of the natural landscape and that the visual appearance of motorized trails and non-motorized trails be recognized as equal in most cases and that the environmental impacts of motorized and non-motorized trails be addressed fairly and equally.

**Response:** Visual impacts associated with motorized and non-motorized trails did not influence route restrictions or closures in the Butte RMP alternatives. All human created trails are considered unnatural intrusions on the landscape and the degree of their visual impact depends on the noticeable contrast a specific trail has on the affected landscape.

## Riparian Habitat

### R1

**Comment:** In the Elkhorn Mountains, re-establish proper riparian function through the use of various management techniques including but not limited to prescribed fire, mechanical treatment, and restoration of riparian areas (e.g. re-establish historic stream flow, encourage willow and aspen development, reduce headcutting, and increase the area of wetland). All prescriptions should be based on an analysis of existing condition in order to ensure that site-specific techniques are used to achieve the desired effect of improving riparian function.

**Response:** The BLM agrees that riparian function should be maintained or improved throughout the Butte Field Office using a variety of management activities. The Vegetation Communities section (Management Common to All Alternatives - Riparian) in Chapter 2 of the RMP provides direction for riparian areas. Additional discussion on management of riparian habitats is found under Management Common to Action Alternatives in Chapter 2 (Vegetation Communities – Riparian) as well as under the different alternatives.

Site-specific riparian restoration projects will address the existing condition, the type and extent of management practices appropriate for that area, and effects from management actions.

### R2

**Comment:** FWP has identified riparian and wetland areas as Tier I communities in our Comprehensive Fish and Wildlife Conservation Strategy (CFWCS). We also understand that BLM policy requires consideration of the habitats and species identified by the CFWCS that were approved by the USFWS in 2005. As such we strongly urge the BLM to consider the treatment of riparian areas with the greatest measure of protection that can be afforded. For example, protection from new roads due to mineral development as outlined in Alternative C, page 144, should be strongly considered. Similar such protections should be incorporated into any alternative selected in the ROD.

**Response:** The Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section of Chapter 2 (Management Common to Action Alternatives) states that all Tier I and Tier II species and ecotypes from Montana's Comprehensive Fish and Wildlife

Conservation Strategy would be considered “priority species and habitats” in the RMP. Priority species and ecotypes would be given additional consideration during site-specific project planning and/or project development. All riparian habitats in the Butte Field Office would be considered “priority habitats” including those identified in the Conservation Strategy (Big Hole and Jefferson Rivers) and, under Alternative B, would be given a substantial increase in protection and emphasis compared to the existing condition.

### R3

**Comment:** Wetlands and riparian areas increase landscape and species diversity, support many species of western wildlife, and are critical to the protection of water quality and designated beneficial water uses. EPA considers the protection, improvement, and restoration of riparian areas and wetlands to be a high priority. Potential impacts on riparian areas and wetlands include: water quality, habitat for aquatic and terrestrial life, flood storage, ground water recharge, and discharge, sources of primary production, and recreation and aesthetics. The draft RMP/EIS says that 42 condition of riparian areas in the Decision Area (or 147 miles) are functioning-at-risk (FAR), and 12 percent (or 40 miles) are non-functioning (NF, page 224, 324), with only 43 percent of the riparian areas (or 150 miles) in proper functioning condition (PFC). This high percentage of BFO riparian areas that are not in proper functioning condition (56 percent of riparian areas), evidences the need to improve BLM BFO management to restore riparian areas and promote healthy aquatic ecosystems.

We support the RMP's stated goal of managing wetland and riparian area to move toward or remain in PFC, and support healthy, diverse, and abundant populations of fish and associated aquatic and riparian dependent species, (page 17), and the emphasis for protection and restoration of riparian areas (page 18), and the statement that, "authorized activities in riparian areas would strive to maintain and restore riparian structure and function , benefit fish and riparian-dependant species, enhance conservation of organisms that depend on the transition zone between upslope and the stream, and maintain or improve the connectivity of travel and dispersal corridors for terrestrial animals and plants" (page 20).

**Response:** As acknowledged in the Butte RMP, riparian conditions could be improved on BLM lands in some cases. In the Preferred Alternative, the BLM has proposed establishment of riparian management zones where the focus of management would be on improving riparian ecological conditions. The BLM believes this should increase the percentage of riparian areas in the Butte Field Office that would meet proper functioning condition (PFC). The BLM notes that in many cases where riparian areas do not meet PFC, the causes for this are beyond the BLM's control (such as county roads in

valley bottoms, management activities on private lands, etc.).

### R4

**Comment:** Since portions of the BFO jurisdictional area are located west of the continental divide (i.e. within the Clark Fork River drainage, and thus, Interior Columbia Basin), it is relevant to note that EPA evaluates land management activities proposed within the Interior Columbia Basin for consistency with the provisions of the Interagency Memorandum of Understanding between the Forest Service, BLM, EPA, USFWS, and NMFS for Forest Service implementation of the Interior Columbia Basin Strategy on National Forest lands (referred to as the ICB Strategy, <http://www.icbemp.gov/html/icbstrat.pdf>; and “A Framework for Incorporating the Aquatic and Riparian Habitat Component of the ICB Strategy into BLM and Forest Service Plan Revisions,” <http://www.icbemp.gov/html/agripfrm7804.pdf>).

Riparian Conservation Areas are an important management element in the ICB Strategy to maintain and restore the health of watersheds, riparian, and aquatic resources to sustain aquatic and terrestrial species and provide water of sufficient quality and quantity to support beneficial uses. It is important that proposed harvest be consistent with the riparian management objectives described in the ICB Strategy, which include:

- Achieve physical integrity of aquatic ecosystems;
- Provide an amount and distribution of woody debris sufficient to sustain physical and biological complexity;
- Provide adequate summer and winter thermal regulation;
- Provide appropriate amount s and distributions of source habitats for riparian- or wetland-dependent species; and
- Restore or maintain water quality and hydrologic processes.
- Restore or maintain naturally functioning riparian vegetation communities.

This gives further support for the need for riparian protections to be consistent with the ICB Strategy at least for BLM lands within the Interior Columbia Basin (west of the continental divide).

**Response:** Management proposed for the Butte Field Office in Chapter 2 is consistent with the ICB strategy. The Missoula Field Office manages 932 acres (0.75 percent) of Butte Field Office land within the Blackfoot watershed under an MOU with the BFO. These lands with their associated riparian areas and forests are managed under conservation plans to implement recovery of special status species including bull trout and westslope cutthroat trout. The management and conservation plan for bull trout incorporates the principles of the Inland Native Fish Strategy and the riparian man-

agement objectives of the ICB strategy. The riparian reaches in this area are currently in Proper Functioning Condition (PFC).

The Butte Field Office manages 649 acres (0.12 percent of Butte Field Office total) in the American Gulch area within the Upper Clark Fork watershed. Approximately 232 of these acres are classified as forest types. Adjacent to the forested areas are two small riparian reaches totaling less than 1 mile with approximately 5 acres of associated riparian/wetland habitat. These areas are primarily grass/sedge/shrub communities with limited forest influence. In the Preferred Alternative for the Butte RMP, these riparian areas would be managed under the direction outlined for Riparian Management Zones in Chapter 2. The RMZs would meet the direction outlined in the ICB strategy. The two reaches in this area are currently in Functioning-At-Risk (FAR) condition with upward trends.

#### R5

**Comment:** Wetlands in particular have experienced severe cumulative losses nationally. Potential impacts on wetlands include: water quality, habitat for aquatic and terrestrial life, flood storage, ground water recharge and discharge, sources of primary production, and recreation and aesthetics. Executive Order 11990 requires that Federal Agencies “take action to minimize the destruction, loss, or degradation of wetlands, and to preserve and enhance the natural and beneficial values of wetlands in carrying out the agency’s responsibilities...” and agencies are further directed to “avoid undertaking or providing assistance for new construction located in wetlands unless the head of the agency finds

(1) that there is no practicable alternative to such construction, and

(2) that the proposed action includes all practicable measures to minimize harm to wetlands which may result from such use...”

In addition national wetlands policy has established an interim goal of No Overall Net Loss of the Nation’s remaining wetlands, and a long-term goal of increasing quantity and quality of the Nation’s wetlands resource base. The EIS should describe how the alternatives will meet the wetland protection goals in E.O. 11990.

We believe the RMP should also include direction to assure that project s tiered from the management plan adequately assess potential impacts on wetland functions; avoid or minimize wetlands impacts wherever possible; and compensate for unavoidable impacts through wetland restoration, creation, or enhancement. We encourage the BLM to assure that projects tiered to the RMP delineate and mark perennial seeps and springs and wetlands on maps and on the ground before disturbance so that disturbance to such areas can be avoided. Also, as noted in the discussion below on Travel Management and OHV Use, we recommend that manage-

ment direction restrict OHV use on ecologically sensitive riparian areas and wetlands.

**Response:** The RMP recognizes that wetlands are ecologically important areas and takes several steps to ensure they are adequately considered when the RMP and subsequent project level planning are implemented. These areas are included in Riparian Management Zones (RMZ) where maintaining and/or restoring riparian and wetland functions is the primary emphasis. The RMP also implements a Riparian and Wetland Land Health Standard, which requires that these areas are either at Proper Functioning Condition (PFC) or making progress towards PFC. The special management area designation and standard would ensure that wetland areas are adequately considered when planning any action that could potentially impact these resources. This includes travel management and any ground disturbing activity. If wetlands (including seeps and springs) are found during implementation they will be protected under the wetland standard.

Chapter 2 of the RMP, under Vegetation Communities, Management Common to All Alternatives, Riparian subheading (Page 21 paragraph 1 right column in Draft RMP/EIS) clearly states the BLM’s position with regard to existing regulations: “Riparian and wetland management would be consistent with all state and federal laws and regulations. Actions would be taken to cooperatively conserve riparian/wetland habitat, minimize the impacts, loss or degradation of wetlands, and preserve values served by floodplains where occurring on public land while reducing hazards to human safety.” All state and federal laws and regulations include Executive Order 11990.

#### R6

**Comment:** We support the proposed goal for Livestock Grazing to manage for sustainable levels of grazing while meeting or progressing toward Land Health Standards, and to maintain, restore or enhance rangeland to meet Land Health Standards is good (page 17). We note that while the Land Health Standards (Standards for Rangeland Health and Guidelines for Livestock Grazing Management Butte District Appendix E) are generally good and address stream channel hydrology, erosion/deposition, and stream bank vegetation, they do not appear to address aquatic habitat fragmentation and connectivity issues, nor do they fully address structure, composition, and functions of aquatic ecosystems. We recommend that additional management direction be considered to maintain and restore habitat connectivity for fisheries and other aquatic life (fish passage through culverts, etc.), and to maintain and restore structure, composition and functions of aquatic ecosystems within historic ranges of variability. For example we suggest adding goals and objectives as follows, “BLM will maintain and restore hydrologic connectivity within and

between watersheds to provide for aquatic habitat needs and connectivity of aquatic habitats.”

“BLM will maintain and restore structure, composition, and functions of aquatic ecosystems within historic ranges of variability.”

We also note the need to assure that the Land Health Standards are adequately monitored and enforced by BLM. It is not clear to us if there is adequate monitoring and oversight of implementation of these grazing Standards, and enforcement of grazing permits when Rangeland Health Standards and State Water Quality Standards are not being met. It would help if this were clarified in the final RMP/EIS.

**Response:** The distribution of Butte Field Office lands is highly fragmented such that it is not practical or implementable for the Butte RMP to include management direction associated with ensuring hydrologic and aquatic habitat connectivity. Management direction for Riparian Management Zones (Chapter 2, Vegetation Communities section, Alternative B – Preferred Alternative subsections, Riparian Management Zones) provides management direction that focuses on riparian values in the Butte Field Office. In addition to the requirement to meet or move toward meeting the Land Health Standards (Appendix F in the Proposed RMP/Final EIS), and the management direction for riparian vegetation in Chapter 2, specifically there are management prescriptions in the Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section which address aquatic habitat and ecosystem function.

The Bureau believes there is adequate monitoring and oversight of implementation of Land Health Standards. As of the end of fiscal year 2006, approximately 229,000 acres (90 percent) of a possible 253,000 acres of currently permitted allotments had been assessed for Land Health Standards. Of the acres assessed, 113,000 acres were meeting standards (49 percent), 80,000 acres were not meeting standards but appropriate action has been taken to ensure significant progress toward meeting standards and livestock is a significant factor (35 percent), 3,000 acres were not meeting standards and appropriate action had not been taken yet to ensure significant progress toward meeting standards and livestock is a significant factor (1 percent), and 34,000 acres were not meeting standards due to causes other than livestock grazing (15 percent). Furthermore, the Bureau regularly monitors allotments on a scheduled basis; i.e. higher priority allotments are monitored annually whereas lower priority allotments are monitored every 3 to 5 years.

#### R7

**Comment:** We support the greater distances for riparian protection as afforded in Alternative C than any other action alternative.

**Response:** The Butte Field Office believes the distances for riparian management afforded by the RMZs outlined under Alternative B in Chapter 2 are adequate to enhance and, where necessary, to protect riparian resources.

#### R8

**Comment:** Include commitments in the RMP to achieve proper functioning condition (PFC) or a strong upward trend in riparian conditions during the planning period. For example, to increase PFC riparian areas from 43 percent to 80 percent; decrease FAR from 42 percent to 20 percent; and NF from 12 percent to 0 percent. We also recommend establishing interim objectives to move currently functioning-at risk and non-functioning riparian areas to PFC during each 5 years of the planning period (this is important since 56 percent of the BFO riparian areas are not in PFC).

**Response:** Chapter 2 of the Butte RMP/EIS outlines BLM’s goal to manage riparian and wetlands communities to move toward or remain in proper functioning condition to the extent practicable. Additionally, the Land Health Standards included in **Appendix F** in the Proposed RMP/Final EIS reiterate that all uses on public land should achieve or make significant progress toward having riparian and wetland areas in proper functioning condition. However, a review of Butte Field Office riparian reaches reveals that at least 40 percent of reaches in functional-at-risk (FAR) or non-functioning (NF) conditions are subject to factors beyond BLM’s management control such as upstream dewatering, the location of highway and county roads, and historic or active mining operations. Furthermore, the fragmented ownership pattern of Bureau lands in the Butte Field Office also affects the ability to effect any significant management change on many of these reaches. Given these limitations, we have not established numerical thresholds over time for riparian improvement. The BLM, however, does work with other parties where feasible to resolve impacts or issues beyond our inherent control. BLM will also continue to monitor riparian and wetland conditions as part of land health assessment work and/or project implementation to ensure actions that BLM has and can take are resulting in moving toward or attaining proper functioning condition.

### Social Conditions

#### S1

**Comment:** Dr. Martin E.P. Seligman has identified that learned helplessness or the belief that your actions will be futile is an epidemic affecting the nation (page 70, ISBN 0-671-01911-2). The evaluation of social issues must also include an evaluation of conditions contributing to learned helplessness including the lack of recognition and attention to the needs of motorized recreation-

ists and the significant social problems that result from these conditions.

**Response:** Potential effects to motorized users are discussed for each alternative in the travel management, recreation, social, and cumulative sections of Chapter 4. Many of these effects are social in nature. The effects for each of the individual travel planning areas are discussed in Environmental Consequences of Five Site-Specific Travel Plans in the latter part of Chapter 4. In addition, this plan incorporates by reference the Off-Highway Vehicle EIS and Plan Amendment for Montana, North Dakota and portions of South Dakota, which discusses off highway travel in great detail. The Preferred Alternative of this plan attempts to balance the needs of users with different goals.

## S2

**Comment:** We are concerned about the protection of our western culture. This culture is characterized by access to the land for multiple-uses, friendliness, good neighborliness, tolerance, and sharing. Motorized access to the land provides opportunities for sightseeing, exploring, weekend drives and picnics, hiking, rock climbing, skiing, mountain biking, riding horses, camping, hunting, target shooting, fishing, viewing wildlife, OHV recreation, snowmobiling, accessing patented mining claims, gathering of firewood, rocks, natural foods, etc. and physically challenged visitors who must use wheeled vehicles to visit public lands. Both our observations and the Social Assessment for Beaverhead-Deerlodge National Forest found that these multiple-use visitors represent over 97% of the total visitors and that these visitors rely on motorized access. We are fortunate to have extensive public lands to support the western culture. While mechanized and multiple-use recreationists are tolerant of others as noted by the District Ranger, this does not mean that non-motorized interests should be allowed to dominate resource allocation decisions. We request that multiple-use management principles be used to protect western culture and values including access to the land for multiple-uses, friendliness, good neighborliness, tolerance and sharing.

**Response:** The activities described in this plan would not affect the western culture of the area as the BLM manages only 4.2 percent of the surface acres and access in the RMP Planning Area. The Preferred Alternative attempts to balance the needs of users with different goals.

## S3

**Comment:** Motorized visitors have had to devote the majority of their available energy and time addressing local and national level travel management actions. The combination of these actions has created a significant cumulative negative effect on motorized visitors by consuming their free time and money, and significantly impacting their quality of life. Additionally, this cumula-

tive negative effect has led to the loss of opportunity for motorized recreationists to further the awareness and education of other motorized visitors in areas such as proper riding ethics, safety, and environmental protection. This cumulative negative effect has also reduced the opportunity for motorized recreationists to improve and maintain existing motorized opportunities. This cumulative negative impact includes reduced maintenance of trailheads and trails and reduced ability to undertake mitigation projects to protect the environment and public safety. We request that these cumulative negative effects be addressed in the analysis, preferred alternative, and decision-making.

**Response:** The BLM believes that the Chapter 4 sections Cumulative Effects on Social and Economic Conditions and Cumulative Effects of Travel Plans at the Planning Area Scale adequately address the cumulative effects associated with land management decisions related to motorized uses. All publics interested in the plan have the same opportunities to participate during the planning process.

## S4

**Comment:** On page 480, volume 1, Social Conditions: "Other federal land management agencies in the Planning area are following a trend of reducing motorized access." This statement is especially disconcerting. First, just because another agency is following the motorized closure trend does not make it right! Secondly, the cumulative effects of the motorized closure trend are being ignored by all agencies and this is very wrong and out of compliance with NEPA guidelines.

**Response:** The statement cited that other federal land management agencies are following a trend of reducing motorized access, is simply stating a trend. It is not endorsing the trend. The BLM believes that the Chapter 4 sections Cumulative Effects on Social and Economic Conditions and Cumulative Effects of Travel Plans at the Planning Area Scale adequately address the cumulative effects associated with land management decisions related to motorized uses.

## S5

**Comment:** The evaluation must adequately consider the growing popularity of motorized recreation, the aging population, and their needs for motorized access, and the increased recreation time that the aging population has and looked forward to enjoying public lands in their motor vehicles.

**Response:** The available research suggests that participation in outdoor activities changes as people age. However, we have little understanding of how the leisure sequence will unfold at the "baby boomer" population ages. We do not know if former backpackers and/or hikers will become OHV users? Therefore it is unclear how the analysis should be adjusted to take the aging

population into consideration and no adjustments have been made.

### S6

**Comment:** The negative social and economic impact experienced by motorized recreationists when motorized recreational opportunities do not exist in nearby public lands must be adequately evaluated and considered in the decision-making. This is especially significant now that fuel is over \$2.00 per gallon. These impacts include the complete loss of recreational opportunities and the cost of having to travel farther and farther in search of fewer and fewer motorized recreational opportunities in times of increasing travel costs. For example, the lack of adequate OHV systems in the Helena National Forest requires us to travel at least 180 miles to adjacent national forests and many more miles to other states including Idaho and Utah. A 180 mile roundtrip costs at least 3 hours and \$70 and that cost will increase substantially in the future. This added cost is a waste of time and energy resources and has not been adequately considered by the agency. Additionally, OHV routes in adjacent forests are being reduced at an alarming rate and are compounding the cost in time and energy even further. We request the evaluation of the economic cost of fewer motorized recreation opportunities on motorized recreationists and the significant cumulative negative effect of all travel management decisions that contribute to these social and economic impacts on motorized recreationists.

**Response:** Potential effects to motorized users are discussed for each alternative in the Travel Management, Recreation, Social, and Cumulative Effects sections of Chapter 4. Many of these effects are social in nature. In addition, effects for each of the individual travel planning areas are discussed in the Environmental Consequences of Five Site-Specific Travel Plans section in the latter part of Chapter 4. Since BLM manages only 4.2 percent of the surface acres and access in the Butte Planning Area, the extent of effects to motorized access is not great.

### S7

**Comment:** Identification of "high social, cultural, or economic value" and "desired" levels are subjective and requires an assessment and balancing of public values. For example, a particular species may have a high social value to a particular segment of the population, but a low social value to another. Similarly, a species may have significant economic value for a particular use (trees cut for timber), but have high social value in the context of an entirely different use (trees observed by hikers). Furthermore, these conflicting values may require entirely different "desired" levels. Despite these extremely complex and subjective determinations, the proposed alternative provide virtually no explanation or guidance regarding how these levels and values were established. This

extreme discretion is not allowed by the Organic Act, MUSYA, and NFMA, which require that forests be managed for a variety of uses.

**Response:** It is true that a particular species may have a high social and/or economic value to one segment of the population and little social and/or economic value to another segment. However, it is unclear what specific parts of the document the comment is referring to. The Organic Act, MUSYA and NFMA are Forest Service management requirements and do not apply to BLM, although we may have similar requirements. The social analysis contained in the Butte RMP/EIS identified impacts to groups that place value on certain resources or uses and how a general emphasis on one type of management or another would affect that group.

### S8

**Comment:** Evaluations and decisions have been limited to natural resource management issues. Issues associated with motorized access and motorized recreation must be adequately addressed during the evaluation and decision-making including social, economic, and environmental justice issues. We are concerned that issues cannot be restricted to just those associated with natural resources. Access and recreation on public lands are essential needs of the public in Montana and we respectfully request that issues associated with the human environment be adequately addressed.

**Response:** Potential effects to the human environment are discussed for each alternative in the Travel Management, Economic, Recreation, Social, Environmental Justice and Cumulative Effects sections of Chapter 4. These sections comply with the guidance in BLM's Planning Handbook.

### S9

**Comment:** Montana ranks very low for social conditions (44th state per Fordham Institute for Innovation in Social Policy,) and social issues are relevant to this action. Motorized recreation is a healthy social activity. These types of issues are associated with motorized access and recreation in the project area and these issues must be adequately addressed. Social issues must be adequately evaluated per the SOCIAL IMPACT ANALYSIS (SIA): PRINCIPLES AND PROCEDURES TRAINING COURSE (1900-03) (<http://www.fs.fed.us/emc/nepa/includes/sia.html>) and Environmental Justice issues per Departmental Regulation 5600-2. The evaluation and resulting decision must adequately consider and address all of the social and economic impacts associated with the significant motorized access and motorized recreational closures.

**Response:** The training course referred to in this comment is a Forest Service course. The social analysis contained in the Butte RMP/EIS complies with all BLM guidance for social assessment. The Environmental

Justice regulations are Department of Agriculture regulations and BLM is a part of the Department of Interior. The social analysis complies with Department of Interior guidance regarding Environmental Justice.

### S10

**Comment:** In the past 30 years, the prevalence of overweight and obesity has increased sharply for both adults and children. Between 1976–1980 and 2003–2004, the prevalence of obesity among adults aged 20–74 years increased from 15.0 percent to 32.9 percent. This increase is not limited to adults. Among young people, the prevalence of overweight increased from 5.0 percent to 13.9 percent for those aged 2–5 years, 6.5 percent to 18.8 percent for those aged 6–11 years, and 5.0 percent to 17.4 percent for those aged 12–19 years. (Reference: <http://www.cdc.gov/nccdphp/dnpa/obesity>). This disturbing trend has prompted the President to promote a health and fitness initiative (<http://www.whitehouse.gov/infocus/fitness/toc.html>) and OHV recreation is an activity that meets the physical requirements of the President’s fitness program. Recent research by the Ontario Federation of Trail Riders studied 12 off-road motorcycle enthusiasts and found that the physical exertion was on the order of 60 percent of VO<sub>2</sub>max, or 80 percent HRmax, or 9.3 METS which is slightly greater than jogging (Characterizing the Physical Demands of Off-Road Motorcycling, Executive Summary, Jamie Burr, Norman Gledhill, Veronica Jamnik, Ontario Federation of Trail Riders, February 2007, [http://www.oftr.org/OFTR\\_Fitness\\_Study.pdf](http://www.oftr.org/OFTR_Fitness_Study.pdf)). While jogging is considered a very healthy activity it is not that appealing to everyone and OHVs are very popular form of recreation and physical workout. We request that the evaluation include adequate recognition of the serious physical fitness problem affecting all age groups of our population. We also ask that the tremendous value of OHV recreation for both mental and physical health benefits (equivalent to jogging) be recognized in the evaluation and used to justify an increase in motorized recreational opportunities.

**Response:** Addressing the obesity problem in the US population is outside the scope of the Butte RMP.

### S11

**Comment:** We believe that federal environmental justice compliance requirements as initiated by Executive Order 12898 should be applied immediately to correct the disproportionately significant and adverse impacts that motorized recreationists have been subjected to. In order to accomplish this we request that this proposed action comply with U.S. Forest Service Departmental Regulation 5600-2 (<http://www.usda.gov/da/5600-2.pdf>) including the DEFINITION of environmental justice provided therein. While some of the guidance published on environmental justice refers to specific minority and low income populations, the intent of the

guidance must be taken in a broader sense as recommended by the EPA in order to avoid discrimination or unfair treatment of any significantly impacted sector of the public. For example, motorized recreationists working full-time plus jobs and simply looking to get away and recreate in the forest on the weekends are pitted against full-time paid representatives for non-motorized interests that are visiting agency staff on a regular basis during the week.

**Response:** The discussion that motorized recreationists should be identified as an environmental justice-covered population is not valid. Executive Order 12898 specifically deals with low-income and minority populations as the subject of this order. Other groups that would be affected are discussed in the Social Conditions sections of this document.

### S12

**Comment:** We request that the proposed action comply with the Council on Environmental Quality (<http://ceq.eh.doe.gov/nepa/regs/ej/justice.pdf>) recommendations in order to correct the disproportionately significant and adverse impacts that motorized recreationists have been subjected to.

**Response:** The discussion that motorized recreationists should be identified as an environmental justice-covered population is not valid. Executive Order 12898 specifically deals with low-income and minority populations as the subject of this order. Other groups that would be affected are discussed in the Social Conditions sections of this document.

### S13

**Comment:** The process should not allow well-organized and funded groups to take opportunities away from less-organized and funded individuals. This certainly is an environmental injustice. Moreover, the development of measures as required by environmental justice regulations to mitigate the disproportionately high and adverse impacts that have affected motorized recreationists have not happened. We request a corrective action and over-arching mitigation plan that will undo the significant impact that all cumulative motorized access and motorized recreational closures has had on motorized recreationists over the past 35 years. We also request a monitoring program be provided by an unbiased third-party to assure that this correction occurs within our lifetime.

**Response:** The BLM sees no indication that “well-organized and funded groups” are taking away opportunities from anyone with the Butte RMP revision. The point that motorized recreationists should be identified as an environmental justice-covered population is not valid. Executive Order 12898 specifically deals with low-income and minority populations as the subject of this order. The BLM does not agree that disproportio-

nately high adverse impacts would occur to motorized recreationists due to the Butte RMP revision. The BLM notes that there are three intensive OHV riding areas in the Butte Field Office that would be carried forward, and motorized uses will continue to be available in the site-specific travel planning areas being addressed with this RMP revision.

#### S14

**Comment:** Motorized recreationists cannot hold full-time jobs and, at the same time, be able to compete with the paid staff of non-motorized for recreational resources. Unfortunately, the agency has adopted the expectation that motorized recreationists must demonstrate a level of involvement equivalent to the involvement of paid staff from non-motorized groups in order to get a reasonable allocation of recreational resources. We have been told that we are politically insignificant by forest supervisors, district rangers, and BLM managers. There are many socio-economic and environmental justice issues associated with this setting if it is not adequately addressed by this action ranging from the allocation of near-term motorized recreational opportunities and the level of human health that it promotes to the ultimate elimination of motorized recreation from public land in the long-term.

**Response:** In association with the Butte RMP revision, the BLM has not told anyone in the public that they are politically insignificant. While the BLM is unclear about the meaning of some aspects of the comment, the suggestion that motorized recreationists should be identified as an environmental justice-covered population is not valid. Executive Order 12898 specifically deals with low-income and minority populations as the subject of this order. The BLM has not proposed to eliminate motorized recreation under any alternative with the Butte RMP.

#### S15

**Comment:** Any significant closing of motorized routes in the project area does not meet the basic requirement of the NEPA act of 1969 as stated in “Sec. 101 (b) (5) achieve a balance between population and resource use which will permit high standards of living and a wide sharing of life’s amenities”. High standards of living and a wide sharing of life’s amenities should include recognizing and meeting the need for motorized access and recreation opportunities in the project area. All visitors should be expected to share the project area with others and to tolerate the presence of others. We have met very few hikers on the multiple-use roads and trails that we use. We have not perceived any problems with the non-motorized visitors that we have met. We ask that the analysis and decision-making be based on sharing and tolerance and to avoid unreasonable accommodation of visitors to public lands that are not reasonably tolerant and sharing.

**Response:** Potential effects to motorized users are discussed for each alternative in the Travel Management, Recreation, Social, and Cumulative Effects sections of Chapter 4. Many of these effects are social in nature. The Preferred Alternative does attempt to balance the needs of users with different goals.

#### S16

**Comment:** The environmental document should be an issue driven document as required under NEPA and the Council on Environmental Quality guidelines. The driving issue is the development of a reasonable travel management alternative that addresses the needs of the public. NEPA requires that agencies “Rigorously explore and objectively evaluate all reasonable alternatives, and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated” [40 CFR 1502.14(a)]. We request that the environmental document adequately addresses the social, economic, and environmental justice issues associated with multiple-use access and motorized recreation. We request that the environmental document include a travel management alternative for the project area that adequately responds to these issues and the needs for multiple-use access and recreation.

**Response:** Potential effects to motorized users are discussed for each alternative in the Travel Management, Recreation, Social, and Cumulative Effects sections of Chapter 4. Many of these effects are social in nature. The Preferred Alternative does attempt to balance the needs of users with different goals.

#### S17

**Comment:** The use of the existing network of motorized roads and trails is part of local culture, pioneer spirit, heritage, and traditions. All of these values have ties to the land. Visitors to public lands benefit from all of the motorized roads and trails that exist today. The quality of life for the multiple-use public is being impacted by the cumulative negative effects of all motorized and access closures. The significant closing of motorized routes in the project area does not meet the basic requirement of the NEPA act of 1969 as stated in “Sec. 101 (b) (5) achieve a balance between population and resource use which will permit high standards of living and a wide sharing of life’s amenities”. We request that the criteria for high standards of living and a wide sharing of life’s amenities include the preservation of motorized roads and trails based on the recognition of the values (ties to the land) that they provide to local culture, pioneer spirit, heritage, traditions, and recreation.

**Response:** The activities described in this plan would not affect the western culture of the area as the BLM manages only 4.2 percent of the surface acres and access in the Butte RMP Planning Area. The Preferred Alterna-

tive attempts to balance the needs of users with different goals.

## Soils

### T1

**Comment:** Concerning soil erosion in burned areas, I am concerned with your statement on page 322 of the “draft” that Alternative B would have more soil impacts than Alternative C. I would suggest that you use BAER (Burned Area Emergency Restoration) funds, requested at the time of the wildfire, to provide for rehabilitation of the soils and vegetation. If erosion occurs later, rehabilitation funds should be requested through normal funding channels using wildlife, fisheries, and vegetation budget codes.

**Response:** Alternative B would require erosion control practices in burned areas where sedimentation had been documented to be definitively impacting streams; however, erosion control practices could be employed at other locations within a burned area. Erosion control practices applied to promote soil stability where needed is allowed under all alternatives as stated in Chapter 4, Soil Resources section under Effects Common to Action Alternatives. The intent of Alternative B would be to direct erosion control practices to sites that would produce the most benefit, first. That would be particularly important when large fires make broad-scale erosion control impracticable.

### T2

**Comment:** The report "Erosional Impact of Hikers, Horses, Motorcycles, and Off-Road Bicycles on Mountain Trails in Montana", Mountain Research and Development, Volume 14, No. 1, and published in 1994 found that multiple comparison test results showed that horses and hikers made more sediment available than wheels, and this effect was most pronounced on pre-wetted trails.

The report "Keeping Visitors on the Right Track - Sign and Barrier Research at Mount Rainer", Park Science 14(4) published in 1994 found that off-trail hiking is a major source of impact that creates trails and erosion throughout the several thousand acres of sub-alpine meadows.

**Response:** The purpose of the RMP is to provide basic program direction, as described in Chapter 1, Purpose and Need. Assessing sedimentation resulting from specific activities would occur at the activity level, or when preparing project specific plans. Site-specific Best Management Practices (BMPs) would be implemented for surface disturbing activities to minimize sedimentation, to the extent possible. Site-specific soil impact assessments and BMPs would reflect local site characteristics, such as soil texture, slope, climate, natural disturbances, and other attributes. This land management ethic is in

keeping with the findings of the authors of the study who note that their results are complicated and difficult to decipher. Although the authors note that it would be challenging to extrapolate their small sample plot studies to other locations and larger areas, their finding that wet soil is more susceptible to erosion does reflect the BLM's concern about soil erosion. This concern played a role in recommending some routes have seasonal travel restrictions.

### T3

**Comment:** We support a stipulation [for oil and gas leasing] to control surface use on steep slopes (>30%) and unstable land areas with active mass soil movement.

We recommend that the proposed Alternative B stipulation (page 911) for controlled surface use on steep slopes and Boulder Batholith soils also include unstable land areas and areas with active mass soil movement in the stipulation.

**Response:** This stipulation has been revised in the Preferred Alternative to now read: “Prior to surface disturbance on areas of active mass wasting, unstable land areas, or slopes of greater than 20 percent on Boulder Batholith soils, or 30 percent on non-Boulder Batholith soils, an engineering/reclamation plan must be approved by the authorized officer.”

## Special Designations – Areas of Critical Environmental Concern

### U1

**Comment:** Doesn't the ACEC process require more specific effort and documentation than what is offered here? The data or lack of data here does not seem to support the desire to further restrict these areas. There is some obvious “in office” work done, but there didn't appear to be much field/on the ground real data. The ACEC designation and such should be determined through a separate process and more appropriate process than this one.

**Response:** Section 202(c) (3) of FLPMA mandates the BLM to give priority to the designation and protection of ACECs in the development and revision of resource management plans. Evaluation of potential ACECs for the Butte RMP is documented in **Appendix I** of the Proposed RMP/Final EIS (formerly **Appendix H** in Draft RMP/EIS). For areas that meet relevance and importance criteria in 43 CFR 1610.7-2(a), BLM policy is to develop management direction to protect the relevant and important values in the resource management planning process. The BLM believes it has done so adequately for the Butte RMP as required under FLPMA and as per BLM policy.

**U2**

**Comment:** The Ringing Rocks proposed Area of Critical Environmental Concern (ACEC) is fully supported and will enhance economic development opportunities. Signage near the I-90 Pipestone interchange should be included as part of the plan.

**Response:** The BLM has included the Ringing Rocks potential ACEC in its Preferred Alternative for the Butte RMP. Decisions about signage are implementation decisions that would be considered after the final RMP decision on whether or not to designate this area as an ACEC.

**U3**

**Comment:** High Ore Creek ACEC: The High Ore BLM lands provide an important connection between the Continental Divide and both the Whitetail-Pipestone and the Bull Mountains and thus to connecting mountain ranges beyond such as the Tobacco Root Mountains and the Highland Mountains. This constitutes part of an important linkage route between the Northern Continental Divide Ecosystem and the Yellowstone ecosystem; routes that are called for in the Grizzly Bear Recovery Plan Supplement (March 2007). The Habitat Based Recovery Criteria for the Yellowstone Ecosystem calls for enhancing linkage connections between Yellowstone and other ecosystems. BLM lands throughout the Resource Management Area are essential to the continuity of linkage connectivity north to the Northern Continental Divide Ecosystem and the Yellowstone Ecosystem.

Although the RMP does not call for ACEC designation for High Ore, MFWP believes that such designation would encourage management of the High Ore area to facilitate wildlife movement. Currently this area is severely impaired because it is lacking adequate travel management. Even Alternative C, the most restrictive travel management alternative still allows a major loop road through the area, and its implementation would require consistent, diligent management and enforcement to regain some of the linkage values that this area is capable of providing for wildlife. One of the Relevance Criteria listed in Appendix H with respect to ACEC designations states:

“Special management is typically needed when one of the following conditions is met:

Current management or management activities proposed in the alternative are not sufficient to protect the relevant and important resource values;

The needed management action is considered unusual or outside of the normal range of management practices typically used; or

The change in management is difficult to implement without ACEC designation.” It appears all of the above criteria are being met, and particularly the first one.

Additionally, the Importance Criteria list 5 items, and at least the first 3 have merit with respect to High Ore and its value for wildlife movement through the landscape and linkage of ecosystems for threatened (grizzly bear, Canada lynx), endangered, or sensitive (wolverine) wildlife. All of these species occur within the planning area.

**Response:** The BLM is required to consider designation of Areas of Critical Environmental Concern (ACECs) as part of its land use planning process. This is done either during the development of the Draft RMP/EIS or as a plan amendment. In so doing, the BLM is required under 43 CFR 1610.7-2 to publish a notice in the Federal Register listing each proposed ACEC and specifying the resource use limitations, if any, which would occur if it were formally designated. Such a notice must provide a 60-day public comment period on each proposed ACEC designation.

During scoping for the Butte RMP, the Butte Field Office solicited ACEC nominations from the public so that review and consideration could take place during the preparation of the Draft RMP/EIS. The ACEC proposal in the comment identifying the particular relevant and important values was not submitted prior to the release of the Butte Draft RMP/EIS. Therefore, consideration of this ACEC at this time would require an additional Federal Register notice along with an additional 60-day public comment period, as well as a supplemental Draft RMP/EIS for public review. Due to the additional costs and timeframe extension for the Butte RMP associated with this requirement, this ACEC proposal will not be considered in the current Butte RMP revision. However, the BLM would encourage the commenter to resubmit this ACEC proposal for consideration after finalization of the Butte RMP. If designation of this potential ACEC is found to be warranted, it could be done with a RMP amendment.

**U4**

**Comment:** It is not clear why all potential ACECs would not be designated under Alternative D. If the relevant and important values for designating these areas currently exist, then management direction for Alternative D should protect them.

**Response:** Not all potential Areas of Critical Environmental Concern (ACECs) would be designated under Alternative D because this alternative was developed with the intention of providing for fewer resource use restrictions than other alternatives.

**U5**

**Comment:** The Draft Plan is woefully inadequate in connection with its analysis of what is described as the Elkhorn Mountains nominated "Area of Critical Environmental Concern" (hereinafter "ACEC") particularly as it applies to the Limestone Hills area utilized by

Graymont and the Guard. Without any analysis of the practical realities in the Limestone Hills, Alternatives B and C include the entire area of the Limestone Hills in a proposed ACEC. The evaluation of the "relevance criteria" and the "importance criteria" contained in Appendix H appears to be focused on other areas of the Elkhorn Mountains and do not relate to the characteristics of the Limestone Hills. There is no evidence contained in the Draft Plan to support a designation of the Limestone Hills as an area where special management attention is required to prevent irreparable damage to fish and wildlife resources.

**Response:** Inclusion of the Limestone Hills area within the potential Elkhorn Mountains ACEC boundary was an inadvertent oversight in the Draft RMP/EIS. Under the Preferred Alternative (Alternative B) in the Proposed RMP/Final EIS, the potential ACEC boundary has been modified to exclude the Limestone Hills area.

#### U6

**Comment:** The BLM was a working partner in the Sage Grouse Strategy (MSGs), yet the protection and enhancements in the Butte RMP is no more developed or more proactive than the Dillon Office RMP was, and as such falls short of the proactive promises given in the MSGs. Given the tentative nature of Sage grouse existence within this management area, MWF advocates a reevaluation and consider protection afforded by an ACEC designation for remaining Sage grouse supporting habitat. They meet the ACEC requirement of being relevant, important, and in need of management especially in the Butte FO managed lands since opportunities to salvage a declining population are few in number and as such increase their intrinsic value.

**Response:** ACEC nominations were solicited during public scoping conducted for the Butte RMP. The BLM is required to consider designation of Areas of Critical Environmental Concern (ACECs) in draft RMPs or plan amendments. In so doing, the BLM is required under 43 CFR 1610.7-2 to publish such consideration in a notice in the Federal Register listing each proposed ACEC and specifying the resource use limitations, if any, which would occur if it were formally designated. Such a notice must provide a 60-day public comment period on each proposed ACEC designation. The ACEC proposal in the comment was not submitted prior to the release of the Butte Draft RMP/EIS. Therefore, consideration of this ACEC at this time would require an additional Federal Register notice along with an additional 60-day public comment period, as well as a supplemental Draft RMP/EIS for public review. Due to the additional costs and timeframe extension for the Butte RMP associated with this requirement, this ACEC proposal will not be considered in the current Butte RMP revision. However, the BLM would encourage the commenter to resubmit this ACEC proposal for consideration after finalization of the Butte RMP. If designation of this potential ACEC

is found to be warranted, it could be done with a RMP amendment.

#### U7

**Comment:** BLM manages several parcels near Mullan Pass in Greenhorn and Skelly Creeks as well as other parcels near the Continental Divide near Marysville. These areas are within Canadian Lynx core areas identified in the Northern Rockies Lynx Planning Area map developed by the US Forest Service. Mullan Pass itself is located at the north end of a narrow pinch-point in a wildlife linkage area recognized by the US Forest Service (2007) as highly important for Canada lynx dispersal. Models completed by Craighead and Walker (2002) indicated that this area is one of the last, best linkage areas between the Northern Continental Divide ecosystem and the Elkhorn Mountain Range which has the potential to reconnect otherwise isolated populations of Canadian Lynx and other Special status species such as Grizzly Bears, and Wolverines to the Greater Yellowstone ecosystem. Recent winter tracking studies confirmed the usage of the general area within 2 miles of these named parcels. As development of nearby private lands increases, available land for wildlife purposes will accordingly be reduced. ACEC designation for these pieces categorically fit the stipulations of relevance, importance and need for management for the increased wildlife security in conjunction with Forest Service lands.

**Response:** ACEC nominations were solicited during public scoping conducted for the Butte RMP. The BLM is required to consider designation of Areas of Critical Environmental Concern (ACECs) in draft RMPs or plan amendments. In so doing, the BLM is required under 43 CFR 1610.7-2 to publish such consideration in a notice in the Federal Register listing each proposed ACEC and specifying the resource use limitations, if any, which would occur if it were formally designated. Such a notice must provide a 60-day public comment period on each proposed ACEC designation. The ACEC proposal in the comment was not submitted prior to the release of the Butte Draft RMP/EIS. Therefore, consideration of this ACEC at this time would require an additional Federal Register notice along with an additional 60-day public comment period, as well as a supplemental Draft RMP/EIS for public review. Due to the additional costs and timeframe extension for the Butte RMP associated with this requirement, this ACEC proposal will not be considered in the current Butte RMP revision. However, the BLM would encourage the commenter to resubmit this ACEC proposal for consideration after finalization of the Butte RMP. If designation of this potential ACEC is found to be warranted, it could be done with a RMP amendment.

## U8

**Comment:** AWL suggests designating additional BLM lands adjacent to United States Forest Service lands as ACECs, especially those near the Mount Haggin Wildlife Management Area and Mullan Pass northwest of Helena, Montana. Inclusion of these areas as ACECs would prove highly advantageous to wildlife. Designating lands as ACEC near the Mount Haggin Wildlife Management Area provides special management for wildlife within a greater block of land. With continued residential expansion of Butte, the I-90 corridor to the north, and an already prolific off-road motorized system in place on nearby forest lands, it is important to create large, secure blocks of wildlife habitat. Recent work performed by AWL indicated that this area was key to future connectivity between the Northern Continental Divide and the Greater Yellowstone grizzly bear populations. This area was also identified as important for the dispersal of wolverines. Mullan Pass is at the north end of a narrow pinch-point in a wildlife linkage area recognized by the US Forest Service (2007) as important for Canada lynx dispersal. Models completed by Craighead and Walker (2002) indicated that this area is one of the last best linkage areas between the Northern Continental Divide ecosystem and the Elkhorns which ultimately could reconnect wildlife populations to the Greater Yellowstone ecosystem. Recent winter tracking studies in an area roughly two miles to the south further confirm that the area is used by ungulates along with both rare and common forest carnivores (Wild Things Unlimited, 2007). While the BLM land may not be along the Continental Divide, evidence from telemetry done on elk by Montana Fish, Wildlife and Parks indicates a seasonal movement up and downslope from the Continental Divide, and that this general area is important for wintering elk. Development of private lands around this area is increasing thus reducing overall available land for wildlife. Special designation of any land in and around this area as an ACEC would further increase wildlife security and preserve wildlife habitat is encouraged.

**Response:** ACEC nominations were solicited during public scoping conducted for the Butte RMP. The BLM is required to consider designation of Areas of Critical Environmental Concern (ACECs) in draft RMPs or plan amendments. In so doing, the BLM is required under 43 CFR 1610.7-2 to publish such consideration in a notice in the Federal Register listing each proposed ACEC and specifying the resource use limitations, if any, which would occur if it were formally designated. Such a notice must provide a 60-day public comment period on each proposed ACEC designation. The ACEC proposal in the comment was not submitted prior to the release of the Butte Draft RMP/EIS. Therefore, consideration of this ACEC at this time would require an additional Federal Register notice along with an additional 60-day public comment period, as well as a supplemental Draft RMP/EIS for public review. Due to the additional costs and timeframe extension for the Butte RMP associated

with this requirement, this ACEC proposal will not be considered in the current Butte RMP revision. However, the BLM would encourage the commenter to resubmit this ACEC proposal for consideration after finalization of the Butte RMP. If designation of this potential ACEC is found to be warranted, it could be done with a RMP amendment.

## U9

**Comment:** Referring specifically to Alternative B, the preferred alternative, the Elkhorn's potential ACEC is identified as containing 53,439 acres. In this alternative, the proposed ACEC would extend East to what appears to be Old Woman's Grave Road within the area of the proposed Guard withdrawal and would contain the entire extent of Graymont's mining area. Graymont submits that there is nothing within the "area" of the Limestone Hills that meets the definition of area of critical environmental concern. The analysis of both the relevance criteria and the importance criteria as contained in Appendix H and as utilized throughout the Draft Plan is inadequate because the unique characteristics and present uses of the Limestone Hills are not isolated and adequately examined. The Draft Plan must be modified prior to adoption by the BLM in order to eliminate any consideration of the Limestone Hills for ACEC designation.

With regard to Alternative B and the text beginning at page 70 regarding the Elkhorn's potential ACEC, the inconsistencies between the Guard's proposed withdrawal, Graymont's operations, and the proposed ACEC become apparent. None of the items mentioned under the heading "Recreation Opportunity Spectrum" appear to apply to the Limestone Hills. Under "Motorized Travel Management" none of the headings appear to apply to the Limestone Hills. Similarly, under the heading "Landownership/ Adjustment" the bullet points would appear to be inconsistent with both Graymont's operations and the content of the recently published LEIS. Again, none of the "major management categories" seems to apply to the Limestone Hills Area and therefore the area occupied by both Graymont's mining operations and the Guard's military activities should be eliminated from all alternatives of the Elkhorn Mountains proposed ACEC.

**Response:** In the Preferred Alternative of the Proposed RMP/Final EIS, the Elkhorns ACEC boundary has been modified to exclude the Montana Army National Guard proposed withdrawal, as well as the Graymont Mine operation, including the Graymont Mine proposed expansion.

## U10

**Comment:** We also ask that in the final RMP, the Sleeping Giant ACEC be expanded so that it includes a portion of the proposed ACEC "Extension." According to the draft RMP, the ACEC Extension was not carried

forward to the preferred alternative because it did not meet the relevance criteria. The roaded upper half of the ACEC Extension probably doesn't fully meet the relevance criteria, but the lower roadless half (Sheep Creek roadless area) is largely indistinguishable from the existing ACEC and therefore it needs to be evaluated separately. No alternative considered just the roadless portion of the Extended ACEC. The overall terrain of the Sheep Creek roadless area is highly natural and scenic views exist. It also provides habitat for many of the important wildlife species including elk, black bear, mule deer, furbearers, and a variety songbirds and raptors. Although sections of private land break up the ACEC, the landscape is clearly connected and it would be incongruous to manage this land in a manner which is incompatible with the existing ACEC. We ask that in the final RMP, you consider an ACEC Extension that analyzes just the Sheep Creek roadless area.

**Response:** ACEC nominations were solicited during public scoping conducted for the Butte RMP. The BLM is required to consider designation of Areas of Critical Environmental Concern (ACECs) in draft RMPs or plan amendments. In so doing, the BLM is required under 43 CFR 1610.7-2 to publish such consideration in a notice in the Federal Register listing each proposed ACEC and specifying the resource use limitations, if any, which would occur if it were formally designated. Such a notice must provide a 60-day public comment period on each proposed ACEC designation. The ACEC proposal in the comment was not submitted prior to the release of the Butte Draft RMP/EIS. Therefore, consideration of this ACEC at this time would require an additional Federal Register notice along with an additional 60-day public comment period, as well as a supplemental Draft RMP/EIS for public review. Due to the additional costs and timeframe extension for the Butte RMP associated with this requirement, this ACEC proposal will not be considered in the current Butte RMP revision. However, the BLM would encourage the commenter to resubmit this ACEC proposal for consideration after finalization of the Butte RMP. If designation of this potential ACEC is found to be warranted, it could be done with a RMP amendment.

#### U11

**Comment:** Elkhorn Mountains ACEC: MFWP endorses the proposed the ACEC designations for the Elkhorn Mountains as described in Alternative C, rather than Alternative B, primarily because the wildlife linkage values the additional lands on the east side of the Elkhorns provides to the Big Belt Mountains. Appendix H recognizes this linkage (p. 778).

**Response:** The BLM has modified the boundaries of the Elkhorns potential ACEC in the Preferred Alternative (Alternative B). This boundary now excludes the Graymont Mine permitted area as well as the currently proposed expansion boundaries. Also, the Montana

Army National Guard proposed withdrawal area is now fully excluded. The recently acquired Iron Mask property has been included in the Preferred Alternative.

#### U12

**Comment:** Sleeping Giant ACEC Extension: Appendix H indicates that the Sleeping Giant ACEC extension does not have any of the wildlife values exemplified by the primary ACEC area, but we do not agree. We think all species that occur within the ACEC area also occur within the proposed extension, and together, both areas constitute a vital linkage for wildlife between ecosystems and island mountain ranges. For these reasons FWP recommends that the extension is included.

**Response:** The proposed Sleeping Giant ACEC extension as described in **Appendix H** (now **Appendix I** in the Proposed RMP/Final EIS) includes areas that are substantially roaded, including being bisected by Interstate 15, where wildlife habitat is reduced in value compared to that within the existing ACEC. In recent travel planning efforts in the area immediately east of I-15, the BLM acknowledged this locality's importance as a wildlife linkage area and reduced open road densities to some degree during that travel planning effort (Sleeping Giant Travel Plan). Some portions of the proposed ACEC extension do have unroaded characteristics and may provide habitat of similar value to that in the existing ACEC. However, the BLM continues to believe this proposed extension on the whole does not meet relevance criteria for wildlife values.

#### U13

**Comment:** The area which was a major corridor for Native Americans for millennia has high historic, recreation, wildlife, and scenic value. The "Bears Tooth" (Sleeping Giant) was one of the few landmarks Lewis and Clark knew about as they planned their expedition through Montana. Members of the Corps of Discovery explored and camped below the Sleeping Giant. They were also awed by the rising cliffs and steep ramparts encountered as they traveled up the Missouri through the Gates of the Mountains – a name given to the area by Lewis and Clark.

The area is home to a spectacular array of wildlife: elk, mule deer, antelope, bighorn sheep, mountain goats, black bear, and grouse. Resident and migrating raptors also inhabit the area and the southern portion of the Gates addition provides critical winter range for elk, turkey, and whitetail deer.

This unique treasure of the big sky state is a source of pride for our region and our family. It seems everyone who visits Helena has the Giant pointed out to them. Folks who have had the experience of hiking to the 'top of the nose' further understand the significance of this landmark. The adjoining lands are largely the same

today as they were when our forbearers, the Synness family, arrived to homestead the area in the 1880s.

Most folks we talk to recognize that Montana is changing very quickly. In order to preserve the existing historic landscape, wildlife corridor and conservation values we support expansion of the Sleeping Giant Area of Critical Environmental Concern

**Response:** ACEC nominations were solicited during public scoping conducted for the Butte RMP. This comment lacks specificity in its geographical description of the suggested expansion of the Sleeping Giant ACEC. The BLM would encourage the commenter to more specifically describe the area in question for ACEC expansion (providing a detailed map is recommended) and resubmit this proposal for consideration after finalization of the Butte RMP. If designation of this potential ACEC is found to be warranted, it could be done with a RMP amendment.

### Special Designations – National Trails/Wild and Scenic Rivers/ Wilderness Study Areas

#### V1

**Comment:** The management consideration of User Conflicts is puzzling w/respect to the Continental Divide Trail. Alternative A notes the winter user conflicts on the Divide between motorized and non-motorized uses. However, Alts B and C note that rerouting the Continental Divide Trail would actually enhance conflicts. Does this mean both Alts B and C would result in closure of the existing Trail to snow machine use?

**Response:** The Continental Divide National Trail segment above Marysville follows a secondary road along the north-south ridge that would remain open to motorized wheeled vehicles yearlong and snowmobiles from December 2 to May 15 (snow conditions permitting). Coordination efforts are currently underway with the Forest Service to identify options for re-routing this trail to enhance user experiences, reduce acquisition costs, and remove conflicts associated with the motorized road. See Volume 1, Chapter 2, Special Designations, National Trails, Management Common to Action Alternatives (B, C, and D) in the RMP.

#### V2

**Comment:** Wild and Scenic Rivers: Guidelines for inclusion of river segments in National Wild and Scenic River System are not arbitrary or capricious, as is suggested by this proposed plan when it claims a river's listing would depend on the alternative selected. Because suitability studies have already been conducted, the BLM should be able to conclude at this time if a particular river segment is currently eligible and suitable. Thus, designation is not dependent on the actions or alternatives proposed by this plan. Furthermore, actions should not be included in this plan, across all alterna-

tives that would degrade currently eligible and suitable river segments.

**Response:** BLM policy is to evaluate river segments within the resource management planning process to determine eligibility, tentative classification, protection requirements, and suitability under the Wild and Scenic Rivers Act. The Wild and Scenic River Suitability Study for the river segments being considered in the Butte RMP revision was developed as part of this RMP revision. The RMP process is used to identify suitable river segments that the BLM recommends to Congress for designation as Wild and Scenic Rivers. BLM Manual 8351, Wild and Scenic Rivers, (page 0.33c) stipulates that one RMP alternative shall provide for designation of all eligible river segments. Another alternative shall provide for no WSR designations. The No Action alternative defers suitability determinations and provides for on-going management to protect all eligible segments. The Record of Decision for the RMP will identify the suitable segments (if any), whose Outstandingly Remarkable Values would then be protected indefinitely under the RMP until Congress acts on the BLM's recommendations. Only Congress can actually designate river segments.

#### V3

**Comment:** I agree with many closures; however the proposed Missouri river closures to motor boats from Hauser dam to Holter Lake I don't agree with. Reasons being is those water flows are regulated by dams which were already mentioned in the Helena IR. That is such a small stretch of river that closing it down to boats wouldn't have a big impact on the environment especially with lakes on each end. There are also many residents in the American Bar subdivision that use boats upstream. I myself also own a jet boat and I enjoy that area on a regular basis. That small stretch of river is the main reason that I purchased that boat. I know that there is controversy and complaints about speeding boats in that area and I have witnessed this myself and have also turned in several of individuals to the local game wardens for not following the no-wake law from Beaver Creek up to Hauser dam which is about 1.5 miles. I will agree that a sign should be put up as a reminder to the boaters who don't read the regulations, however in the end it is there responsibility. I agree that certain areas need protection but for such a small section between two large lakes that are regulated by dams, have old dam structure everywhere on the banks and in the water, and permanent houses built next door to each other, doesn't sound all that wild and scenic.

**Responses:** No designations will be made by the Butte RMP for the river or the adjacent Forest Service lands. The Forest Service will study its lands for suitability in their next Land Use Plan. River use issues such as motorized vs. non-motorized travel could be decided by Congress as part of its designation decision or more likely

through a specific Wild and Scenic River management plan should the area be designated. Closure of motor boat uses on the Missouri River immediately below Hauser Dam within the preliminarily suitable Wild & Scenic River segment is not proposed at this time and is beyond the scope of this RMP Revision.

#### V4

**Comment:** Consideration is being given to declaring the stretch of Missouri River between the Hauser Dam and the Gates of the Mountains be designated a wild and scenic river status thus outlawing any type of motor use on the river. This is a very popular area for local fishermen with boats and the older I get the more difficult it is for me to hike long distances to enjoy that portion of the river. Thus, taking a boat there is the only viable means for me to access that area. The area, although very beautiful, is hardly wild in that there are numerous residences in the lower section of the river and numerous old structures closer to Hauser Dam, including the power plant and residences just below the dam. Also with no viable means to launch a drift boat in that area, it would become strictly a walk in area except for the access at Nelson. I agree with maintaining our wilderness areas but this just isn't one of them so please do not restrict motor boat access to that area.

**Responses:** The Butte Field Office has found 3.1 miles of the Missouri River below Hauser Dam downstream to the end of the BLM boundary in T12N, R3W, Section 13 to be preliminarily suitable for inclusion in the National Wild and Scenic Rivers System. No designations have been made for the river or the adjacent Forest Service lands at this point for it is beyond the legal scope or decision making authority of this document. The Forest Service will study its lands for suitability in their next Land Use Plan. River use issues such as motorized vs. non-motorized travel could be decided by Congress as part of its designation decision or more likely through a specific Wild and Scenic River management plan should the area be designated. Closure of motor boat uses on the Missouri River immediately below Hauser Dam within the preliminarily suitable Wild & Scenic River segment is not proposed at this time and is beyond the scope of this RMP Revision.

#### V5

**Comment:** EPA encourages the BLM to also consider recommending the Upper Big Hole River and Moose Creek for wild and scenic river designations. The information presented in the Wild and Scenic Rivers Suitability Study (Appendix I) appears to show that these river segments possess eligible characteristics for wild and scenic river designation, and we believe that such designation would promote improved long-term protection of these river segments.

**Response:** The BLM considers these river segments eligible for Wild and Scenic River designation. However

the BLM continues to consider these rivers not *suitable* for designation based on management difficulties and challenges associated with suitability criteria described in **Appendix I** of the Draft RMP/EIS (**Appendix J** in Proposed RMP/EIS).

#### V6

**Comment:** Segment between Upper Holter and Lower Holter Lake: MWA urges the BLM to also assess the segment of river between Upper Holter Lake, through the Gates of the Mountains, to lower Holter Lake for inclusion in the NWSRS. This segment of the Missouri River deserves careful consideration because it:

- (1) is “free-flowing” as that term is defined and understood in the Wild & Scenic Rivers Act (“WSRA”) and Interagency Guidelines (47 Fed. Reg. 39455); and
- (2) contains many of the same, if not more, outstandingly remarkable values than the segment below Hauser.

Indeed, this segment of the Missouri River is bounded almost entirely by public lands, most of which already have a protective designation, including the Sleeping Giant Wilderness Study Area, Sleeping Giant Area of Critical Environmental Concern, the Beartooth Wildlife Management Area, and the Gates of the Mountains Wilderness Area. Most of the river corridor remains primitive with little evidence of human activity. The only exceptions are the campgrounds in the Gates of the Mountains, and some developed cabins on the west side of Oxbow Bend, accessible only by water, on the boundary of Sleeping Giant WSA. MWA therefore asks that BLM carefully study whether this segment is both “eligible” and “suitable” for inclusion in the NWSRS.

**Free-Flowing:** While it is true that the Missouri River is controlled and the dam below Holter Lake affects the natural “flow” of the river (just as it does on other segments of the river including the Wild and Scenic segment between Fort Benton and Kipp Landing), such control does not affect the segment’s qualification for inclusion in the NWSRS. The segment still qualifies as “free flowing” under the Wild and Scenic Rivers Act (WSRA) and Interagency Guidelines. The definition of “free-flowing” in section 16 of the WSRA (16 USC 1286) explicitly states that a river segment qualifies as free-flowing flows between large impoundments. There are no specific requirements in the Act concerning the length or flow of an eligible river segment. In fact, a river need not even be “boatable or floatable” in order to be eligible. The eligibility criteria only requires that a river segment be of sufficient length if, when managed as a wild, scenic, or recreational river area, the outstandingly remarkable values are protected. As such, we ask that the BLM carefully review and follow the interagency guidelines and manual in determining whether this segment of river is free-flowing.

Data obtained from the U.S. Geological Survey (“USGS”) (“Real-Time Data for Montana: Streamflow”

web site) indicates that the river has a substantial flow. USGS gauges located below Hauser Dam show that the long-term median flow is 3,050 cfs and the gauge located below Holter Dam shows that the long-term median flow is 3,910 cfs. While there are no other water gauges between these two locations, according to Larry Dolan, a hydrologist at the Water Management Bureau, Montana Department of Natural Resources and Conservation, the river flow in between the two gauges should be similar to the flow recorded at the two gauges. According to his calculations, a typical discharge for the Missouri River below Hauser Dam might be about 4,000 cubic feet per second (cfs). All of the water that flows out of Hauser Dam must ultimately move downstream. Discharge is a product of the channel area times velocity. Dividing the 4,000 cfs flow rate by the above computed X-sectional area results in an average water velocity through the section of 0.32 feet per second (4,000 ft<sup>3</sup>/sec /12,500 ft<sup>2</sup>). This is a slow velocity compared to what might typically occur prior to the construction of the dams, but the important point is that there is a flow in this segment of the river between Upper and lower Holter Lake.

**Outstandingly Remarkable Values:** MWA believes that this segment of the Missouri River includes four outstandingly remarkable values: scenic, historic/cultural, recreation, and wildlife. As outlined below, both individually and in the aggregate, these values make this river segment an exceptional candidate for consideration as a Wild and Scenic River. Designating this segment of the Missouri as Wild and Scenic would help ensure that river corridor's outstandingly remarkable values remain special and that the future management of the river corridor will be compatible with the adjacent protective designations.

**Scenic Values:** The Sleeping Giant is a BLM Wilderness Study Area which was studied and recommended for Wilderness in 1991. The 1991 BLM Wilderness Study Report describes the Sleeping Giant WSA as "providing outstanding scenic values within the unit. Offsite vistas of the surrounding landscape are outstanding." Lewis also named the Gates of the Mountains, another widely recognized landmark along the Lewis and Clark Historic Trail. In mid-July, 1805, when Captain Meriwether Lewis first viewed the Gates of the Mountains, he described the area in his journal as follows:

"We entered the most remarkable cliffs that we have yet seen. These cliffs rise from the water's edge on either side perpendicularly to the height of 1,200 feet. Solid rock for the distance of 5.75 miles." This view is still available for today and it looks virtually the same as when Capt. Lewis and his Corps of Discovery first laid eyes upon it. The canyon area through the Gates of the Mountains is only accessible by water or traveling more than a dozen miles over trails through the Helena National Forest and Gates of the Mountains Wilderness Area. A pamphlet describing the boat tour of the Gates

of the Mountains describes the tour's main attraction as the "inexhaustible scenery – wooded slopes, rugged rock formations, and the placid beauty of the timeless Missouri." Across the river from the Sleeping Giant is the Beartooth Wildlife Management Area which is managed by the State of Montana. In addition to providing valuable wildlife habitat, this primitive area provides a scenic backdrop comparable to the Sleeping Giant WSA.

**Historic/Cultural:** Along the shoreline, Indian pictographs painted on the rock wall are visible, indicating that indigenous people lived in the area and used the river long before the arrival of the first white explorers. Two sons of Chevalier Vendrye, the French explorer, for instance, passed through the area known as the Gates of the Mountains as early as 1742. They were probably the first white men to gaze upon its precipices. However, the Corps of Discovery explored and camped below the Sleeping Giant when they traveled through Montana in 1805 and Lewis left a record of his passage through the Sleeping Giant/Gates area. This segment of the river is one of the few remaining sections of the Lewis and Clark National Historic Trail that has changed very little since 1805-06. Evidence of the early white settlers also exists. In the Sleeping Giant Wilderness Study Area there are several deteriorating structures near the river which provide a glimpse into their lifestyles.

The area also features more contemporary history. Mann Gulch in the Gates of the Mountains Wilderness is the site of the raging forest fire that killed 13 smokejumpers 50 years ago. The tragedy was the main subject matter of Norman Maclean's book "Young Men and Fire." A popular guided boat tour provides interpretation of historic and cultural events in the area.

**Wildlife:** A diversity of important wildlife species live in the Sleeping Giant WSA, including a thriving population of mountain goats that occupies the high outcroppings. Other common species include elk, black bear, bighorn sheep, mule deer, osprey, and golden eagles. Across the river from the Sleeping Giant WSA is the Beartooth Wildlife Management Area, the purpose of which is to provide wildlife habitat for a variety of species, especially elk. All of Montana's big game animals live on or visit the Beartooth Wildlife Management Area at various times. Upland game birds, songbirds, raptors, furbearers and numerous small mammals can be found through much of the year. In the Gates of the Mountains, Bighorn sheep and Mountain Goats scamper in the rocks high above the water. Ospreys, eagles (bald and golden), vultures, and falcons (peregrine and prairie) still soar on the updrafts. The canyon is also home to otters, deer, squirrels, ermine, beaver, mountain lions, black bears, and other wild creatures. The life list for bird species is over 120.

**Recreation:** High quality recreation opportunities associated with the river corridor include bird watching, hunting, hiking, horseback riding, picnicking, swimming, tent camping, wildlife viewing and fishing. Hunt-

ing for big game and grouse accounts for about half of the use of the Gates of the Mountains Wilderness, along with hiking, backpacking, and horseback riding. Wildflowers are also considered a star attraction.

A stated purpose of the Beartooth Wildlife Management Area is to provide recreational opportunities. It is a popular area for big game hunting and wildlife viewing. The Sleeping Giant also provides a non-motorized backcountry hunting experience. The river provides an important means for the public to access the surrounding protected public lands. It is frequently used to access or return from the Gates of the Mountains Wilderness trail system and it provides the only public access to the Gates of the Mountains Wilderness Study Area. The river also provides access to the canyon's few campgrounds and picnic sites. This segment of the river corridor attracts people from across the nation because of its unique scenic beauty and the historic, wildlife, and recreation values associated with the river corridor. It would make a strong candidate for inclusion in the National Wild and Scenic River System.

**Response:** While the BLM agrees with the commenter that the area in question has many values as described in the comment, the BLM ultimately considers the area from Upper Holter Lake down to Holter Lake to be impounded. The BLM acknowledges that water is certainly moving through the impounded portion of the Missouri River in this area as described in the comment, but such is the nature of many impounded lakes and reservoirs. The BLM continues to consider this area ineligible for Wild and Scenic River designation due to the impoundment at Holter Dam. The BLM notes that existing management of the Sleeping Giant WSA combined with management of the Gates of the Mountains Wilderness Area provide for protective management of the values described in the comment.

#### V7

**Comment:** Based on the public concern for protecting the primitive values of the area that has arisen during past studies of the Sleeping Giant area, many local citizens have expressed support for a Wilderness bill to finally provide this area with permanent Wilderness protection. In order to preserve these Wilderness Study Areas so that they can be considered for Wilderness protection, I urge the BLM to retain the current non-motorized character of these areas in the updated Resource Management Plan. To further preserve the primitive qualities of this area, I urge the BLM to provide the same protection for the roadless area southwest of the Sheep Creek Area and to recommend Wild and Scenic River status to all eligible nearby sections of the Missouri River.

**Response:** The BLM is required to continue managing for wilderness values in the Sleeping Giant area (Sheep Creek and Sleeping Giant WSAs) until Congress decides whether or not to designate these areas as wilderness.

The roadless area southwest of Sheep Creek is not contiguous with the Sheep Creek Wilderness Study Area, nor does it meet minimum size criteria of 5,000 acres to potentially stand on its own as a Wilderness Study Area. While the Butte RMP revision will retain the non-motorized character of these areas, the BLM cannot recommend any additional Wilderness Study Areas in this RMP revision. The BLM has identified the segment of the Missouri River from below Hauser Dam to the upper end of Upper Holter Lake as suitable for Wild and Scenic designation, pending Forest Service concurrence.

#### V8

**Comment:** BLM presented only proposals for more road closures and wilderness study areas with no public access.

**Response:** Chapter 2 of the RMP presents proposed management for a wide range of resources and resource uses. While some road closures are proposed under various alternatives, and management of existing Wilderness Study Areas is addressed, there are no proposals for additional Wilderness Study Areas in the Butte RMP.

#### V9

**Comment:** Issue 5: Protect WSAs: The BLM IMP, H8550-1 JULY 1995, does not preclude motorized use in the area. Any road/trail in the area that is in use now could be recovered to wilderness character if and when Congress decides to designate them as wilderness.

**Response:** The BLM agrees that vehicle travelways existing during the intensive inventories and establishment of the wilderness study area are available for continued motorized use unless specific land use travel plan decisions have been completed since that time. There are no open vehicle ways in the six existing WSAs except for several routes in the Black Sage WSA that lack public access due to land ownership patterns, and one route through a corner of the Humbug Spires WSA. No new trails are permitted in existing WSAs unless they are needed to meet minimum necessities for public health and safety and to protect wilderness resource values.

#### V10

**Comment:** The national BLM policy bans bicycles from Wilderness Study Areas. This is wrong as a blanket policy, and should be applied selectively. I saw no WSA area in the Butte District of concern for bike riders, but I could be wrong.

**Response:** There is no national BLM policy that bans bicycles from Wilderness Study Areas (WSAs). Bicycle use in WSAs is limited to motorized vehicle ways existing at the time of inventory. There are no open vehicle ways in the six existing WSAs except for several routes in the Black Sage WSA that lack public access due to land ownership patterns, and one route through a corner of the Humbug Spires WSA.

**V11**

**Comment:** After watching what happens to the land, the air, the wildlife, the burden on taxpayers, as well as firefighters, I believe the “let-it-burn” policy for the wilderness areas, is insanity. Our family has decided we have no choice but to oppose the proposed wilderness designation for the Sleeping Giant. The Sleeping Giant is now categorized as ACEC (Area of Critical Environmental Concern) which fully protects its ecosystems and long term ACEC values (naturalness, primitive and unconfined forms of recreation, solitude experiences, visual resources, native wildlife, and cultural resources).

**Response:** The BLM has no authority to designate wilderness areas. Only Congress can designate wilderness. The BLM is required to continue managing Wilderness Study Areas (such as Sleeping Giant) so as not to preclude wilderness designation until such time as Congress decides to either designate them as wilderness, or release them from further wilderness consideration.

**V12**

**Comment:** Wilderness Study Areas: management for wilderness character would be enhanced through Alternative C in that stipulations would benefit wildlife. MFWP endorses Alternative C for all four Wilderness Study Areas: Sleeping Giant, Sheep Creek, Humbug Spires, and Elkhorns Tack-on.

**Response:** Management of the four identified WSAs would be same under both the Preferred Alternative and Alternative C. Management for these WSAs is presented in Chapter 2, under sections identified as Wilderness Study Areas and ACECs. These WSAs under both alternatives would be managed under the Interim Management Policy and Guidelines for Lands under Wilderness Review until Congress decides to either designate them as wilderness or release them from further wilderness review. These four areas would be managed as ACECs should Congress release them from further wilderness review. ACEC management for these four WSAs does not change under either Alternative.

**Special Status Species**

**W1**

**Comment:** Thank you for providing information on the Special Status species in the BFO area (Table 3-15, pages 241-245). We are pleased that RMP management direction for Special Status Species promotes T & E and sensitive species protection and recovery (pages 40-41). If proposed management direction could affect threatened or endangered species, the final EIS should include the Biological Assessment and the associated USFWS Biological Opinion or formal concurrence for the following reasons:

(1) NEPA requires public involvement and full disclosure of all issues upon which a decision is to be made;

(2) The CEQ Regulations for Implementing the Procedural Provisions of NEPA strongly encourage the integration of NEPA requirements with other environmental review and consultation requirements so that all such procedures run concurrently rather than consecutively (40 CFR 1500.2(c) and 1502.25); and

(3) The Endangered Species Act (ESA) consultation process can result in the identification of reasonable and prudent alternatives to preclude jeopardy, and mandated reasonable and prudent measures to reduce incidental take. These can affect project implementation.

EPA recommends that the final EIS and Record of Decision not be completed prior to the completion of ESA consultation. If the consultation process is treated as a separate process, the Agencies risk USFWS identification of additional significant impacts, new mitigation measures, or changes to the preferred alternative. If these changes have not been evaluated in the final EIS, a supplement to the EIS would be warranted.

**Response:** The BLM has worked closely with the U.S. Fish and Wildlife Service throughout the development of the Butte RMP. As discussed in the Formal Consultation Section of Chapter 5, a representative from the U.S. Fish and Wildlife Service was a member of the planning team during development of the plan to adequately address and discuss the effects of management actions on listed and proposed species and their critical habitats. Early drafts of alternatives were also provided to the U.S. Fish and Wildlife Service for discussion and review. A draft biological assessment that evaluates the impacts of the preferred alternative on federal threatened and endangered species was submitted concurrently with the public release of the Draft RMP to the U.S. Fish and Wildlife Service. **Appendix G** in the Proposed RMP/Final EIS includes the U.S. Fish and Wildlife Service’s biological opinion.

**W2**

**Comment:** Biodiversity has become a significant issue in the northern Rocky Mountains (e.g. diversity and uniqueness of flora and fauna, connectivity of habitats, gene pools, species diversity, etc.). Maintenance of biodiversity can minimize the need for listing species as threatened or endangered. Upland and stream corridors and special habitats (i.e. wetlands, threatened and endangered species habitat) in the planning area may need to be maintained to protect genetic diversity. The state of the art for this issue is changing rapidly. CEQ prepared guidance entitled, “Incorporating Biodiversity Considerations into Environmental Impact Analysis under the National Environmental Policy Act,” <http://tis.eh.doe.gov/nepa/tools/guidance/Guidance-PDFs/iii-9.pdf>. We encourage the BLM to include improved evaluation and discussion of biodiversity considerations in the RMP and EIS.

**Response:** Biodiversity of vegetation (including forests, grasslands, shrublands, and riparian vegetation) and native animal species were identified as issues during the development of the RMP. From these issues, goals were developed that also emphasized biodiversity of native plants and animal species.

Vegetation management prescriptions in Chapter 2 also emphasize the concept of maintaining or improving biodiversity across the landscape. Although the acres of restorative treatments differ by action alternative, the emphasis of all action alternatives is on maintaining and restoring healthy, diverse, and productive native plant communities. All action alternatives would actively restore vegetation on the landscape level to conditions more consistent with landform and climate as well as with the biological and physical components of the ecosystem. Vegetation structure, density, species composition, patch size, pattern, and distribution would be managed to provide habitat for a variety of wildlife species. Management actions would maintain or mimic natural disturbance regimes to provide for diverse and sustainable ecosystems.

The Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section of Chapter 2 also emphasizes maintaining and supporting healthy, productive, and diverse populations and communities of plant and animal species. There would also be an emphasis on conserving federally listed and sensitive species. As described under Management Common to Action Alternatives, the BLM would maintain suitable habitat conditions and minimize fragmentation of linkage corridors in areas occupied by special status species. The intent would be to maintain the function and diversity of all habitats in large “patches” across the landscape. All action alternatives would stress maintaining diverse, healthy, and productive and well distributed aquatic habitats and communities.

General biodiversity principles and considerations were also applied to each step of the NEPA analysis associated with developing Montana/Dakotas Standards for Rangeland Health and Guidelines for Livestock Grazing (BLM, August 1997). During the scoping process for Rangeland Health and Guidelines for Livestock Grazing, BLM identified biodiversity issues and opportunities to meet biodiversity goals and objectives. Standards of physical and biological conditions or degree of function required for healthy sustainable ecosystems and guidelines for livestock grazing management were established. These standards and guidelines for grazing management for the Butte Field Office have been incorporated into the Butte RMP (Goals Common to All Alternatives for All BLM Activities). The Land Health Standards would not only be applied to rangelands but would also be applied to all habitat types and for all BLM authorized activities.

### W3

**Comment:** RMP management direction should also include standards, guidelines and procedures that ensure threatened, endangered and sensitive species are considered whenever the use of pesticides are contemplated. Language should be included in Special Use and other permits (i.e. grazing, recreation, etc.) that require the permittee to present requests of all use of pesticides on Federal lands to the BLM for review and approval.

Montana Water Quality Standards do not identify numerical criteria for aquatic life protection for many herbicides, however, it should be recognized that the research and data requirements necessary to establish numerical aquatic life water quality criteria are very rigorous, and many herbicides and weed control chemicals in use are toxic, although numerical aquatic life criteria have not been established. The Montana Water Quality Standards include a general narrative standard requiring surface water to be free from substances that create concentrations which are toxic or harmful to aquatic life. The National Pesticide Telecommunication Network (NPTN) website at <http://nptn.orst.edu/tech.htm> which operates under a cooperative agreement with EPA and Oregon State University, has a wealth of information on toxicity, mobility, and environmental fate on pesticides which may be helpful (phone number 800-858-7378).

**Response:** The BLM follows all requirements and recommendations as outlined on herbicide/pesticide labels. The use of herbicides and their affect on the environment has been analyzed in the Vegetation Treatment on BLM Lands in Thirteen Western States Final EIS. This document addresses the use of herbicides on BLM lands. The BLM uses the direction in the Vegetation Treatment on BLM Lands in Thirteen Western States EIS as well as the herbicides labels to provide for proper application of herbicides to protect the environment, birds, wildlife (including threatened, endangered, and sensitive species), and aquatic species. Since public release of the Draft RMP/EIS, the Record of Decision (ROD) has been signed for Vegetation Treatments Using Herbicides on Bureau of Land Management Lands in 17 Western States. The Preferred Alternative in the Proposed RMP/Final EIS has been revised to indicate that this ROD is the guiding and authorizing document for invasive vegetation species management.

The use of any proposed pesticide (to kill insects or other pests) would require site-specific analysis before application that would identify the effects to birds, wildlife (including threatened, endangered, and sensitive species), and aquatic species. The BLM appreciates the information provided by the commenter and will take this into consideration when addressing the use of pesticides. The BLM will use the direction on pesticide labels to provide proper application of pesticides to protect birds, wildlife, and aquatic species.

**W4**

**Comment:** We are pleased that the goal under Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plants and Animal Species indicates that impacts would be minimized to riparian areas and wetlands (page 40), but recommend more specific guidance be provided to assure that riparian and wetland functions are considered and protected. We recommend that the RMP include direction that assures that projects tiered from the management plan adequately assess the potential impacts on riparian conditions and functions, and protect riparian conditions and functions. We suggest that it would be appropriate to include management direction focused on restoration of riparian functions and conditions, consistent with the ICB Strategy, since this Strategy provides for improved restoration and maintenance of riparian functions.

For example:

“The BLM will restore and/or maintain riparian structure, composition, and processes, including physical integrity of riparian ecosystems, amount and distribution of woody debris to sustain physical and biological complexity, adequate summer and winter thermal regulation, water quality and hydrologic processes, distribution and diversity of riparian vegetative communities and source habitats for riparian dependent species.”

**Response:** The BLM agrees with the comment and has added the following wording to the goal in Chapter 2:

“The BLM would restore and/or maintain riparian structure, composition, and processes, including physical integrity of riparian ecosystems, amount, and distribution of woody debris to sustain physical and biological complexity, adequate summer and winter thermal regulation, water quality and hydrologic processes, distribution and diversity of riparian vegetative communities and source habitats for riparian dependent species.”

**W5**

**Comment:** BLM discussed threatened and endangered species, not a BLM responsibility. BLM is responsible for HABITAT and SPECIES MANAGEMENT is with other agencies. BLM did not mention that the gray wolf as well as the grizzly bear is undergoing a delisting process by the USFWS now. Populations are fully recovered under the USFWS recovery plans.

**Response:** BLM requirements for management of federally listed and proposed species come from the Endangered Species Act of 1973 (ESA). There are a total of 18 sections within the ESA, 9 of which contain requirements or authorizations for the BLM. Section 7 of the ESA requires the BLM to look at the impacts to threatened, endangered and candidate species from proposed actions on Federal lands.

In addition, BLM Manual 6840 (Special Status Species Management) identifies that the BLM will conserve

listed species and the ecosystems upon which they depend and also ensures that all actions authorized, funded, or carried out by the BLM are in compliance with the ESA.

The proposed de-listing of the gray wolf and grizzly bear are not discussed in the RMP because, even when de-listed (such as with the Yellowstone population of the grizzly bear), these species will stay on Montana BLM’s sensitive species list. As outlined under the Wildlife section in Chapter 2 of the RMP, management actions will promote conservation of special status (sensitive) wildlife species and the ecosystems on which they depend. The BLM is required to conduct monitoring and assessment of de-listed species under BLM Manual 6840.

**W6**

**Comment:** Hikers and wolves impact wildlife more than OHV use yet hikers and wolves are unrestricted.

**Response:** The BLM has found no evidence that hikers and wolves impact wildlife more than OHV use. The influence of high open road density on grizzly bear, wolverine, elk, and sage grouse, and wildlife in general, are well-documented in the scientific literature. Avoidance of otherwise suitable habitat, habitat fragmentation, mortality from collisions, increased disturbance, and loss of security habitat are all factors that effect how roads influence wildlife use of an area as well as the quality of wildlife habitats.

**W7**

**Comment:** The Agency must support any claim that various recreational activities (e.g., off-highway vehicle use, camping, equestrian use, hunting etc.) pose significant threats to endangered species. Claims that are highly speculative and based on little or no reliable data should be excluded from the environmental analysis.

The Agency must establish much more than a causal connection between recreation activities and any perceived declines in the population of any threatened or endangered species known to reside in the project area. At most, the technical data shows that some recreational activities, in some areas, have the potential to displace some species on a very local level. This, however, cannot establish that recreational activities pose a substantial threat to an entire population or subpopulation of a particular plant or animal.

**Response:** There are three wildlife species that are listed under the Endangered Species Act found in the Field Office; gray wolf, Canada lynx and the Northern Continental Divide population of grizzly bear. Of these listed species, the grizzly bear was identified as the most sensitive to open roads. The Special Status Species section of Chapter 4 (Alternative A), as well as the Wildlife section in the Lewis and Clark County NW Travel Plan Area in Chapter 4 of the RMP provide a discussion on

the effects of open roads to grizzly bear. The influence of open roads on grizzly bear is well documented in the scientific literature and research has found that grizzly bear avoid areas adjacent to open roads and areas with high road densities. A target of one mile of open road per square mile or less has long been used for evaluating habitat effectiveness for grizzly bear and is routinely used by Montana Fish, Wildlife and Parks, US Forest Service, U.S. Fish and Wildlife Service and the BLM.

#### W8

**Comment:** AWL praises the BLM's recognition of the importance of ecological corridor restoration and recommends that the BLM go one step further: the South Fork study by Mace and Manley (1993), the Selkirk/Cabinet-Yaak study by Wakkinen and Kasworm (1997) and two studies cited in the DEIS (on page 559: Mace et al. 1996; McLellan and Shackleton (1989) found that grizzly bears underutilized habitat with >1 mile/mile<sup>2</sup> of open roads and >2 miles/mile<sup>2</sup> of total roads. AWL suggests the BLM actually set a standard for open road density at 1 mile/mile<sup>2</sup> or lower and total road density of 2miles/mile<sup>2</sup> or lower in important grizzly bear corridors, as identified by Craighead et al (2002).

**Response:** The BLM is concerned about movement corridors for a variety of species including the grizzly bear, and believes this issue is adequately addressed in the Butte RMP. The Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section (Management Common to Action Alternatives) of Chapter 2 describes the BLM's proposal to maintain suitable habitat conditions and minimize fragmentation in wildlife linkage corridors occupied by special status species.

The BLM will also continue to apply the appropriate level of protection to grizzly bears based on peer reviewed scientific literature, recommendations of the U.S. Fish and Wildlife Service and the Grizzly Bear Management Plan for Southwest Montana (2002).

#### W9

**Comment:** Lewis and Clark TPA: This area is recognized by the United States Forest Service as an important corridor for lynx dispersal by the Lynx Management Direction, adopted by the Forest Service in July 2007/ (USFS 2007). AWL would suggest the BLM consider yearlong or seasonal closures above and beyond those presented in Alternative C in light of the importance of this area to lynx.

**Response:** Lynx habitat was taken into consideration during travel planning. The BLM believes that the Preferred Alternative adequately considers lynx habitat and other resource and management needs.

The BLM will continue to follow the Lynx Conservation Assessment and Strategy and work with the U.S. Fish

and Wildlife Service on how to best protect or restore habitat for lynx in this area.

#### W10

**Comment:** We are pleased that a goal has been included to protect, maintain, or restore sagebrush habitat in occupied or historic sage grouse habitat (page 40). The 2005 Management Plan and Conservation Strategies for Sage Grouse in Montana are recommended for further guidance.

**Response:** As stated in the Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species section (Management Common to All Alternatives) in Chapter 2 of the RMP, management activities would be designed and implemented to be consistent with the National and Montana Management Plan and Conservation Strategies for Sage Grouse in Montana (2005).

#### W11

**Comment:** Some interests are pushing the wildlife corridor concept as a reason to close areas to motorized use. We have not seen adequate documentation or reasoning to justify this position and suspect that it is being used inappropriately as a reason to justify de facto wilderness by non-motorized interests. Significant issues must be answered before this concept can be given any credibility. Issues include:

1. Why would wildlife follow physically challenging basin divides where food and water is scarce versus other corridors? They don't. This is easily verified by open areas such as McDonald Pass or the jagged areas of the continental divide where we have never observed any significant number of wildlife crossings versus great numbers of wildlife crossings that we have observed in other areas that are more favored by wildlife.
2. There is no data or credible documentation that the continental divide or other basin divides are favored for wildlife migration. Especially theories that purport that wildlife will migrate from Mexico to Canada. This is counter to the types of habitat that different species require in order to survive. There is a significant lack of credible evidence to support the wildlife corridor hypothesis.
3. The lack of authorization or mandate from congress for this sort of designation and use of public land.

**Response:** The BLM has not limited the discussion on movement corridors to the Continental Divide. Chapter 3 of the RMP (Wildlife Section) discusses the importance of wildlife corridors that vary in size and importance depending on the species and the how the habitat is being used. Movement corridors are described as areas of predicted movement between blocks of suitable habitat. A corridor can function at several scales. It can allow

seasonal movements for a species such as elk migration between summer and winter range or provide for dispersing juveniles such as a subadult cougar who have to leave fully occupied habitat of other adult cougars.

Movement corridors may be small, such in the case of amphibians or small mammals, or large such as with grizzly bear or big game species. If a patch of habitat is too small to support a population over time, corridors connecting patches of habitats can provide a larger habitat structure, and thus support a larger effective population. Movement corridors can also be critical for the flow of genetic material between populations.

Although it may be difficult to know the exact route an animal may take, the importance of movement corridors is documented in the literature and is a pertinent wildlife issue that should be addressed at the landscape level. Therefore the Butte RMP provides discussion and analysis of movement corridors.

#### W12

**Comment:** Conservation Actions for Grizzlies (p.737) north portion in Lewis & Clark Co and Jefferson County are connected more to the Northern Continental Divide Ecosystem than to the Yellowstone Ecosystem. The Butte RMP area provides critical connections between ecosystems.

**Response:** The BLM agrees with the commenter. With the delisting of the Yellowstone population of the grizzly bear, this section of **Appendix F** from the Draft RMP/EIS (now **Appendix G**) has been deleted in the Proposed RMP/Final EIS.

#### W13

**Comment:** Alternative D – Oil & Gas Stipulations (p.927) does not provide for grizzly bear at all.

**Response:** The stipulation for threatened, endangered, and special status species would provide protection to grizzly bear and grizzly bear habitat during oil and gas exploration. Under this controlled surface use stipulation, the BLM could require modifications on those exploration and development proposals that contribute to the listing of a sensitive species (such as the Yellowstone population of grizzly bear). This stipulation would also require modifications to or disapprove a proposed activity that is likely to result in jeopardy to the continued existence of a proposed or listed species or result in the destruction or adverse modification of critical habitat. While two additional Controlled Surface Use stipulations specifically for grizzly bears were inadvertently omitted from **Appendix L** in the Draft RMP/EIS, their proposal for use under Alternative D was included in Chapter 2 (Table 2-21 of Draft RMP/EIS). These stipulations have been added to the fluid minerals appendix for Alternative D (now **Appendix M**) in the Proposed RMP/Final EIS.

#### W14

**Comment:** The west-slope cutthroat trout does not qualify for listing [federal listing under Endangered Species Act].

**Response:** Although it is unclear what the comment is referring to, the Butte RMP refers to westslope cutthroat trout as a special status or sensitive species. The U.S. Fish and Wildlife Service found westslope cutthroat trout were not warranted for listing under the Endangered Species Act. However, to prevent listing under the ESA and to promote the conservation and recovery of this species, a Memorandum of Understanding and Conservation Agreement for Westslope Cutthroat Trout and Yellowstone Cutthroat Trout in Montana was signed by multiple agencies (including the BLM). This Memorandum of Understanding was updated in July, 2007.

#### W15

**Comment:** Several times within the EIS analysis of the Bozeman, Livingston, and Helena [oil and gas] areas, the RMP/EIS states that habitat for Arctic Grayling and Bull trout doesn't exist in the planning area. MWF believes these statements are categorically in error. Admittedly, much of their historic habitat is currently unoccupied; it is disingenuous and unprofessional to claim that the habitat does not exist; perhaps this is an oversight and can be corrected in the final. MWF believes the waters near Livingston and Bozeman still retain high potential for grayling restoration and that any and all options for reestablishing fluvial grayling in the state must be given elevated priority. At the very least, to be a viable portrayal of the biological reality on the ground, the RMP should refer to the waters here as potential grayling habitat even if the habitat is unoccupied.

**Response:** Although the BLM agrees that suitable habitat may be present in the areas identified by the comment and that re-introductions of certain fish species could be likely in the future, oil and gas stipulations focus on protecting habitat occupied by a species (such as arctic grayling and bull trout) and not potential habitat. The BLM based the mapping of these species on data from Montana Fish, Wildlife Parks (MFISH). When site-specific leases for oil and gas are identified, the BLM will again verify the presence of all fish species in the proposed lease area to determine the appropriate stipulations that should be applied to that lease. **Appendix M** of the Proposed RMP/Final EIS describes the process for oil and gas leases.

#### W16

**Comment:** In regard to streamside or riparian management buffer zones, we believe riparian buffers should be wider where there are steeper slopes and more erosive soils, and forested streamside buffer zones need to protect canopy cover and shade to buffer water temperatures, and to provide a sustainable source of large woody

debris needed for instream channel structure and aquatic species habitat. Adequate riparian buffer zones also are needed to protect ephemeral and intermittent streams to protect both these streams and their downstream tributaries.

A greater level of the riparian protection is provided for in the Forest Service's Inland Native Fish Strategy (INFS) than is proposed with the preferred alternative (Alternative B) in the draft RMP/EIS. The INFS provides for riparian management zones (RMZs) for forested fish bearing streams that consist of the stream and the area on either side of the stream extending from the edges of the active stream channel to the top of the inner gorge, or to the outer edges of the 100-year floodplain, or to the outer edges of riparian vegetation, or to a distance equal to the height of two site-potential trees, or 300 feet slope distance (600 feet, including both sides of the stream channel), whichever is greatest.

The proposed RMZ for Alternative B, however, only includes a proposed RMZ distance equal to the height of two site potential trees.

Alternative B does not include the additional language stating, "...or to the outer edges of the 100-year floodplain, or 300 feet slope distance, whichever is greatest."

We believe the riparian protections included in Alternative C are closer to providing the appropriate level of riparian buffer protection for fisheries, and should be included in the preferred alternative, particularly for any surface waters with populations of threatened bull trout within the jurisdiction of the BFO (e.g., Blackfoot River, page 230). We also note that while the Interim Bull Trout Habitat Conservation Plan Strategy (USDI-BLM 1996) is identified among the Plans that need to be considered (page 14), we do not see a clear commitment to provide adequate riparian protections for bull trout in Alternative B. We believe the Alternative C riparian protections are needed at a minimum for bull trout habitat protection.

We also recommend that Alternative C riparian buffers be considered for waters with populations of native westslope cutthroat trout and Yellowstone cutthroat trout and arctic grayling and Class I fisheries (e.g., for Clark Fork, Upper Missouri, Madison, Jefferson, Gallatin, Boulder, and Big Hole Rivers and their tributaries with native westslope cutthroat trout populations, page 219, and especially Muskrat/ Nursery Creek with its genetically pure population of westslope cutthroat trout, page 95, and Upper Yellowstone River and its tributaries with native Yellowstone cutthroat trout). The Alternative C or INFS riparian protection guidelines are more protective of stream resources and promote recovery of native fish populations, and are recommended for consideration by BLM wherever there are important native fish populations that need protection and/or recovery.

**Response:** The BLM provided for a range of riparian management strategies in the Butte RMP. The riparian

management zones under Alternative C follow the more "protective" approach of management consistent with this alternative. The BLM believes that Alternative B provides adequate prescriptions for management of riparian zones in this specific planning area.

The BLM will follow the Interim Bull Trout Habitat Conservation Plan Strategy (USDI-BLM 1996) in occupied bull trout habitat. To make this clearer in the document, reference to the Interim Bull Trout Habitat Conservation Plan has been included under the Wildlife, Fish, Wildlife habitat, Special Status and Priority Plant and Animal Species section in Chapter 2 of the Proposed RMP/Final EIS. It should be noted that the Missoula Field Office administers the limited lands that contain bull trout habitat under an administrative agreement with the BFO.

#### W17

**Comment:** We support low road density in watersheds with native trout populations, particularly in bull trout watersheds. Salmonids are sensitive to the direct, indirect, and cumulative effects of roads, and bull trout are exceptionally sensitive to road effects. The USFWS in its 1998 Bull Trout Interim Conservation Guidance identified the importance of road densities for bull trout conservation showing general exclusion of bull trout in watersheds with high road densities (e.g. over 1.7 mi/mi<sup>2</sup> of roads), and showing bull trout strongholds to have low road densities (e.g. on average 0.45 mi/mi<sup>2</sup> of roads). We also recommend that road densities within crucial winter ranges and along migration corridors be reduced. It would be of interest to identify in the EIS the existing and future road density that would result following road closure and restoration of user-built roads.

We recommend management direction that addresses the adverse effects of high road densities and many road stream crossings upon watershed condition and aquatic health. At the very least it should be assured that roads are not contributing adverse amounts of sediment to waters with sensitive or listed fish species. We encourage BLM to consider including direction that would promote road densities protective of water quality, bull trout and westslope cutthroat trout, and critical wildlife habitats. For example, "In watersheds with native trout population, road density would be at a level that is favorable to water quality and indigenous trout populations, and critical wildlife habitats."

**Response:** Travel planning under the five site-specific travel plan areas did address the effects of roads on watershed function, riparian function, aquatic habitats and species, fragmentation of habitats, movement corridors, big game winter range, calving habitat, security habitat and disturbance as well as the direct and indirect effects of roads on a variety of wildlife and aquatic species. All action alternatives propose a reduction in road densities in important wildlife habitats. Any future travel planning would also address the above mentioned fac-

tors and existing travel plans could be modified to provide additional protections or improve wildlife habitats when new information becomes available.

The Wildlife, Fish, Wildlife Habitat, Special Status and Priority Plant and Animal Species Section (Management Common to Action Alternatives) of Chapter 2 of the RMP states that the negative effects of the transportation system on fish would be reduced. To the extent possible, roads would be located, designed, and maintained to reduce sedimentation, remove barriers to fish passage and to restore or maintain riparian vegetation.

## Travel Management - General

### X1

**Comment:** The 3 state 01 OHV Rule also provides for and states: “Motorized cross-country travel by the most direct route would be allowed to retrieve a big game animal that is in possession only in the following field units in Montana: Miles City (FO), Billings (FO), Malta (FO), Lewistown (FO) with the exception of the Great Falls Field Station, and the Custer National Forest with the exception of the Beartooth Ranger District.” Does the Butte RMP recognize the need for big game retrieval and identify appropriate cross country travel areas?

**Response:** Motorized cross-country travel for game retrieval was allowed and analyzed under three of five alternatives in the 3 state OHV EIS. However, in the Record of Decision signed in June 2003, cross-country travel for game retrieval is prohibited with few exceptions on BLM land in Montana and the Dakotas.

The Butte RMP provides for big game retrieval on existing routes, but no cross-country motorized use would be allowed for the retrieval of big game.

### X2

**Comment:** Coordination with affected counties is essential in protecting the counties’ property and resources. Many of the counties that will be affected by the Butte RMP have expressed concerns about additional closures of roads and trails to multiple use. The future management activities of federally managed public lands depend largely on the ability to access these lands. Emergency rescue, trail and road maintenance, fire suppression and access to leased areas of mineral, gas and cattle allotments are all important for the health, safety, and welfare of county residents.

**Response:** In an effort to help the BLM develop site-specific travel management alternatives, two community based collaborative working groups were established. The working groups represented a wide range of public land users and were managed under the sponsorship and involvement of the Lewis and Clark County Board of Commissioners. One working group was assigned to assist with travel planning for the Helena and East Helena Travel Planning Areas while the other group assumed

responsibility for travel planning in the Lewis and Clark County NW Travel Planning Area. Each group held a series of five or six meetings and group recommendations for route-specific management were based on consensus.

All counties were invited to be cooperating agencies with the Butte BLM on the RMP. In addition, all counties were briefed on the Draft RMP/EIS, which included travel planning.

### X3

**Comment:** The 2005 legislature passed HJ18 which clearly stated: “Be it resolved that the United States Congress be urged to adopt legislation that would require the U.S. Forest Service and the BLM to not arbitrarily close roads and access to Montana's public lands and to instead that these agencies be properly funded and maintain the current means of access to and on Montana's public lands, trails, and streams.” This was a clear mandate from the legislature of the State of Montana to the public land management agencies of the Federal Government that the arbitrary closures of access to federally managed public land in Montana be stopped and current levels of multiple use access be protected. Governor Schweitzer signed HJ18 in April of 2005 as he agreed with the actions of the 2005 Montana House and Senate.

The Montana House and Senate are standing with the citizens of this state to say that enough is enough. The actions by the BLM in the Butte RMP does not follow the mandate set forth in HJ18 or HJ31 and CBU requests that the BLM coordinate with the Montana legislative branches, as required by federal law, when road and trail closures are being proposed. The Montana legislature and Montana citizens have a very large stake in the resources of this state and they are rightfully concerned with the management practices of both the Forest Service and the BLM in recent years. Closures must only be considered as a last resort and then only after resource damage has been identified and mitigation measures have failed. CBU finds it unacceptable that any road and trail closures by your agency are made prior to attempts to mitigate identified resource damage.

**Response:** The BLM does not arbitrarily close roads and trails in the Butte Field Office. As outlined in **Appendix A** of the RMP, the BLM follows a comprehensive travel planning process to determine how roads and trails are used as well as how natural resources are impacted by those routes. This process, along with input from the public and other government agencies, allows the BLM to determine the appropriate road and trail system for a particular travel plan area.

### X4

**Comment:** The proposed Pipestone Special Recreation Area (SRA) is a good proposal that meets a need for the

increased OHV popularity. The sustainment of the hill climb in the Pipestone area for open use also meets the needs for individuals interested in this growing popular recreation opportunity. This proposed new RMA is adjacent to a much larger area managed by the Forest Service and should be coordinated with their proposed travel management plans to maximize the potential benefit from this proposal and ensure that future management plans are not in conflict.

**Responses:** The Butte Field Office will continue to stress the importance of this riding area and will strive for collaborative management with the Forest Service so that priority funding and attentive management continues to be a mutual objective.

The BLM believes that the different alternatives as described in the Activity Level Planning for Five High Priority Travel Planning Areas of Chapter 2 provide a suitable range of closed, open, and seasonally restricted roads to meet multiple objectives. The BLM is a multiple use agency and does not manage land for the sole benefit of any one type of use.

#### X5

**Comment:** Because there are two levels of management with respect to Travel, definitions describing how management will be conducted for the “Field Office Level” is important. Page 46 indicates that “travel management would be conducted in a manner that would meet, or move toward meeting, Land Health Standards.” Time frames should be attached to the “moving toward” statement.

**Response:** Because of the variables associated with land management, such as budgets, priorities and agency direction, it is difficult for the BLM to attach timeframes with the above mentioned statement. As identified in the Travel Management and Access section of the RMP, travel planning for “high priority” areas is supposed to be initiated within two years of the Off Highway Vehicle Record of Decision. The highest priority travel planning areas in the Butte Field Office are being completed concurrently with the RMP. The four remaining travel plan areas (Missouri River Foothills, Jefferson County Southwest, Broadwater County South, and Park/Gallatin) are considered “moderate priority” and travel planning will be completed for these areas after the RMP is completed. Indeed all of these travel management plans are designed to meet or move towards meeting Land Health Standards. Additionally, during routine monitoring and implementation of these plans, if problems are discovered, management actions are implemented to ensure that progress is being made towards meeting Land Health Standards.

#### X6

**Comment:** We concur with the statement on page 48, “BLM would provide for interagency travel manage-

ment consistency and route connectivity with adjoining public lands”, however there is sometimes a lack of continuity in management between adjoining public land ownerships in some BLM/FS areas within the RMP. For example, the existing BLM travel plan for Clancy-Unionville (Sheep Mountain) does not conform to this statement in that the surrounding National Forest lands have route densities at levels that are substantially less than what occurs on BLM lands. In order to bring this area into conformance with Forest Service travel management, and into alignment with other areas of the RMP, we recommend that this area be reevaluated under the RMP provision stating, “Throughout the course of implementing the RMP, site-specific route management decisions may need to be reevaluated and adjusted by BLM in order to accommodate interagency (Forest Service) connectivity.” (p. 48)

**Response:** During this RMP planning process, the BLM did not re-visit decisions made under existing travel plans. Site-specific modifications and changes to existing travel plan areas could be made in the future.

#### X7

**Comment:** We request that the significant negative and inequitable impacts that Executive Orders 11644 and 11989 have imposed on motorized recreationists be adequately evaluated, and factored into the preferred alternative. We request that the decision-making provide for actions necessary to provide responsible use of these two Executive Orders. We request that revisions to Executive Orders 11644 and 11989 be made in order to return equitable guidance to federal land-use managers.

**Response:** Executive Orders are instituted by the President. BLM has no authority to revoke such orders. BLM is required to abide by these Executive Orders. These orders were initiated many years ago in order to ensure that the use of off road vehicles on public lands would be controlled and managed to protect natural resources, promote the safety of all users, and minimize conflict among the various uses of those lands. The BLM supports motorized use, but must take into account resource protection objectives and opportunities for non-motorized use as well. The BLM has no authority to revise executive orders.

#### X8

**Comment:** The use of RS 2477 rights-of-way over nearly a century has resulted in an extensive body of case law in the state and federal courts, in which owners of various types of rights-of-way have competed with holders of RS 2477 rights-of-way and in which the availability of those various rights-of-way has been decided by the courts, including the modern State Supreme Court as well as the federal 9th Circuit Court of Appeals, in such cases as *Robertson v. Smith*, Supreme Court Montana Ten., 1871; *Butte v. Mikosowitz*, 39 Mont. 350, 102 P. 593, (1909); *Moulton v. Irish*, 67

Mont. 504, 218 P. 1053 (1923); and *Shultz v. Dept. of Army*, 10 F.3d 649 (9th Cir. 1993).

RS 2477 rights-of-way have been given a liberal interpretation by state and federal courts in those judicial decisions interpreting what constitutes a “highway” within the meaning of RS 2477, those judicial opinions holding that even the barest foot trail could qualify as a “highway” and that no particular way across federal lands has even been identified, it being sufficient that travelers used an area of federal land as a method of access between two geographic points. After 110 years of public use of RS 2477 rights-of-way, the U.S. Congress repealed the most recent version of RS 2477, 43 USC. 932, but that repeal was, by 43 USC. 1701, specifically made subject to valid rights-of-way existing as of the date of repeal which was 1976.

Schiller, chairman of the High Desert Multiple-Use Coalition, told the Kern County Board of Supervisors at a meeting held on February 19, 2002 to address RS 2477 issues that “the roads represent our custom, our culture, our economy, and our family traditions. I know it's been argued that this is about OHV uses and off-highway vehicles,” said Schiller. “It is really about access”. We request that any routes proposed for closure and in existence before 1976 be considered as having RS 2477 rights-of-way in order to provide citizens with access to public lands.

**Response:** Current BLM guidance on recognition of RS 2477 right-of-way claims is contained in Washington Office Instruction Memorandum 2006-159: Non-Binding Determinations of RS 2477 Right-of-Way Claims. Briefly, this guidance states that the BLM does not have the authority to make binding determinations on the validity of RS 2477 right-of-way claims. The BLM may, however, make informal, non-binding determinations for its own land use planning and management purposes. A non-binding determination that the right-of-way exists is required before completing consultation with states or counties on any proposed improvements to a claimed RS 2477 right-of-way, i.e., any work beyond routine maintenance. A non-binding determination may also be appropriate before taking action to close or otherwise restrict the use of a claimed RS 2477 right-of-way. Such determinations must be based on the particular laws of each state in which a claimed right-of-way is situated.

#### X9

**Comment:** In Table 4-110 we are not aware of 151 miles of motorized trails in the Elkhorn Mountains after that action. This number must either be in error (which must be corrected and publicly announced) or it is a blatant attempt at misrepresentation of the facts for the purpose of justifying motorized closures (which must be corrected and publicly announced).

**Response:** The information regarding the Elkhorn Mountains came directly from the “Decision Notice and Finding of No Significant Impact for the Elkhorn Mountain Travel Management Plan” document (August 1995). According to the Decision Notice, there are 151 miles of motorized trail system available on both BLM and Forest Service lands under the selected alternative, Alternative 4-Modified. According to Table 1, page 9, 60 miles of motorized trails are Open from 5/16-10/14, 56 miles are Open from 10/15-12/1, and 35 miles are Open from 12/2-5/15; for a total of 151 miles of available trail. In Alternative 4-Modified, motorized trails that have no width restrictions are also included in the motorized road system miles since they may be used by full-sized motorized vehicles as well as trail vehicles.

#### X10

**Comment:** In order to adequately evaluate and disclose motorized and non-motorized recreational resource and opportunity information to the public, the following information using tables and maps must be used and presented in an accurate and concise manner.

1. The miles of non-motorized recreational opportunities available in the project area including all possible cross-country routes and the number of acres available for cross-country non-motorized recreation under the existing condition (it is infinite),
2. The miles of roads and trails and number of acres to be closed to non-motorized recreationists in the proposed condition,
3. The miles of existing motorized roads, ATV trails, and motorcycle trails in the project area meeting the 3-States OHV decision definitions,
4. The acres within the project area open to motorized recreationists under existing and proposed conditions,
5. The percent of motorized and non-motorized recreational opportunities in the project area,
6. The miles of ATV trails, motorcycle trails and roads and acres closed to motorized recreationists under both existing and proposed conditions,
7. The cumulative miles of roads, ATV trails, motorcycle trails meeting the 3-State OHV definitions and number of acres closed to motorized recreationists over the past 35 years at 5 year intervals in both the project area and regional area. Once this information is adequately and concisely presented, one can easily see that motorized recreational opportunities are limited in the existing condition and then severely reduced in the proposed condition. This information must be presented in order to understand the significant imbalance of recreational opportunities that exists and the decision is deficient without this information.

**Response:** The BLM believes the information presented in the Butte RMP is adequate for public analysis. Tables 2-6 through 2-13 provide a full range of summary information for proposed management of BLM routes at the Field Office level and for the five activity level decision areas. Information presented includes area availability for wheeled motorized use; area availability for snowmobile use; miles of motorized routes available for various uses, and miles of non-motorized trails available (includes Closed routes). The maps, particularly the electronic versions, also help illustrate the existing situation and range of alternatives.

### X11

**Comment:** When roads are closed to motorized recreationists, then they in reality become a non-motorized recreational resource and they must be disclosed as such. Unfortunately this procedure has not been practiced to date and the miles of recreational resources have been understated in favor of non-motorized recreationists. All planning projects should disclose the added benefit to non-motorized recreational resources resulting from the closure of roads by adding the miles of closed roads to the miles of existing non-motorized trails. We request that this procedure be used by this project and all future agency projects. Additionally, we request that the cumulative negative impact on motorized recreationists resulting from this lack of adequate accounting be evaluated and adequately mitigated.

**Response:** Table 2-6, Field Office Level Route Management Summary, in Chapter 2 of the RMP discloses the miles of closed roads proposed under each alternative. Depending on their location, however, some closed roads may be of interest to non-motorized users, while others may provide no interest, and with non-use, eventually fade into obscurity. Some non-motorized users, such as horseback riders and mountain bike riders, may enjoy using closed roads as a convenience form of travel. Others, however, will avoid closed roads, preferring to hike cross-country in a more primitive setting. While closed roads may technically be available for non-motorized use, they do not offer the same quality experience as a trail designed for non-motorized use. This distinction is also shared by motorized users, who prefer to recreate on developed OHV trail systems, rather than on roads, which are often referred to as “troads”.

### X12

**Comment:** In many cases illegal trails are created in response to the lack of adequate motorized opportunities. If there were an adequate number of OHV trail systems, then the need to create illegal trails would be greatly diminished. Therefore, the catch-22 of the closure trend is that in the end it feeds the illegal activity. In other words, it would be a more advantageous and equitable situation to proactively manage motorized recreation.

**Response:** Illegal trails are created by individuals who have made a conscious decision to violate the law and disregard the BLM’s management of public lands. Illegal activity undermines, rather than promotes the future of motorized recreation; in some cases leading to more restrictive management due to ongoing concerns about such activity. The BLM believes that the Preferred Alternative provides adequate opportunities for motorized recreation.

### X13

**Comment:** Agencies are encouraged to avoid trail closures associated with other actions including timber sales, mining, and livestock grazing. Corrective action should be taken where trail closures in the past have resulted from these sorts of past actions. Loss of motorized trails because of past timber sales should be mitigated by connecting old and new travelways to create looped trail systems. Connector trails should be constructed to avoid dead-end trails. These systems could provide recreation opportunities for a variety of skill levels and visitors.

**Response:** Temporary road and trail closures are sometimes necessary for public safety during commercial operations, such as timber sales or mining. With regards to permanent closures, when large scale projects (such as timber sales) are proposed in an area with no existing travel plan, the NEPA analysis for the project will often-times incorporate travel planning as well. As with any travel planning effort, the analysis looks beyond the impacts and duration of the immediate project, and takes into account a broad range of resource impacts and human use needs for the overall area. The final analysis may result in either more, or less motorized opportunities throughout the travel planning area.

### X14

**Comment:** Some of [the factors contributing to growing OHV popularity] are:

- greater public interest in unconfined outdoor recreational opportunities;
- rising disposable income ...
- advances in vehicle technology
- the rapid growth of the West’s cities and suburbs ...
- a population with an increasing median age with changing outdoor recreational interests.

**Response:** The BLM recognizes the growing popularity of OHV recreation. During the past 10 years, the Butte Field Office has spent the majority of its travel plan implementation funding on OHV trail and facility development. In addition, the BLM has successfully received funding from many Montana OHV Trail Ranger grants used to help develop and manage OHV recreation.

**X15**

**Comment:** The reason often given by the agency that motorized trail projects including those using OHV grant money cannot be undertaken is that there is a current travel planning process under way or one about to begin or that NEPA compliance must be undertaken. There is a continuous cycle of travel planning undertaken and the public is not able to undertake NEPA compliance. The result is that motorized RTP funding is often under-utilized. At the same time, there is a tremendous need for projects on motorized routes. We need to find a way to break this Catch-22 situation.

**Response:** With some exceptions, federal law prohibits BLM from implementing any earth disturbing activity, such as OHV trail/facility development, or travel plans (area/route designations) until the proper NEPA documentation has been completed. Once a NEPA decision has been finalized, BLM may move forward with implementation work.

The Butte Field Office has four existing (NEPA compliant) travel management plans. Over the past 10 years, in addition to agency funding, the BLM has successfully applied for and utilized Montana OHV Program Trail Ranger Grants in order to help implement and manage these plans. Five additional plans are being addressed at the activity plan level, concurrent with this RMP revision. Once decisions for these plans have been approved, implementation work can proceed, but not before then.

**X16**

**Comment:** A new standard for motorized recreational trails could be developed that would be more beneficial for the environment and motorized recreationists. This new standard would be as nonlinear as possible. The original system of roads and trails was constructed with the shortest distance from point A to point B in mind. The new standard for motorized recreational trails would not necessarily follow the shortest distance and would include many curves to keep the speed down. Advantages of this approach would include: routes could easily be moved to avoid cultural resources and sensitive environmental areas; less visible on the ground and from the air; aesthetically pleasing; lower speeds and greater safety; and greater enjoyment by motorized recreationists. These sorts of trails could be built as mitigation for any motorized closures required as part of an action. Please contact Doug Abelin for more information on the non-linear approach to trail construction.

**Response:** The BLM agrees that motorized recreation trails should be designed as described in the comment, subject to NEPA and approved travel management plans. The Butte Field Office uses this approach as much as possible for designated OHV trail systems where appropriate.

**X17**

**Comment:** Provide open or play areas for motorized recreation opportunity and trials bikes where acceptable in selected areas.

**Response:** The Preferred Alternative includes two Open designated riding areas, Radersburg, and a motorcycle hill climb located in Whitetail-Pipestone.

**X18**

**Comment:** The integrity of the “loop” trail system should be maintained. Loop systems minimize the number of on-trail encounters because non-motorized trail users don’t encounter motorized users going both directions, as they do on non-loop trails. Loop trails also offer trail users a more desirable recreational experience. Agencies are encouraged to provide opportunity for “motorized loop trail systems” to lessen impacts and to provide a better recreational experience. Spurs are useful for exploration and reaching destinations.

**Response:** Loop trails were considered during the development of travel plan alternatives, and incorporated where feasible. Loop trails do not prevent two-way traffic, however, unless they are managed as one way only.

**X19**

**Comment:** OHV owners in Montana, as part of their vehicle registration, contribute \$1.50 to a noxious weed abatement program. Non-motorized visitors do not contribute to a weed abatement program. We request that the analysis be based on a balanced discussion of the noxious weed problem. The discussions, decisions, and measures used to mitigate noxious weeds should recognize the relatively minor impact that OHVs have on the noxious weed problem and credit OHV visitors for contributing to a program to control noxious weeds. Additionally, this is another example of predisposition because motorized recreationists have not been given credit for the positive action that they have taken and we have only been penalized for our past cooperation and the initiative taken to control noxious weeds.

**Response:** All Montana vehicle owners (not just OHV owners) contribute \$1.50 of their vehicle registration fees towards the state’s weed abatement program.

**X20**

**Comment:** We request that the over-arching management goals for all multiple-use public lands be to:

- (1) Manage multiple-use lands for the greatest benefit to the public;
- (2) Manage multiple-use lands in an environmentally sound and reasonable manner;
- (3) Manage multiple-use lands in a way that avoids the pursuit of environmental extremism; and

- (4) Manage multiple-use lands in a way that promotes the shared-use that they were intended for versus segregated-use or exclusive-use.

**Response:** The BLM agrees with this comment and believes that it is providing for these concepts with the alternatives presented in the Butte RMP revision.

### X21

**Comment:** We request that the process include consideration of the negative impacts that proposed motorized road and trail closures will have on fire management, fuel wood harvest for home heating, and timber management. The analysis should include an analysis of the benefits to the public from the gathering of deadfall for firewood from each of the roads and trails proposed for closure. These analyses are especially significant following a devastating fire season and a period of rising energy costs. The need for firewood gathering is increasing given the increasing energy costs [http://www.helenair.com/articles/2003/11/02/montana/a01110203\\_05.txt](http://www.helenair.com/articles/2003/11/02/montana/a01110203_05.txt) and we have noticed a significant increase in firewood gathering this past year. The closure of roads and trails is occurring at a large scale on all public lands. Therefore, the analysis should also evaluate the cumulative negative impacts of motorized road and trail closures and the conversion of multiple-use lands to limited-use lands on fire management, timber management, and firewood gathering.

**Response:** The Butte RMP considers impacts of road and trail closures on the wide range of resources and resource uses. These impacts are disclosed in Chapter 4 of the Butte RMP. In implementing the process described in **Appendix A** of the Butte RMP to develop road management proposals, the resource uses referenced in the comment were considered in travel route-specific assessments. Roads identified as “closed” in the Butte RMP would retain roadbeds and could be used in the future to meet needs such as fire suppression and vegetation treatments to reduce wildland fuels buildup. The Butte RMP also provides for firewood gathering throughout the Butte Field Office associated with open routes.

### X22

**Comment:** A reasonable approach to the assessment of equal recreational opportunity would use a comparison of acres and miles of trails per non-motorized visit versus acres and miles of trail per motorized visit. An equal number of acres and trail miles per visit should be the goal but the current management scheme is not achieving this goal. Clearly non-motorized visitors have a significant advantage in acres and miles of trail per visit at this time. Moreover, current management trends are creating more non-motorized acres and trails and significantly adding to the disparity. In order to be responsible to the public, we request that the preferred alternative

address this disparity and reverse the trend by managing all of the project area as motorized multiple-use.

**Response:** The Butte Field Office provides about three times more OHV trails than non-motorized trails and dedicates about 90 percent of its travel funding for the management of motorized uses. In addition to designated trails there are over 415 miles of roads available for riding yearlong or seasonally under the Preferred Alternative in the RMP.

### X23

**Comment:** Agencies are encouraged to keep trails in proposed non-motorized/ wilderness/roadless areas open. Motorized-use on trails in these areas does not detract from the wild characteristics in the proposed non-motorized/wilderness area. Additionally, the Roadless Rule specifically allows for OHV activity in Roadless areas.

**Response:** With the exception of one route through a portion of Humbug Spires Wilderness Study Area, there are no existing motorized routes with public access in any of the six WSAs within the Butte Field Office and therefore this comment is not pertinent. The Roadless Rule applies to Forest Service Roadless Areas on National Forest lands, but does not apply to BLM lands.

### X24

**Comment:** Equal treatment and access to public lands must be provided for all people including motorized visitors. One example of unequal treatment is demonstrated by the agency sponsored hikes. We have never seen an agency sponsored OHV outing. Another example is the number of agency publications and information on agency web sites promoting non-motorized recreation versus the publications and web site information pages provided for motorized recreationists. Non-motorized recreation opportunities are easy to find using agency web sites and printed information. Yet another example is the use of hiking information signs posted along highways at ranger stations and the lack of the same signs and information for OHV recreation. The Condon Ranger Station is one of many examples of this situation. Most often little or no information is provided about motorized recreation opportunities. The one good example of a motorized web site can be found at <http://www.fs.fed.us/r6/centraloregon/recreation/cohvops>. There is a need for every forest and district to have a similar motorized recreation web site. Another example of bias is the fact that signs say “Non-motorized Uses Welcome” and we have never seen a sign that says “Motorized Uses Welcome”.

**Response:** The BLM makes a concerted effort to treat motorized and non-motorized recreation users with equality for program support and interaction. On June 24<sup>th</sup>, 2005, the BLM co-sponsored an OHV ride in the Pipestone area during the Montana Trail Vehicle Rider

Association's three day State Ride. On September 17<sup>th</sup>, BLM led a hike in the Humbug Spires WSA in support of a three day Montana State, Recreation and Parks Association conference. BLM is currently updating its website so that opportunities for OHV riding and non-motorized use are better identified and explained. The three major OHV riding areas within the Butte Field Office are signed and trailhead facilities have been installed to assist motorized riders. Facilities include parking areas, unloading ramps, maps, riding information, signs, and toilets. Overall, if there have been any errors in balance, they have been in favor of motorized recreation.

#### X25

**Comment:** The evaluation team is being strongly directed to seek segregation of visitors for this action. This is not a reasonable goal. We do not seek to separate the public in other public facilities and, in fact, it is illegal. Sharing of public resources among all visitors and especially on multiple-use lands is the over-arching goal that is most reasonable expectation for visitors to those lands. Additionally, segregation of visitors is being used to manipulate recreation resource allocation such that motorized visitors are ending up with a less than adequate and less than representative share of access and recreational opportunities, (miles, acres, and number of quality opportunities). Moreover, the use of segregation as a goal is also a tactic that works against the majority multiple use/motorized recreationists by dividing and conquer the different interests within that large sector.
