GREAT LAKES STATES MONTHLY PRECIPITATION DATA - BEGINNING OF RECORD TO 1990¹

Raymond A. Assel, Cynthia E. Sellinger, Don E. Meyer, and Raymond N. Kelly

ABSTRACT. Monthly precipitation data for 2,0 15 stations from beginning of record to 1947 for the eight Great Lakes states were digitized using an electronic scanner and optical character recognition software. These data were combined with digital monthly station precipitation data from 1948 to 1990 that was obtained from the National Climate Data Center (NCDC) in Asheville, North Carolina. The total number of stations in the combined data set is 3,447. Station latitude, longitude, elevation, and station name and changes in these metadata was also digitized. A complete list of stations is given as an appendix to the report. Data reduction, verification, quality control, and analysis methods are summarized. The spatial and temporal distribution patterns of the number of stations is presented. The digital data has been archived and is available from NCDC in Asheville.

1. INTRODUCTION

Much of the historical National Weather Service (NWS) precipitation data for the eight Great Lakes states prior to 1948 are available only in paper copy or microfiche, making them virtually unusable for most computer applications. The Great Lakes Environmental Research Laboratory (GLERL) developed a project, under the Environmental Research Laboratories Endangered Data and Increased Access Program and funded under the National Environmental Satellite and Data Information Service's Earth System Data and Information Management Program, to make these data accessible for use in our own ongoing climate and lake hydrology related research programs, for use by other researchers, and for use by the public at large. Monthly precipitation data from 2,0 15 stations in Minnesota, Wisconsin, Illinois, Indiana, Michigan, Ohio, Pennsylvania, and New York were digitized from beginning of record to 1947. These data were quality controlled for data reduction errors and original data input errors (such as typographical errors but not for observer errors) and then combined with existing National Climatic Data Center (NCDC) digital monthly precipitation data from 1948 to 1990 for the states listed above. The total number of stations when including the 1948- 1990 period is 3,447. The station number and name, latitude, longitude, and elevation changes for each station were abstracted and digitized from NCDC state Summary of Station History forms (US Department of Commerce, 1956). The NCDC and state climatologists from several of the Great Lakes states provided important supplementary data and information that were helpful in the analysis of station changes and comparison data. Station history data reduction was completed under contract by NCDC as a GLERL-funded project.

This report documents sources of the monthly precipitation data and describes procedures, equipment, and software used to abstract, reduce, and quality control these data. Discontinuities in the time series of each station's monthly precipitation data are identified using a non-parametric test. The spatial and temporal distribution patterns of the precipitation stations are illustrated and discussed. A complete

¹GLERL Contribution No. 926

tabular summary of the monthly precipitation data at the 3,447 stations digitized for this study is not included with this report, but a listing of these stations is included along with their location (latitude, longitude, elevation) and period of record as Appendix A. A complete set of computer files of the precipitation data and station history data was provided to NCDC for archiving.

2. METHODS

2.1 Equipment and Procedures

Digitization of published precipitation data was accomplished using an HP Scanjet II scanner that produced electronic image files. The computer image files were processed using Calera's Optical Character Recognition (OCR) software that captured the character images and wrote them to a DOS ASCII file. That ASCII file was then edited using programs written in FORTRAN code to correct OCR interpretation errors and suspected errors in the original unscanned data, Figure 1a.

2.2 Data

Sources of historical precipitation data digitized for this project include the following: monthly records from the beginning of record to 1930 published in the Climatic Summary of the United States (USDA, 1933), and monthly records from 1931 to 1952, published in the supplement to this volume (USDC, 1955-1964). Questionable data in the above noted publications were checked using USDA (1896-1913) and USDA (1914-1940). Hydrologic Bulletin (USDA, 1941-1948) data were included in Climatological Data (USDC, 1940-1948), starting August 1948, and for the 1948-1951 period were also digitized as part of this project. However, after September 1951 the Hydrologic Bulletin stations were discontinued from the USDC publication Climatological Data and were subsequently published elsewhere (Hourly Precipitation Data, USDC, 1951-present). These data are available from the above listed publication but were not digitized as part of this project.

Daily digitized data from 1948 to 1990 were obtained from NCDC (primarily from Tape Deck-3200 summary of the day data). Some stations on TD-3200 had pre-1948 daily data that was already digitized. If a station's data inventory showed it to be one of these stations, then the previously digitized data were used and the published data were used to fill in any data holes. These stations were the exception and not the rule. In-house software was developed to quality control, calculate the monthly mean, reformat, and combine these data with the pre- 1948 digital data to form one continuous record for stations that started prior to 1948 and continued after that year, Figure 1 b.

2.3 Statistical Quality Control

The data were quality controlled for both scanning errors and for outliers. These procedures were necessary to alleviate any errors created from using an electronic scanner; errors resulting from unreadable text, old discolored paper, document misregistration on the scanner, and dust on the scanner screen. In-house software was developed to read scanned characters and to replace misread characters such as the letter '1' with the number '1'. This interactive software permitted the operator to determine if a questionable character should be replaced. Another interactive part of this software controlled outliers by totaling

Figure 1a.

Flow chart for scanning data.

Figure 1b. Flow chart for processing scanned data.

up the months of data for that year and comparing it to that year's total, which had also been scanned and listed in the file. If the totals did not match, the program searched for a value one-fifth larger or smaller than the total. Once found, this value was presented to the operator for a decision. The one-fifth criteria was selected because it contained a range of values that were **significantly** larger or smaller than a typical monthly value for that year. After these scanned data were quality controlled for inconsistencies with the published data, they were combined with the already digitized data (1948-1 990), and this entire data set was checked in the following manner. The mean and standard deviation for each month for the entire period of record was calculated, then monthly values were compared to this mean to see if they fell within +/- 2 standard deviations (SD) of the mean. Monthly values that were not within 2 SD of the long-term monthly mean were checked with other published data to verify their value. Also, any monthly values greater than 10 inches were scrutinized to verify the values. Ten inches was selected as the threshold value for two reasons. First, an analysis of the sum of the monthly mean plus 3 SD for a number of selected stations in each state in the region has demonstrated that 10 inches precipitation criteria for any given month is generally a good measure of the extreme value for the region as a whole. Second, depending on the condition of the original text, a decimal point '.' can be misinterpreted by the OCR software as a 'O', thus 1.94 may be processed as 1094.

2.4 Examples of Data Inhomogeneities

Examples of several types of inhomogeneities existing in these data are identified by a subjective evaluation of plots of precipitation time series and verified by **metadata** information. Figure 2, gage # 203940 from Howard City, Michigan is an example of instrumentation and human error. Analysis of this time series plot revealed there were three different precipitation regimes. These regimes can be explained by documentation listed in the Substation History Record (Weather Bureau, 1956). These explanations were (1) from 1915 to 1922 it was reported that the rain gage was located too close to growing trees resulting in inaccurate catchment, (2) beginning in 1922 the gage was moved 25 feet south of the first location; this shows up clearly in Figure 2 as a positive sloping mean for the period 1922- 1927 and, (3) in 1931 the station was moved away from the trees to a more secluded spot away from visitors to the farm on which it was located; the station history states, "the visitors molested the rain gage." This move is also apparent by a positive sloping mean from 1931 to 1936.

Another example of inhomogeneities that exist in these data (Figure 3), Station # 20 1704 Coloma 3 NNW, Michigan, shows inhomogeneity due to human error. According to the substation history record: (1) from 1925 to 1938 this station was maintained by the Soil Conservation Service as part of a Benton Harbor project; (2) from 1938 to 1948 the station was closed due to "inefficiency of the observer."

A final example of the lack of homogeneity is given by Tomah Ranger Station [Wisconsin] (Figure 4) which is typical of the problems that can result with an instrumental change. This discontinuity is due to a change from a Recording Rain Gage to a Standard Rain Gage. In 1951 several stations switched their instruments from Recording Rain Gages to Standard Rain Gages. The difference between the two is that a Recording Rain Gage typically has an undercatchment; it records less precipitation than a Standard Rain Gage. This is evident by the higher mean precipitation after 1951 (Figure 4).

Although these stations and others like them show shifts in the means due to human or instrument error, there were other stations with mean shifts that had no accompanying explanation in their station history records; these would be likely candidates for climate variation evaluation.

3.0 RESULTS

3.1 Computer File Documentation

A separate computer file was created for each of the 3,447 stations containing tabular summaries of monthly precipitation data. The name of a station's data file is based on that station's number. All file names follow the format of **P<state #><station #>.DAT**. For example, (Table 1) West Salem is station number 9119 in Wisconsin, state number 47, thus giving the file name **P479119.DAT**. Stations with a state number of 99 are ones that have not had an NCDC number assigned. NCDC will assign numbers to these stations at a later date. The first three lines of each data file contain the header information. The first line tells the type of data (precipitation). The second line gives the NCDC station number, latitude, longitude, station name, and elevation in feet above sea level. The third line shows the period covered. The fourth line is blank. Following the header are data for each year covered. The format for these data is the year followed by the data for each month (January through December). The FORTRAN format is **(1X,I4,2X,12F6.2)**. Following the data is a blank line followed by a footer. The footer contains notes regarding the data. The first two lines of the footer give the data codes for trace amounts and missing values. Some files may also have information regarding combined data from nearby locations or station name changes.

3.2 Precipitation Stations' Spatial and Temporal Distribution Trends

The temporal distribution of the number of stations in the data set for each year is given as Figure 5. In Figure 5, a station is counted as active for a given year if it has at least one month with data in that year. The number and distribution of precipitation stations for the entire period of record shows adequate coverage to define spatial patterns over the entire region beginning near or after 1900. Before 1900 the spatial distribution of stations may be suitable for smaller sub-regional studies, but the spatial coverage is not sufficient for a regional analysis. Based on changes in slope and increases and decreases in the total number of stations in Figure 5, the temporal distribution of the annual number of active stations was divided into five periods.

3.2.1 Period 1: 18174882

From 1817 through 1882 (Figure 6) there was a gradual, nearly steady increase in the number of precipitation stations in the data set. During this period there were a total of 283 stations that recorded data for some months or years. The stations are not evenly distributed throughout the Great Lakes states. Most of the southern portion of the region had a relatively even spatial station distribution; the northern region, Minnesota, Wisconsin, and Northern Michigan, had very few stations. The monthly precipitation data could be used for describing the precipitation patterns for some sub-regions, such as southeastern Pennsylvania or the Hudson River Valley. It is not advisable to use these data for detailed spatial analysis over the entire region; there are too few stations.

Figure 5. Stations with one or more months of data per year.

Figure 6. Distribution of stations for period 1: 1817-1882.

Figure 7. Distribution of stations for period 2: 1883-1897.

3.2.2 Period 2: 1883-1897

The number of stations increased greatly during this period, from 283 in the previous period to 822, (Figure 5) and were much more evenly distributed than during the previous period (Figure 7). Northern Minnesota, north-central Wisconsin, the central portion of the Upper Peninsula of Michigan, and the Adirondack Mountains of New York still had little to no data representation.

3.2.3 Period 3: 1898-1938

During the next 41 years the number of stations in the data set per year was fairly steady (Figure 8). Throughout this time, there was a total of 1,510 stations open at some point. However, the maximum number of stations taking data in any one year was 940, indicating frequent station opening and closing.

3.2.4 Period 4: 1939-1961

The spatial distribution of stations during this period is similar to that of the previous period, in that there are no large unrepresented areas (Figure 9). The temporal distribution of the number of stations

Figure 8. Distribution of stations for period 3: 1898-4938.

Figure 9. Distribution of stations for period 4: 1939-1 961.

during these years can be seen as three distinct sub-periods (Figure 5). The first sub-period (1939- 1948) continues the trend of a moderate increase in the number of stations in the data set. The second sub-period (1948-1951) shows a spike in the number of stations digitized. A leveling off in the number of stations occurred in the third sub-period (1951- 1961). The spike in the second sub-period results from the Hydrologic Bulletin (USDA, 1941 - 1948) data being included in Climatological Data (USDC, 1940-1948), starting August 1948 to September 1951. During the years 1941-48 the stations in the Hydrologic Bulletin were not part of the climatological network, and were published as hourly data. From 1951 to the present these stations were published in the Hourly Precipitation Data, also not part of the climatological network. Therefore, we only included these stations during the second subperiod (1948-51), when they were published in the Climatological Data as part of the climatological network.

3.2.5 Period 5: 1962-1990

During the last three decades there was a nearly steady decline in the number of stations operating each year. The number of open stations ranged from 1,324 in 1989 to 1,565 in 1963, with a total of 1,971 stations taking observations at some point. The spatial distribution of stations during this period (Figure 10) has no large blank areas.

Figure 10. Distribution of stations for period 5: 1962-1990.

4. DISCUSSION

4.1 Caveats on Data Usage

These data have not been corrected for instrumental change, observer error, or changes in instrument location or exposure. A recent study (Legates and DeLiberty, 1993) indicates that the annual bias in precipitation gage measurements expressed as a percentage of the bias-adjusted precipitation is on the order of 8-12% for the Great Lakes states. While Groisman et al. (1991) point out that corrections to precipitation data often require detailed metadata including local wind, surrounding elevation, and surrounding vegetation in the vicinity of the rain gage. Thus, care must be taken in using the monthly precipitation in their present form.

4.2 Future Work

We plan to make a statistical analysis of station homogeneity and to examine the spatial and temporal distribution pattern of monthly and annual precipitation. The objective of this analysis will be to identify regional and seasonal trends and changes in long-term means over the period of record, similar to the work described in Quinn (1981) but updated to include the long period of record and expanded to include finer resolution with respect to spatial scale.

5. ACKNOWLEDGEMENTS

This GLERL data rescue project is part of the Environmental Research Laboratories' Endangered Data and Increased Access Program, and the work was funded by NOAA's National Environmental Satellite and Data Information Service's Earth System Data and Information Management Program. The cooperation of the state climatologists of the eight Great Lakes states and of Pam Hughs of NCDC in providing information and data on various aspects of this task is appreciated. This work was completed while Don Meyer was with the Cooperative Institute of Limnological and Ecosystems Research (CILER) at NOAA/GLERL in Ann Arbor.
