ABSTRACT

Research on child and adolescent conduct problems has proliferated over the past 15 years, resulting in an extensive array of risk factors, processes, and targets for intervention. To capitalize fully on this extensive research base and contribute effectively to public mental health, the field now needs to take stock of what is known about child and youth conduct problems. In 1998, The National Institute of Mental Health (NIMH) began a process known as "Taking Stock of Risk Factors for Child/Youth Externalizing Behavior Problems." "Externalizing behavior problems" refers to a range of rule-breaking behaviors and conduct problems, including physical and verbal aggression, defiance, lying, stealing, truancy, delinquency, physical cruelty, and criminal acts. The "taking stock" process involves three key objectives: (1) to identify and describe what is known about risk factors and processes that contribute to externalizing behavior problems; (2) to identify gaps in our knowledge about risk factors and processes; and (3) to describe the kinds of research and research methodologies needed to advance the field. This report provides a summary of the first of these objectives--describing what is known about existing risk factors and processes that contribute to externalizing behavior problems. This report provides a summary of expert consensus and evaluation of what is currently known about the factors and processes that contribute to the initiation, enhancement, prevention, and termination of conduct problems in children and youth. Specific information about the research studies that document these findings can be found in the accompanying tables. (Contains 285 references and 4 tables.) (GCP)

Introduction

Research on child and adolescent conduct problems has proliferated over the past 15 years, resulting in an extensive array of risk factors, processes, and targets for intervention. To capitalize fully on this extensive research base and contribute effectively to public mental health, the field now needs to take stock of what is known about child and youth conduct problems. In 1998, The National Institute of Mental Health (NIMH) began a process known as "Taking Stock of Risk Factors for Child/Youth Externalizing Behavior Problems." "Externalizing behavior problems" refers to a range of rule-breaking behaviors and conduct problems, including physical and verbal aggression, defiance, lying, stealing, truancy, delinquency, physical cruelty, and criminal acts. A diagnosis of conduct disorder can be made when these conduct problems become repetitive and persistent and occur in a variety of settings, such as home, school, or community (American Psychiatric Association, 1994). The "taking stock" process involves three key objectives: (1) to identify and describe what is known about risk factors and processes that contribute to externalizing behavior problems; (2) to identify gaps in our knowledge about risk factors and processes; and (3) to describe the kinds of research and research methodologies needed to advance the field.

This report provides a summary of the first of these objectives—describing what is known about existing risk factors and processes that contribute to externalizing behavior problems. To accomplish this objective, four primary domains of risk were identified: child characteristics; family factors and processes; peer influences; the broader social environment, communities, and schools.

Within each domain, leading experts were convened in small groups (typically six to eight experts) to summarize the risk factors and processes. (A list of experts involved in these groups is included at the beginning.) Each group met for a day and a half to discuss which factors were most well-documented and "known" by the field. Through a consensus process, each small group "took stock" and identified the most well-established risk factors and processes in a given domain. To document these factors, each expert was asked to identify, evaluate, and summarize a minimum of three key references for each factor. All evaluations used a framework developed by Kraemer et al. (1997) to describe three types of risk factors. At the most basic level, factors can be *correlates* when shown to occur concurrently with externalizing behavior problems. Next, factors that are found to reliably precede behavior problems can be described as *predictive risk factors*. Finally, factors that can be manipulated through experimentation or intervention and shown to lead to changes in behavior problems can be described as *causal risk factors*. It is important to note that this framework also implies a "developmental course" to risk factor research. Once factors are found to be correlated with outcomes, further research should document the potential for prediction and, ultimately, the potential for causation. Causal risk factors then become the empirical foundation for building effective interventions.

This report provides a summary of expert consensus and evaluation of what is currently known about the factors and processes that contribute to the initiation, enhancement,

prevention, and termination of conduct problems in children and youth. Specific information about the research studies that document these findings can be found in the accompanying tables.

Although in some cases more than or fewer than three references were evaluated, in general, the tables were limited to three entries per factor.

It is important to note that this summary is not intended to be a complete literature review of all factors related to externalizing behavior problems and conduct disorder. Instead, the summary provides an integrated overview of what experts in the field regard as the most well-studied factors and processes and further evaluates these factors in terms of their status as correlates, predictive risk factors, or causal risk factors. The objective of the summary is to document what is known about externalizing behavior problems and conduct disorder in order to highlight what causal risk factors are already known and can be used in interventions, as well as which factors need further research to document their potential for prediction and causation. The expert consensus and evaluation process used to develop this summary was considered a richer and more expeditious route to accomplishing this objective than a comprehensive literature review. In addition, this summary is limited to research on child and adolescent externalizing behavior problems and conduct disorder. Although there is some overlap between externalizing behavior problems and violence, the current summary is not intended as a complete review of all forms of youth aggression, violence, and antisocial behavior. Readers interested in this broader field of research are referred to recent reviews and edited volumes (Coie & Dodge, 1997; Loeber & Farrington, 1998; Stoff, Breiling, & Maser, 1997; U.S. Department of Health and Human Services, 2001).

Development of Externalizing Behavior Problems

Before reviewing the status of risk factors, it is important to consider how externalizing behavior problems change over development. In the past 20 years, several longitudinal studies have provided a picture of the changing forms of aggression and conduct problems from early childhood through adolescence (Cairns & Cairns, 1994; Loeber, Farrington, Stouthamer-Loeber, Moffitt, & Caspi, 1998; Patterson, Reid, & Dishion, 1992). Their findings converge to suggest that no single child characteristic or situation can account for the development of externalizing behavior problems. Rather, these problems result from interactions between characteristics of the child and situations within the family, peer group, school, and community. Some research suggests that there are two entry points to developing externalizing behavior problems—in early childhood and in early adolescence—with potentially different patterns of risk factors associated with each (Bartusch, Lynam, Moffitt, & Silva, 1997; Hinshaw, Lahey, & Hart, 1993; Moffitt, 1993). Children who exhibit persistently high levels of externalizing behavior problems early in their lives are at high risk for intensifying to lying, bullying, and fighting in middle childhood, and more serious behaviors such as cruelty to animals, vandalism, and aggressive criminal behaviors in adolescence. A significant number of these antisocial youth continue to exhibit correlated problem behaviors (e.g., drug use, precocious sexual activity) throughout adolescence and into adulthood, although the types of difficulties experienced by antisocial boys and girls tend to diverge with development.

In contrast to children with an early onset of externalizing behavior problems, some youth begin to exhibit problem behaviors during early adolescence. Their entry into conduct problems

generally occurs through associations with deviant peers. Initial data on these "late starters" suggest that much of their antisocial behavior tends to be nonaggressive and that they are more likely to desist in problem behaviors as they become older. However, other ongoing research is suggesting that some late starters may be involved in highly aggressive and problematic behaviors. Additional research is needed to fully understand the pathways and outcomes for late starters.

It is important to note that the early starter/late starter model of two developmental pathways for externalizing behavior problems is controversial. Several research groups are actively examining data to detect other potential pathways, as well as distinct developmental patterns related to child gender. However, this two-pathway model is important because it incorporates the notion that behaviors exhibited by children with conduct problems differ with development and changes in the social environment. The basic forms of externalizing behavior problems evident in early childhood, middle childhood, and adolescence are summarized below.

Early Childhood

Most children engage in rule-breaking and defiant behaviors during early childhood (ages 2–6); therefore, this is the stage of life at which externalizing behaviors are at their peak. During the early years, the primary manifestations of externalizing behavior problems include noncompliance, oppositional behaviors, and overt physical and verbal aggression. With developing cognitive, language, and social abilities, most children replace their aggressive problem-solving strategies with prosocial ones. A small minority of children continue to engage in high rates of externalizing behavior and exhibit these behaviors (e.g., coercive interactions with parents, hitting young peers) in home and school settings. Children

who show early and persistent externalizing behavior problems and who experience additional psychiatric and academic problems (e.g., attention deficit hyperactivity disorder [ADHD]) are at highest risk for developing serious delinquency and engaging in juvenile crime in adolescence. Thus, children who, from an early age, show persistent externalizing behavior problems appear to be developing along the early onset pathway for conduct problems, failing to learn prosocial ways of interacting with others, and laying the foundation for continuing problematic behaviors.

Middle Childhood

With the increased cognitive and social sophistication of middle childhood (ages 7–13), children expand their repertoire of conduct problems from those that are evident to observers (i.e., overt, direct) to those that are hidden or secretive (i.e., covert, indirect, relational). Both boys and girls who are aggressive are at risk for being actively rejected and marginalized by their peers. When evaluating their social encounters, these children are often likely to attribute hostile intent to others. Although coercive family interactions may continue and escalate, processes within the peer group gain in importance in continuing the development of externalizing behavior problems.

Adolescence

Externalizing behavior problems can intensify during adolescence, when peer influences enhance the diversity of rule-breaking behaviors to include delinquent and antisocial behaviors (e.g., vandalism, theft, assault), substance use, and, in some cases, gang involvement and drug dealing. For many antisocial young men and women, there is a developmental acceleration into precocious

sexual activity and sexual promiscuity. Of these antisocial youth, a small proportion will intensify their aggressive behaviors and commit serious violent offenses.

Given what is known about the developmental course of externalizing behavior problems, it is clear that behaviors targeted for intervention, as well as the immediate expected outcomes from such interventions, will differ depending on the age of the children involved. Also, because externalizing behavior problems have not been found to be attributable to a single source or situation, interventions for changing these behaviors need to focus on multiple risk factors across multiple settings. Similarly, the relative contribution of individual risk factors may change with development, suggesting different targets for interventions at different ages. What are the multiple risk factors and situations that should be targeted in interventions? Are there additional developmental pathways other than the early and late starter pathways? These are questions of tremendous importance to the field, with equally important ramifications for public mental health. To advance this research, however, it is important to review and take stock of what is known currently about the many risk factors for externalizing behavior problems and to use this information when considering which combinations and interactions of factors hold greatest promise for understanding and decreasing child and adolescent externalizing behavior problems. The sections that follow summarize what is currently known about risk factors in four domains: child characteristics; family factors and processes; peer influences; the broader social environment, communities, and schools.

Child Characteristics

A number of child characteristics have been shown to be associated with high levels of externalizing behavior problems. These characteristics span multiple aspects of the individual, including behavioral, emotional, and cognitive functioning; autonomic, neuroendocrine, and neurochemical systems; and prenatal conditions and genetics. The conclusion that emerges is that conduct problems likely involve difficulties in regulation across behavioral, emotional, cognitive, and biological functioning. However, the extent to which problems in regulation of one aspect of functioning (e.g., emotional) affect the ability to regulate another aspect (e.g., biological) or how development of regulation in any one affects other aspects is not known.

Behavioral and Emotional Factors

A number of behavioral and emotional characteristics have been hypothesized to play a role in externalizing behavior problems. One prospective longitudinal study found that the display of empathic, sympathetic, and prosocial behaviors in childhood predicts a lower risk of conduct problems in early adolescence (Tremblay, Pihl, Vitaro, & Dobkin, 1994). This work is supported by research using concurrent designs showing that children and youth with conduct problems perform more poorly on measures of empathy compared with normal children and youth (Cohen & Strayer, 1996; Eisenberg et al., 1996; Miller & Eisenberg, 1988).

Research on child emotionality has focused on two forms of early emotional/behavioral characteristics: difficult-irritable-oppositional and shy-inhibited. Several longitudinal studies have found that a pattern of difficult-irritable-oppositional behavior during early childhood predicts increased risk for later externalizing behavior problems in childhood and adolescence (Bates, Pettit, Dodge, & Ridge, 1998; Caspi, Moffitt, Newman, & Silva, 1996; Guerin, Gottfried, & Thomas, 1997). The strength of these associations typically falls in the moderate range (Cohen, 1988).

In addition, several longitudinal studies have found that a pattern of inhibited behavior during early childhood predicted decreased risk for later antisocial behavior (Raine, Reynolds, Venables, Mednick, & Farrington, 1998; Tremblay et al., 1994). However, other studies have found that behavioral inhibition in early childhood predicted either later aggression or later increased antisocial behavior (Caspi et al., 1996; Goldsmith, 1996). Clearly, more research is needed on the influence of early behavioral inhibition.

Complementing this work on emotionality is newer research examining behavioral and attentional regulation (i.e., a child's ability to maintain calm, purposeful action and attention rather than acting in daring, impulsive, and poorly controlled ways). This research indicates that childhood daring and impulsive behaviors (i.e., lack of regulation) (Farrington & Hawkins, 1991), particularly when combined with irritable emotionality, are predictive risk factors for later adolescent antisocial behavior (Eisenberg et al., 2000). Both behavioral and

attentional regulation contribute to this finding, and the pattern of relations, while low-moderate in predictive strength, has been found in the United States (Lengua, West, & Sandler, 1998) and New Zealand (Henry, Caspi, Moffitt, & Silva, 1996).

Cognitive Factors

Research on ADHD provides further information about the role of attention and other cognitive processes in the development of externalizing behavior problems. A number of studies have documented that boys who meet criteria for ADHD in childhood are at increased risk for conduct disorder and antisocial behavior in adolescence and early adulthood (Mannuzza et al., 1991). However, when comorbid oppositional defiant behavior is measured, some evidence suggests that increased risk for conduct disorder is correlated with early oppositional defiant behavior rather than ADHD (Biederman et al., 1996; Moffitt, 1990). Thus, while the evidence indicates an association between ADHD and conduct problems, it is not clear whether ADHD operates as a predictive risk factor or a moderator.

In trying to clarify the implications of ADHD, researchers are incorporating indices of basic cognitive functioning and development, specifically executive function and inhibitory control processes. Executive function refers to the ability to take in information, formulate plans of action and thinking, and execute behaviors consistent with these plans. Involved in this process is the ability to exert inhibitory control, that is, to inhibit other sources of information and other incompatible behaviors.

There is some debate as to whether executive function and inhibitory control are relevant to conduct disorder or whether they are best thought of as related to ADHD and, therefore, pertinent only in instances of comorbid conduct disorder and

ADHD. However, recent studies using improved measures of these cognitive processes and refined sampling techniques have indicated that inhibitory control is correlated with conduct disorder, even in the absence of ADHD (Oosterlaan, Logan, & Sergeant, 1998; Oosterlaan & Sergeant, 1996). Children with more persistent or pervasive conduct problems seem more likely to demonstrate deficits in executive function and inhibitory control. These associations appear to be relatively independent of IQ and other cognitive functions, such as memory (Seguin, Boulterice, Harden, Tremblay, & Pihl, 1999). This independence of effect from IQ is particularly important because a large number of studies have found lower IQ and verbal abilities to be predictive risk factors for later antisocial behavior (Fergusson & Horwood, 1995; Stattin & Klackenberg-Larsson, 1993; White, Moffitt, & Silva, 1989). Note, however, that much of the research on executive function is based on concurrent assessments of cognitive functioning and problematic behavior. Additional research is needed to identify the predictive associations and potential causality of these processes for conduct problems.

Related to IQ and verbal abilities is a young person's academic achievement. Research consistently documents low correlations between poor academic performance and externalizing behavior problems (Maguin & Loeber, 1996). Again, it has been difficult to determine if this association holds for children who show conduct problems in the absence of ADHD; several studies show correlations among poor academic achievement, conduct, and attention problems, but weak or no relationships between poor academic achievement and conduct problems alone (Frick et al., 1991). However, children who develop conduct problems in middle childhood are at increased risk of later negative educational outcomes, including early school dropout (Fergusson & Horwood, 1998). Thus, the direction of effects between academic achievement and externalizing behavior

problems may be complex and may change across development.

In contrast to research on basic cognitive functioning and academic achievement, strong evidence exists about the role of social information processing as both a predictive and a causal risk factor for externalizing behavior problems. Findings from prospective longitudinal studies (Dodge, Bates, & Pettit, 1990; Dodge, Pettit, Bates, & Valente, 1995) and intervention studies (Hudley & Graham, 1993) provide clear evidence that biased social information processing—that is, the tendency to attribute hostile intentions to others—predicts and is a causal risk factor for the development and maintenance of physically aggressive behavior patterns. Similarly, initial studies suggest that biased social information processing may be involved in the development of other forms of aggressive behavior (e.g., relational aggression) (Crick, 1995). The work on relational aggression, however, has progressed only to the extent of finding concurrent associations.

Consistent evidence also documents modest correlations between conduct problems and problems in moral reasoning and social problem solving. When faced with interpersonal conflicts or social dilemmas in an experimental situation, aggressive preschool and elementary school-aged children are more likely than their nonaggressive age-mates to recommend using aggressive, manipulative, and/or commanding strategies for resolving problems (Rubin, Bream, & Rose-Krasnor, 1991; Rubin, Moller, & Emptage, 1987). Among older youth and adults, delinquent and antisocial behavior is correlated with poorer and less sophisticated moral reasoning abilities (Gregg, Gibbs, & Basinger, 1994; Nelson, Smith, & Dodd, 1990; Trevethan & Walker, 1989). Additional research is needed to determine whether social problem solving and moral reasoning abilities predict or follow externalizing behavior problems or whether improvements in these abilities can lead to improvements in externalizing behaviors.

Autonomic Factors

Another aspect of child functioning that has been related to emotional and behavioral regulation is the autonomic system, particularly indices of heart rate. Lowered heart rate and damped heart rate variability are consistently correlated with disruptive and antisocial behaviors from early childhood through adolescence and adulthood (Mezzacappa et al., 1997). These autonomic measures have been found to predict later aggression in childhood (lower heart rate or vagal tone) (Raine, Venables, & Mednick, 1997), and the ceasing of antisocial behavior in young adulthood (higher heart rate) (Raine, Venables, & Williams, 1995). These data, however, are limited to males, because only a few studies have examined links between heart rate and externalizing behavior problems in girls. Additional research is needed to document whether heart rate regulation indices predict the onset and persistence of diagnosed conduct disorder.

Neuroendocrine Factors

Hormones produced by the hypothalamic-pituitary-adrenal axis appear to be related to the pathophysiology of externalizing behaviors, based on correlational studies. Basal levels of cortisol tend to correlate negatively with indices of childhood externalizing behavior (McBurnett, Pfiffner, Capasso, Lahey, & Loeber, 1997; Moss, Vanyukov, & Martin, 1995). Also, there is evidence that increased cortisol reactivity (changes in level) predicts conduct problems one year later among adolescents (Susman, Dorn, Inoff-Germain, Nottelmann, & Chrousos, 1997). Additional research is needed that employs consistent methods and procedures for collecting basal cortisol and monitoring cortisol reactivity (a likely contributor to inconsistent findings) in long-term longitudinal studies to determine the direction of effects.

The hypothalamic-pituitary-gonadal axis is responsible for producing gonadotropin-releasing hormones (LHRH), the gonadotropins (luteinizing hormone and follicle stimulating hormone), and sex steroids (testosterone, estrogen, and progesterone). The findings for these hormones and sex steroids vary across ages and studies. Specifically, no single study or group of studies establishes the relationship between LHRH and gonadotropins and externalizing behavior problems. There is evidence that higher testosterone correlates with greater aggression and irritability during adolescence (Olweus, Mattsson, Schalling, & Low, 1988). In one randomized double-blind experiment with youth experiencing pubertal delay, boys and girls who were administered mid-level doses of testosterone and estrogen, respectively, showed increased aggressive behavior compared with those receiving placebo (Finkelstein et al., 1997). However, developmental differences were suggested, with stronger patterns of association found between testosterone and externalizing behavior in older adolescents boys than in younger adolescents. Given the small sample size for this study, additional research is needed to clearly understand potential effects. In addition, few studies have included measurement of estrogen and other sex steroids.

Neurochemical Factors

In comparison to many of the other areas of influence discussed in this report, evidence for the influence of regulation of brain neurochemicals on externalizing behaviors is not as clear or abundant. Two neurochemical systems, serotonin and dopamine, have been studied. Serotonin is a regulatory neurotransmitter that can be involved in inhibitory responses to stimuli. Evidence relating the serotonergic system with externalizing behavior is derived from both animal and human studies. There is some indication that enhanced serotonergic activity in early childhood correlates

with increased externalizing behavior (Halperin et al., 1997; Kruesi et al., 1992; Pine et al., 1997). This statement, however, is only tentative. Few studies have been done with children and young adolescents. The studies to date have included small and unrepresentative samples. Also, this research is complicated by differences in measurement strategies across studies (cerebrospinal fluid indexes versus peripheral indexes following pharmacological challenge) that make cumulative interpretations difficult.

The empirical evidence to support the role of dopamine in externalizing behavior in humans also is not well developed. Limited studies with children provide unclear findings. Lower levels of homovanillic acid (the metabolite of dopamine) (Limson et al., 1991) and lower levels of dopamine beta-hydroxylase (D β H, the enzyme facilitating conversion of dopamine to norepinephrine) were correlated with externalizing behavior (Galvin, Stilwell, & Shekher, 1997). However, a positive relationship was found between plasma D β H and disinhibition and sensation seeking (Kuperman, Kramer, & Loney, 1988). Overall, the functioning of the dopaminergic and serotonergic systems has not been sufficiently researched to draw conclusions about their contribution to externalizing behavior problems.

Prenatal Conditions and Genetic Factors

Several prenatal conditions associated with adverse reproductive outcomes also have been associated with externalizing behavior problems in offspring. These include young maternal age, smoking, and alcohol and drug use during pregnancy. It is important to note that this area of research is challenged by the extent and complexity of co-occurring factors (e.g., low socioeconomic status [SES], violence in the environment, family

conflict). Sorting out these confounding factors is extremely difficult and requires caution in drawing inferences about causal relationships.

Given these difficulties, there is substantial evidence that offspring of mothers who give birth earlier in life are more likely to have externalizing behavior problems during childhood and adolescence (Christ et al., 1990; Fergusson & Lynskey, 1993; Spieker, Larson, Lewis, White, & Gilchrist, 1997). This predictive association between maternal age and child conduct problems still holds even when maternal and paternal conduct problems, substance use, perinatal factors, demographic factors, parent-child interactions, and related variables have been controlled in regression analyses (Fergusson & Lynskey, 1993; Wakschlag et al., 1997). Although it is not clear how maternal age is related to child behavior problems, at least two kinds of variables can be hypothesized as mediators. First, having a child earlier in life often restricts maternal educational and occupational attainment and related life circumstances, such as neighborhood of residence, that are associated with youth conduct problems and crime (see the Broader Social Environment, Communities, and Schools section). Second, less mature mothers may be more likely to raise their children in ways that may foster conduct problems, such as use of harsh and inconsistent discipline (see Family Factors and Processes section). Also, other as-yet-unknown biological variables, environmental variables, or both may mediate this relationship.

In addition to maternal age, consistent evidence exists that prenatal maternal smoking is a predictive risk factor for later child conduct problems. Evidence from methodologically strong epidemiological and clinical studies in several countries has found maternal cigarette smoking during pregnancy to predict inattention and impulsivity during early childhood and conduct problems and antisocial behavior during middle childhood and adolescence (Brennan, Grekin, & Mednick, 1999; Fergusson, Woodward, &

Horwood, 1998; Wakschlag et al., 1997; Weissman, Warner, Wickramaratne, & Kandel, 1999). Even when potential mediators and confounds are considered (e.g., maternal age, drug use, psychopathology, SES, parent-child interactions), the findings suggest linear relationships between the number of cigarettes smoked per day and the increased predictive risk of child and adolescent conduct problems. As in the research on maternal age, the reasons why maternal smoking is related to child conduct problems are not clear. It could be that maternal smoking is a marker for some other set of risk factors (e.g., parental behavior, neighborhood effects [see respective sections on these topics]), or that prenatal exposure to nicotine affects fetal neurodevelopment, which in turn increases the child's vulnerability to conduct problems, or that these biological and social risk factors interact in some way. Indeed, controlled animal studies consistently show that exposure to low levels of nicotine alters fetal neural development (Navarro et al., 1989). Clearly, additional research is needed to help explain why prenatal maternal smoking is a predictive risk factor for later child conduct problems.

Two other classes of prenatal insults that have been related to later child conduct problems are exposure to alcohol and exposure to illegal drugs. Although research on prenatal exposure to alcohol has shown robust effects on cognitive development and neurodevelopment (e.g., attentional and intellectual deficits) during childhood and adolescence (Coles et al., 1991), research on conduct-related behaviors among these children suggests low to modest effects (Brown et al., 1991; Coles et al., 1991; Olson et al., 1997). Similarly, research on prenatal exposure to illegal drugs (e.g., cocaine) has found subtle and modest differences in intellectual behavior and arousal regulation between exposed children and nonexposed comparison children (Eyler, Behnke, Conlon, Woods, & Wobie, 1998; Lester, LaGasse, & Seifer, 1998). A recent study found prenatally exposed

boys to show more problems with undercontrolled behavior compared with nonexposed children from similar environmental backgrounds (Delaney-Black et al., 2000). Much of this work is ongoing and has so far followed children only through middle childhood; thus, the effects on adolescent behavior are not known.

A distinct yet equally challenging area of research concerns the study of genetic contributions to externalizing behavior problems. Generally, studies in this area can be subdivided into two categories: those examining the genetics of conduct disorders and those examining the genetics of behaviors that are relevant to the development of conduct problems. These behaviors are potentially important because they typically emerge earlier than conduct problems and may be developmental precursors.

In studying the genetic influences on conduct disorder, it has become clear that accurate description and subtyping of phenotypic behaviors are essential. Research has shown that levels of genetic and environmental influence appear to differ markedly for different patterns of conduct problems (Edelbrock, Rende, Plomin, & Thompson, 1995; Silberg et al., 1995). In the early starter pattern, adolescent boys with an earlier age of onset tend to be highly oppositional, to exhibit comorbid ADHD, and to engage in physical aggression, property crimes, and truancy. In the late starter pattern, boys with onset during adolescence typically do not have ADHD and restrict their problematic behavior to property crimes and truancy. Initial research examining concordance between twins suggests that early starter conduct disorder may be more strongly influenced by genetic factors than the developmental type of conduct problems that emerges during adolescence (Silberg et al., 1995).

A number of adoption studies, however, provide evidence for more complex relationships among genetic and environmental factors. The likelihood of

conduct problems in adopted-away offspring of antisocial parents (i.e., parents with criminal records) is significantly lower if they were raised by well-adjusted adoptive parents (Cadoret, Yates, Troughton, Woodworth, & Stewart, 1995). However, the ability to parent such children also may be affected in that genetically influenced characteristics of the child can evoke parenting behaviors that in turn increase the risk of developing externalizing behavior problems. Several studies of adopted offspring of antisocial parents have shown gene-environment evocative effects; adolescent externalizing behavior problems partially mediate the relationship between biological parent antisocial behavior and adoptive parent harsh/inconsistent discipline (Ge et al., 1996; O'Connor, Deater-Deckard, Fulker, Rutter, & Plomin, 1998). These results are supported by behavioral genetic studies of twins showing that the correlation between harsh parenting behavior and adolescent antisocial behavior problems is partially accounted for by variations in the adolescent's genetic background (Neiderhiser, Reiss, Hetherington, & Plomin, 1999). Thus, parenting and other environmental features appear to interact in complex ways with genetic dispositions in relation to youth conduct problems.

In addition to research on the genetic influences of conduct disorder, there has been research examining genetic influences on behaviors related to conduct disorder. Of the many childhood characteristics considered to be likely developmental precursors to serious conduct problems, two characteristics—ADHD and difficult-irritable-oppositional behavior—have been examined in a number of twin studies. Collectively, these studies indicate substantial genetic influence on attention problems and ADHD (Edelbrock et al., 1995; Gjone, Stevenson, & Sundet, 1996; Levy, Hay, McStephen, Wood, & Waldman, 1997; Sherman, McGue, & Iacono, 1997) and difficult-irritable-oppositional behavior (Cyphers, Phillips, Fulker, & Mrazek, 1990; Goldsmith, Buss, & Lemery, 1997), with heritability estimates generally

above .50. Unfortunately, most twin studies of difficult-irritable-oppositional behavior have confounded its measurement with aggressive behavior. Other child characteristics relevant to conduct disorder include lowered levels of empathy and lowered levels of harm avoidance/behavioral inhibition (Cyphers et al., 1990; Emde et al., 1992; Goldsmith et al., 1997). Twin studies consistently indicate low to moderate heritability of these behaviors, as well.

It is important to note, however, that behavioral genetic studies frequently are limited by their small, nonrepresentative samples and by methodological problems associated with restriction of range. A preponderance of the studies in Table 1 used Caucasian samples, with little attention to description or variations related to SES.

Implications for Malleable Child Risk Factors and Developmental Processes

The term *child factors* refers to characteristics of children that increase or decrease their risk for externalizing behavior problems. Such factors frequently have not been considered candidates for demonstrating "causal" relationships because they typically are conceptualized more as static traits or "unmalleable" predispositions. Our growing knowledge about development and the tremendous interplay among biology, environment, and behavior, however, challenges this thinking and suggests that many child factors may indeed be malleable, particularly during early development. An example of this social information processing, including hostile attributional bias. Interventions targeting these processes have shown that hostile attributions are malleable and that decreasing those attributes decreases child externalizing behaviors. Additional child factors reviewed here that similarly could serve as experimental targets

for preventive interventions are child empathy, moral reasoning, and social problem solving.

Even if child factors are not malleable, greater attention to these factors could be of great value to prevention research by improving the ability to focus interventions on children who are most at risk. A number of child factors reviewed here could be evaluated in terms of their usefulness as selection factors for high-risk studies, including individual differences in executive function, early academic difficulties, and early impulsivity and irritable emotionality, particularly when these characteristics co-occur with environmental risk factors.

In addition to highlighting targets for intervention, the current review indicates that additional research is needed to confirm the potential predictive risk of some child characteristics, particularly individual differences in autonomic activity, neuroendocrine factors, and neurochemical factors. Similarly, there is little to no existing information about the potential interactive effects among different child characteristics. For example, it is not known how individual differences in autonomic regulation relate to differences in cortisol regulation, emotional regulation, or both. Also, no one knows how interactions among such characteristics may vary across age groups or how family, peer, and other social environmental factors may affect these patterns. Research is needed to examine such interactions and investigate how the accumulation and interaction of child risk factors and environmental factors affects the developmental course and severity of conduct problems.

Future research on child characteristics related to conduct problems should consider two important issues. First, many potentially malleable child factors appear early in life, so researchers need to focus on an earlier part of the lifespan. Advancing such research may require collaborations between psychiatrists and developmental researchers with

an understanding of early childhood. Indeed, some findings (on maternal age and maternal smoking during pregnancy) suggest that research may need to focus on pregnancy and the behavior of young women that leads to early birth and child rearing; this research would require an even greater range of expertise and scientific disciplines. Second, it is vital that research testing experimental interventions targeting child factors include both males and females, as well as children from diverse ethnic backgrounds. The ratio of males with conduct problems to females with conduct problems is not as great as previously suspected. It is essential to determine whether risk factors for externalizing behavior problems in girls are the same as or distinct from those for boys and whether these factors are robust across ethnic groups.

Finally, it is important to note that there may be several opportunities for testing the potential causality of some child risk factors by partnering with intervention research on related outcomes. Current intervention trials that target maternal smoking, drug use, and alcohol use and that include long-term followup should be encouraged to examine child externalizing behavior problems. Similarly, intervention trials targeting early IQ, verbal abilities, and academic achievement should be encouraged to include assessment of externalizing behavior problems. This recommendation extends to psychiatric intervention trials focusing on the reduction of oppositional behavior and ADHD in early life. It is important to examine whether successful modification of these behaviors can reduce the incidence of conduct problems in later childhood and adolescence.

**Table 1: Child Characteristics—Research Summaries
Behavioral and Emotional Influences—Empathic, Sympathetic, and Prosocial Behaviors**

Authors	Year	Design	Representativeness	Size	Age*	% Male	SES**	Ethnicity	Result
Cohen & Strayer	1996	Concurrent group comparisons	Source specific/convenience: recruited conduct-disordered adolescents in residential treatment & local high school students without conduct problems	62	14–18 yrs	47%	Low-middle "majority of parents"	N/R	Conduct-disordered boys & girls scored lower than a comparison group of children without conduct disorder on affective & cognitive measures, including measures of empathic concern & perspective taking.
Eisenberg, Fales, et al.	1996	Concurrent correlational	Convenience: recruited suburban grade school children, parents, & teachers	199	K-3rd gr	51%	Middle M = \$46.5k (\$8k-\$150k) income/yr M = 14.6 yrs maternal ed M = 15 yrs paternal ed (8-20 yrs)	4% AfRA <1% AsPA 79% Cauc 10% Hisp 5% Mix 2% NaA	Children with low levels of baseline distress & fewer gaze aversions during a distress film had higher mother, father, & teacher ratings of behavior & conduct problems, respectively.
Miller & Eisenberg	1998	Meta-analysis	6 aggression, picture/story empathy 9 aggression, questionnaire 8 externalizing, questionnaire	N/R	2,065 A/IQ = 378 E/Q = 801	>70%	N/R	N/R	Greater empathy was associated with lower levels of aggression & externalizing negative behaviors when assessed by questionnaire methods. For children school age 5 & older, empathy assessed by the picture/story method was also related to lower levels of aggression.
Tremblay, Ph., et al.	1994	Prospective longitudinal	Population: boys in 53 public schools, low-SES areas, Montreal, Canada; rated by kindergarten teachers, eligible boys had Canadian-born, French-speaking parents with < 15 yrs of education	915	K > 13 yrs	100%	Low M = \$21k U.S. income/yr M = 10.5 Yrs maternal ed	100% Cauc (French Canadian)	Low reward dependence (empathy/prosociality), high novelty seeking, & low harm avoidance/inhibition in kindergarten predicted delinquency at ages 11–13.

Key Statistics

Empathy
 $F(1, 60) = 26.87, p < .0001$
 $M_F^2 = 40.67$ conduct disorder, 64.20 comparison

Empathy—Affective
 $F(1, 60) = 18.34, p < .0001$
 $M_F^2 = 11.53$ conduct disorder, 30.75 comparison

Empathic Concern
 $F(1, 60) = 8.14, p < .007$
 $M_F^2 = 24.68$ conduct disorder, 28.31 comparison

Perspective Taking
 $F(1, 60) = 11.08, p < .01$
 $M_F^2 = 19.92$ conduct disorder, 24.39 comparison
(ANOVAs)

Baseline Distress & Behavior Problems

Partial $r(185) = -.19, p < .01$ mother
 Partial $r(127) = -.16, p < .06$ father
 Partial $r(185) = -.20, p < .006$ teacher
 Gaze Aversions & Conduct Problems
 Partial $r(178) = -.15, p < .05$ mother
 Partial $r(127) = -.21, p < .02$ father
 Partial $r(185) = -.20, p < .007$ teacher
(partial correlations)

Questionnaire Empathy—Aggression

$\chi^2(14, N = 15) = 23.72, p < .05$
 $z^+ = -.18, z = 4.90, p < .001$
 $CI = (-11) - (-0.25)$

Questionnaire Empathy—Externalizing

$\chi^2(9, N = 10) = 10.27, p = ns$
 $z^+ = -.15, z = +2.28, p < .001$
 $CI = (-21) - (-0.08)$

Picture/Story Empathy—Agg (> 5 yrs old)

$\chi^2(8, N = 9) = 7.26, p = ns, CI = (-24) - (-0.03)$
 $z^+ = -.13, z = 2.52, p < .02$
(meta-analysis, chi-square, z scores)

Delinquency

Goodness of fit $\chi^2(910) = 894.62, p = .54$
 Low reward dependence (empathy/prosociality)
 Wald's $\chi^2(1) = 4.8, p < .03$
 High novelty seeking
 Wald's $\chi^2(1) = 20.1, p < .0001$
 Low inhibition
 Wald's $\chi^2(1) = 5.9, p < .02$

(logistic regression analysis)

Difficultness was associated with being above the borderline clinical cutoff for hostile-aggressive behavior at 3.5 yrs, aggressive behavior at 4-12 yrs, & externalizing at 4-12 yrs.	Difficultness, 1.5 Yrs $r = .39, p < .001$ problem behavior 3.25 yrs $r = .34, p < .001$ hostile/aggressive 3.5 yrs $r = .57, p < .001$ externalizing 4-6, parent $r = .54, p < .001$ externalizing 7-9, parent $r = .43, p < .001$ externalizing 10-12, parent $r = .22, p < .05$ externalizing 6-8, teacher Hostile Aggressive Behavior, Preschool $\chi^2 = 6.35, p < .05, 12\% not, 43\% difficult$ 3.5 yrs Aggressive Behavior $\chi^2 = 21.15, p < .001, 4.6\% not, 50\% difficult$ 4-6 yrs $\chi^2 = 8.23, p < .01, 3.4\% not, 29\% difficult$ 7-9 yrs $\chi^2 = 6.50, p < .05, 4.6\% not, 29\% difficult$ 10-12 yrs Externalizing $\chi^2 = 6.89, p < .05, 25.3\% not, 60\% difficult$ 4-6 yrs $\chi^2 = 9.08, p < .01, 12.6\% not, 50\% difficult$ 7-9 yrs $\chi^2 = 6.70, p < .01, 11.5\% not, 43\% difficult$ 10-12 yrs (correlations, chi-square)

Child Characteristics-Behavioral and Emotional Influences

Child Emotionality: Shy-inhibited and Irritable-difficult	Year	Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Raine, Reynolds, et al.	1998	Prospective longitudinal 8 yrs	Population: unselected suburban cohort, 1969; two towns in Mauritius (island country in the Indian Ocean)	1,130	3 > 11 yrs	51%	N/R	< 5.6% Asian < 5.6% Cauc 26% Creole 69% Indian	High aggressive children at age 11 scored higher on stimulation seeking (or lower on harm avoidance/ behavioral inhibition) at age 3 than children low in aggression in analyses with gender & ethnicity, SES, body size, & fearlessness controlled.

Tremblay et al., 1994; see "Empathic, Sympathetic, and Prosocial Behaviors"

Combined Regulation & Negative Emotionality

Eisenberg, Guthrie, et al.	2000	Prospective longitudinal 2 yrs	Convenience: recruited suburban grade-school children, parents, & teachers	146	K-3rd > 2-5th gr	50%	Middle $Mdn = \$45k$ $N = 14.9$ yrs parental ed	1% AfA 82% Cauc 11% Hisp 3% Mx 2% Nata	In the best-fitting model, the path between attentional control (att control) & moderated by children's negative emotionality (NE); lower attentional control predicted problem behaviors for children high in NE. Behavioral regulation (den reg) predicted T1 & T2 behavior problems for high or low NE children.
Farrington & Hawkins	1991	Prospective longitudinal 10 yrs, 24 yrs	Population: sampled boys ages 8-9 yrs from 6 state primary & 1 special ed school in working- class area of London, 1961-1962; Cambridge Study in Delinquent Development	411	8-9 > 18-19 yrs, 32 yrs	100%	Low 23% < 15 30% > 20 income/wk	90% Cauc <10% W 1nd <10% Cypriot delinquent older siblings, & poor housing predicted convictions between ages 10 & 20, taking into account high nervousness, poor parent child rearing, & low commitment to family.	High daring (age 8-10), high troubleness, a convicted parent, low school attainment, delinquent older siblings, & poor housing predicted convictions between ages 10 & 20, taking into account high nervousness, poor parent child rearing, & low commitment to family.
Henry, Caspi, et al.	1996	Prospective longitudinal 15 yrs	Population: consecutive births, Spring 1972-1973, Dunedin, New Zealand	475	3 > 18 yrs	100%	Low-upper 39% 1-3 35% 4 22% 5-6 (1 hi-6 low)	>93% Cauc <7% Maori <7% Polyn ages 3-5 predicted violent criminal status by age 18.	Low regulation combined with negative emotionality & negative (lack of control) at ages 3-5 predicted violent criminal status by age 18.
Lengua, West, & Sandler	1998	Concurrent correlational	Convenience: 83% recruited from AZ court records of divorce petitions, mothers with child custody; 18% recruited through ads; self- & other referrals; metro area of Phoenix, AZ	232	9-12 yrs	50%	Low-middle $M = \$27k$	1% AfA 1% AsnA 7% Hisp 89% Cauc 2% Other	Mother reports of impulsivity & attention focusing (regulation) & negative emotionality were related to mother & child reports of conduct problems. This study attempted to reduce item contamination by eliminating items determined to be overlapping according to confirmatory factor analysis & expert ratings.

Child Characteristics—Cognitive Influences

Social Information Processing	Authors	Year	Design	Size	Age	% Male	SES	Ethnicity	Result
Hudley & Graham	1993	Intervention random assignment	Convenience: recruited students rated by teachers & peers as aggressive, 1) attribution intervention	66	4th–6th gr <i>M</i> = 10.5 yrs	100%	Low	100% AfrA	Aggressive boys showed improved social information processing & were rated by teachers as less aggressive following an attributional intervention. Specifically, aggressive boys in the attributional treatment group showed reductions in attributions of hostile intent in response to ambiguous, hypothetical peer provocation (questionnaire measure), compared to boys in the attention training or control groups. Observations in a lab setting found that boys in the attribution treatment group were less likely to infer intentionality in peer provocation than boys in the other 2 groups.
Gregg, Gibbs, & Basinger	1994	Concurrent group comparisons	Source specific/convenience: recruited incarcerated youth & nondelinquent suburban public high school students	323	13–19 yrs	54%	Low ^a	26% AfrA	Delinquent female & male adolescents had lower moral reasoning scores than nondelinquents, controlling for del = 48% Cau, age, SES, & verbal intelligence.
Nelson, Smith, & Dodd	1990	Meta-analysis	Not reported: 11 studies did not control comparison group delinquency	673	11–17 yrs <i>n</i> 's = 8 to 60	54%	Middle ^b Nondelinquent 1% Other	73% Cau 1% Other 1% Other	Across 15 studies, delinquents had lower levels of moral reasoning than nondelinquents.
Rubin, Bream, & Rose-Krasnor	1991	Concurrent group comparisons	Convenience: recruited from elementary school, Southern Ontario	54	3rd–4th gr <i>M</i> = 9.36 yrs	50%	N/R	N/R	Peer-nominated aggressive children had more aggressive social goals (gain attention & stop or redirect peers' behavior) to resolve hypothetical social dilemmas & more aggressive social strategies (including hitting & grabbing) to resolve naturalistic social dilemmas compared to nonaggressive children.
Rubin, Moller, & Empage	1987	Concurrent correlational	Convenience: recruited from 4 1st-gr classes in Southwestern Ontario	72	<i>M</i> = 80 mths	47%	Lower–upper middle	N/R	1st-gr children rated by teachers as hostile/aggressive had less flexible or relevant solutions to a friendship initiation test (offered fewer invitations & showed more abnormal strategies). These children had fewer prosocial & more aggressive solutions to a dilemma requiring object acquisition from peers.

Wakschlag, Luter, et al.	1997	Retrospective correlational followed for 6 yrs, T1 not predicting T6	Source specific: children referred to university psychology & psychiatry out- patient clinics in PA & GA; Developmental Trends Study	177	7-12 yrs T1 12-17 yrs T6	100%	Low-Upper	29% AfA 71% Cau	Mothers who smoked more than half a pack of cigarettes a day during pregnancy (based on retro- spective reports 7-12 yrs later) were 1.5 times more likely to have a child with conduct disorder (CD) than mothers who smoked less than half a pack per day, controlling for SES & parental antisocial personality disorder (APD). Smoking continued to predict CD in models including parental psych- opathologic conditions, pregnancy, family, & parenting risk factors. Maternal age, harsh discipline, & little supervision also predicted CD.	Key Statistics	Basic Model Maternal Smoking & Childhood CD $\chi^2 = 36.2$, df = 5, $p < .001$ Maternal smoking OR = 3.3, CI = 1.3-8.6, $p = .01$ SES OR = 0.65, CI = 0.5-0.9, $p = .003$	Behavioral Functioning, Social Competence, Teacher $F (4, 90) = 4.15$, $p < .004$ MANCOVA Externalizing $F = 8.98$, $p = .001$							
Weissman, Warner, et al.	1999	Prospective longitudinal 10 yrs	Source specific/ convenience: recruited parents with hx of depression from tx clinics & normal controls (matched on age) from community surveys	147	6-23 yrs 17-36 yrs $M_S = 16.4$ > 27 yrs	48%	Low-Upper 10% 1 15% 2 23% 3 42% 4 10% 5	100% Cau	The risk of developing prepubertal onset conduct disorder was 4 times greater for boys of mothers who smoked 10 or more cigarettes daily during pregnancy than boys of mothers who did not smoke at all. Results were adjusted for maternal major depression disorder (MDD), offspring age, & divorce. The relationship was not explained by parental diagnosis, family risk factors, postnatal smoking, or prenatal/early development history. Girls whose mothers smoked had a 5 times greater risk for adolescent drug abuse/dependence.	Final Model Maternal Smoking & Childhood CD $\chi^2 = 56.1$, df = 8, $p < .001$ Maternal age OR = 0.90, CI = 0.84-0.97, $p = .01$ Poor supervision OR = 2.6, CI = 1.1-6.2, $p = .03$ Harsh discipline OR = 2.1, CI = 0.56-2.2, $p = .04$	P_s 's = ns both models; SES, paternal APD, maternal NMPI, maternal smoking less than 1/2 pack/day (logistic regression analyses)	Nervous/overactive $F = 8.28$, $p = .001$ $M_s = 52$ never, 52 stopped, 64 continued Aggressive $F = 4.38$, $p = .02$ $M_s = 60$ never, 59 stopped, 66 continued Inattentive $F = 6.71$, $p = .003$ $M_s = 56$ never, 58 stopped, 66 continued Nervous/overactive $F = 8.28$, $p = .001$ $M_s = 56$ never, 57 stopped, 67 continued Aggressive $F = 6.00$, $p = .005$ $M_s = 57$ never, 57 stopped, 65 continued Social competence $F = 9.73$, $p = .0004$ $M_s = 49$ never, 46 stopped, 56 continued (covariate: mother's current absolute alcohol, oz/wk)

Child Characteristics—Biological Influences

Prenatal Exposure to Alcohol	Authors	Year	Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Coles, Brown, et al.		1991	See previous entry	See previous entry				See previous entry		Comparisons of children whose mothers drank throughout pregnancy, discontinued drinking in the 2nd trimester, or never drank found that the drinking group had lower sequential processing & mental composite (IQ) summary scores than the other 2 groups, while the never-drink group had higher achievement scores than the other 2 groups. Math skill scores were higher for the never-drink than for the other groups, while reading/decoding scores were higher for the never-drink than the continued-to-drink group. No group differences were found for adaptive behavior. Analyses controlled for mother's current drinking (oz/wk).

Child Characteristics—Biological Influences

Authors	Year	Design	Size	Age	% Male	SES	Ethnicity	Result
Eyer, Bernke, et al.	1998	Prospective longitudinal	Representativeness Source specific: screened > 2,500 pregnant women at prenatal clinics & hospitals for cocaine users* & matched controls (race, parity, SES, location of care); eligible: healthy, age 18+, English speaks *use cocaine & marijuana, nicotine, alcohol only	274-285 days old	3.7-5.2	N/R	Low Hollingshead	Aler responsiveness, general irritability, regulatory capacity, state regulation, examiner persistence, & reinforcement value of infant's behavior (Brazeltton subscales) were lower for infants exposed to cocaine prenatally than for nonexposed infants. Controlling for alcohol, tobacco, & marijuana use, alert responsiveness remained lower for infants exposed to cocaine & tobacco.
Lester, Lagasse, & Seifer	1998	Meta-analysis	8 studies n = 16-137	Prenatal > twins n = 530, 1 IQ	4-11 yrs twins	N/R	N/R	Children prenatally exposed to cocaine had lower IQ scores (3.26 points) than children not exposed. Effect size was small for IQ & medium for receptive & expressive language.
Edelbrock, Rende, et al.	1995	Concurrent correlational twin study	Convenience: from birth records, same-sex twin pairs; Western Reserve Twin Project	181	7-15 yrs	54%	Middle $M = 3.1$ (1-9) Hollingshead	Aggressive behavior, externalizing, & attention showed significant genetic effects. Delinquency showed significant shared environmental effects.
Silberg, Meyer, et al.	1995	Concurrent correlational twin study	Convenience: unselected sample recruited from Virginia schools	389	11-16 yrs	100%	N/R	Membership in the hyperactive/conduct disorder & multisymptom groups was predominately explained by genetic effects. Membership in the pure conduct disorder group was explained by shared environmental factors.
Caloret, Yates, et al.	1995	Concurrent correlational adoption study	Convenience: recruited from 4 adoption agencies in Iowa; biological mothers with a history of antisocial personality disorder (APD) or substance abuse & nonsyndromatic matched controls	197	18-47 yrs	48%	N/R	Conduct disorder showed genetic effects (biological parent APD) environmental effects (adverse adoptive home environment), & genetic-environmental interaction effects (biological parent, antisocial behavior x adverse adoptive home environment). Adolescent aggressivity also showed genetic & genetic x environmental interaction effects.

Family Factors and Processes

This section focuses on children's immediate social environment, including those who live with and influence them on a regular and personal basis. The primary focus is on qualities of family social interaction that either increase or reduce the risk of developing externalizing behavior problems and conduct disorder. These interaction qualities have been categorized into six domains: engagement/ attentiveness versus disengagement/ inattentiveness; validation versus invalidation; firm discipline and conflict management versus harsh, inconsistent discipline and escalation of conflict; effective problem solving versus ineffective problem solving; structure versus lack of structure in the learning environment; and modeling of norm-maintaining behavior versus modeling of antisocial behavior.

These domains were developed at a level sufficiently general to characterize interaction across development, spanning infancy, toddlerhood, middle childhood, early adolescence, and late adolescence. In many cases, the specific behaviors that reflect a given domain will look quite different across different periods of development, because it is important to take into account the growing sophistication and contributions of the child in family interactions.

It is also important to note that each domain of family interaction is shaped by and responds to a number of other factors that have received considerable attention, such as characteristics of individual family members (attitudes, presence of

psychopathology) and characteristics of the social context (family structure and transitions). These factors can exert powerful effects. For example, research on family structure and transitions has shown that adolescents are at increased risk for conduct problems if they live in single-parent families or have experienced multiple transitions in family composition or residence (Aneshensel & Sucoff, 1996; Henry, Caspi, Moffitt, & Silva, 1996; Patterson, Forgatch, Yoerger, & Stoolmiller, 1998; Smith & Jarjoura, 1988). The reasons for these effects, however, are not clear. Indeed, some studies have shown these effects to be mediated by more immediate and malleable family processes (e.g., engagement, discipline) (Harnish, Dodge, & Valente, 1995). Although such factors help to identify potential target populations for interventions, the focus of the present review will be on family interaction qualities that either have been shown to be or may be malleable risk processes that would serve as targets for interventions.

Another important context for family interaction is that of culture. Indeed, some argue that processes within the family are the primary means by which culture is expressed. However, there is limited research on cultural differences in family processes related to externalizing behavior problems. The most serious gap is in research with Native American and Asian-American populations. Also, very few studies with diverse samples have included young children (ages 0–5). Finally, available research with African-American and

Hispanic populations is almost exclusively based on low-income, inner-city, high-risk samples. Where available, cultural generalizability and distinctions will be mentioned in the following review of family processes.

The first three domains of interaction—engagement, validation, and discipline/conflict—account for the lion's share of studies to date. Many of the studies measured more than one aspect of parenting, and there is substantial evidence that engagement, validation, and discipline/conflict tend to correlate with each other. This point has not gone unnoticed in intervention work. It is typical for interventions targeting family processes to emphasize more than one process, such as engagement, validation, and discipline. Research in this area has not tested experimentally the effects of interventions aimed at distinct domains of interaction before building comprehensive preventive interventions.

Engagement/Attentiveness Versus Disengagement/ Inattentiveness

In infancy and toddlerhood, the concept of engagement has been studied in terms of mother-infant responsiveness and infant attachment security (i.e., quality of the affective bond between infant and caregiver). Evidence indicates that the quality of early parental engagement predicts infant attachment security and that both parental engagement and infant attachment predict the development of early onset externalizing problems (Lyons-Ruth, Alpern, & Repacholi, 1993; Shaw, Keenan, & Vondra, 1994; van den Boom, 1994). Maternal unresponsiveness during infancy has been shown to predict later child externalizing behavior problems (Shaw et al., 1994). Also, there is evidence that avoidant and disorganized attachments during infancy predict later parental and teacher reports of externalizing behavior

problems in preschool (Erickson, Sroufe, & Egeland, 1985; Shaw, Owens, Vondra, Keenan, & Winslow, 1996). This result also has been demonstrated among higher risk samples (e.g., low income, parental psychopathology) (Lyons-Ruth et al., 1993).

Additional work indicates that the relationship between parental responsiveness and infant attachment security and child behavior problems may be moderated by child gender and negativity. Several studies have found the impact of maternal responsiveness and attachment security to be more pronounced for boys than girls (Shaw et al., 1994). Other work indicates that it is the combination of infant negative emotionality and attachment security that places children at greater risk for externalizing behavior problems rather than attachment security alone (Shaw et al., 1996).

Several early intervention programs with a primary focus on changing mother-infant responsiveness and engagement have provided evidence suggesting that these early family processes are causal risk factors for child conduct problems. Through intervention, early maternal unresponsiveness can be changed, and this change, in some cases, was related to more secure infant attachment (van den Boom, 1994; van IJzendoorn, Juffer, & Duyvesteyn, 1995; Wendland-Caro, Piccinini, & Millar, 1999). In addition, a well-known early intervention that included changes in early maternal engagement, validation, and problem solving (in addition to other forms of maternal support) showed long-term effects on reducing conduct problems in adolescence (Olds et al., 1998).

Interestingly, the issues of parental responsiveness and engagement have received less attention in preschool-aged children. The limited research suggests that lack of parental supervision and attention during this period of development predicts increased aggression and delinquency in grade school boys (Haapasalo & Tremblay, 1994).

Similarly, interventions that have addressed parental engagement (as well as validation, discipline, and problem solving) during toddlerhood have been successful in decreasing later childhood externalizing behavior problems (Sheeber & Johnson, 1994; Webster-Stratton, 1998; Webster-Stratton, Kolpacoff, & Hollinsworth, 1988). Thus, evidence exists that parental engagement continues to be a causal risk factor during toddlerhood.

In middle childhood and early adolescence, the concept of engagement has been studied in terms of the amount of time spent with the child, the degree of attentiveness, and monitoring of the child's activities. Consistent evidence indicates that greater involvement, stronger focus of attention, and higher levels of monitoring are related concurrently to lower levels of conduct problems and predict lower risk for developing delinquency or criminal activity (Farrington & Hawkins, 1991; Fridrich & Flannery, 1995). There is some evidence that the lack of parental monitoring may be of particular importance in middle childhood; it was found to be a stronger predictor of early arrests (prior to age 15) than of later arrests (Farrington & Hawkins, 1991; Patterson & Yoerger, 1995). Also, some research indicates possible reciprocal effects between monitoring and delinquency in the period from 13 to 15 years, with weak monitoring promoting delinquency, which, in turn, further erodes monitoring (Jang & Smith, 1997).

Monitoring and involvement continue to show effects on conduct problems into adolescence. During middle and late adolescence, engaged parenting has been related to a reduction in antisocial behavior over time (Aseltine, 1995; Barnes, Farrell, & Banerjee, 1994; Simons, Johnson, Conger, & Elder, 1998). Although the total effect of engagement is low to moderate, the fact that it continues to have a direct impact is important in light of the impact of peer characteristics, personal characteristics, and other environmental factors operating at this period of

development. Moreover, even small reductions in rates of serious conduct problems can yield very significant economic, health, and social benefits.

The concurrent and predictive associations of parental engagement during middle childhood and adolescence also are seen in research with African-American and Hispanic families (Forehand, Miller, Dutra, & Chance, 1997; Fridrich & Flannery, 1995). Although the effects range from mild to moderate, the consistency of findings indicates that poor parental engagement is a significant predictive risk factor for youth conduct problems in African-American and Hispanic families. A number of intervention trials have included parental monitoring among the family process variables to target in intervention (Patterson, Chamberlain, & Reid, 1982; Wahler, Cartor, Fleischman, & Lambert, 1993). During middle childhood and adolescence, results of these programs consistently show parental monitoring as a causal risk factor for reducing adolescent conduct problems (Bank, Marlowe, Reid, Patterson, & Weinrott, 1991; Tremblay et al., 1991), with stronger effects found when parents are encouraged to extend their supervision and monitoring to the peer and academic setting (Borduin et al., 1995). Although interventions that include improved parental monitoring also have shown effects for youth already involved in criminal behavior, stronger effects are found in therapeutic foster homes where parental monitoring is enhanced (Chamberlain & Reid, 1998).

Validation Versus Invalidation

"Validation" refers to behavior likely to comfort children, increase their sense of security, or communicate that they are valued and valuable. "Invalidation" refers to behavior that is physically painful, increases a sense of insecurity, or communicates to children that they are deficient, defective, or not valuable.

The impact of invalidation has been studied in infants by measuring their response to hostile and rejecting behavior. Evidence consistently shows that such parental behavior is correlated with externalizing behavior problems (Belsky, Hsieh, & Crnic, 1998; Renken, Egeland, Marvinney, Mangelsdorf, & Sroufe, 1989; Shaw et al., 1998). This effect appears to be as robust for girls as for boys, and for middle-SES as well as lower-SES families. It has been found in both European-American and African-American families. In much of the work, parental hostility precedes the onset of externalizing behavior problems. However, some research indicates that parent hostility and rejection may co-occur with child early disruptive behavior and negative emotionality, reflecting a more interactive and mutually escalating parent-child interaction pattern (Shaw et al., 1998).

Parental warmth and hostility continue to show moderate to strong effects during toddlerhood (Campbell, Breaux, Ewing, & Szumowski, 1986; Stocker, 1993) and middle childhood (Metzler, Biglan, Ary, & Li, 1998), and a persistent but lower effect in early adolescence (Conger & Conger, 1994; Conger, Ge, Elder, Lorenz, & Simons, 1994). Parental validation and warmth correlate and predict lower levels of externalizing behavior and delinquency (Feldman & Weinberger, 1994; Scaramella, Conger, & Simons, 1999; Stocker, 1993), while parental hostility, criticism, and rejection correlate with and predict disruptive youth behavior (Campbell et al., 1986; Conger & Conger, 1994). Although the effect sizes tend to be small, parental validation/invalidation has been shown to be a predictive risk factor across African-American, European-American, and Hispanic families (Brody, Stoneman, & Flor, 1996; Harnish et al., 1995; Knight, Virdin, & Roosa, 1994; Lindahl, 1998). Changes in parental warmth that accompany changes in parental engagement, monitoring, and discipline have been shown to lead to reductions in child and adolescent conduct problems (Webster-Stratton, 1998).

As in the case with young children, there is evidence to support interactive effects between parental hostility and middle childhood conduct problems. However, as children move into early adolescence, some evidence suggests that child conduct problems predict reductions in parental warmth but not the converse (Jang & Smith, 1997). Thus, in childhood and adolescence, modest to moderate predictive effects have been documented for parental invalidation and problem behavior. In addition, results of several intervention trials indicate that parental validation, when combined with other family processes, can be modified and serve as a causal risk factor for child and adolescent conduct problems (Borduin et al., 1995; McNeil, Eyberg, Eisenstadt, Newcomb, & Funderbunk, 1991; Patterson et al., 1982; Tremblay et al., 1991; Webster-Stratton, 1998; Webster-Stratton et al., 1988).

Firm Discipline and Conflict Management Versus Harsh Discipline and Conflict Escalation

"Firm discipline" refers to parental strategies for managing and controlling child behavior that consistently use rules and set limits, provide reasons for the rules, and offer nonpunitive consequences for rule breaking. "Harsh discipline" refers to nonabusive parental strategies for controlling child behavior that may involve inappropriate or inconsistent use of rules, little reasoning, and punitive or excessively negative reactions to rule breaking. Frequently, these parental strategies are studied within the context of parent-child conflict and the ability to manage calmly and resolve conflicts rather than engaging in coercion and escalating conflict.

As early as age 2, parental use of coercion has been identified as a predictive risk factor for

externalizing behavior problems at school entry (Crockenberg & Lourie, 1996; Fagot & Leve, 1998). Similarly, evidence indicates that negative parental control and harsh parental discipline during toddlerhood predict increased risk for child aggression and externalizing behavior problems one, two, and five years later (Campbell, 1994; Campbell, March, Pierce, Ewing, & Szumowski, 1991; Campbell, Pierce, Moore, Marakovitz, & Newby, 1996). Some of this work has examined the role of early child negative emotionality and finds that both child negativity and parental coercion predict child behavior problems (Kingston & Prior, 1995; Schwartz, Dodge, Pettit, & Bates, 1997).

In middle childhood, and in early and later adolescence, consistent relationships between highly conflictual, inconsistent, harsh, and restrictive parenting and child externalizing, delinquent, and antisocial behavior have been found in research using concurrent correlational designs (Knight et al., 1994; Sampson & Laub, 1994; Shumow, Vandell, & Posner, 1998). Predictive longitudinal studies also indicate that harsh and inconsistent parenting predicts later youth conduct problems (Patterson et al., 1998; Wasserman, Miller, Pinner, & Jaramillo, 1996). However, the direction of this influence may change over time, with a reciprocal relationship between disciplinary style and antisocial behavior in early and middle childhood, but fading reciprocity as the child moves into adolescence (with parental behavior predicting child behavior) (Cohen & Brook, 1995). Also, there is some evidence that the experience of parental punitive discipline may more strongly predict early childhood behavior problems than it does adolescent conduct problems (Feehan, McGee, Stanton, & Silva, 1991). It is important to note, however, that modest to moderate effects of parental discipline and parent-child conflict with externalizing behavior problems still are detected in adolescence (Neighbors, Forehand, & Bau, 1997;

Steinberg, Lamborn, Darling, Mounts, & Dornbusch, 1994).

Evidence exists that the effects of parental discipline and conflict management may vary as a function of ethnicity and community context. Several studies have documented concurrent correlations and predictive risk between harsh or inconsistent parental discipline, or both, and child/adolescent conduct problems in African-American and Hispanic samples (Knight et al., 1994; Lindahl, 1998), but other studies have found different effects. For example, harsh discipline had different effects on European-American and African-American children. In a study of children in early elementary school, physical discipline (e.g., spanking) predicted increased externalizing behavior for European-American but not for African-American children (Deater-Deckard, Dodge, Bates, & Pettit, 1996). These differences, however, were significant only in the nonabusive range of corporal punishment; physically abusive parenting is associated with antisocial behavior for both African-American and European-American children (Dodge, Pettit, Bates, & Valente, 1995; Shumow et al., 1998). In adolescence, unilateral parental decision making was related to fewer conduct problems among African-American youth and was unrelated to externalizing behavior problems among European Americans, Hispanics, and Asian Americans (Lamborn, Dornbusch, & Steinberg, 1996).

Parental discipline and conflict management have been primary targets for many intervention programs. These trials have consistently documented that improvement in these aspects of parenting leads to improvements in child and adolescent conduct (Webster-Stratton, 1998). Beginning in toddlerhood, through middle childhood and adolescence, interventions that include improvement in parental discipline, in addition to monitoring and validation, show reductions in youth conduct problems and antisocial behavior (Bank et al., 1991; Patterson

et al., 1982; Tremblay et al., 1991; Wahler et al., 1993). For adjudicated youth, improvements in parental discipline have stronger effects on youth conduct when parents are supported to intervene in peer and academic settings outside the home (Borduin et al., 1995). Also, therapeutic foster home placements that emphasize effective parental discipline have shown significant reductions in delinquency among adjudicated youth (Chamberlain & Reid, 1998). Thus, there is substantial evidence that parental discipline and conflict management are causal risk factors for child and youth externalizing behavior problems and conduct problems.

Family Problem Solving

"Family problem solving" refers to behaviors that aid in exploring a given problem and that generate potential solutions. For young children this also includes parental exploration of problems, helping to give structure to the situation and encourage prosocial means of understanding the situation. Although a relatively large body of research has examined basic family problem solving, little of this research has been directed toward understanding externalizing behavior problems. This is striking because many family-based interventions use training in problem solving as part of the intervention package.

The limited work that has been conducted suggests that parental problem solving, from the early years of child development through adolescence, is correlated with less problematic child and adolescent behavior. In early childhood, parental exploration of child emotional experiences, particularly anger and sadness, has been correlated with fewer behavior problems (Hooven, Gottman, & Katz, 1995; Zahn-Waxler, Iannotti, Cummings, & Denham, 1990). There is some evidence that poorer family problem solving in middle childhood may predict later delinquent behavior (Coughlin &

Vuchinich, 1996; Vuchinich, Wood, & Vuchinich, 1994). However, it tends to be associated with other problems in parenting (e.g., engagement, discipline) and, in general, accounts for less of the variance in externalizing behavior outcomes than engagement, discipline, and validation. Some research indicates, however, that changes in family problem solving can lead to reductions in child aggression (Sayger, Horne, Walker, & Passmore, 1988).

Parental Structuring of the Learning Environment

Parents and families can structure children's time in ways that enhance access to learning opportunities in the home, neighborhood, or community and protect children from negative environmental influences. Although this concept is theoretically and practically relevant, there is little research regarding the influence of family structuring of children's time and activities on externalizing behavior problems.

Research to date, conducted with school-aged children and adolescents, suggests that families that encourage involvement with school and maintain contact with the school have children who show fewer problematic behaviors than do families that are less involved with school (Jenkins, 1997; Ketsetzis, Ryan, & Adams, 1998). Also, parents who provide firm discipline and monitoring of their adolescents tend to have children who become involved with peers with similar parental discipline styles (Fletcher, Darling, Steinberg, & Dornbusch, 1995). Being involved in networks of this type appears to be protective against delinquency, because parental monitoring protects against association with deviant peers (Aseltine, 1995). These few findings suggest that parental structuring correlates with child conduct; however, more research is needed to determine the

predictive and possible causal relationship with conduct problems.

Family Modeling of Norm-Maintaining Versus Antisocial Behavior

Family modeling of norm-maintaining behavior involves exposing the child to prosocial behavior versus rule-breaking and antisocial behavior by other family members. Three different types of evidence can be used to support the contribution of family modeling in externalizing behavior problems.

A sizable body of literature has examined whether the presence of antisocial behavior, delinquency, or criminal behavior in other family members places children at increased risk for similar behaviors. Much of this work has found increased risk when mothers, fathers, or siblings were rated as more antisocial or had a history of delinquency or criminal behavior (Farrington & Hawkins, 1991).

It is not known whether this increased risk stems from modeling; from poorer parental discipline, monitoring, and engagement; or from sharing some common genetic predisposition.

A second body of literature concerns the relationship between marital conflict and child outcomes, where greater marital discord is assumed to model behaviors relevant to externalizing behavior problems in children. Research over three decades documents modest to moderate correlations between parental conflict and children's externalizing behavior problems. Younger and older children appear to be comparably influenced by parental conflict (Brody et al., 1996; Jouriles et al., 1991). Family conflict in more than one area (i.e., parent-parent, parent-child, sibling-sibling) is correlated with child aggression (Schwartz, Dodge, Pettit, & Bates, 1997). This pattern continues to be seen among

adolescents, where greater marital discord is modestly correlated with increased delinquency and problem behavior in both boys and girls (Davies & Windle, 1997; Mekos, Hetherington, & Reiss, 1996; Neighbors et al., 1997). Again, it is not clear whether these effects are due to modeling, disruptions in parenting behavior, increased physiological dysregulation, or some combination of these factors.

A third, more poorly documented area of literature focuses on parental values, attitudes, or beliefs concerning deviance and law-abiding behavior. These few studies have found evidence of a correlation between parental antisocial attitudes and externalizing behavior problems/youth offending (Gorman-Smith, Tolan, Loeber, & Henry, 1998). However, additional research is needed to examine these relationships for younger children and to support predictive relationships.

Implications for Malleable Family Risk Factors and Developmental Processes

It is clear from the research that a number of aspects of family interaction can increase the risk for developing externalizing behavior problems from early childhood through adolescence. Specifically, lower levels of engagement, greater use of invalidation, and harsh and inconsistent discipline have all been identified as causal risk factors for the development of externalizing behavior problems. Although parental problem solving, structuring of the learning environment, and modeling of normative behavior show some correlation with the development of conduct problems, research on these processes has not advanced to a level where inferences about predictive or causal risk can be made soundly.

It is important to note that the three most frequently studied family processes—engagement,

validation, and discipline—also tend to correlate strongly with one another. This is to say that parents who are less engaged also tend to be less validating and to use harsher and less consistent discipline. Thus, it is not surprising that empirically driven family-focused intervention trials typically target all three processes. These trials have provided evidence for the malleability of these processes and the causal nature of the relationship by demonstrating that intervention can substantially decrease child externalizing behavior problems. Interventions beginning during pregnancy and extending into the second year of life have shown consistent effects on these parenting processes. Indeed, one such early intervention trial has shown long-term effects on serious delinquent behavior during adolescence. Also, a number of randomized trials have tested interventions aimed at families of preschoolers and young children in elementary school. These trials have consistently shown both immediate and longer term reductions in externalizing behavior problems. Similarly, in later childhood and adolescence, randomized trials aimed at family processes have shown effects.

Given these important intervention results, it is imperative that strategies for enhancing family interactions be transported and implemented in community services and mental health practice. Research is needed that identifies opportunities within communities for providing effective interventions, explains how to provide the interventions cost-effectively, and develops community infrastructure and buy-in for sustaining the interventions. In many cases, this process will involve building collaborative relationships with community leaders and policymakers, as well as people in other scientific disciplines such as community psychology, sociology, and social work.

In addition to the effectiveness and dissemination research needed on established risk factors and interventions, further research is needed on the predictive and potentially causal role of family/problem solving, structuring of the learning environment, and family modeling. Do these processes significantly contribute to conduct problems over and above the effects of engagement, validation, and discipline? Are there developmental periods in which some family processes are more influential than others? When family processes are disrupted, does this increase the child's vulnerability to being affected by factors in other domains, such as characteristics of the child, the peer group, the school, and the neighborhood? This last question is particularly challenging, given the wide array of factors that could be influential at any given time. However, considering these interaction effects—which involve the child, the family, the peer group, and the broader social environment—may prove to be the most insightful for developing interventions for real-world settings.

Whether conducting future research on the effectiveness and dissemination of interventions or studying basic processes of family problem solving, structuring of the learning environment, or modeling, scientists must address cultural issues. The research to date on cultural effects has suggested some interesting distinctions, particularly in the study of parental discipline. It is essential for future research on family processes relevant to conduct problems to include diverse ethnic samples and methodologies sensitive to potential cultural distinctions. These efforts will provide not only a richer empirical understanding of how risk factors are similar or differ across ethnic groups but also a much stronger base on which to develop interventions relevant to the world's diverse population.

Family Characteristics—Engagement/Disengagement

Ages 0–3		Authors					
Year	Design	Representativeness	Size	Age	% Male	SES	Ethnicity
1985	Prospective longitudinal	Convenience: high-risk mothers recruited from urban public health clinics, MI	96	12 > 60 mths	54% < 12 yrs maternal ed	Low	13% AfR 80% CauC < 75% Hisp < 7% Nata (mother)
Snouff, & Egeland	4 yrs						

Key Statistics
 Hostility $F = 3.36, p = .04$
 $M^2 = .25 \text{ AA}, -.71 \text{ AR}$
 Impulsivity $F = 5.32, p = .008$
 $M^2 = .56 \text{ AA}, -.23 \text{ secure}, -.39 \text{ AR}$
 Compliance $F = 3.53, p < .04$
 $M^2 = 4.30 \text{ AA}, 5.58 \text{ secure}, 5.60 \text{ AR}$
 AA = anxious/avoidant; AR = anxious/resistant
 (ANOVA, Student Newman-Keuls post hoc comparisons)

Lyons-Ruth, Alpern, & Repacholi	1993 Prospective longitudinal 3.5 yrs	Convenience: recruited from infant study of high-risk, low-income families; 3 same-sex classmates, matched on birth date, were controls	62 18 mths > 5 yrs 182 dasm controls	60% < 12 yrs ed	60% < 12 yrs ed	Low 46% N/R% AfR N/R% CauC N/R% Hisp *23% of families included minority parent*	N/R% AfR N/R% CauC N/R% Hisp Infant attachment security, maternal home hostile-intrusive behavior during infancy, & maternal history of psychosocial problems* predicted teacher ratings of preschool children's deviant hostile behavior toward peers, controlling for classmate's behavior. Children with disorganized infant attachment were rated more hostile than securely attached children. *current depression, hx child maltreatment, psychiatric hospitalization
Shaw, Keenan, & Vondra	1994 Prospective longitudinal 2 yrs	Convenience: high-risk mothers recruited from WIC program, metro Pittsburgh, PA, area	82 12 mths > 3 yrs	59% 73% < 12k 74% < 12 yrs maternal ed	59% 73% < 12k 74% < 12 yrs maternal ed	39% AfR 61% CauC	Maternal responsiveness (observed at 12 mths) was correlated with maternal ratings of aggression at age 2 & externalizing at age 3 for boys but not girls. Multivariate analyses found that maternal responsiveness & infant noncompliance at 18 mths predicted age 2 aggression for boys after accounting for infant persistence at 12 mths. Maternal responsiveness interacted with boys' aggression at age 2, & marginally predicted maternal ratings of externalizing at age 3. No significant predictors were found for girls.
Shaw, Owens, et al.	1996 Prospective longitudinal 4 yrs	Convenience: high-risk mothers recruited from WIC program, metro Pittsburgh, PA, area	77	12 mths > 5 yrs	59% 73% < 12k 74% < 12 yrs maternal ed	39% AfR 61% CauC	Aggression at age 5 was predicted by observed disorganized attachment at 12 mths, maternal ratings of infant difficulty during yr 2, & the attachment by difficulty interaction. Children exhibiting disorganized attachment and high difficulty had higher aggression scores than children with 1 or neither risk factor.

(Stepwise multiple regression, ANOVA)

(Hierarchical multiple regression)

Family Characteristics—Engagement/Disengagement

Ages 0–3	Authors	Year Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Van den Boom	1994	Intervention random assignment	Source specific located low SES families through birth registry & midwives in Leiden, Netherlands, area; selected firstborn infants, high on irritability; IV took place at home, three two-hr sessions over 3 months	100 dyads	6 mths > 9, 12 mths	47%	Low	100% Cauc (Netherlands)	Compared to controls, dyads in the maternal responsiveness intervention group showed effects on maternal & infant interactive behavior (mother more responsive, visually attentive, stimulating, & controlling of behavior while infants more self-soothing, sociable, & exploring), <i>infant exploration</i> (more sophisticated exploring & less mouthing), & <i>infant attachment</i> (IV group more likely to be securely than insecurely attached at 12 mths).
									Maternal Interactive Behavior, Responsiveness $F(1, 96) = 176.8, p < .001; M's = 4.3 IV, -1.8 ctrl$ ($p < .001$: stimulate, visual attention, control behavior*)
									Infant Interactive Behavior, Sociable Behavior, Self-soothing, Exploring $F(1, 96) = 31.7, p < .001; M's = 1.4 IV, .22 ctrl$ ($p < .001$: self-soothing, exploring*)
									Infant Exploring, Mouthing $F(1, 96) = 4.6, p < .05; M's = -.31 IV, .31 ctrl$ ($p < .001$: sophisticated exploring*)
									Quality of Attachment* $L'(1) = 15.96, p < .001$ 38% IV, 78% ctrl insecure; 62% IV, 28% ctrl secure (See study for additional results) (2 x 2 MANOVAs, log linear analyses)
Ages 4–6	Haspasol & Tremblay	1994 Prospective longitudinal 8 yrs	Population: boys in 53 public schools in low-SES area, Montreal, Canada rated by kindergarten teachers; only boys with Canadian-born, French-speaking parents, < 15 yrs ed eligible	948	6 yrs > 14 yrs	100%	Low	100% Cauc $M = \$21k (US)$ $N = 10.5 \text{ yrs}$ maternal ed	Fighter Group Status: Nonfighters Wilks' $\Lambda = 0.92, \Delta F = 5.75, p < .001$ $F(4, 877) = 8.43, p < .001$ supervision $F(4, 877) = 5.83, p < .001$ punishment $F(4, 877) = 4.46, p < .001$ rules at home (MANOVA, Newman-Keuls)
									Delinquency Age 13 $t' = 782.06, p < .39$ $\beta = .07, \text{ Wald } (1) = 0.03, p = .46$ family adversity $\beta's = -.12 \text{ to } -.05, \text{ Wald } = 3.6-17.6, \rho's = .00 \text{ to } .056$ fight grp $\beta = .12, \text{ Wald } (1) = 4.33, p < .05$ supervision (stepwise logistic regression, step 1 forced)
									Early Offending, Ages 10–13 $R'^2 = .46 (n = 128)$ $R = .26, \Delta F = 7.51, p < .01$ time with father Recarcerated Ages 21–32 $R^2 = .50 (n = 124)$ $R = .25, \Delta F = 5.80, p < .05$ time with father (See study for additional predictors)
									Parental Supervision & Likelihood of Conviction $\phi = .20, p < .001 (N = 411)$ 48.6% poor parental supervision—conviction 25.6% not poor supervision—conviction (stepwise multiple regressions, chi-square)
54	Farrington & Hawkins	1991 Prospective longitudinal 24 yrs	Population: sampled all boys ages 8–9 from 6 state primary & 1 special ed school, working-class area of London, 1951–1962	411	8–9 > 32 yrs	100%	Low	90% Cauc $< 10\% W \text{ Ind}$ $30\% > 40\% Crypt$ Income/mth	Low paternal involvement in leisure activities ages 8–10 was the strongest predictor of early convictions (10–13) & persistence of offending between ages 21 & 32. High troublesomeness, authoritarian parents, poor psychomotor skills, & convicted parent also predicted early convictions while heavy drinking, low commitment to school, poor housing, low verbal IQ, & unemployment predicted persistence. Poor parental supervision increased the likelihood of a criminal conviction.
									Early Offending, Ages 10–13 $R'^2 = .46 (n = 128)$ $R = .26, \Delta F = 7.51, p < .01$ time with father Recarcerated Ages 21–32 $R^2 = .50 (n = 124)$ $R = .25, \Delta F = 5.80, p < .05$ time with father (See study for additional predictors)
									Parental Supervision & Likelihood of Conviction $\phi = .20, p < .001 (N = 411)$ 48.6% poor parental supervision—conviction 25.6% not poor supervision—conviction (stepwise multiple regressions, chi-square)
Jang & Smith	1997 Prospective longitudinal 1.5 yrs	Population: recruited from all 7th & 8th graders	838	8th–9th gr > 9th–10th gr	75%	N/R	N/R% AfA N/R% Cauc N/R% Hisp	Parental supervision was associated with lower delinquency at time 1 & change in delinquency between times 1 & 2. Delinquency at time 1 was associated with reduced change in perceived supervision between times 1 & 2. The model included affective bias at times 1 & 2.	
		T1 = parenting wave 2 in public schools, controls wave 2 Rochester, NY; overall delinquency w/w 3 sampled high-risk T2 = parenting wave 3 youth (male, high-delinquency w/w 4 crime areas)		$M's = 14 > 15 \text{ yrs}$	T1			$t' = 260.67, \Delta F = 113, p < .001, GEI = .972$ $\beta = \text{N/R parent supervision T1} \rightarrow \text{delinquency T2}$ $\beta = -.16 \text{ delinquency T1} \rightarrow \text{parent supervision T2}$ $\beta = -.36 \text{ parent supervision T1} \rightarrow \text{delinquency T1}$ (all $p < .05$ unless noted)	
								(See "Validation" section for affective bias results) (multivariate structural equation model)

Authors	Year Design	Representativeness	Size	Age	% Male	SES	Ethnicity
Patterson & Yoemeyer	1995 Prospective longitudinal 4 yrs	recruited from 2 birth cohorts of all 4th-grade boys attending randomly selected schools in 10 neighborhoods with highest delinquency rates, metro area, midsize OR city	206	10–11 > 14 yrs	100%	Low <i>Mdn</i> = \$15k	99% Cauc 1% N/R

Ages 14–19

Ages 14–19		Engagement/Disengagement						
Authors	Year Design	Representativeness	Size	Age	% Male	SES	Ethnicity	
Aseltine	1995 Prospective longitudinal 2 yrs	Convenience: probability sample of 9th–11th graders from the only public high schools in 3 communities, Boston, MA, metro area	435	9th–10th gr pairs 11th–12th gr	43% T1	Low-middle <i>Mdn</i> = \$37k–\$51k 13% < 12 yr: 43% = 12 yr 17% > 16 yrs 26% > 16 yrs maternal ed	< 23% AfA < 2% AsIA < 2% Cauc < 2% Hisp T1	According to high school youths' self-reports, delinquency at time 1 predicted lower attachment to mother & father 1 yr later (time 2), & attachment to mother at time 2 was associated with less delinquency the following year (time 3). Parental monitoring at time 2 was associated with reduced exposure to delinquent peers at time 3.

Population:

recruited adolescents & families via random digit dialing, Buffalo, NY, metro area; oversampled African-American families

Ages 14–19		Engagement/Disengagement						
Authors	Year Design	Representativeness	Size	Age	% Male	SES	Ethnicity	
Barnes, Farrell, & Banerjee	1994 Prospective longitudinal 1 yr	Population: recruited adolescents & families via random digit dialing, Buffalo, NY, metro area; oversampled African-American families	658	13–16 > 14–17 yrs	45%	Low-middle <i>Mdn</i> = \$21k African-Am <i>N</i> = \$37.5k Caucasian	30% AfA 70% Cauc	Adolescents' reports of parental monitoring, mother support, & positive communication with mother were associated with fewer deviant behaviors 1 yr later, after accounting for race, gender, age, parents' substance abuse, family structure, mother's education, family income, mother religion, & religiosity; (MANCOVA, means not reported in paper)
Simons, Johnson, et al.	1998 Prospective longitudinal 2 yrs	Population: recruited from all 7th-grade students in 34 public & private schools in communities s 6,500; 8 counties in N. Central Iowa, 1989; 2-parent families; Iowa Youth & Families Project	179	7th > 9th gr	100%	Low-upper <i>Mdn</i> = \$29,642 (\$0k–\$135k) 13.5 yrs (8–20 yrs) parents' ed	100% Cauc	Youths' reports of quality parenting (low hostility & harsh discipline, high monitoring & consistency) mediated the relationship between observed & parent-reported oppositional/delinquent behavior in late childhood & self-reports of delinquency in early adolescence. High-quality parenting led to a positive decline in problem behavior over time, taking into account deviant peers.

Family Characteristics—Engagement/Disengagement

Authors	Ethnic Minority Populations	Year Design	Representation	Size	Age	% Male	SES	Ethnicity	Result	
Forehand, Miller, et al.	1997 Concurrent correlational	Congruence: 4 samples of adolescents & their mothers recruited from public high schools, Bronx, NY, (2), Montgomery, AL, & San Juan, PR; adolescents & mothers resided in area for past 10 yrs or more	907	14-16 yrs <i>M</i> = 12.7 yrs	43%	Low	\$12-\$24k <i>M</i> = \$12-\$24k	47% Afr. 91% Afr. 7% W Ind. 2% Other 89% PuRic 6% Domincan 5% Other	African-American, Montgomery, AL African-American, Bronx, NY adolescent age beta = .23, unique R^2 = .04 gender beta = -.31, unique R^2 = .08 parent monitoring beta = .40, unique R^2 = .16 gender beta = -.31, unique R^2 = .06 parent monitoring beta = .33, unique R^2 = .11 adolescent age beta = .20, unique R^2 = .04 gender beta = -.29, unique R^2 = .06 parent monitoring	Low parental monitoring (combined parent & child ratings) & being male were associated with higher levels of self-reported deviance in four samples: African-American adolescents, Montgomery, AL & Bronx, NY; & Hispanic adolescents, San Juan, PR & The Bronx, NY. Older age was related to more deviancy for NY youth. Other variables included parental communication, maternal age, education, marital status, residence in city, income, & parenting by age, gender interactions. Ethnic/geographical differences were found for parenting, deviance, & all of the demographic control variables. Hispanic families from San Juan had the highest levels of parental monitoring & the lowest levels of self-reported deviance.
Fridrich & Flannery	1995 Concurrent group comparisons, correlational	Convenience: recruited from all 7th & 8th graders in 3 schools, 1 school district, midsize Southwestern city; no ESL classes; 81% participation rate	1,021	7th & 8th gr <i>M</i> = 12.7 yrs	52%	Low-middle from census track data: <i>M</i> = \$32,272 (\$17k-\$48.6k)	63% Cau 24% Hisp 13% N/R (Mexican-Am)	Caucasian R^2 = .50 beta = -.28 parent monitoring-delinquency beta = -.47 parent monitoring-susceptibility ASPP beta = .53 susceptibility ASPP-delinquency	Parental monitoring had a direct negative effect on delinquency for Caucasian youth. Susceptibility to antisocial peer pressure mediated the relationship between youths' reports of parental monitoring & delinquency for Caucasian & Mexican- American youths. Mexican-American youths reported greater susceptibility to antisocial peer pressure & more delinquency than Caucasian youths; reports of parental monitoring did not differ. When acculturation* was examined, parental monitoring was higher for recent immigrants than for acculturated Mexican-American youths. Only acculturated Mexican- American youths reported more de- linquency than Caucasian youths. *Acculturated: parents born in U.S., speak English; Unacculturated by Choice: parents born in U.S., speak Spanish; Unacculturated Recent Immigrant: parents born in Mexico, speak Spanish

Family Characteristics—Engagement/Disengagement

Authors	Year	Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Oics, Henderson, et al.	1998	Intervention random assignment	Convenience: recruited pregnant women from free clinics & private obstetricians, semi-nursing, part of upstate NY	315	Birth > 15 yrs	52% T2	59% Low T1 M = 11.3 yrs maternal ed	88% Cau 12% N/R T2	Adolescents whose mothers received prenatal or pre- & postnatal nurse visits at home in addition to prenatal & well-child care had fewer arrests & conviction/probation violations than adolescents whose mothers were in the comparison group (prenatal & well-child care without nurse visits). Intervention effects were found for a subsample of low SES, unmarried mothers as well. Intervention groups did not differ on parent, child, or teacher reports of adolescents' behavior problems. The intervention targeted parental engagement, validation, & problem solving.

Key Statistics

Total Sample, Arrests
 $p = .005$ tx infant

M's = .36 ctt, .16 tx preg, .17 tx infant

Total Sample, Convictions
 $p < .001$ tx infant

M's = .27 ctt, .06 tx preg, .10 tx infant

High Risk, Low SES & Unmarried, Arrests
 $p = .02$ tx infant

M's = .45 ctt, .15 tx preg, .20 tx infant

High Risk, Low SES & Unmarried, Convictions
 $p < .001$ tx infant

M's = .47 ctt, .07 tx preg, .09 tx infant

(all models adjusted for child's gender, maternal age, ed, SES, work, marital status, support from significant other, & paternal public assistance)

tx preg = nurse visit during pregnancy

tx infant = nurse visit during pregnancy & infancy

(statistics not reported)

Externalizing, Maternal Report

F (1, 35) = 9.33, $p < .01$ post-treatment

F (1, 32) = 8.52, $p < .01$ post-treatment

M's = 66.5 pre, 58.2 post, 56.5 fu parent training

M's = 63.4 pre, 63.1 post, 61.3 fu wait list control

Child Behavior Problems, Maternal Report

F (1, 28) = 6.86, $p < .01$ post-treatment

F (1, 28) = 7.64, $p < .01$ followup

M's = 11.9 pre, 8.3 post, 8.8 fu parent training

M's = 11.8 pre, 10.8 post, 11.1 fu wait list control

Attachment to Child, Maternal Report

F (1, 34) = 4.79, $p < .05$ post-treatment

F (1, 30) = 12.28, $p < .01$ followup

M's = 15.3 pre, 13.6 post, 13.3 fu parent training

M's = 15.2 pre, 15.3 post, 15.9 fu wait list control

(univariate F's, controlling for pretest scores)

Parental Sensitivity

Effect size $d = .58$, $p = n/a$, range = -.01 - 2.62

Children's Attachment

Effect size $d = .17$, $p = .036$, range = -.42 - .97 (Cohen's d)

Interventions aimed at changing parental sensitivity to infants were moderately successful while interventions aimed at changing children's attachment insecurity had small effects.

*1 infant Korean
1 infant Sri Lankan

Family Characteristics-Engagement/Disengagement

Treatment & Preventative Interventions	Year Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Wendland-Cam, Piccini, & Miller	1999 Intervention random assignment	Convenience: volunteer mothers & their newborns, Porto Alegre, Brazil	36	2-3 days > 1 mth	44%	M = 4 yrs maternal ed semi- & unsilled paternal occ	100% Brazil	Mothers of newborns who took part in an intervention designed to increase sensitivity showed greater responsiveness to infant vocalizing & looking at mother & less unresponsiveness to infant cries, vocalizations, & involuntary behaviors during home observations at 1 mth of age, compared to mothers in the control group who had received basic caregiving instructions. Maternal education, paternal occupation, & infant birth weight were controlled.
Besky, Hsieh, & Crnic	1998 Prospective longitudinal	Convenience: recruited from birth announcements, semi-rural university town, central PA, firstborn son from intact families	125	10 mths > 37 mths	100%	Low-Upper (\$51<\$100K)	100% Cauc	Observed negative mothering (intrusiveness & negative affect), during the 2nd & 3rd yrs of life predicted age 2 parent reports of externalizing problems for <i>highly negative</i> infant boys. Positive mothering was not related to externalizing.
Renken, Egeland, et al.	1989 Prospective longitudinal	Convenience: recruited high-risk mothers receiving prenatal care at public health clinic, MI, 1977-1979	191	12 mths > 7-8 yrs	55%	Low maternal ed	N/R	Maternal hostility & physical abuse at 42 mths predicted teacher ratings of aggression in grades 1-3, after accounting for avoidant attachment with negative affect & life stress.

Validation/Invalidation—Ages 0-3

								Negative Mothering, 2nd Year $R^2 = .07, \Delta R^2 = .07, \Delta F = 4.45, p < .05$ $\beta = -.07, p = ns$
								Negative Mothering, 3rd Year $R^2 = .16, \Delta R^2 = .06, \Delta F = 5.46, p < .05$ $\beta = .40, p < .05$
								(β 's = ns; positive mothering) (regression)
								Aggression, Teacher Ratings, Boys $R^2 = .33, F (9, 65) = 3.62$
								Developmental history set (attachment & affect) $R^2 = .25, F (4, 91) = 4.69, p < .01$
								Maternal hostility set $R^2 = .19, \Delta F = .02, F (2, 97) = 11.73, p < .01$
								Life stress set $R^2 = .18, \Delta F = ns, F (3, 74) = 5.28, p < .01$
								Aggression, Teacher Ratings, Girls $R^2 = .25, F (54) = 2.05, p < .05$
								Developmental history set (attachment & affect) $R^2 = .08, F (4, 70) = 1.60, p = .18$
								Maternal hostility set $R^2 = .11, \Delta F = .04, F (2, 77) = 4.83, p < .01$
								Life stress set $R^2 = .17, \Delta F = ns, F (3, 66) = 3.01, p < .03$

attachment = avoidant, affect = negative affect

(multiple regressions with sets)

Family Characteristics—Validation/Invalidation
Ages 0–3

Authors	Year Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Shaw, Winslow, et al.	1998 Prospective longitudinal 2.5 yrs	Convenience: high-risk mothers In WIC Nutritional Supplement Program, metro area of Pittsburgh, PA, cohort 2	103	12 mths > 3.5 yrs	59%	Low $M = \$1,132$ $M = 30$	< 4% AsIA 57% Cauc < 4% Hisp Hollingshead	For boys, age 1 high maternal responsiveness & age 2 maternal rejection predicted age 3.5 mother reports of child externalizing. For boys, age 2 maternal rejection & child noncompliance predicted mother-rated externalizing at 3.5 yrs, accounting for age 2 externalizing. For girls, the interaction of maternal rejection & child noncompliance predicted mother-rated externalizing at 3.5 yrs, accounting for age 2 externalizing.
Ages 4-6	1986 Prospective longitudinal 3 yrs	Source specific/ convenience: recruited parents of children with behavior problems & nonsympomatic controls from doctor's offices & child groups	51-63	$M = 36 >$ $M = 48 >$ $M = 73 >$ mths	60% T1 middle Hollingshead	N/R	N/R	Negative & directive maternal behavior at age 3 showed increasing correlation with maternal ratings of child aggression at ages 3, 4, & 6, after controlling for SES, family stress, & number of siblings.
Campbell, Granick, et al.	1993 Condundat correlative data collected over 3 yrs. T1 not used to predict T2	Convenience: nonclinical sample of families from the Colorado Adoption Project; sampling method not reported	64	$M = 4.5 >$ 81 yrs pals	N/R	N/R	N/R	Positive maternal affection was associated with less externalizing for both older & younger siblings. Younger siblings who had less positive affection from their mothers at the same or different age as their older siblings had higher levels of externalizing.
Stockner	1994 Prospective longitudinal longer, See et al.	Population: recruited from all 7th graders in all public & private schools in all towns $\leq 5,000$, 8 adjacent rural counties, Iowa, 1989; region had experienced economic decline	378	$M = 12.6$ yrs	48%	Low middle-middle $Mdn = \$33,8k$ 11% under poverty line	100% Cauc	Maternal & paternal hostility toward the adolescent mediated the relationship between parent-adolescent financial conflict & adolescent externalizing for boys & girls. $r = .42, p < .05$

Jang & Smith	1997 Prospective longitudinal 3 waves	Population: recruited from all 7th & 8th graders in public schools, Rochester, NY; oversampled high-risk youth (male, high crime areas)	Age: 8-14 yrs	Size: 838	% Male: 75% sampled M/F's = 14 > 15 yrs	SES: N/R	AfA: N/R% AfA N/R% Cau N/R% Hisp	Child-reported affective ties to parents in 7th/8th grade were <i>not</i> associated with child-reported changes in delinquency in 9th/10th grade; however, delinquency in 7th/8th grade predicted lower affective ties in 9th/10th grade. Affective ties & delinquency were not related concurrently at T1 or T2. The model included parental supervision T1 & T2.	Positive Family Relations* & Antisocial Behavior (trust, warmth, fun, togetherness)	$r^2 = .260, 67, df = 113, p < .001, GFI = .972$ $r = .17, p < .05$ delinquent ties T1 → delinquency T2 $r = .02, p = ns$ affective ties T1 → delinquency T1 $r = -.03, p = ns$ affective ties T2 → delinquency T2 (see "Engagement" section for super-sision results) (multivariate structural equation model)	$r = -.17, p < .05$ $r = -.17, p < .05$ $r = -.35, p < .05$
Metzler, Biglan, et al.	1998 Prospective longitudinal 6 mths	Convenience/ source specific: students randomly sampled &/or rated by teachers as at risk; public schools in 2 small Pacific NW communities	Age: 5th-7th gr	Size: 174	% Male: 53% Low-middle 21% < 12 yrs 26% = 12 yrs 37% < 16 yrs 12% = 16 yrs 5% > 16 yrs	SES: N/R	AfA: 2% AfA 6% Nata 74% Cau 2% Hisp 8% Hisp	Positive family relations & positive reinforcement by parents (latent variables based on 3 child reports, 6 mths apart) were associated with lower antisocial behavior at wave 3.	Positive Reinforcement & Antisocial Behavior (latent variable structural equation models)	Father $\chi^2(5, N = 359) = 11.92, AGFI = .954$ $\beta = .15, t = 2.01$ hostility T1 > delinquency T2 $\beta = .06, t = 0.72$ delinquency T1 > hostility T2 $\beta = .22, p < .05$ hostility T1 > hostility T2 Mother $\chi^2(5, N = 359) = 6.59, AGFI = .975$ $\beta = .16, t = 2.37$ hostility T1 > delinquency T2 $\beta = -.14, t = 1.78$ delinquency T1 > hostility T2 $\beta = -.26, p < .05$ hostility T1 > delinquency T1 (β 's = rs, hostility T2 > delinquency T2)	$r = -.67, p < .05$ $r = -.35, p < .05$
Conger & Conger	1994 Prospective longitudinal 2 yrs	Population: recruited from all 7th grade students, 34 public & private schools, communities in North central Iowa, 1989; all 2-parent families	Age: 7th - 9th gr	Size: 359	% Male: 48% Low-middle $Mdn = \$33k$ $M = 13$ yrs parents ed 11% < poverty	SES: N/R	AfA: 100% Cau	The sibling treated with the most hostility by the mother or father reported the greatest increase in delinquency from early to mid-adolescence.	Father $\chi^2(5, N = 359) = 11.92, AGFI = .954$ $\beta = .15, t = 2.01$ hostility T1 > delinquency T2 $\beta = .06, t = 0.72$ delinquency T1 > hostility T2 $\beta = .22, p < .05$ hostility T1 > hostility T2 Mother $\chi^2(5, N = 359) = 6.59, AGFI = .975$ $\beta = .16, t = 2.37$ hostility T1 > delinquency T2 $\beta = -.14, t = 1.78$ delinquency T1 > hostility T2 $\beta = -.26, p < .05$ hostility T1 > delinquency T1 (β 's = rs, hostility T2 > delinquency T2)	$r = -.37, p < .05$ differential mother/father hostility delinquency = differences in sibling delinquency (latent variable structural equation models)	
Feldman & Weinberger	1994 Prospective longitudinal 4 yrs	Convenience: 6th grade boys & their families were recruited from 2 school districts, San Francisco, CA area	Age: 6th > 10th gr	Size: 81	% Male: 100% Middle 70% > 12 yrs parent ed $M = 3.7$ 1 hr/low Hollingshead	SES: N/R	AfA: 5% AfA 12% Asia 69% Cau 8% Hisp 6% Other	Parent/child reports of effective parenting (consistent, nonaversive, nonrejecting) & observations/reports of positive family functioning in 6th grade were associated with lower parent/child reports of delinquency in 10th grade. In mediational analyses, effective parenting & father's family functioning indirectly influenced delinquency, through boys' positive self-restraint. For mother's parenting, positive family functioning exerted a direct negative influence on delinquency.	Parenting, Family Functioning, & Delinquency (latent variable structural equation models)	$r = -.22, p < .05$ effective parenting 6th, delin 10th $r = -.37, p < .01$ family functioning 6th, delin 10th Father Parenting Model $\beta = .55, p < .001$ effective parent T1 → restraint T1 $\beta = .37, p < .05$ restraint T1 → restraint T2 $\beta = -.39, p < .05$ restraint T2 → delinquency T2 $\beta = .32, p < .05$ family function T1 → restraint T2 $\beta = -.39, p < .01$ restraint T2 → delinquency T2 Mother Parenting Model $\beta = .40, p < .01$ effective parent T1 → restraint T1 $\beta = .32, p < .05$ restraint T1 → restraint T2 $\beta = -.34, p < .05$ restraint T2 → delinquency T2 $\beta = -.33, p < .05$ family functioning T1 → restraint T2 $\beta = .35, p < .01$ parent T1 → del T2; same mode family T1 → parent T1	$r = -.17, p < .05$ $r = -.17, p < .05$ $r = -.35, p < .05$

Family Characteristics—Validation/Invalidation

Ages 14–19

Authors	Year	Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Scaramella, Conger, & Simons	1999	Prospective longitudinal 5 yrs	Population: recruited from all 7th-grade students in 34 public & private schools in communities of 55,500, 8 counties in north central Iowa, 1989, 2-parent families	319	7th–8th > 8th–12th gr	47%	Low–Upper M = \$33.7k <i>M</i> = 13 yrs parents ed	100% Cau	Adolescents whose parents were above the median on warmth & low hostility reported lower levels of externalizing each year from 8th to 12th grades & lower rates of growth in externalizing over this time than adolescents of parents below the median.
Ethnic Minority Populations									
Brody, Stoneman, & Flor	1995	Concurrent correlational	Convenience: 2-parent families with firstborn children ages 9–12 were recruited from schools, churches, & community contacts in rural population under 2,500 GA & SC	90	9–12 yrs	47%	Low–middle <i>M</i> = \$29,053 (\$2.5k – \$37.5k) 19% < poverty	100% AfrA	Observed family cohesion had an indirect negative effect on mother & teacher ratings of externalizing, through higher youth self-regulation, after taking into account per capita income & parental religiosity.
Hanish, Hodge, & Valentine									
61	1995	Concurrent correlational	selected kindergarten children & their parents from schools with high at-risk populations; no father-only house- holds; representative of schools distribution on race, gender, behavior problems; Durham, NC, Nashville, TN, central PA, & Seattle, WA	376	K–1st gr <i>M</i> = 6.5 yrs In gr 1	51%	Low–Upper 3.7% 1 16.1% 2 19.5% 3 28.5% 4 32.2% 5 1-H–5 Low Hollingshead	43% AfrA 51% Cau 6% Other	The relationship between maternal depressive symptoms & teacher ratings of externalizing was partially mediated by the quality of mother-child interactions (observed) for Caucasian, but not for African-American, families. For both groups, a positive/warm mother-child relationship was associated with lower externalizing scores. For African-American mothers, level of maternal depressive symptoms did not affect the quality of the mother-child interaction, as it did for Caucasian mothers. For all families, mother-child interaction quality mediated the relationship between SES & child externalizing.

Family Characteristics—Validation/Invalidation

Authors	Year Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
McNeil, Eyberg, et al. 1991 Intervention not random	Source specific: tx. group referred for behavior problems at home & school, 1 child with behavior problems, not treated, & 1 child with average behavior picked from tx. child's classroom for deviant & normal control groups	27	30-86 mths	77% 100% tx grp	Low-middle M = \$21.4k tx grp Mdn = \$12k	20% AfRA 77% Cauc 36% Hisp	Children who participated in a 14-week parent-child interaction intervention (no direct classroom intervention) had fewer teacher reported behavior problems & more observed compliance to teacher requests than did deviant & normal classroom controls, accounting for level of pre-tx problem behaviors. Treated children also showed improved behavior at home according to observations & mother reports.	F(1, 15) = 5.03, p < .05 (pre-, post-IV) M's = 20, 10 IV; 13, 10 deviant ctrl; 0.67, 1.1 ctrl % Compliance, Classroom, Observed F(1, 15) = 4.59, p < .05 M's = 54, 87 IV; 64, 75 deviant ctrl; 73, 80 ctrl Home, Treatment Group (n = 10) Problem behavior, mother report t = 5.03, p < .01, M's = 23.3 pre-, 6.1 post-tx % compliance, Observed t = 7.59, p < .01, M's = 40.7 pre-, 70.4 post-tx (ANOVA, Duncan's MRIT on difference scores, t tests)
Webster- Stratton 1998 Intervention random assignment 1 yr followup	Source specific: entering Head Start, 9 centers in 1 urban district; 2 cohorts, fall 1993 & 1994; Seattle, WA	296	M = 56.5 f-up 394	53% M = \$10k post-tx	Low M = \$10k	17% AfRA 49% Aspa 63% Cauc 6% Hisp 6% Mix 4% Nata (pre-tx)	Families who attended a parent-training intervention in addition to Head Start showed greater improvements in maternal parenting & child behavior than families in Head Start alone. During home observations, intervention group mothers were less negative, harsh, & critical, & displayed more positive affect than control mothers, while intervention group children had a greater reduction of problem behaviors, negativity, & noncompliance than control children. All improvements were maintained after 1 yr. Mother- & teacher-reported child behavior problems did not differ across intervention groups.	Mother, Harsh or Critical Style, Observed F = 7.95, p < .01 (pre-post) M's = 1.49, 1.49 IV; 1.40, 1.37 control F = 4.17, p < .05 (pre-followup) M's = 1.52, 1.30 IV; 1.38, 1.33 control Mother, Positive Affect, Praise, Observed F = 7.72, p < .001 (pre-post) M's = 22.1, 31.96 IV; 23.6, 25.1 control F = 3.67, p < .05 (pre->followup) M's = 14.25, 9.94 IV; 9.66, 7.24 control Child, Deviance & Noncompliance, Observed F = 8.16, p < .01 (pre-post) M's = 1.50, 1.35, 1.36 IV; 1.33, 1.34, 1.25 control F = 4.12, p < .05 (pre-followup) (*pre test, M's reflect smaller followup sample) (P's < .05 - .001, MANOVAs, ANOVA, t's for tx vs control)
Webster- Stratton, Kolpacoff, & Hollingsworth	1988 Intervention random assignment 1) VM; indiv. videotape modeling 2) GDM; group discussion & VM 3) GD; group discussion 4) wait list control	Source specific: families of children with primary problem of misconduct, self- or professionally referred for treatment	114	M = 4.5 yrs (3-8 yrs)	69%	Low-Upper 12% 1 21% 2 29% 3 23% 4 15% 5	N/R	Externalizing, Mother Report F' = 4.05 VM & 2.27 GDM (vs. ctrl), p's < .001 F = 2.21, p < .05 GD vs. ctrl (pre-, post-IV) M's = 61.1, 37.96 VM; 53.20, 31.07 GDM M's = 48.5, 34.30 GD; 53.77, 46.48 control Father Criticisms, Observed F' = 2.75 VM, 2.65 GDM (vs. ctrl), p's < .01 F = 2.37, p < .05 GD vs. ctrl (pre-, post-IV) M's = 13.30, 7.18 VM; 19.75, 8.70 GDM M's = 15.96, 8.14 GD; 11.0, 12.07 control (see study for other significant results) (MANOVA, ANOVA)

Family Characteristics—Discipline and Conflict

Ages 0–3

Authors	Year	Design	Representativeness	Size	Age	% Male	SES	ethnicity	Result
Crodenberg & Louie	1996	Prospective longitudinal/concurrent	Convenience: N/R	42	2 > 6 yrs	48%	Middle 63% mother 11% father 16 yrs ed	81% Cauc 7% Hisp 11% Mixed	Age 6 Externalizing (father report) was associated with fathers' (boys') & mothers' (girls') reports of coercion. Child reports of manipulative behavior with peers at age 6 were predicted by age 2 observed negative maternal control for boys & less observed maternal guidance for girls.
Fagot & Leve	1998	Prospective longitudinal	Convenience: from metro area of midsize OR city, sampling method N/R	122	18 > 60 mths	53%	Low-middle T1 Men = \$15K T1 \$20K T2	2% AfA 1% AsnA 95% Cau 1% Hisp 1% Pacis	Parent overinvolvement at age 2 predicted teacher ratings of age 5 externalizing, taking into account family structure & negative child behavior in play group (observed), attachment, temperament, negative behavior at home, parent ratings of externalizing, gender, income, contact with police, & family agency use.
Ages 4–6				105	M/5 = 46 > 64 mths	100%	Low-upper middle M's = 48-55 Hollingshead	1% AfA 1% AsnA 98% Cau 71	Maternal negative control at time 1 was highest for boys with behavior problems (parent & new teacher ratings) that continued for 2 yrs after pre-school, followed by boys whose behavior problems did not continue, followed by controls.
Campbell, March, et al.	1994	Prospective longitudinal	Convenience: recruited from 16 suburban preschools, teacher-rated ADD & matched (birthday) controls & parent referred from clinics, dr.'s offices, preschools	108	M = 42.8-47.5 mths > M = 59 mths	100%	Middle	1% AfA 1% AsnA 98% Cau	Negative Maternal Control & Externalizing predicted higher ratings of externalizing 1 yr later for boys referred by parents or recruited from preschools for problem behavior. For the parent-referred group, this relationship remained significant even after initial symptom level was taken into account.
Campbell, Pierce, et al.	1996	Prospective longitudinal	Convenience: recruited from 16 suburban preschools, teacher-rated ADD & matched (birthday) controls & parent referred from clinics, dr.'s offices, preschools	104	4 > 9 yrs	100%	Middle M = 52 Hollingshead	1% AfA 1% AsnA 98% Cau	Observed negative maternal control at age 4 predicted externalizing at age 9. Externalizing at age 4 did not predict maternal control at age 9. Negative maternal control & externalizing showed positive concurrent relationships as well.

Family Characteristics—Discipline and Conflict

Age 4–6	Authors	Year Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Kington & Prior 1995 Prospective longitudinal 5 yrs	Covenience/ source specific/ sampled at ages 7–8 from 1,721 ongoing participants of the Australian Temper- ament Project; selected children with high scores on aggression, & random sample of nonaggressive children	175 2–3 yrs > 7–8 yrs	61%	N/R					Parental use of nonphysical discipline, parental control through guilt & anxiety, & hostile sibling interactions (parent reports) differentiated stable aggressive children (ages 2–3 & 7–8) from nonaggressive children, along with child's temperament at ages 2–3, 3–4, 5–6, & 7–8, & mother's overall perception of child at ages 2–3, 5–6, & 7–8.

Key Statistics
 $\chi^2(14) = 35.05, p < .001$ (64% F1, 14.2% F2)
 Nonphysical discipline
 $r_s = .41$ F1, -.12 F2
 $M_s = 4.01$ stable agg, 3.01 non agg
 Parental control, guilt
 $r_s = .31$ F1, -.10 F2
 $M_s = 3.50$ stable agg, 2.77 non agg
 Sibling interaction, hostile
 $r_s = .56$ F1, .27 F2
 $M_s = 4.31$ stable agg, 2.95 non agg
 Child temperament F1, F2
 $r_s = .34, .35$ (2–3 yr); .49, .40 (3–4 yr);
 .62, .25 (5–6 yr); .59, .20 (7–8 yr)
 Mother perception F1, F2
 $r_s = .47, .26$ (2–3 yr); .62, -.26 (5–6 yr);
 .75, -.45 (7–8 yr)

F1 = function 1, F2 = function 2

(stepwise discriminant function analysis)

Wilks's $\lambda = .61, F(27, 394) = 2.39, p < .001$

Restrictive discipline
 $F(3, 190) = 3.32, p < .05$

$M = 3.4$ aggressive victims

$M = 2.8$ passive victims

$M = 2.7$ nonvictim aggressors

$M = 2.7$ controls

(MANOVA, ANOVA, planned contrasts)

Punishment & Conduct Disorder ages 10–18
 $OR = 2.02, CI = 0.99–4.15$ ($n = 721$)
 (controls: age, gender, SES, early problems)
 Punishment & Conduct Disorder ages 12–20 ($n = 723$)
 $OR = 3.35, CI = 0.98 – 11.4$ boys
 $OR = 3.34, CI = 0.74 – 15.0$ girls
 (controls: early problems, age, SES, marital
 conflict, parent psychopathology)

Younger Children (1–5 yrs at T1)
 $r = .19$ behavior problem T1—punish T2
 $r = .10$ punish T1—behavior problem T2
 $r = .13$ punish T2—behavior problem T3
 $r = .25$ behavior problem T1—punish T1
 $r = .29$ behavior problem T2—punish T2
 (P's = ns behavior problem T3—punish T2 & T3)

Older Children (6–10 yrs at time 1)
 $r = .42$ behavior problem T1—punish T1
 $r = .27$ behavior problem T2—punish T2
 (P's = ns beh T1 — punish T2, punish T1—beh T2)

(cross-lagged correlations)

Family Characteristics—Discipline and Conflict

Ages 7–13

Authors	Year	Design	Representativeness	Size	Age 7–9 yrs > 15 yrs	% Male N/R	SES N/R	Ethnicity N/R% Cau/ 2% Maori/ Polyn	Results
Feehan, McGee, et al.	1991	Prospective longitudinal 6–8 yrs	Population: consecutive births, spring 1972–1973, Dunedin, New Zealand	849					Parents' reports of early behavior problems were associated with inconsistent discipline, male gender, & poor maternal mental health, taking into account family adversity & parental strictness. Externalizing in adolescence was predicted by inconsistent & relaxed (ax or neutral) discipline, accounting for gender & early behavior problems.
Patterson, Forgatch, et al.	1998	Prospective longitudinal 10 yrs	Population: recruited from 4th-grade boys in 11 randomly selected schools in neighborhoods with high delinquency rates, metro area of mid-size NW city.	206	9–10 > 18 yrs	100% Md7 = \$15K	N/R% "majority"	Ineffective discipline (observed coercion, negative behavior, verbal and/or physical aggression) increased the risk of antisocial behavior, early arrest, & chronic offending, after accounting for parental monitoring, marital transitions, & social disadvantage.	
Shumow, Vandell, & Posner	1998	Prospective longitudinal/ concurrent 2 yrs	Convenience/ Source specific: parents of 3rd graders in 9 urban public schools with highest % of subsidized school lunch, Milwaukee, WI; children in after school programs & matched (gender) random sample with mother after school	184	3rd > 5th gr T1	47% Md = \$15,365	Low maternal ed 54% subsidized school lunch	48% AfA 52% Cau	Parenting variables did not predict child behavior problems over time. Harsh parenting was concurrently associated with 3rd & 5th-grade behavior problems (parent report), & misconduct in 5th gr (child report) & lower adjustment in 5th gr (teacher report), accounting for family income & structure, parent education, race, & maternal unemployment. Firm-responsive parenting was associated with more child responsibility in 3rd grade & less 5th-grade misconduct & behavior problems. Permissive parenting was not associated with adjustment in 3rd or 5th gr.

Key Statistics		Early Problem Behavior, Age 7–9 Predictors		Adolescent Problem Behavior, Age 7–9 Predictors

Family Characteristics—Discipline and Conflict

Treatment & Preventative Interventions	
Authors	Year Design
Borduin, Mann, et al.	1995 Intervention random assignment 4-yr followup

Representativeness: Source specific: detained youth & their families were referred by juvenile services; youth had 2+ arrests & lived with at least 1 parent; Missouri Delinquency Project

Size: 126

Age: 12-17 yrs

% Male: 68%

SES: Low-middle (69% lower Hollingshead 1 in=5 low)

Ethnicity: 30% AfR 70% Cau

Result: Adolescents & their families who completed multisystemic therapy (MST) demonstrated greater improvements in family relationships & parent-reported adolescent behavior than those who completed individual therapy (IT). Observations of mother-adolescent, father-adolescent, & mother-father dyads found increased supportiveness & reduced conflict-hostility for MST families. At 4-yr followup, MST completers had a lower risk of arrest than IT completers. In addition, MST completers who were arrested again had fewer overall arrests, and fewer arrests for violent crimes, & they were arrested for less serious crimes, compared to IT completer recidivists.

Key Statistics

Supportiveness, Pre - Post Intervention

$F(1, 123) = 6.42, p < .01, \text{gr} \times \text{tx}$ mother-youth

Family Characteristics—Discipline and Conflict Treatment & Preventative Interventions

Authors	Year Design	Representativeness	Size	Age 4-6 yrs <i>M</i> = 56.5 mths	% Male 53%	SES <i>M</i> = \$10k	Ethnicity 1.7% AfA 4% AsIA 63% CauC 6% Hisp 4% Mix 4% NAtA	Result
Webster-Stratton	1998 intervention random assignment	Source specific: recruited families entering Head Start program; 9 centers in 1 urban district; 2 cohorts, Fall 1993 & 1994; Seattle, WA	296 f-up 394 post-ex					Families who took part in a parent training intervention in addition to Head Start showed greater improvements in maternal parenting & child behavior than families in Head Start alone. Mothers in the parent training IV reported less use of harsh & inconsistent discipline & more appropriate limit setting & were observed to use more competent discipline than mothers in the Head Start-only group. Children in the intervention group showed a greater reduction of observed problem behaviors, negativity, & noncompliance than did children in the control group. Treatment effects were maintained after 1 yr. Mother & teacher reports of child behavior problems did not show treatment effects.

Key Statistics
Harsh Maternal Discipline, Self-Report
Pre-Post: $t = -4.41, p < .001$ IV ($n = 394$)
M''s = 1.28 pre, 1.18 post IV
 $t = -6.04, p < .001$ IV ($n = 296$)
M''s = 1.26 pre, 1.16 post IV, 1.09 followup IV
Inconsistent Maternal Discipline, Self-Report
Pre-Post: $t = -7.25, p < .001$ IV
M''s = 1.38, 1.13 IV
Pre-Followup: $t = -6.35, p < .001$ IV
 $t = -2.21, p < .05$ control
M''s = 1.36, 1.14, 1.1 IV; 1.29, 1.19, 1.19 cbfI
Appropriate Limit Setting, Self-Report
Pre-Post: $t = 10.34, p < .001$ IV
 $t = 3.39, p < .01$ control
M''s = 4.33, 6.02 IV; 3.67, 4.38 control
Pre-Followup: $t = 8.30, p < .001$ IV
M''s = 4.32, 6.26, 5.7 IV
Discipline Competence, Observed
Pre-Post: $t^* = 6.83, p < .001$ IV
 $t^* = 2.20, 2.42$ IV
 $t^* = 2.22, 2.4, 2.39$ IV
 t^* 's = ns; control group, unless otherwise noted
(see Website-Stratton, 1998 in "Validation" section for results of child behavior changes)

 $\beta = .44, \Delta F (8, 31) = 5.17, p = .05$
(steepwise multiple regression)

Family Characteristics—Problem Solving

Ages 4-6	Authors	Year Design	Representation	Size	Age	% Male	SES	Ethnicity	Result
Hooven, Gottman, & Katz 1995 Prospective longitudinal 3 yrs		Convenience: recruited nondclinical sample from Champaign-Urbana, IL, community through newspaper ads; screened for range of marital satisfaction	56	4-5 yrs > 8 yrs	56%	Low-middle	N/R	Mother Coaching, Age 5 $r = -.27, p < .10$ mother CBCL, age 8 $r = -.36, p < .05$ teacher internalizing, 8 $r = -.32, p < .05$ opposition, age 5 $r = -.31, p < .05$ negative play, age 5 Father Coaching, Age 5 $r = -.30, p < .05$ negative play, age 5 (correlations)	Mother's coaching of child's anger at age 5 predicted lower mother-rated oppositional behaviors (age 5), lower teacher ratings of internalizing (age 8). Coaching of child's anger by either parent was associated with less negative play with peers (age 5).
Ages 7-13	Coughlin & Vuchinich 1996 Prospective Longitudinal 7 yrs	Population: recruited from schools in neighborhoods with high delinquency rates, metro area of midsize OR city	194	10 > 17 yrs	100%	Low $M = \$16k$ $(\$3k-\$35k)$	98.5% Cauc 1.5% Mix	N/R	Better family problem solving at age 10 predicted fewer arrests by age 17 for boys from single-parent families, taking into account success in peer relations & child's antisocial traits (child, parent, & teacher reports of antisocial acts). Better family problem solving was associated with more arrests in single-mother families. (logistic regressions)
Vuchinich, Wood, & Vuchinich 1994 Concurrent group comparisons correlational		Convenience: (1) referred, behavior problems; (2) 4th gr.; no risk or problems; 20% response; (3) at-risk 4th-gr; boys, high-delinquency areas midsize NW city	188	8-13 yrs triads	69%	Low-middle	N/R	Better family problem solving was related to lower levels of externalizing. Children referred for behavioral problems had the lowest levels of family problem solving, followed by children in the at-risk group, followed by the comparison group.	
Treatment & Preventative Interventions	Sanger, Home, et al.	1988 Intervention random assignment followup 9-12 mths	37 families 20 T2	2nd-5th gr	100%	N/R	N/R	Externalizing, Parent Report $F = .001, M's = -10.90 \Delta, -7.60 \Delta$ Aggressive Behavior, Parent Report $F = .001, M's = -11.75 \Delta, -12.12 \Delta$ + Solutions, Obsvd $p = .02, M's = 12.2 \Delta, -5.22 \Delta$ - Solutions, Obsvd $p = .005, M's = -10.4 \Delta, 9.67 \Delta$ (ANOVAs on gain scores, F^* = not reported) Reduction, Deviant Classroom Behavior, Teacher Report Followup, 9-12 mths ($n = 20$) Externalizing $F = 7.48, p < .001$ $M's = 73.4 \Delta, 62.3 \Delta$ post, 62.3 Aggressive Behavior $F = 7.35, p < .001$ $M's = 12.9 \Delta, 6.3 \Delta$ post, 8.7 followup Positive solutions $F = 9.07, p < .001$ $M's = 64 \Delta, 75 \Delta$ post, 76 followup Negative solutions $F = 7.65, p < .001$ $M's = 26 \Delta, 14 \Delta$ post, 15 followup (repeated measures ANOVA)	Children & families in the intervention group showed improved problem solving abilities (more positive & fewer negative solutions) compared to controls. Reductions in parent reports of aggression & externalizing, & teacher reports of deviant classroom behavior were greater for children in the intervention group compared to controls. These changes were maintained at 9-12-mth followup.

Family Characteristics—Structuring of the Learning Environment

Ages 7–13

Authors	Year	Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Jenkins	1997	Concurrent correlational	Convenience: recruited from middle school in DE, students from urban & suburban areas; 83% participation	754	7th & 8th gr 11–15 yrs	50%	Low-middle free/reduced- price lunch	22% Afri 66% Cau 3% Aspa 4% Hisp 4% Other	Parent involvement in school was indirectly associated with lower school crime & lower school misconduct through students' greater attachment & commitment to school, & belief in school rules, taking into account gender, mother's education, race, grade, math ability, sibling in school, & living with a step-parent.

Peer Influences

Peers play an important role in child development. Particularly as children mature into adolescents, peers play a large role in shaping both appropriate and inappropriate behaviors. However, newer evidence indicates that as early as preschool, peers begin to exert noticeable influences on child aggressive behavior. Research on the influence of peers on externalizing behavior problems can be categorized into three domains—peer rejection of aggressive behavior, peer victimization, and peer enhancement of aggression and antisocial behavior.

At first glance, the first and third domain may appear contradictory. How can aggressive behavior be rejected and also enhanced by peers? This seeming contradiction is at the heart of peer influence on externalizing behavior problems. Aggressive behavior may be rejected by conventional peers and at the same time negatively and positively reinforced. Rejection by conventional peers encourages similarly aggressive and rejected children to find one another, form friendships, and develop ways of approving and accepting aggression. Although much is known about predictive and causal risks within each domain, the interdependence, possible sequencing, and points of vulnerability across domains of peer influence are not well established.

Peer Rejection of Aggressive Behavior

Peer rejection has been shown to be a middle-

childhood predictive risk factor for adolescent conduct problems over and above its concurrent correlation with childhood aggression. Several longitudinal studies have documented that children who are both rejected by their peers and highly aggressive exhibit the poorest overall adjustment in elementary school (Bierman & Wargo, 1995; Lochman & Wayland, 1994). As early as first grade, children who come from families marked by higher amounts of conflict and coercion are more likely to engage in aggressive interactions with peers (Dishion, Duncan, Eddy, Fagot, & Fetrow, 1994; Schwartz, Dodge, Pettit, & Bates, 1997). In turn, aggressive children who are rejected by their peers are at increased risk for behavior problems prior to middle school (Bierman, Smoot, & Aumiller, 1993; Bierman & Wargo, 1995). For boys, the predictive relationship between early aggression and peer rejection and later externalizing behavior problems has been documented into adolescence (Coie, Terry, Lenox, Lochman, & Hyman, 1995).

To understand why peer rejection has such negative effects for children, one must recall research described in the Child Characteristics section. Children who are both rejected and aggressive show a more pervasive pattern of behavioral and social deficits—including inattention, argumentative and disruptive behaviors, and poor prosocial behavior—unlike children who are aggressive but not rejected or rejected but not aggressive. Also, children who are both rejected and aggressive are more likely than their nonaggressive well-liked peers to develop biased social information processing involving a

tendency to attribute hostile intentions to others (Dodge, 1980; Dodge & Frame, 1982). This attributional style increases the likelihood that they will respond toward other children in a retaliatory, aggressive manner (see Child Characteristics section for more details).

Evidence exists that peer rejection associated with aggression is malleable and can function as a causal risk factor for externalizing behavior problems. By specifically targeting children who appear rejected because of their aggressive behavior, interventions that provide anger management skills and prosocial means of solving peer conflicts have resulted in increased peer acceptance and decreased child aggressive and externalizing behavior problems (Conduct Problems Prevention Research Group, 1999; Lochman, Coie, Underwood, & Terry, 1993).

Victimization

In addition to the negative attributional biases exhibited by rejected and aggressive children, evidence shows that peers are more likely to attribute hostile intentions and respond more aversively when the perpetrator is considered an aggressive youngster (Dodge, 1980; Dodge & Frame, 1982). Rejected youth are more likely to be treated negatively by their peers and are more likely to be victims of peer attack and abuse (Perry, Kusel, & Perry, 1988). Newer research has documented that the victimization experienced by socially rejected children includes not only physical attacks but also acts that undermine their relationships with other peers (i.e., relational aggression) (Crick, Casas, & Ku, 1999; Crick & Grotpeter, 1996). The correlation between peer rejection and relational aggression victimization has been found for children in preschool and elementary school.

Adding to the work on early peer victimization is the consistent correlation between being a victim of crime and being a criminal offender (Esbensen & Huizinga, 1991; Sampson & Lauritsen, 1990; Singer, 1986). Adolescents who are offenders are likely to be victims, and vice versa. It is not clear whether criminal victimization predicts later offending or whether early offending predicts later victimization. Also, it is not known whether criminal victimization in adolescence is predicted by the experience of peer victimization in elementary and middle school.

Peer Enhancement

Although aggressive children are at higher risk for peer rejection, aggressive and rejected children do have friends, and their friends also tend to be aggressive (Cairns, Cairns, Neckerman, Gest, & Gariepy, 1988; Haselager, Hartup, van Lieshout, & Riksen-Walraven, 1998; Tremblay, Masse, Vitaro, & Dobkin, 1995). As early as preschool, research has documented aggressive children to be part of social cliques that are particularly likely to be characterized by aggression (Farver, 1996). Aggressive friendships tend to be stable (Giordano, Cernkovich, & Pugh, 1986), and being a member of a group with other aggressive children and/or adolescents is a predictor of later conduct problems for both girls and boys (Kupersmidt, Burchinal, & Patterson, 1995).

Selection of mutually aggressive and deviant friends can expand in adolescence to pairings with the opposite sex. Antisocial behavior is a strong selection factor in couple formation. Individuals with a history of antisocial behavior in adolescence are likely to become partners with similar individuals (Krueger, Moffitt, Caspi, Bleske, & Silva, 1998). In turn, assortive pairing for antisocial behavior is associated with continued involvement in antisocial behavior during the adult years (Yamaguchi & Kandel, 1993). In contrast,

supportive, nondeviant partners are a source of protection, breaking the continuity in antisocial behavior between adolescence and adulthood (Quinton, Pickles, Maughan, & Rutter, 1993).

Peers also serve to reinforce aggressive behavior, particularly for children who have difficulty with aggression (Snyder, Horsch, & Childs, 1997). Young (preschool- and elementary school-aged) aggressive children are much more likely to initiate, reciprocate, and persist with aversive behavior with their peers than are nonaggressive children (Snyder & Brown, 1983). In elementary school, research on bullying (the assertion of power through aggression, repeated over time and intended to cause harm) has found the peer group to be critical in maintaining, exacerbating, and terminating bullying. Peers tend to give positive attention to bullies by watching, cheering, and sometimes joining the bully. The positive attention has been correlated with longer bouts of bullying (O'Connell, Pepler, & Craig, 1999). Also, boys who bully in early adolescence have been shown to be at higher risk for antisocial behavior in adulthood (Farrington, 1993). Although several antibullying programs have been developed for schools, these interventions have not specifically targeted peer processes in bullying.

The role of peers in enhancing delinquent and antisocial behavior in adolescence is well established. Most of the externalizing behavior problems of adolescents—including violent acts toward others—occur in deviant peer groups. For elementary- and middle school-aged boys, association with deviant peers is not only correlated concurrently with conduct problems but is also a predictive risk factor for increased involvement over time (Elliott, Huizinga, & Menard, 1989; Keenan, Loeber, Zhang, Stouthamer-Loeber, & Van Kammen, 1995; Patterson, 1993; Vitaro, Tremblay, Kerr, Pagani, & Bukowski, 1997). Deviant peers also engage in forms of deviancy training in which antisocial talk (e.g., bragging about physical assaults, discussing

delinquent acts) meets with approval and positive reinforcement (Dishion, Eddy, Haas, Li, & Spracklen, 1997). In highly deviant groups (i.e., juvenile street gangs), group membership is correlated with increased delinquent behavior (Bjerregaard & Smith, 1993). Studies following youth before, during, and after their gang membership show that rates of delinquency, especially violent delinquency, are substantially higher when a young person is a member of a gang than either before or after membership (Esbensen & Huizinga, 1993; Thornberry, Krohn, Lizotte, & Chard-Wierschem, 1993).

The most powerful evidence for documenting peer enhancement of conduct problems as a causal risk factor comes from failed interventions that involved grouping together high-risk youth. Interventions that group together high-risk youth, even in the presence of therapeutic intervention, have been shown to result in increasing delinquent behavior (Dishion & Andrews, 1995; Dishion, McCord, & Poulin, 1999). In contrast, research on therapeutic foster homes for delinquent youth that involve definitive changes in parenting and strict enforcement of no contact with deviant peers shows that these interventions result in decreased delinquency (Chamberlain & Reid, 1998).

Clearly, peer enhancement of conduct problems is a significant causal risk factor for antisocial behavior. By adolescence, the only established way to effectively reduce this influence is to remove contact with deviant peers. It is not known whether interventions aimed at reducing early peer reinforcement of aggressive behavior or bullying also may be effective in reducing conduct problems and deterring development of delinquent behavior. Nor is it known whether interventions designed to decrease peer rejection also may decrease peer enhancement of aggressive behavior. Given the strength of evidence about the role of peers in externalizing behavior problems, these questions appear ripe for investigation.

Implications for Malleable Peer Risk Factors and Developmental Processes

Research on peer influences shows that, beginning in elementary school, peers can have profound causal effects on externalizing behavior problems. Within the first years of school, one can see peer rejection of aggressive children, aggressive children beginning to form relationships with similarly aggressive children, and peers beginning to attribute greater hostile intent and aversion to aggressive classmates. At the same time, aggressive children are more likely to engage in and escalate their aggressive behavior with aggressive peers, to develop hostile attributional styles for interpreting social encounters with others, to be the victim of peer attacks, and to bully others. This vicious cycle of early peer rejection, hostile attributional processes, and increased aggressive behavior, however, is malleable. Interventions that target early aggressive behavior by providing anger management skills and prosocial means of solving peer conflicts and reducing hostile intent toward others have resulted in increased peer acceptance and decreased externalizing behavior problems.

It is critical to expand on these important results in two ways. First, the outcomes from these interventions should be expanded beyond peer rejection and hostile intent to include indices of peer victimization and formation of peer cliques. Are the skills learned through intervention generalizable to these domains of peer influence? Also, long-term effects need to be documented. If these early interventions are successful in deterring the formation of aggressive and antisocial cliques, this could have profound effects during adolescence by deterring association with deviant peers and preventing the escalation of serious antisocial behavior. Clearly, long-term followup of these interventions is needed.

The second way to expand these interventions is through research to determine ways of effectively translating the interventions for use by communities, schools, and mental health service systems. School policies, classroom structure, and classroom management also may correlate with externalizing behavior problems (see the Broader Social Environment, Communities, and Schools section), which could intensify or constrain interventions. Critical issues will need to be addressed: who will receive the intervention (all children or only targeted high-risk children), when in development the intervention will be most effective (e.g., early versus late elementary school), for whom the intervention should continue, who should administer and deliver the intervention, and what should administering and delivering the intervention cost? However, the potential gain of decreased externalizing behavior problems is well worth the effort.

Although the potential for early peer interventions to affect adolescent association with deviant peers requires further empirical testing, the current data on deviant peers are quite clear: association with deviant peers during adolescence is a significant causal risk factor for antisocial behavior. Grouping similarly deviant adolescents together, even in the presence of therapeutic interventions, serves only to maintain and possibly enhance antisocial behavior. This finding is in direct conflict with many educational, community, and state policies and services that group troubled youth together in classrooms or in group homes. Clearly, these policies deserve re-examination given these research findings. Also, there needs to be more research that examines alternatives to group placement (e.g., therapeutic foster care) and that addresses ways of preventing association with deviant peers during pre- and early adolescence (e.g., after-school programs, increased parental monitoring).

In looking over the research on peer rejection, victimization, and enhancement of aggressive

behavior, it is not clear how these three forms of peer influence interact or mutually develop over time. Although research indicates that rejected and aggressive children are more likely to be victimized in grade school, it is not clear whether these children are also at risk for victimization during adolescence. Also, how does early victimization affect peer acceptance and the formation of social cliques? Are there developmental events, child characteristics, or family influences that increase vulnerability to peer influence and, therefore, could be used to more effectively target preventive interventions? Some of the fundamental peer processes involved in the development of externalizing behavior problems have been established; research is needed that pursues more complex interactions and the developmental timing of peer influences from early childhood through adolescence.

Peer Influences—Peer Victimization

Victimization & Criminal Offending

Authors	Year	Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Sampson & Laurnsen	1990	Concurrent Replications	Population: randomly selected an age 16+ person from households in 238 (1982) & 300 (1984) electoral districts, England & Wales, for a national representative sample; British Crime Survey	21,935 (10,905 1982 11,030 in 238 (1982) & 300 (1984))	16+ yrs	N/R	Low	2% AfA 95% Cau 3% Other	Risk of self-reported personal assault, theft, or vandalism (assault, theft, or vandalism) was related to self-reported offending (Violence, theft, or vandalism), area crime rate, male gender, & age, taking into account college education, single marital status, & lifestyle (drinking behavior & number of nights out per week). In a modified replication study, risk of victimization was related to minor self-reported deviance, taking into account the above-mentioned variables.

Victimization & Criminal Offending

Authors	Year	Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Singer	1986	Retrospective correlative	Convenience: randomly sampled 10% of participants from earlier study of males born in 1945, Philadelphia, PA	567	26	100%	Low-middle	N/R% AfA N/R% Cau	The probability of committing a serious assault was related to retrospective reports of victimization (confined here to serious assault with a weapon—shooting or stabbing), gang membership, & weapon use. Victims were more likely to have an adult arrest record than non-victims.

Peer Enhancement—Peer Selection

Authors	Year	Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Cairns, Cairns, et al.	1988	Concurrent group comparisons	Convenience/ Source specific: recruited 695 children from 4 elementary & 3 middle schools in suburban & rural areas of 2 counties; selected 40 children rated as highly aggressive by school personnel & nonaggressive controls matched on gender, race, SES, age, size, & classroom	80	4th & 7th gr	50%	Low-upper $M = 30.9$ ($T = 38$) Duncan scale	75% "Minor" (mostly AfA)	Highly aggressive children & nonaggressive matched controls (based on school personnel ratings) were equally distributed among nuclear, secondary, peripheral, & isolated status in social clusters. Aggressive children did not differ on peer's judgment of isolation or number of times chosen as a reciprocal best friend, although they were rated by teachers as less popular than controls. Ratings of aggression were similar for best friend boys in 4th & 7th grade, 7th-grade girls, & 7th-grade nonreciprocal boy best friends.

Peer Influences—Peer Enhancement

Peer Selection

Authors	Year	Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Tremblay, Masse, et al.	1995	Concurrent correlational cross-sectional sequential; data collected over 3 yrs; T1 not used to predict T3	Population: recruited boys in 53 public schools, low- SES areas, Montreal, Canada; boys who had Canadian-born, French-speaking parents & a mutual friend were eligible	1,034	10, 11, & 12 yrs	100%	Low	100% Cauc (French Canadian)	Peer ratings of aggression were similar for boys & their friends at ages 10, 11, & 12. Boys' & friends' likeability at ages 10, 11, & 12 were taken into account.

Associative Pairing

Authors	Year	Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Krueger, Hoffitt, et al.	1998	Concurrent correlational	Convenience: recruited at age 21 from Dunedin study participants & their partners of 6 mths or more; original sample; consecutive births, spring, 1972– 1973, Dunedin, New Zealand	360 couples	21 yrs	50%	N/R	N/R% Cauc N/R% Pac Is	Intimate partners at age 21 had similar self-reports of antisocial behavior, including variety of offenses & peers' delinquency. They also had similar attitudes about the consequences of crime.

93

96

Quinton, Picides, et al.	1993	Prospective longitudinal 15 yrs approximate	Convenience: 4 samples, (1) young adults reared in children's homes; (2) quasi- random low-SES comparison group; (3) random pop sample of 10 yr olds; (4) children high on behavioral deviance; all from inner city London	150– 352	M = 10.5 Yrs T1	47%	Low	N/R	Continuity of Conduct Disorder & Partner χ^2 (2) = 10.44, $p < .005$ ($n = 150$) $M = 0.0$ (with nondisruptive partner $M = 17.7$ (without nondisruptive partner (latent class models)
Yamaguchi & Kandel	1993	Retrospective correlational lifetime reports	Convenience: recruited 50% of participants in earlier study & their partners, married or cohabitating; 1st recruited as 10th–11th graders, 18 public high schools, NY, 1971–1972	545 dyads	26–31 yrs cohort 19–60 yrs partners	50%	N/R	N/R	First Cohabitation With Deviant Partner Conduct disorder ($n = 352$) OR = 1.67, CI = 1.1–2.5, Wald $p = .01$ Deviant peers' OR = 2.72, CI = 1.3–5.3, Wald $p = .007$ (Cox proportional hazards model)
									Concordance of Drug Behavior, Partners $K = .34$ ever lifetime $K = .34$ ever prior marriage $K = .43$ last 12 mbms (all p 's < .001) (see study for loglinear models) (weighted kappas)

There was moderate concordance
between partners on measures of
illicit drug use over the lifetime,
prior to marriage, & in the past
12 months for adults who had used
a class of drug 10 or more times.
Latent trait log-linear models controlling
for population heterogeneity indicated
that this concordance was due to
associative mating, not socialization.

Snyder & Brown	1983	Prospective longitudinal 6 wks	Source specific: recruited children rated 5 highest & lowest on conduct disorder scale from day care center in Kansas	20	3-5 yrs	50% $M = \$11K$ income/yr	50% Cauc 50% "Minority"	Oppositional children observed in a day care setting were more likely than children rated by teachers as nonoppositional to initiate oppositional behavior (respond aversively to a positive antecedent); reciprocate opposi- tional behavior (respond aver- sively to aversive consequence), & continue aversive behavior once begun. Oppositional children were also more likely to receive aversive stimuli.
Snyder, Horsch, & Childs	1997	Prospective longitudinal 4 mths	Convenience: recruited from 4 preschool classrooms, high-crime area, Denver, CO	72	49-62 mths	50%	Low poverty	100% AfRA Aggressive behavior increased over a 4-month period for children who associated a substantial amount (teacher ratings & observations) or a moderate amount (teacher ratings) of time with aggressive peers.
O'Connell, Pepler, & Craig	1999	Concurrent group comparisons, correlations	Convenience: recruited from 2 preschools, Toronto, Canada area; male/ female stratified sample of bullies, victims, bully-victims, & comparison-children; based on self, peer, or teacher nominations; had 1 bully & 2 or more peers	219 53	14 > 18-19 yrs, 32 yrs	100% $23\% < \leq 15$ $30\% > 20$ income/week	90% Cauc < 10% Ind < 10% Criypt	Bullying at age 14 predicted bullying at age 32, independent of aggression at age 32. Self-reports of bullying at age 32 were almost twice as likely for boys who had reported bullying at age 14, almost 5 times as likely for boys who reported bullying at 18. Men who reported bullying at age 32 were over 2 times more likely to have been convicted of a violent crime.
Farrington	1993	Prospective longitudinal 5, 18 yrs	Population: sampled boys ages 8-9 yrs from 6 state primary & 1 special ed school in working- class area of London, 1961-1962; Cambridge Study in Delinquent Development	378	14 > 18-19 yrs, 32 yrs	100% $23\% < \leq 15$ $30\% > 20$ income/week	90% Cauc < 10% Ind < 10% Criypt	Bullying at age 14 predicted bullying at age 32, independent of aggression at age 32. Self-reports of bullying at age 32 were almost twice as likely for boys who had reported bullying at age 14, almost 5 times as likely for boys who reported bullying at 18. Men who reported bullying at age 32 were over 2 times more likely to have been convicted of a violent crime.

Broader Social Environment, Communities, and Schools

Research on the impact of community and broader social environmental factors differs from research discussed in other areas of this report in several fundamental ways. First, many of the community and social environmental features that elevate risk for externalizing behavior problems operate in a cluster. That is, while one can statistically identify distinct factors (e.g., minority group membership, economic disadvantage), in reality, risk of youth conduct problems is particularly elevated in social areas characterized by a confluence of these structural features.

Second, in the other sections of this report, assessments of risk are associated with individual variation in externalizing behavior problems and conduct problems. However, research examining the influence of community and broader social environment factors traditionally has focused on rates of violence and crime across particular geographic entities rather than on individual variation. For example, neighborhoods characterized by high rates of unemployment often have a high overall crime rate. These variables may not be strong in predicting which youth will exhibit externalizing behavior problems. However, the "strain" associated with the inability to achieve along traditional educational and occupational lines may be an important contextual factor influencing antisocial behavior.

Broader Social Environment

Within the broader social environment, two key factors have been related to aggression and delinquent behavior—culture and SES. Indeed, it can be very difficult to distinguish the effects of these two factors because SES is frequently confounded with ethnic membership. As noted above, it may be the interaction of culture and SES that is most germane to youth conduct problems. Given this caveat, cross-cultural research on aggression and violence has shown American culture to be more accepting of aggressive behavior (Hartz, 1995; Kumagai & Straus, 1983) compared with other cultures. This can be particularly striking within some U.S. subcultural groups (Heimer, 1997), such as street gangs (Bjerregaard & Smith, 1993; Esbensen & Huizinga, 1993; Thornberry, Krohn, Lizotte, & Chard-Wierschem, 1993). Research on lower SES and poverty consistently shows these variables to correlate with elevated rates of crime (Heimer, 1997). Rates of crime are likely to increase where there is a decline in access to jobs or where unemployment is high (Almgren, Guest, Immerwahr, & Spittel, 1998; Catalano, Novaco, & McConnell, 1997).

Economic discrimination also is associated with increased violence (Messner, 1989). In the criminal justice system, lower SES and minority youth were

more likely to be referred to court and to receive more intensive police scrutiny than higher SES and Caucasian youth (Sampson, 1986).

Communities and Neighborhoods

Studying the impact of communities and neighborhoods on children, researchers have examined three major features: (1) structural and demographic features, (2) exposure to situations or events, and (3) community-level processes and forms of social control. In terms of structural and demographic features, research on the extent to which neighborhoods are characterized by deteriorating housing (Spelman, 1993), overcrowding (Wallace, 1990), greater population density, and greater numbers of female-headed households (Harries & Powell, 1994; Smith & Jarjoura, 1988) consistently shows correlations with neighborhood crime rates and violence.

Children and young people who live in deteriorating neighborhoods with higher crime rates are more likely to be exposed to and witness robberies, assaults, and murders. Experiencing their neighborhood as dangerous, young people may become anxious, depressed, defiant, and/or aggressive (Aneshensel & Sucoff, 1996; Gorman-Smith & Tolan, 1998; Greenberg, Lengua, Coie, & Pinderhughes, 1999; Griffin, Scheier, Botvin, Diaz, & Miller, 1999). Children who have seen or been the victim of violence are more likely to perceive themselves as vulnerable to violence and are more likely to report carrying weapons to school (Simon, Dent, & Sussman, 1997; Uehara, Chalmers, Jenkins, & Shakoor, 1996).

A newer line of research has begun to examine how community-level processes and forms of social control may be related to youth delinquency. Studies have shown that the extent of collective social control (e.g., the extent to which members of the community have local friendship networks and

share collective willingness to intervene in youth misbehavior, such as skipping school, painting graffiti, showing disrespect to adults) correlates with decreased rates of delinquency and problem behaviors and partially mediates the relationship between community structure variables and delinquency (Bursik & Grasmick, 1993; Elliott et al., 1996; Sampson, 1997; Sampson & Groves, 1989; Sampson, Raudenbush, & Earls, 1997).

Social Environment and Community Influences on Families and Children

Another strategy for assessing the impact of the broader social environment and community is to examine how these broader contextual factors influence group and individual processes (e.g., family, peer, or child individual characteristics). The basic notion is that structural or demographic variables—such as SES, culture, and community deterioration—probably influence everyday social routines and ways of relating, which may in turn affect the risk of antisocial behavior.

Compared with lower-SES parents, those in middle-class families are more likely to monitor their children's friendships and less likely to use harsh discipline (Heimer, 1997); both are parenting behaviors shown to be causal risk factors for child externalizing behavior problems (see Family Factors and Processes section). Additional research has documented that higher levels of perceived economic stress are associated with parental distress, which in turn increases parental hostility, decreases parental monitoring, and subsequently increases youth externalizing behavior (Conger et al., 1992). Other research has documented differences between children of middle-SES families and children of lower-SES families; middle-SES children show less physical aggression and more cooperative interactions with peers (Ramsey, 1988).

Schools

Recently, incidents of school violence have drawn people's attention to the nature of schools and the identification of educational policies, educational practices, and student behavior that can contribute to child and youth conduct problems and violence. It is important to note that the majority of youth who receive any help for a mental health problem receive interventions through their school (Burns et al., 1995). However, such services tend to be brief (approximately one visit per quarter for outpatient or three days for inpatient) and are more typical for younger children (Farmer, Stangl, Burns, Costello, & Angold, 1999).

A number of school policies may affect youth conduct. These policies include zero-tolerance practices (the suspension and expulsion of students for problem behaviors), proficiency testing (requiring students to pass standardized exams to qualify for graduation), full inclusion (providing uniform services in the general classroom regardless of the intensity of the problem), and use of the social maladjustment clause of the federal definition of students with serious emotional disturbance, which indicates that students who are socially maladjusted are not eligible for special education services and civil rights protections unless it is determined that they have an emotional disturbance. Little systematic research, however, has examined how these school policies affect youth conduct. Limited research examining the impact of the social maladjustment clause indicates that this policy may be extremely difficult to apply appropriately. Current rating scales for discriminating between social maladjustment and emotional disturbances have been found to be unreliable (Costenbader & Buntaine, 1999). Similarly, research on teacher assessments of those in need of special education services has shown that while students with externalizing behavior problems are deemed troubled, many are not identified for special education services (Farmer,

Rodkin, Pearl, & Acker, 1999). However, in another study, boys recommended for special services showed higher rates of conduct disorder than boys who were referred but not recommended (Mattison, Morales, & Bauer, 1992). This unreliability and lack of clear identification can have profound implications under the social maladjustment clause. By not identifying children with externalizing behavior problems as emotionally disturbed, schools are able to suspend and expel these children without invoking any of the civil rights protection practices that are required for students with identified disabilities.

Even when children are identified as emotionally disturbed, the impact of placement into special classrooms is difficult to assess. Placement into special services is governed by legal mandates, and students placed in more restrictive settings are expected to have more intensive needs than those placed in less restrictive settings. Thus, special placements cannot be experimentally manipulated, and studies comparing outcomes of students in different settings must be conducted with nonequivalent groups. Given these limitations, research indicates that interventions designed to decrease disruptive classroom behavior do result in desired outcomes in both special services classrooms and typical classrooms, with children in restricted classrooms more likely to evidence reduction in disruptive behavior than students in regular classrooms (Stage & Quiroz, 1997). Interestingly, interventions designed to prevent school dropout found that correlated reductions in conduct problems in youth ages 9, 10, and 11 also helped to prevent placement in special classrooms, which in turn reduced the risk of dropping out of school (Vitaro, Brendgen, & Tremblay, 1999). Cumulatively, these results suggest that special classroom placement supplemented with interventions to reduce disruptive behavior may be effective. However, it is not clear whether these effects are similar for children and youth in elementary, middle, and high school or whether

prevention of special classroom placement may be even more effective.

Changing schools frequently is associated with a variety of problems, including lower academic performance, worse behavior in school, lower grade retention, school dropout, and serious disciplinary problems (Rumberger & Larson, 1998; Swanson & Schneider, 1999; Tucker, Marx, & Long, 1998). Based on data collected by the National Educational Longitudinal Survey, changes that occur during the early school years have little impact on child behavior problems. However, school changes during high school were correlated with a moderate increase in behavioral problems (Swanson & Schneider, 1999). The importance of number of school changes may be mediated by family structure. In families with two biological parents, excessive mobility (eight or more moves) correlated with school problems. However, for all other family configurations, any move was associated with problematic youth behavior (Tucker et al., 1998). Also, school changes and dropout were predicted by high rates of absenteeism, misbehavior, and low-educational expectations (Rumberger & Larson, 1998).

Another school variable considered relevant to child conduct is the type of disciplinary practices invoked for misbehavior. Although disciplinary practices are aimed at reducing problem behavior in schools, surprisingly few studies have directly examined the relationships between school discipline and the development and maintenance of externalizing behavior problems. Given the growing trend of adopting zero-tolerance policies, this lack of data is cause for concern. In a survey on school suspension, the majority of middle school and high school students who received suspensions did not consider this form of discipline to be very helpful in solving problems (Costenbader & Markson, 1998). Data on less punitive forms of school discipline also are limited. However, there is some evidence that use of less punitive forms of school discipline in elementary school (e.g.,

reminders to be safe and respectful) did result in reduced problem behavior (Lewis, Sugai, & Colvin, 1998).

Another school practice that has received attention is tracking (i.e., the arrangement of students in classrooms by levels of ability). Tracking is a complex factor, as it is intertwined with other characteristics of students, families, friends, and schools in ways that seem to solidify differences among students. Students who come from low-SES backgrounds, attend low-SES schools, are members of ethnic-minority groups (Jones, Vanfossen, & Ensminger, 1995), and display behavior problems (Farmer, 1993) are over-represented among low-ability tracks. Being placed in a low-ability track is associated with less effective instruction, more disruptive off-task behavior by students, and lower than expected academic attainment (Gamoran, Nystrand, Berends, & LePore, 1995).

Public concerns about class and school size have grown with concerns about violence in the schools and poor pupil performance. Yet educational researchers have had difficulty determining whether reduced class size positively affects student performance and behavior. Part of this difficulty comes from the fact that schools do not randomly assign students to classes (e.g., there is tracking) and that there are state and federal regulations that limit the size of special education classes. However, when special education restrictions are taken into account, smaller class size does correlate with enhanced performance (Akerhielm, 1995). Research on the size of schools has focused on academic outcomes rather than behavioral outcomes (Lee & Smith, 1997; McGiverin, Gilman, & Tillitski, 1989). This research indicates that the most effective high schools serve 600–900 students. Neither small schools (< 300) nor large schools (> 2,100) are associated with strong learning environments. Similarly, the effect of school size is more profound in schools with lower-SES students and in schools with higher concentrations of minority students (Lee & Smith,

1997). It is not known, however, whether these same effects would be useful indicators of student behavior and conduct.

Within schools, youth develop social hierarchies and groups that, in some cases, can set the tone for conduct problems and delinquency. Students in high-status cliques can wield considerable social power with peers and classmates. Recent research has shown that aggressive behavior by boys can enhance the likelihood of their obtaining prominent positions in social structures (Xie, Cairns, & Cairns, 1999), particularly when accompanied by high athleticism or above-average academic performance (Rodkin, Farmer, Pearl, & Van Acker, 2000). Additional research, however, is needed to understand how social cliques and hierarchies develop and contribute to student conduct in schools.

Two features of the classroom also have been related to child externalizing behavior problems—the level of classroom disruption/aggression and teacher-student interactions. One study has documented that the overall level of classroom aggression can have significant effects on individual children's risk for aggression over time (Kellam, Ling, Merisca, Brown, & Ialongo, 1998). More aggressive boys who were assigned to first grade classrooms that were high in disruption and aggression were at markedly increased risk for continuing to be aggressive over the next years of elementary school. This was in comparison with aggressive boys who were not placed in aggressive/disruptive classrooms. In addition, recent research on teacher-student interactions indicates that teachers interact differently with students who have externalizing behavior problems. Students with behavior problems receive more teacher reprimands and fewer opportunities to respond appropriately to teacher requests (Van Acker, Grant, & Henry, 1996; Wehby, Dodge, & Valente, 1993). To some extent, lowering teacher-student ratios, particularly in special education classrooms, can mitigate these

teacher-student interactions (Thurlow, Ysseldyke, Wotruba, & Algozzine, 1993).

Complementing research on the impact of schools on children and youth is research that examines how children and youth feel about their schooling experience. "School bonding" consists of attachment to school, commitment to educational pursuits, and belief in the fairness of school rules. Evidence shows that school bonding is related to delinquency in middle school, with decreased bonding associated with increased rates of delinquency (Jenkins, 1997). Further, interventions designed to modify elementary school teaching practices to increase school bonding showed bonding to be a predictive risk factor for externalizing behavior problems in adolescence. Through an intervention designed to modify teacher behavior, successful changes in school bonding were associated with improved academic achievement (Abbott, O'Donnell, Hawkins, Hill, & Kosterman, 1998). Long-term effects of this intervention program, when combined with parent training and social competence training for the children, showed that the package of interventions provided throughout elementary school had enduring modest effects in reducing self-reported violent behavior, heavy drinking, and sexual intercourse before age 18 among multiethnic urban children (Hawkins, Catalano, Kosterman, Abbott, & Hill, 1999).

Implications for Malleable Community Risk Factors and Developmental Processes

Existing research on the broader social environment, communities, and schools indicates that many factors affect the development and likelihood of youth conduct problems. As noted at the beginning of this section, many of the social and community factors that have been associated with youth conduct problems operate in

conjunction. Lower SES, income inequality, and deteriorated housing frequently occur together and, as a cluster, are associated with high rates of crime and delinquency. However, much of this research is correlational and has focused on rates of problem behavior across geographic regions rather than individual variations in conduct. Also, social and community variables are difficult to conceptualize as "malleable" because altering income, housing, and employment opportunities would require major social change and incredible financial resources.

How then do we go about incorporating these relevant variables into developmental models for predicting and intervening with child and youth conduct problems? One strategy frequently employed by researchers is to use SES, income, violent neighborhoods, and so forth as selection criteria for determining high-risk groups and targeting interventions. This way, such social and community factors serve as contextual variables and are conceptualized as factors that potentially moderate the salience of other child, family, and peer risk factors and processes (e.g., parental monitoring, peer deviance). Although a useful strategy (it increases the probability not only that those most in need will be in the intervention but also that it will be possible to detect a change), it does little to help understand *how* such social and community factors affect conduct problems.

This question of "how" has motivated researchers interested in identifying variables that mediate the association between social and community factors and child/youth conduct problems. To date, two important sets of factors have been identified as mediators—family processes and a community process known as collective social control. Lower-SES families or families experiencing economic distress are more likely to engage in harsh discipline and provide less effective monitoring, which, in turn, partially mediates the effect of these broader variables on youth conduct problems. Similarly, the research on collective social control indicates that it partially mediates the relationship

between community disadvantage and rates of delinquency and violent crime. Although research on family processes has shown that parental monitoring and discipline are causal risk factors for child and youth conduct problems, additional research is needed on collective social control to determine its malleability and the resulting impact on youth behavior. Studying the malleability of collective social control is a critical next step that could have profound implications for indicating the causal potential of this variable and developing more effective community-level interventions to prevent youth problem behavior. Given the number of child, family, and peer processes reviewed in previous sections, it is clear that much more research is needed to examine how correlates, predictive risk factors, and causal risk factors at lower levels of analysis may either mediate or be moderated by broader social factors.

The information reviewed here about school effects on child and youth conduct problems also suggests a range of important factors. School policies, classroom placement, tracking, and classroom size all could affect youth conduct. Although many of these school variables have been related to academic success and failure, surprisingly few studies have examined these issues in relation to child and youth conduct. Those studies that have examined behavioral and conduct-related outcomes suggest that school variables do correlate with problematic behavior. However, more systematic research is needed to establish the strength of these associations and the degree to which school policies and practices predict youth behavior.

Promising research has been conducted on classroom aggression, teacher-student interactions, and school bonding. Each of these school variables has been related to child and youth conduct. In the case of classroom aggression, levels of classroom aggression in first grade reliably predicted increased aggressive behavior in later grades for children who were already showing some problem behavior. Similarly, the research on early school

bonding has shown it to reliably predict decreases in conduct problems in adolescence.

These important results need to be advanced to determine ways to modify early classroom aggression levels, improve school bonding, and evaluate the impact of these changes on child behavior. However, it is equally important that this work be integrated with research reviewed in previous sections—child characteristics, family processes, and peer factors. What are the consequences of altering early classroom aggression on child development of hostile attributions, peer rejection, and bullying? By improving school bonding, is one also influencing parental monitoring of child behavior or structuring of the learning environment? Are school-based interventions more or less effective in different neighborhood and community contexts? Clearly, many important questions remain to be investigated, questions whose answers could have enormous impact on the development of more effective preventive interventions for child and youth conduct problems.

Communities & Neighborhoods—Housing

Hartes & Powell	1994	Pattern analysis geocoding 8 spatial analysis	Population: census data & police records of juvenile gun crimes, Baltimore, MD, 1980–1990	2,369 JV gun crimes	14–17 yrs offenders	98%	Low–upper locations	91.6% Afra 8.1% Cau 0.3% Other	Spatial & temporal analyses of juvenile gun crimes between 1980 & 1990 in Baltimore, MD, found that (offenders) most incidents clustered in high social stress (HSS) census tracts. Patterns varied by age, race, & location. For example, crimes by black juveniles on black victims crimes against other juveniles; crimes on white victims occurred all over, with boundary effects along the edges of HSS areas. Crimes by white juveniles on black & white victims were committed outside of HSS areas. These patterns showed stability over time.
-----------------	------	---	--	------------------------	------------------------	-----	------------------------	--------------------------------------	--

Juvenile Gun Crimes & High Social Stress* Tracts
 * overall
 * black juvenile offender, black victim
 * black juvenile offender, black juvenile victim
 * white juvenile offender, black victim
 * white juvenile offender, white victim
 *Social Stress Index: persons/occupied housing unit,
 median home value, % female, % black, % under 18

Postintervention Disruptiveness		$R^2 = .07$, $p < .05$		$\beta = .20$, $p < .05$ age 6 disruptiveness		$\beta = -.16$, $p < .10$ program participation		$\beta = -.05$, $M^2_s = 8.74$ IV, 10.72 ddf	
Vitato, Brendgen, & Tremblay	1999	Intervention random assignment	Population: boys in 53 public schools in low-SES area, Montreal, Canada, were rated by kindergarten teachers; only boys with Canadian-born, French-speaking parents, < 15 yrs ed, eligible; at-risk boys (> 70% disruptive) took part in intervention; 12% not included because of parent refusal or missing data	149	6 > 17 yrs	100%	Low	100% Cau	Participation in a dropout prevention intervention program (social skills training for boys & parent training) predicted lower average disruptiveness from ages 9 to 11, controlling for age 6 disruptive behavior, family configuration, IQ, & parent education. Post-intervention disruptiveness mediated the relationship between program participation & non-age-appropriate regular classroom placements (non-AARC), retention, & special ed class. Less disruptiveness was associated with fewer non-AARC placements. In turn, non-AARC placements at age 12 mediated the effect of the IV program on school dropout. In both analyses, family configuration, parent education, & children's IQ were significant predictors; age 6 disruptive behavior was not. The risk of dropping out of school was 4.95 times higher for retained & 4.75 times higher for combined retained/speciacl classroom students.

Broader Social Environment, Communities, and Schools—Schools

Authors	Year	Design	Representativeness	Size	Age	% Male	SES	Ethnicity	Result
Kelam, Ling, et al.	1998	Prospective longitudinal	Population: children from 18 public elementary schools in 5 areas of E. Baltimore; schools & teachers were randomly assigned to IV/control classrooms; students were assigned sequentially to 1st-grade classrooms balanced for kindergarten aggression & remained in classroom 1st & 2nd grades	403	1st > 6th gr	50%	Low-middle 46% in school lunch program	64% Afra 29% Cauc 7% Other T1	Boys' 1st-grade classroom aggression, classroom poverty, * & the interaction of 1st-grade individual & classroom aggression predicted teacher ratings of highly aggressive behavior in 6th grade. Highly aggressive 1st-grade boys in high-aggression classrooms were 2.7 times more likely to be rated as highly aggressive in 6th grade than highly aggressive boys in 1st-grade classrooms low in aggression. For girls, 6th-grade aggression was predicted by individual aggression & classroom poverty in 1st grade, but not by classroom aggression.
Thurlow, Ysseldyke, et al.	1993	Concurrent Correlational	Source specific: Students in special education & regular education, & regular services, 27 schools, 8 school districts; 114 learning disabled, 19 emotional/behaviorally disturbed, 6 & 6 educable mentally retarded students	139	1st–6th gr	66%	N/R	N/R	Qualitative & quantitative aspects of instruction in special education classrooms showed improvements with smaller student:teacher ratios. Observations of teacher instruction found that relevance of assigned tasks, feedback from teachers, & checking for student understanding were greater in classes with smaller ratios. Similarly, students in classes with smaller student:teacher ratios had higher academic responding & academic engaged times, & they spent less time on task management & teacher tasks.
Van Acker, Grant, & Henry	1996	Concurrent group comparisons	Convenience: Students above median for risk of aggression, 2 inner-city & 2 metro area Midwest schools; Metropolitan Area Child Study control schools	206	2nd, 3rd, 5th gr students	59%	N/R	56/20% Afra 11/66% Cauc 31/11% Hisp 3/2% Other (students/teachers)	Teachers gave more reprimands, fewer opportunities to respond academically, & more behavioral requests to students at high risk for aggression than mid-risk students.
Wehby, Dodge, & Valente	1993	Prospective longitudinal	Convenience: Students chosen from larger study, Southeast, 3-stage screening for risk: school, class, parents over 2 mths	82	K > 1st gr	57%	N/R	52% Afra 48% Cauc	Children identified in kindergarten as at high risk for developing conduct problems were given more negative commands in structured & unstructured settings by their 1st-grade teachers than low-risk students.

Key Statistics
 Boys 1st Grade on 6th Grade Aggression ($n = 202$)
 OR = 1.30, CI = 0.85 – 1.98, $\rho = \text{ns}$ individual aggression
 OR = 0.07, CI = 0.01 – 0.61 classroom aggression
 OR = 2.27, CI = 1.08 – 4.77 individual \times classroom aggression
 OR = 1.07, CI = 1.32 – 6.47, $\rho < .01$ classroom poverty
 Hi-Aggression vs. Low-Aggression Classrooms
 OR = 1.7 – 58.7 vs. OR = 1.1 – 2.7

Girls 1st Grade on 6th Grade Aggression ($n = 201$)
 OR = 1.75, CI = 1.03 – 2.97 individual aggression
 OR = 10.83, CI = 1.36 – 86.15 classroom poverty
 $(\rho < .05 \text{ unless noted})$

*Classroom aggression: Mean aggression score of children in classroom (teacher-rated). Classroom poverty: % of students in the classroom who receive a free lunch (hierarchical linear regressions)

Task Relevance $\chi^2 = 20.46, p = .0004$ ($n = 106$)
 M's = 3.59, 3.43, 3.08, 3.10, 3.23
 Checking Student Understanding

Abbott, O'Donnell, et al.	1998	Intervention nonrandom 2 yrs	Convenience: consenting 5th grade students (76%) in 18 public schools, high-crime areas, Seattle; part of a longitudinal study of 1st–6th-gr. intervention; 20 classrooms in 10 schools IV, 18 class- rooms in 8 schools controls; 1985–1987	808	spr 4th > spr 6th gr	51%	Low-middle 52% eligible for school lunch program	24% AfRA 46% Cauc 21% Asia 9% Other	Greater implementation of targeted teaching strategies, classroom management, interactive teaching, & cooperative learning resulted in greater student-reported bonding to school, involvement in the class- room, & opportunity for & reinforce- ment of classroom involvement. IV group students also had higher CAT achievement scores at the end of 6th grade (controlling for 5th-grade CAT) but showed no differences on school bonding variables when on school bonding variables when implementation was not examined.
Hawkins, Catalano, et al.	1999	Intervention nonrandom 2–6 yr IV; 5th–6th or 1st–6th; 6-yr followup age 17; CAT achievement, court records; age 16; self- report	Convenience: consenting 5th-gr students (79%) in 18 public schools, high-crime areas, Seattle; 1/3 received IV since 1st-Gr.; 1/3 5th–6th-gr.; 1/3 controls; 1985–1993	598	5th gr > T2 17/18 yrs	50%	Low-middle 57% eligible for school lunch program	26% AfRA 22% AsIA 44% Cauc 5% Asia 3% Other	High school seniors in preventive intervention classrooms during 1st–6th grades reported more commitment & attachment to school; less school misbehavior, heavier drinking, or repeating a grade, & less lifetime violence, sexual activity, or pregnancy than students in control classrooms. Poverty interacted with intervention status. School attachment was higher for poor IV students than poor controls, fewer poor IV than controls repeated a grade, & fewer working-/ middle-class IV students were/got a woman pregnant than controls. The late IV (5th & 6th grade only) showed no treatment effects.
Jenkins	1997	Concurrent correlational	Convenience: recruited students from middle school in DE; urban & suburban areas, 83% participation	754	7th & 8th gr 11–15 yrs	50%	Low-middle 20% eligible for school lunch program	22% AfRA 66% Cauc 3% AsIA 5% Hisp 4% Other	Components of the school social bond predicted self-reported school delinquency. Educational commitment & belief in school rules directly predicted school crime (drug use, vandalism), school misconduct (cheating, talking in class) & school nonattendance (cutting or tardiness, class or school). Attachment to school directly predicted misconduct & nonattend- ance. Involvement in school activities was an indirect predictor of school delinquency, through the school social bond.
									Bonding to School—Implementation Score $\chi^2 = 222.7$ ($df = 41$), $p = .001$; $t = 2.23$, $p < .05$ Opportunity for Involvement—Implementation $\chi^2 = 220.9$ ($df = 36$), $p < .01$; $t = 3.14$, $p < .01$ Actual Involvement—Implementation $\chi^2 = 106.5$ ($df = 41$), $p = .001$; $t = 2.49$, $p < .01$ Reinforcement Involvement—Implementation $\chi^2 = 244.1$ ($df = 41$), $p = .001$; $t = 2.36$, $p < .05$ (N 's not reported for high & low implementation) (controlling for 5th-grade baseline scores) (t test, hierarchical linear modeling, Bayes estimation)
									School Crime $R^2 = .32$, $p < .05$ $r = -.35$ educational commitment $r = -.23$ belief in school rules $r' = -.13$ sibling at school, 14 male School Misconduct $R^2 = .29$, $p < .05$ $r' = -.26$ ed commit, -.15 belief, -.26 attach $r' = .07$ family size, 18 male $r' = -.06$ 8th grader, 10 single-parent family School Nonattendance $R^2 = .29$, $p < .05$ $r' = -.36$ ed commit, -.12 belief, -.16 attachment $r = .08$ family size (See study for results with <i>Indirect predictors:</i> parental involvement in school, mothers education, grade, ethnicity, male, math ability, living w/step-parent) (path analysis)

Synthesis and Epilogue

This review of empirical studies was guided by two objectives: (1) to identify the significant risk factors associated with externalizing behavior problems; and, (2) to estimate the likelihood that each factor influences the occurrence of externalizing behavior problems. In pursuing these objectives, an evaluative framework developed by Kraemer et al. (1997) was used to categorize factors as correlates, predictive risk factors, or causal risk factors based on the scientific evidence to date. Three important lessons were learned quickly. First, research in this area has blossomed in the past decade, resulting in hundreds of empirical papers covering a wide range of possible factors. Second, while a number of significant causal risk factors have been identified (i.e., child hostile attributional processes; parental engagement, validation, and discipline; peer rejection and association with deviant peers), a number of factors have empirical support as predictive risk factors and many more have been identified as concurrent correlations. Third, many researchers have moved beyond a simple risk-factors perspective, driven by findings that pointed to a more complex and richly textured view of children and how they develop from infancy through early adulthood.

The preceding sections of this report have, with some exceptions, stayed close to the original objectives, focusing in turn on each of the many factors discussed in this literature. It is important, however, to expand on these objectives to take into account the complexity of externalizing behavior problems and to encourage the next generation of empirical studies. This expansion includes: (1) the importance of defining externalizing behavior in developmental terms; (2) the need to "put the

organism back together" in considering individual child characteristics as they relate to risk and protection; (3) the problem of "correlated environments" and their implications; and (4) the necessity of studying child characteristics and environmental factors in concert.

Defining Externalizing Behavior in Developmental Terms

The past decade has seen a movement from defining externalizing behavior problems as isolated acts or static traits to defining externalizing behaviors as an organized system of responses that emerges, grows, and changes over the course of development. These responses are multifaceted, including not just overt actions but also patterns of thinking and feeling (e.g., hostile attributions, irritability). To completely characterize externalizing behavior problems, researchers must describe not only the kinds of actions, thoughts, and emotions involved, but also how they are interrelated and how these interrelated patterns develop and change over the months and years from infancy through childhood, adolescence, and early adulthood. While a number of recent longitudinal studies have given some initial picture of these developmental "trajectories," "pathways," or "reorganizations," a great many questions remain unanswered. For instance, there are questions about continuity and discontinuity (Which young children remain aggressive throughout childhood, and which do not?) and questions about reorganization of behavior (Which aggressive children later become bullies, which

later become involved with drugs, and which become prosocial and lose their aggressiveness?). Given the richness of some of the existing longitudinal studies, some of the questions may be answerable through secondary data analysis.

This more dynamic view of externalizing behavior problems already has had important implications for studying risk factors. Etiology becomes more complicated. A factor that *leads to* early aggressive behavior may not have as great an effect on later conduct problems. A factor that *maintains* conduct problems may have had little to do with the initial onset. A factor that leads to *desistance* from delinquency may have had nothing to do with either bringing about or maintaining the behaviors in the first place. And a factor that puts one child at risk for externalizing behavior in one context may actually protect another child from developing that same behavior in another context.

Putting the Organism Back Together in Considering Individual Child Characteristics

A substantial number of studies have focused on the question, what is it about individual children that puts them at risk for engaging in externalizing behavior? Researchers have studied a range of individual characteristics that span multiple levels of analysis within the child, including neurotransmitters, neurohormones, physiology, cognitive processes, expression of emotion, and patterns of behavior. They have developed better and better ways to study these various components of child functioning and have greatly increased our understanding of such characteristics. While such work needs to continue, there is a growing need to develop complementary studies that will expand this focus in two directions.

First, most of the studies reviewed here examine these individual child factors only in relation to

single points in time in the development of externalizing behavior problems (e.g., difficult/irritable temperament in young childhood, hostile attributional processes in elementary school-aged children). A few studies have begun to place these factors in a developmental context, studying how such characteristics change with development and are involved in trajectories for externalizing behavior.

Second, most studies to date have restricted their focus to one child characteristic, studying how that characteristic is related to externalizing behavior but providing no information about relationships among different characteristics. Research that attends to more than one characteristic will be important for two reasons. When two or more characteristics are implicated as risk factors, understanding how these systems influence one another is essential in learning how to treat or prevent such behavior. For example, social information processing may shape emotion regulation, emotional regulation may shape social information processing, or the two may reciprocally influence one another or be controlled by a third unknown process. Understanding the nature of these links will help people ascertain whether interventions that target social information processing will be effective independent of any attention to emotion regulation, or whether both need targeting. The latter strategy may be essential if these two systems influence one another.

In addition, cross-characteristic studies can help identify risk factors that moderate other child factors and account for meaningful increases in risk. For example, neural processes related to ADHD may constrain social information processing, which, in turn, increases the child's risk for externalizing behavior problems. Not only might social information processing interventions be the best way of approaching such cases, but such interventions may require tailoring when used with children with ADHD.

Studying Correlated Environments

This review found that a wide range of environmental factors from a variety of social contexts are likely to influence the developmental course of externalizing behavior problems. Single variables by themselves do a poor job of describing the environments that influence developmental pathways. In addition, the variables we use to describe these environments often co-occur with one another, both within and between social contexts. Recent literature uses terms such as "correlated constraints," "correlated environments," or "bundled risk factors" to describe such co-occurrence. These findings have important implications for research and effective intervention.

- Simple risk factor studies have played an important but more preliminary role in the field. They provided initial evidence about where attention needed to be focused. Now, research on environmental risk factors needs to move to describing environments in more complex ways. Indeed, this review organized environmental factors into three primary areas—family, peer, and the broader social environment. Many correlations and predictive risk factors were identified in each area, as well as several noted causal risk factors. Research now must build on this foundation by examining how factors within and across these areas converge to increase or decrease risk for conduct problems at various phases of development.
- Interventions that focus on single environmental risk factors are very likely to be compromised by hidden constraints, threshold problems, and even boomerang effects. *Hidden constraints* are linked risk factors that are overlooked. For example, parent training programs may fail to change important parenting behaviors

because they fail to appreciate the constraints on parenting imposed by parental depression, interparental conflict, work, or economic conditions. *Threshold problems* occur when interventions fail to target a broad enough array of important factors. For example, programs that target only reductions in conduct problems may not reach a threshold for effectiveness if they do not also include training in how to carry out prosocial alternatives. *Boomerang effects* occur when interventions to reduce one risk factor actually enhance other risk factors. For example, interventions that bring children with conduct problems together in groups to work on social skills may inadvertently enhance the formation of self-reinforcing deviant peer groups.

Recent studies have made some headway, suggesting important directions for studying correlated environments and their effects.

- Studies involving *more comprehensive assessments* of the child's developmental context find important continuities across aspects of the environment. For example, various dimensions of parenting behavior tend to co-occur (validation, monitoring, engagement, discipline) (Barnes, Farrell, & Banerjee, 1994; Farrington & Hawkins, 1991; Haapasalo & Tremblay, 1994; Patterson, Chamberlain, & Reid, 1982; Sampson & Laub, 1994; Scaramella, Conger, & Simons, 1999; Simons, Johnson, Conger, & Elder, 1998; Wasserman, Miller, Pinner, & Jaramillo, 1996).
- Studies that include *measurement of more than one social context* also find cross-context links (Borduin et al., 1995). For example, parenting patterns are related to peer relationships (Aseltine, 1995; Dishion, Duncan, Eddy, Fagot, & Fetrov, 1994; Schwartz, Dodge, Pettit, & Bates, 1997), and communities may reinforce local friendship networks that enhance the operation of these effects (Brody et al., 2001; Sampson, Raudenbush, & Earls, 1997).

- Studies that include *assessment of broader social factors*, such as regional economic conditions or density of local friendship networks, find that these factors can place constraints on peer and family contexts in ways that are related to externalizing behavior problems. In some cases, these constraints can even eliminate the association between such context factors and externalizing. For example, there is evidence for cultural variation in the effects of parenting on externalizing, such that some parenting variables are related to externalizing in Caucasian families but not in African-American families (Deater-Deckard, Dodge, Bates, & Pettit, 1996)

Studying Child Characteristics and Environmental Factors in Concert

While the study of child factors and environmental risk factors has proliferated, evidence is emerging to suggest that these two domains must be studied together. Three sets of findings demonstrate this, suggesting important directions for future work.

- *Child behavior both shapes the child's environment and is a response to that environment.* A number of recent studies suggest that trajectories of child development are shaped by patterns of reciprocal influence between the child and the child's social context. Negative emotionality in the infant and young child increases the likelihood of parental hostility and rejection, which in turn increases negative emotionality (Shaw et al., 1998). Conduct problems in middle childhood reduce effective parenting (discipline, monitoring, validation), which reinforces antisocial behavior (Simons et al., 1998). Reduced parental monitoring and warmth in late childhood increases the risk of delinquency, and increased delinquency reduces monitoring and warmth (Jang & Smith, 1997). Recent studies of evocative gene-environment correlations further support the thesis that a range

of child characteristics both shape and are shaped by social context (Ge et al., 1996; O'Connor, Deater-Deckard, Fulker, Rutter, & Plomin, 1998).

- Social contexts can have different effects on the developmental trajectories of different children, depending on what the children bring to the context. Several studies now suggest that specific environmental factors may be risk factors for some children, have no effect on others, and be protective factors for still others. For example, high levels of parental control appear to increase risk for children with one temperament but protect children with a different temperament (Bates, Pettit, Dodge, & Ridge, 1998). Again, these patterns also appear in behavioral genetics studies, indicating that heritable child characteristics and particular environmental factors interact in influencing the developmental trajectories of externalizing behavior problems (Cadoret, Yates, Troughton, Woodworth, & Stewart, 1995).

- These two patterns, *reciprocal effects* and *child-environment interaction effects*, must also be considered in a developmental context. There is evidence that the reciprocal effects between child conduct problems and lax parental monitoring are strongest before age 15 and that in later adolescence it is delinquency that leads to lax monitoring (Jang & Smith, 1997). Similar fading of reciprocal effects may occur for conduct problems and poor parental disciplinary practices, with the latter much more likely to drive the former in late adolescence (Cohen & Brook, 1995). This change may also be concomitant with increasingly reciprocal effects among antisocial adolescent peers.

Implications for Future Research

The four issues discussed above reflect the progress of a scientific field as it grapples with the complexities of human development. Investigators

concerned with externalizing behavior problems are moving beyond simple risk factor studies into the study of *risk and protective mechanisms* that not only explain variance in predicting outcomes, but also suggest malleable processes that can be tested for causality and become targets for intervention. These risk mechanisms are developmental and appear to involve more complex interactions between organism and environment, which themselves change in potency over the course of development.

Acknowledging and truly taking into account this complexity will be the task of the next generation of risk research in externalizing behavior problems. Indeed, several recent studies have moved in this direction by studying how selected child factors interact with specific environmental factors at critical points in development and examining how patterns among these factors affect the development of externalizing behavior problems (Conger et al., 1992; Deater-Deckard, Dodge, Bates, & Pettit, 1998; Henry, Caspi, Moffitt, & Silva, 1996; Pettit, Bates, Dodge, & Meece, 1999; Shaw, Owens, Vondra, Keenan, & Winslow, 1996). These initial studies are taking on the challenge of reducing the now-overwhelming four-plus-dimensional matrix (resulting from the intersection of child, family, peer, broader social environment, and development) to workable sets of multiple factors that hold significant power for predicting risk and revealing stronger groupings of causal risk factors for externalizing behavior problems.

What can be used to guide this complex and challenging work? The research reviewed here suggests four strategies for advancing research on risk factors and interventions for externalizing behavior problems.

- Several important factors have been identified as causal risk factors, including child hostile attributional processes; parental engagement, validation, and discipline; and peer rejection and

association with deviant peers. It is critical that these findings be disseminated to the public and that effectiveness research be conducted with the intervention strategies known to affect these factors to ensure appropriate implementation by communities, schools, and mental health service systems.

- The framework provided by Kraemer et al. (1997) suggested that research on risk factors relevant to developing interventions can follow a developmental course of its own. Once factors are found to be correlated with outcomes, further research should document the potential for prediction and, ultimately, the potential for causation. The current review identified a number of predictive risk factors and concurrent correlations with externalizing behavior problems. It is critical that this research be advanced (i.e., that concurrent correlations be tested for predictive risk and effect size, and that potent predictive risk factors be tested for potential causality). This type of research will provide the foundation for developing more effective interventions.
- Studying multiple factors simultaneously is critical for furthering intervention and risk factor research. Simple risk factor studies have played an important role, but the field must advance to describing, measuring, analyzing, and experimentally intervening with child factors and environments in more complex ways.
- A developmental perspective will need to be incorporated into all research. Externalizing behavior problems have a developmental course, and it is likely that the risk factors and mechanisms that lead to this development also change over time. In particular, it is important to know if there are particular points in development when specific risk factors converge to substantially increase vulnerability or when there are windows of opportunity for intervention.
