The proposed rule does not specify particular timing requirements for your information collection proposal, but does require review and approval of the proposal by the Director. In general, EPA expects that it would be submitted well in advance of the other permit application materials, so that if the Director determined that additional information was needed to support the application, the facility would have time to collect this information, including additional monitoring as appropriate.

DOMINION COMMENTS: The permittee, as part of its permit application package, should be allowed to propose a schedule for developing the data collection plan, to get the plan approved by the state's permitting authority, to collect and analyze the data, to use the data to assess technologies, and to prepare the BTA recommendation. After being reviewed and approved by the state's permitting agency, this process would be written as a permit condition.

Once the data are collected and the BTA selection has been made, the permit would be modified. The §316(b) rule should make it clear that reasonable time for state agency review must be built into any schedule either prescribed by the rule itself or required by an NPDES permit condition.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion. In the case of a permit that is reissued prior to the submission of the required studies, the rule leaves to the Director's discretion whether to modify the permit to include section 316(b) requirements based on those studies or to wait for permit reissuance. EPA notes, however, that the initial permit must include section 316(b) requirements determined on a BPJ basis.

Permit applications/implementation schedule

Reasonable compliance schedules are necessary.

Regulatory Reference: Preamble VII. Implementation

C. How Would the Director Determine the Appropriate Cooling Water Intake Structure Requirements? (p. 17178)

If the Director determines that the Comprehensive Demonstration Study submitted does not demonstrate that the technologies, operational measures, and supplemental restoration measures employed would achieve compliance with the applicable performance standards, the Director may issue a permit requiring such compliance. If such studies are approved and a permit is issued but the Director later determines, based on the results of subsequent monitoring, that the technologies, operational measures, and supplemental restoration measures did not meet the rule standards, the Director could require the existing facility to implement additional technologies and operational measures as necessary to meet the rule requirements. In general, this would occur at the next renewal of the permit. The Director would also review the facility's Technology Verification Plan for post-operational monitoring to demonstrate that the technologies are performing as predicted.

DOMINION COMMENTS: If EPA were to make the new § 316(b) rule immediately applicable, it would lead to even more delay in the NPDES permitting process than currently exists. The available consultants skilled in biological monitoring and intake technology design undoubtedly would be overwhelmed with work and would have to put many licensees on waiting lists. Negotiations over consent orders might bog down the permit process in some States, and the backlog of unprocessed NPDES permit applications would grow worse. Reasonable compliance schedules are a matter of administrative necessity as well as of fairness to state regulators and permittees.

The permittee, as part of its permit application package, should be allowed to propose a schedule for developing the data collection plan, to get the plan approved by the state's permitting authority, to collect and analyze the data, to use the data to assess technologies, and to prepare the BTA recommendation. After being reviewed and approved by the state's permitting agency, this process would be written as a permit condition.

Subject Matter Code 21.09
Permit applications/implementation schedule

Permits should have technology “upset” and “bypass” provisions.

Regulatory Reference: Preamble VII. Implementation

E. How Would Compliance Be Determined? (p. 17180)

This proposed rule would be implemented by the Director placing conditions consistent with this proposed rule in NPDES permits. To demonstrate compliance, the proposed rule would require that the following information be submitted to the Director:

Data submitted with the NPDES permit application to show that the facility is in compliance with location, design, construction, and capacity requirements;

Compliance monitoring data and records as prescribed by the Director. Proposed § 125.97 would require existing facilities to keep records and report compliance monitoring data in a yearly status report. In addition, Directors may perform their own compliance inspections as deemed appropriate (see CFR 122.41).

DOMINION COMMENTS: The permit should have a provision analogous to EPA’s “upset” and “bypass” provisions in the NPDES permit regulations to allow an intake technology to be temporarily bypassed if necessary for plant operation. For example, if the screens are fouled so as to jeopardize plant operation, the permittee should be allowed to bypass them until they can be cleared. Similarly, if because of emergency conditions water levels in a reservoir are reduced to the point where technologies are inoperative, bypassing to allow continued operation should be allowed. Such exceptional bypasses should be allowed only for short periods of time, until the emergency has passed and the permittee has had time to restore the intake technology to proper operation. As for any exceptional event, the permittee would be required to report the circumstances of the upset or bypass to the state permitting authority in a timely manner.

Permit applications/implementation schedule

Permits should be “grandfathered” if they are due to expire very near the application deadline.

Regulatory Reference: Preamble VII. Implementation

A. When Does the Proposed Rule Become Effective? (p. 17173)

Phase II existing facilities subject to today’s proposed rule would need to comply with the Subpart I requirements when an NPDES permit containing requirements consistent with Subpart J is issued to the facility. See proposed § 125.92. Under existing NPDES program regulations, this would occur when an existing NPDES permit is reissued or, when an existing permit is modified or revoked and reissued.

DOMINION COMMENTS: For a facility whose permit renewal application is undergoing agency review when the § 316(b) rule becomes effective, the permittee should not have to resubmit its application. In such a case, the subsequent permit renewal process should trigger the permittee’s compliance with the new rule requirements.

Similarly, if the new rule becomes effective when a permittee is very near the time when its renewal application is due (for example, between 365 and 180 days before the permit expires), it would be almost as unreasonable to require the permittee to adjust its application process in midstream. The practical difficulties in preparing a permit application, especially if biological monitoring is needed, suggest that the new rule should not apply until the succeeding permit term, to any permittee that has one year or less until its permit expires when the rule takes effect

EPA Response

EPA has clarified timing requirements for the submittal of the required studies and permit compliance issues in today's final rule. See response to comment 316bEFR.034.066 for a discussion. See also response to comments 316bEFR.021.006 and 316bEFR.035.019.

RFC: Proposed use of restoration measures

Restoration measures could be employed in lieu of, or in combination with other measures.

Regulatory Reference: Subpart J—Requirements Applicable to Cooling Water Intake Structures for "Phase II Existing Facilities" Under Section 316(b) of the Act

§ 125.94 How will requirements reflecting best technology available for minimizing adverse environmental impact be established for my Phase II existing facility?

(d) Restoration Measures. (p. 17221-17222) In lieu of, or in combination with, reducing impingement mortality and entrainment by implementing design and construction technologies or operational measures to comply with the performance standards specified in paragraph (b) of this section or the Director's determination pursuant to paragraph (c) of this section, you may, with the Director's approval, employ restoration measures that will result in increases in fish and shellfish in the watershed. You must demonstrate to the Director that you are maintaining the fish and shellfish within the waterbody, including community structure and function, to a level comparable to those that would result if you were to employ design and construction technologies or operational measures to meet that portion of the requirements of paragraphs (b) or (c) of this section that you are meeting through restoration. Your demonstration must address species that the Director, in consultation with Federal, State, and Tribal fish and wildlife management agencies with responsibility for fisheries and wildlife potentially affected by your cooling water intake structure, identifies as species of concern.

DOMINION COMMENTS: Dominion supports allowing permittees, on a voluntary basis, to employ restoration measures in lieu of, or in combination with other technologies or operational measures that will result in increases in fish and shellfish species of concern in the watershed. We support the idea of providing improvements to populations using proven technologies and/or strategies, if they are warranted.

EPA Response

For a discussion of the extent to which restoration measures are voluntary, see EPA's response to comment 316bEFR060.022.

Under the final rule, restoration measures may be used in lieu of or as a supplement to design and construction technologies and/or operational measures.

RFC: Appropriate spatial scale for restoration

Regulatory Reference: Preamble VI. Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities

A. What Is the Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities?

5. What Is the Role of Restoration Under Today's Preferred Option? (p. 17146) EPA also seeks comment on the most appropriate spatial scale under which restoration efforts should be allowed "should restoration measures be limited to the waterbody at which a facility's intakes are sited, or should they be implemented on a broader scale, such as at the watershed or State boundary level.

DOMINION COMMENTS: Dominion supports expanded state-wide and even interstate watershed spatial boundaries for restoration projects. This approach appropriately provides the flexibility to locate a restoration project in an area that may provide greater overall environmental benefit and/or enhance an ecosystem that may benefit more than the area in the near proximity of a facility's intakes.

EPA Response

For a discussion of the appropriate scale on which to conduct restoration measures, see EPA's response to comment 316bEFR.212.001.

RFC: Restoration above BTA level

Regulatory Reference: Preamble VI. Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities

A. What Is the Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities?

5. What Is the Role of Restoration Under Today's Preferred Option? (p. 17147)

EPA recognizes that substantial information exists regarding wetlands mitigation and restoration. For example, tools and procedures exist to assess wetlands in the context of section 404 of the Clean Water Act. However, restoration of other aquatic systems such as estuaries is complex and continues to evolve. EPA seeks comment on how it may measure the success or failure of restoration activities given the high degree of uncertainty associated with many areas of this developing science and that many of these activities do not produce measurable results for many months or years after they are implemented. For these reasons, EPA requests comment on whether to require that a facility using restoration measures restore more fish and shellfish than the number subjected to impingement mortality or entrainment. EPA believes that restoring or mitigating above the level that reflects best technology available for minimizing adverse environmental impact (e.g., restocking higher numbers of fish than those impinged or entrained by facility intakes or restoring aquatic system acreages at ratios greater than one-to-one) would help build a margin of safety, particularly when the uncertainties associated with a particular restoration activity are known to be high.

The concept of compensatory mitigation ratios being greater than one-to-one is found in other programs. For example, under the CWA section 404 program no set mitigation ratio exists, however, current policies require no net loss of aquatic resources on a programmatic basis. The permitting authority often requires permit applicants to provide more than one-to-one mitigation on an acreage basis to address the time lapse between when the permitted destruction of wetlands takes place and when the newly restored or created wetlands are in place and ecologically functioning. The permit may also require more than one-to-one replacement to reflect the fact that mitigation is often only partially successful. Alternatively, in circumstances where there is a high confidence that the mitigation will be ecologically successful, the restoration/ creation has already been completed prior to permitted impacts, or when the replacement wetlands will be of greater ecological value than those they are replacing, the permitting authority may require less than one-to-one replacement

DOMINION COMMENTS: Dominion does not support a requirement to restore populations above the level of BTA. However, a facility should receive credit if the restoration effort achieves this status during the verification monitoring period and should become eligible to negotiate for reduced monitoring.

EPA Response

For a discussion of the roles and responsibilities of the permitting authority in determining the appropriate level of performance to satisfy the requirements of the final rule, see EPA's responses to comments 316bEFR.060.026 and 316bEFR.212.001.

Any restoration measure must meet all the requirements described in the final rule.

Role of States and Tribes (alt./equiv. programs)

Approval authority should remain with the state permitting agencies.

Regulatory Reference: Preamble VI. Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities

A. What Is the Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities?

11. State or Tribal Alternative Requirements That Achieve Comparable Environmental Performance to the Regulatory Standards Within a Watershed (p.17151-17152)

In § 125.90, today's proposal includes an alternative where an authorized State or Tribe may choose to demonstrate to the Administrator that it has adopted alternative regulatory requirements that will result in environmental performance within a watershed that is comparable to the reductions in impingement mortality and entrainment that would otherwise be achieved under § 125.94. If a State or Tribe can successfully make this demonstration, the Administrator is to approve the State or Tribe's alternative regulatory requirements. EPA is proposing that such alternative requirements achieve comparable performance at the watershed level, rather than at larger geographic scales or at the individual facility-level, to allow States and Tribes greater flexibility and, potentially, greater efficiency in efforts to prevent or compensate for impingement mortality and entrainment losses, while still coordinating those efforts within defined ecological boundaries where the increased impacts are directly offset by controls or restoration efforts. Requiring performance level assessment to take place at the watershed level ensures that facility mitigation efforts take the overall health of the waterbody in the target watershed into account. The Agency requests comment on all aspects of this approach, including the appropriate definition of watershed.

EPA also recognizes that States sometimes assign higher priority to protecting some waters over others. This may be due to the exceptional environmental, historic, or cultural value of some waters, or conversely to a concern with multiple stresses already occurring in a watershed. It could also be based on the presence of individual species of particular commercial, recreational, or ecological importance. For these reasons, States with alternative requirements might choose to provide more protection that would be achieved under § 125.94 in some watersheds and less protection in others. Under current language in proposed § 125.90, States could not use such an approach because they would not be able to demonstrate comparable environmental performance within each watershed. EPA requests comment on whether it should instead allow States to demonstrate comparable environmental performance at the State level, thus allowing States the flexibility to focus protection on priority watersheds. The standard provided in proposed §125.90 for evaluating alternate State requirements is "environmental performance that is comparable to the reductions that would otherwise be achieved under § 125.94." EPA recognizes that it may not always be possible to determine precisely the reductions in impingement and entrainment associated with either § 125.94 or the alternate State requirements, particularly at the watershed level or State-wide. Furthermore, alternate State requirements may provide additional environmental benefits, beyond impingement and entrainment reductions that the State may wish to factor into its comparability demonstration. However, in making this demonstration, the State should make a reasonable effort to estimate impingement and entrainment reductions that would occur under § 125.94 and under its alternate requirements, and should clearly identify any other environmental benefits it is taking into account and explain how their comparability to impingement and entrainment reduction under §125.94 is being evaluated. EPA invites comment on the most appropriate scale at which to define a watershed to reflect the variability of the nature of the ecosystems impacted by cooling water intake structures within a State or Tribal area and on methods for ensuring ecological comparability within watershed-level assessments. EPA also invites comment on whether defined watershed boundaries for the purpose of section 316(b) programs should lie entirely within the political boundaries of a Tribe or State unless adjoining States and/or Tribes jointly propose to establish alternative regulatory requirements for shared watersheds.

DOMINION COMMENTS: Dominion supports giving state agencies the flexibility to focus their protection effort on priority watersheds. States also should be allowed to demonstrate overall comparable environmental performance at the State level instead of at the watershed level. Streamlined decision-making is inextricably linked with preserving state authority. Where a state has already made a careful determination of the best technology available for a particular intake, a change in the state's decision is warranted only if there has been a significant change in circumstance since the determination was made.

EPA Response

See response to 316bEFR.023.001 for a discussion on State program approval and response to 316bEFR.040.001 for details on the use of historical BTA determinations.

Performance standards

EPA should clarify the definition of calculation baseline.

Regulatory Reference: Subpart J—Requirements Applicable to Cooling Water Intake Structures for "Phase II Existing Facilities" Under Section 316(b) of the Act

§ 125.93 What special definitions apply to this subpart? (p. 17220)

Calculation baseline means an estimate of impingement mortality and entrainment that would occur at your site assuming you had a shoreline cooling water intake structure with an intake capacity commensurate with a once-through cooling water system and with no impingement and/or entrainment reduction controls.

DOMINION COMMENTS: EPA should clarify the definition of "calculation baseline" by assuming that the baseline plant is equipped with standard 3/8-inch mesh screens and the hypothetical baseline intake has the similar cooling water requirements as the actual facility.

EPA Response

In response to comments that the proposed definition for the calculation baseline was overly vague, EPA published in the NODA a series of additional specifications aimed at clarifying the definition of the calculation baseline. These specifications are as follows and are included in today's final rule at § 125.93.

1. Baseline cooling water intake structure is located at, and the screen face is parallel to, the shoreline. EPA believes it is appropriate to allow credit in reducing impingement mortality from screen configurations that employ angling of the screen face and currents to guide organisms away from the structure before they are impinged.

2. Baseline cooling water intake structure opening is located near the surface of the source waterbody. EPA believes it is appropriate to allow credit in reducing impingement mortality or entrainment due to placement of the opening in the water column.

3. Baseline cooling water intake structure has a traveling screen with the standard 3/8 inch mesh size commonly used to keep condensers free from debris. This allows a more consistent estimation of the organisms that are considered "entrainable" vs. "impingeable" by specifying a standard mesh size that can be related to the size of the organism that may potentially come in contact with the cooling water intake structure.

4. Baseline practices and procedures are those that the facility would maintain in the absence of any operational controls implemented in whole or in part for the purpose of reducing impingement mortality and entrainment. This recognizes and provides credit for any operational measures,

including flow or velocity reductions, a facility had adopted that reduce impingement mortality or entrainment.

Comment ID 316bEFR.085.019

Author Name Pamela F. Faggert
Organization Dominion Generation

Subject Matter Code 7.02
Performance standards

The methods of measuring the calculation baseline should be redefined.

Regulatory Reference: Preamble VII. Implementation

B. What Information Must I Submit to the Director When I Apply for My Reissued NPDES Permit?

4. Comprehensive Demonstration Study

(d) Design and Construction Technology Plan (p. 17176)

Reductions in impingement mortality and entrainment from this calculation baseline as a result of any design and construction technologies already implemented at your facility would be added to the reductions expected to be achieved by any additional design and construction technologies that would be implemented in order to determine compliance with the performance standards. Facilities that recirculate a portion of their flow may take into account the reduction in impingement mortality and entrainment associated with the reduction in flow when determining the net reduction associated with existing technology and operational measures. This estimate must include a site-specific evaluation of the suitability of the technology(ies) based on the species that are found at the site, and/or operational measures and may be determined based on representative studies (i.e., studies that have been conducted at cooling water intake structures located in the same waterbody type with similar biological characteristics) and/or site-specific technology prototype studies. If your facility already has some existing impingement mortality and entrainment controls, you would need to estimate the calculation baseline. This calculation baseline could be estimated by evaluating existing data from a facility nearby without impingement and/or entrainment control technology (if relevant) or by evaluating the abundance of organisms in the source waterbody in the vicinity of the intake structure that may be susceptible to impingement and/or entrainment.

DOMINION COMMENTS: The preamble to the proposed rule says that the calculation baseline could be estimated by evaluating existing data from a nearby facility. This method should be written into the rule itself with some clarification. The representative facility need not necessarily be “nearby” or even on the same waterbody. A permittee should be able to use fish or larval abundance data from power plant locations similar to its own to estimate how much impingement mortality and entrainment would occur with no reduction controls. Also, a permittee should be allowed to do upstream studies in an area near the intake to predict baseline impingement mortality and entrainment.

EPA Response

Please see response to comments 316bEFR.018 and 316bEFR.063.022.

In addition, the final rule authorizes use of data from your facility or another facility with comparable design, operational, and environmental conditions. This should address the commenter's concerns.

Subject Matter Code 18.02

RFC: Use of previous demonstration studies

Author Name Pamela F. Faggert
Organization Dominion Generation

§ 316(b) should be a one-time only requirement.

Regulatory Reference: Subpart J—Requirements Applicable to Cooling Water Intake Structures for "Phase II Existing Facilities" Under Section 316(b) of the Act

§ 125.98 As the Director, what must I do to 'comply with the requirements of this subpart?

(a) Permit Application. (p. 17224)

As the Director, you must review materials submitted by the applicant under 40 CFR 122.21(R) and § 125.95 before each permit renewal or reissuance.

(1) After receiving the permit application from the owner or operator of a Phase II existing facility, the Director must determine which of the standards specified in § 125.94 to apply to the facility. In addition, the Director must review materials to determine compliance with the applicable standards.

(2) At each permit renewal, the Director must review the application materials and monitoring data to determine whether requirements, or additional requirements, for design and construction technologies or operational measures should be included in the permit.

DOMINION COMMENTS: Once "best technology available" is determined for a plant, installing and operating that technology ought to relieve the plant of further §316(b) obligations unless or until the plant is significantly modified. The "location, design, construction, and capacity" of the cooling water intake structures are matters of design and construction, not operation. Congress could not have intended that power plants be in the business of redesigning, demolishing, and reconstructing their physical plant every five or ten years. The most- appropriate way to apply §316(b) would a one-time review designed to achieve minimal "adverse environmental impact" at a reasonable cost.

EPA's proposed rule suggests a "comprehensive reevaluation" of the § 316(b) demonstration every time a permit is renewed. Once a successful § 316(b) demonstration is made, maintaining and operating the technology for the life of the plant should be sufficient. Dominion suggests that § 125.98(a)(2) be changed as follows: "Unless there have been significant changes in plant operations or adverse changes to the aquatic population, after a successful demonstration of compliance with EPA's performance standards, at each subsequent permit renewal the permit writer should accept the initial demonstration."

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to 316bEFR 041.126 for a discussion.

Comment ID 316bEFR.085.021

Author Name Pamela F. Faggert
Organization Dominion Generation

Subject Matter Code 21.03
Monitoring requirements

Compliance monitoring should verify BTA efficiency.

Regulatory Reference: Preamble VII. Implementation

D. What Would I Be Required To Monitor? (p. 17179)

Proposed § 125.96 provides that Phase II existing facilities would have to perform monitoring to demonstrate compliance with the requirements of § 125.94 as prescribed by the Director. In establishing such monitoring requirements, the Director should consider the need for biological monitoring data, including impingement and entrainment sampling data sufficient to assess the presence, abundance, life stages, and mortality (including eggs, larvae, juveniles, and adults) of aquatic organisms (fish and shellfish) impinged or entrained during operation of the cooling water intake structure. These data could be used by the Director in developing permit conditions to determine whether requirements, or additional requirements, for design and construction technologies or operational measures should be included in the permit. The Director should ensure, where appropriate, that any required sampling would allow for the detection of any annual, seasonal, and diel variations in the species and numbers of individuals that are impinged or entrained. The Director should also consider if a reduced frequency in biological monitoring may be justified over time if the supporting data show that the technologies are consistently performing as projected under all operating and environmental conditions and less frequent monitoring would still allow for the detection of any future performance fluctuations. The Director should further consider whether weekly visual or remote or similar inspections should be required to ensure that any technologies that have been implemented to reduce impingement mortality or entrainment are being maintained and operated in a manner that ensures that they function as designed. Monitoring requirements could be imposed on Phase II existing facilities that have been deemed to meet the performance standard in § 125.94(b)(l) to the extent consistent with the provisions of the NPDES program.

DOMINION COMMENTS: Dominion recommends that after a verification monitoring period, the data should be analyzed to determine whether the newly installed technology is indeed achieving the projected 80-95% reduction in impingement mortality and 60-90% reduction in entrainment As long as the data shows performance within these ranges, the technology should be deemed to comply with the rule. Assuming the data showed performance within the ranges given, then biological monitoring requirements should be significantly reduced. Thereafter, the permittee should be required only to monitor and document that it continues to operate and maintain the technology.

On the other hand, if the initial monitoring showed that the technology was not meeting the performance standards, then a period of additional study should be provided to determine why projected reduction targets are not being met and what should be done to fix it. Once the permittee had demonstrated that the technology performed within the performance standard ranges, it would have only to maintain and operate the same technology for the life of the plant and would not have to make repeated demonstrations. This is a reasonable proposal, given that § 316(b) is a construction-oriented requirement and that fish populations are highly variable and subject to many stresses other than cooling water intakes.

EPA Response

Please see EPA's response to comment 316bEFR.041.119.

Comment ID 316bEFR.085.022

Author Name Pamela F. Faggert
Organization Dominion Generation

Subject Matter Code 21.03
Monitoring requirements

Two years of verification monitoring could be shortened.

Regulatory Reference: Subpart J—Requirements Applicable to Cooling Water Intake Structures for "Phase II Existing Facilities" Under Section 316(b) of the Act

§ 125.95 As an owner or operator of a Phase II existing facility, what must I collect and submit when I apply for my reissued NPDES permit?

(b) Comprehensive Demonstration Study

(7) Verification Monitoring Plan. (p. 17178)

You must include in the Study a plan to conduct, at a minimum, two years of monitoring to verify the full-scale performance of the proposed or implemented technologies, operational measures, or restoration measures. The verification study must begin once the technologies, operational measures, and restoration measures are implemented and continue for a period of time that is sufficient to demonstrate that the facility is reducing the level of impingement and entrainment to the levels documented pursuant to paragraphs (b)(4)(iii), (b)(5)(ii), and/or (b)(6)(iii)(B) of this section. The plan must describe the frequency of monitoring and the parameters to be monitored and the basis for determining the parameters and the frequency and duration for monitoring. The plan must also describe the information to be included in a yearly status report to the Director. The Director will use the verification monitoring to confirm that you are meeting the applicable requirements of § 125.94.

DOMINION COMMENTS: A two-year period of verification monitoring is excessive and unnecessary. If a plant had already collected abundant data and no change to the plant was required by the new rule, then this period should be shortened to a maximum of one year or waived.

EPA Response

Comment ID 316bEFR.085.023

Author Name Pamela F. Faggert
Organization Dominion Generation

Subject Matter Code 18.01
RFC: Definition of "adverse environmental impact"

Dominion suggests assigning a three-level standard of significance to the definition of adverse environmental impact - SMALL, MODERATE or LARGE - used by the Nuclear Regulatory Commission to evaluate environmental issues and developed using the Council on Environmental Quality guidelines.

-SMALL - Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource, i.e. population structure.

-MODERATE - Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

-LARGE - Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

If a facility had determined that impingement or entrainment losses are SMALL or MODERATE, the facility should be eligible for a site-specific determination of best available technology independent of whether either of the cost tests for site-specific determination have been met.

Cooling Lakes and Ponds

Although AEC does not have a surface impoundment that serves as a cooling lake or pond, EPA should consider any such impoundment as a treatment system and not “Waters of the United States”, thereby exempting a facility with this type impoundment from the 316(b) regulations. Even if EPA decides not to designate such type surface impoundment as a treatment system, EPA should determine that a cooling system using any such surface impoundment constitutes a “closed-cycle recirculating system” and is, therefore, in compliance with the 316(b) rules.

RFC: Appropriateness of "significantly greater"

"Significantly Greater"

The proposal provides for a site-specific determination of the "best technology available" if the costs of compliance at a site would be "significantly greater" than either the benefits of meeting the performance standards or the cost of what the agency considered. EPA must provide a clear definition of what is meant by "significantly greater." To maximize net benefits to society, economic theory would dictate that this should be interpreted to mean any cost benefit ratio greater than 1:1. This reflects the most cost-effective, performance-based outcome.

RFC: Use of previous demonstration studies

Author Name Keith M. Stephens

Organization Alabama Electric Cooperative, Inc.

Application to Existing Facilities

The proposal should include a process for approving existing intake technologies as “best available” if it can be shown that the facility is not causing adverse environmental impact or the technologies have been deemed “best available” by the state. Such a process is reasonable since Section 316(b) has been in effect since 1972 and has been implemented case-by-case at many sites. There are many electric generating facilities for which there is already a high degree of confidence that the facility is not causing adverse environmental impacts or that it has already installed the best technology available. In addition, if the facility has data indicating that the amount of entrainment and impingement is so small that there is no significant harm to the aquatic community or the environmental impact is of so little economic and environmental significance that the costs of a comprehensive 316(b) study would be significantly greater than its benefits, then there should be no need for either further studies or for additional intake technology.

Determination of compliance

Compliance Assessment

Since there is such variability in biological systems, it is not practical to require the permittee to meet a specific numerical reduction in affected organisms. The proposed performance criteria should not be directly implemented as enforceable permit limitations. Rather, when the existing technology is not the "best available", the permit should require the installation of technology identified collaboratively by the permittee and the state. Then compliance with the permit would be based on installation, operation and maintenance of the selected technology.

We were not able to gain access to critical analyses and data needed to evaluate the proposed Phase II Existing Facilities Rule (“Phase II Rule) and the alternative regulatory options because this information has been designated as Confidential Business Information.

EPA Response

EPA is obligated to comply with the confidential business information requirements specified in 40 CFR Part 2, subpart B. EPA believes, however, that there was considerable data and information in the public record, including discussion of the rationale, methodologies and assumptions underlying this rule, that provided a meaningful opportunity for public participation.

Economic impacts on consumers/households

The costs of complying with the alternative regulatory options that would require cooling towers would be minor in the context of overall electricity costs to consumers.

EPA Response

EPA's decision to reject cooling towers was based on a number of factors, the most important of which was the total costs involved for facilities to make these retrofits. Even if its true that secondary effects (i.e., those experienced by the consumer) would be "minor" the very high capital costs, coupled with the energy penalty and other considerations, persuaded EPA that cooling towers were not the BTA for minimizing adverse environmental impact for the category of existing facilities as a whole. Data Availability

We were not able to gain access to critical analyses and data needed to evaluate the proposed Phase II Rule and the alternative regulatory options because this information has been designated as "Confidential Business Information" ("CBI"). In particular, it is impossible to identify, let alone assess the reasonableness of, the individual facility and firm level costs and reliability impacts of the proposed rule and the alternative options because (1) we cannot determine which individual facilities and firms would be affected by the alternative regulatory options and (2) there is insufficient non-CBI information to allow any detailed plant or firm-specific assessment of the analyses provided by the EPA. It also is impossible to assess how realistically the IPM models the effect of the various regulatory options because so much of the underlying information has been designated CBI.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

Reliability Impacts

Finding: There would be no adverse impact on electric system reliability from the implementation of the proposed Phase II Rule, the All Cooling Tower Option (Federal Register Option 1) or the Waterbody/Capacity-Based Option (Federal Register Option 3).

The installation of the Impingement and/or Entrainment ("I&E") controls that would be required under the proposed Phase II Rule would have no energy penalty or any effect on facility reliability and availability. Affected facilities would not have any incremental outage time to install these measures because they can be installed while the plant is in operation or during normally scheduled maintenance downtime. Thus, electric system reliability would not be affected by the installation of I&E controls at affected facilities.

Consequently, only the regulatory options requiring the installation of Flow Reduction Technologies could potentially have any impacts on electric system reliability. However, as explained below, even these more aggressive options would only have negligible impacts on system reliability.

As shown in Table B8-1 in the EBA, under the Waterbody/Capacity-Based Option a total of 52 facilities, representing 5.9 percent of National Pre-Run Capacity, would have to add cooling towers. However, EPA has assumed that the new cooling towers could be built while an affected facility is operating and that the attachment of the new tower to the existing cooling system would have only a one-time effect, extending a planned maintenance outage by one month. Therefore, if the transition took place over five years and the extra month of downtime occurred randomly throughout the year, the total 5.9 percent affected capacity actually would become an average reduction in national generating capacity at any one time of only 0.1 percent. <FN 1> Such a minor reduction in available capacity would have no effect on the reliability of the national electric system during the five-year transition period, especially considering the 26-percent summer 2005 and the 53-percent winter 2005/2006 reserve margins projected by NERC. <FN 2>

Moreover, the cooling system conversions would undoubtedly be scheduled to occur preferentially during the off-peak seasons when system loads are lower and capacity reserves and reserve margins are much higher. Therefore, the implementation of this option would have even less of an effect on electric system reliability than even these minor impacts would suggest.

The same would be true for the individual regional NERC electric systems. For example, Table B8-1 reveals that, when considered on a regional basis, the maximum fraction of generating capacity that would be affected by the Waterbody/Capacity-Based Option would be 16.7 percent in both the FRCC and the NPCC NERC regions. However, if the transition were planned to take place over five years with the extra month of downtime spread throughout the year, this 16.7 percent of affected capacity would become an average reduction of only 0.3 percent in the amount of capacity available in each of these regions. <FN 3> Again, this extremely minor decrease in the amount of generating capacity that would be available during the five-year transition period would not have any adverse effect on electric system reliability in the FRCC and NPCC NERC regions given the 23.1 percent (FRCC) and 28.2 percent (NPCC) reserve margins forecast for these regions for the summer of 2005. <FN 4> The proposed Waterbody/Capacity Based Option would have even less of an effect on electric system reliability in the other NERC Regions where EPA estimates that significantly less generating capacity would be affected. <FN 5>

The implementation of the Dry Cooling Option (EBA Option 5) would have similarly minor impacts on the amounts of electric generating capacity that would be available at any one time during the five year transition period and, therefore, also would not have an adverse effect on electric system reliability.

Under the All Cooling Towers Option, 416 facilities representing 33.1 percent of National generating capacity would have to add cooling towers. But the facility outages required to connect these new cooling towers also could be scheduled to occur throughout the five-year transition period. As a result, on average, only 0.5 percent of the nation's electric generating capacity would be out of service at any one time as a result of the implementation of this regulatory alternative. <FN 6> As noted above, such a minor reduction in available capacity would have no effect on the reliability of the national electric system during the five-year transition period considering the 26-percent summer 2005 and the 53-percent winter 2005/2006 reserve margins projected by NERC. <FN 7>

At the same time, only 0.75 percent of the generating capacity in the ECAR and NPCC regions, on average, would be out of service at any one time. <FN 8> An even smaller percentage of the generating capacity would be out of service at any one time, on average, in the other NERC regions as a result of the implementation of the All Cooling Towers Option.

As noted above, this assumes that the extra downtime needed to connect the new cooling towers would be spread evenly throughout the year. It is far more likely that the extra downtime would be preferentially scheduled to occur during the off-peak seasons when system loads are lower and capacity reserves and reserve margins are significantly higher. As a result, the implementation of the All Cooling Towers Option would have even less of an effect on national and regional electric system reliability than these figures would suggest.

The EPA also assumes that there would be continuing energy penalties from the conversion to recirculating systems with wet or dry cooling towers. <FN 9> However, the reductions in net plant capacity from such conversions would have a negligible effect on electric system reliability, as shown by the EPA itself. For example, Table B8-3 in the EBA reveals that implementation of the Waterbody/Capacity-Based Option would reduce the total national domestic generating capacity in 2013 by about 800 MW which would be only a 0.1 percent reduction from EPA's estimated 922,740 MW. The same Table reveals that implementation of the All Cooling Towers Option would reduce the total national domestic generating capacity in 2013 by only 3,380 MW, or only 0.4 percent. Clearly, such minor reductions would not have a significant impact on electric system reliability.

However, there are a number of reasons why even these extremely minor reductions in available capacity overstate the effect that the implementation of either the All Cooling Towers or the Waterbody/Capacity-Based Options would have on electric system reliability.

First, the EPA analyses significantly understate the amount of generating capacity that should be available during and after the five-year transition period. For example, EPA assumes that there would be 941,990 MW of national generating capacity in 2008. <FN 10> This is more than 200,000 MW less than the 1,045,335 MW of generating capacity forecast by the individual NERC regions and approximately 178,000 MW less than NERC's Reliability Assessment Subcommittee believes to be the "most likely scenario going forward." <FN 11>

The EPA then appears to make the extremely unrealistic and unreasonable assumption that the amount of national generating capacity actually will decrease from 941,990 MW in 2008 to 922,740 MW in 2013. <FN 12> Such an assumption is entirely unwarranted and unrealistic in light of the tremendous growth in electric generating capacity projected for the period 2001 through 2010. For example, the NERC assumes that approximately 134,000 MW of new capacity will be added nationally by 2010. <FN 13> There is no basis to expect that this growth will end and that the amount of generating capacity actually will decrease after 2010.

Second, the EPA analyses ignore the additional capacity that would be available from the repowering of coal-fired facilities. Instead, the EPA defines repowering a facility as the change from oil/gas capacity to combined-cycle capacity. By doing so, it excludes any consideration that an affected coal-fired facility could be repowered to combined-cycle capacity. As discussed in more detail later in these comments, a literature review reveals that at least 15 coal-fired facilities have been or are planning to be repowered to use combined-cycle technology. The repowering of these coal-fired plants could add thousands of additional megawatts of generating capacity to the national electric system and, thereby, improve system reliability while reducing water usage.

Third, the EPA analyses ignore the additional capacity that will be available from the implementation of power uprates at nuclear power plants. A power uprate means increasing the thermal power produced by the plant. A power uprate increases the output of the plant at a relatively low cost. The U.S. Nuclear Regulatory Commission has approved more than 60 such power uprates of between 5 and 20 percent. Requests for additional uprates are currently under review by the NRC or are planned for submission in the near future. An average increase of 10 percent in the power levels of the nation's nuclear plants would add approximately 9,000 megawatts of additional capacity to the electric system.

Fourth, it appears that EPA has assumed that the service lives of some, but not all, nuclear power plants, will be extended beyond the current 40 year terms of their Nuclear Regulatory Commission-issued operating licenses. <FN 14> However, it is impossible to tell how many nuclear units, and which individual facilities, are assumed to have their operating lives extended Given the NRC's recent actions and stated intentions, it is reasonable to expect that the NRC will allow any owner that wants to extend the operating life of its nuclear plant to do so. Therefore, there may be more generating capacity available over the next 30 to 50 years than has been assumed in the EPA analyses.

Fifth, the EPA analyses reflect the costs of condenser upgrades <FN 15> but not the improved performance (in terms of fewer tube failures and lower forced outage rates) that can be expected from such upgrades. In other words, the facilities which have implemented condenser upgrades should be available for service for more of the year than they previously had been. This additional capacity can be expected to further enhance electric system reliability.

Finally, the EPA analyses assume that some generating capacity will be retired as a result of the implementation of the All Cooling Towers and Waterbody/Capacity-Based Options. <FN 16> As explained below, we believe that the assumption that significant nuclear capacity would be retired as a result of the proposed All Cooling Towers or Waterbody/Capacity-Based Options is unreasonable and unrealistic. The availability of this nuclear capacity that EPA assumes would be retired would further reduce system reliability impacts.

In any event, the retirement of some of the facilities that would have to add cooling towers might spur the construction of additional new combined-cycle plants that would use less water.

EPA Response

EPA notes that it revised its assumption regarding installation outages required for technologies other than cooling towers. At proposal, EPA assumed that I&E controls other than cooling towers would not require installation outages. However, for the NODA and final rule analyses, this assumption was revised. Some of the I&E technologies are now estimated to require between 2 and 11 weeks of installation outage.

Please refer to section VII of the preamble for information about EPA's decision to reject cooling towers.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

Capacity Retirements

Finding : The EPA Analyses over-estimate the amount of capacity that would be retired under the All Cooling Towers and Waterbody/Capacity-Based Options.

The EPA notes that 2,550 MW of nuclear capacity in the NPCC and WSCC would be retired as a result of the adoption of the Waterbody/Capacity-Based Option. <FN 17> The EPA does not identify the number of MW of nuclear capacity that would be retired as a result of the adoption of the All Cooling Towers Option. However, it is reasonable to expect that the same nuclear facilities that EPA predicts would close in its analysis of the Waterbody/Capacity-Based Option also would be predicted to close in EPA's analysis of the All Cooling Towers Option.

Unfortunately, the analyses and underlying data which form the basis for the EPA conclusion that this nuclear capacity would be retired as a result of these options has been designated CBI. Therefore, we have been unable to evaluate, let alone validate, these results. <FN 18> Moreover, based on previous Synapse work, we believe that it is extremely unrealistic to expect that currently operating nuclear power plants will be retired as a result of the adoption of any of the flow reduction technology based regulatory options. This conclusion is based on (a) the improved performance and reduced O&M costs achieved at nuclear plants since the mid-1990s, (b) the fact that nuclear plants' low operating and fuel costs allow them to compete successfully in bid-based wholesale markets, and (c) the significant economic benefits that are available from relatively low cost investments in plant power uprates and operating life extensions.

For example, a recent Synapse analysis concluded that a $36 million investment in increasing the power level of the Vermont Yankee Nuclear Plant by 13 percent would result in a net present value benefit of $56 million (in 2001 dollars). <FN 19> A similar investment in extending the unit's operating life by twenty years would produce a net present value benefit of $253 million. <FN 20> With the opportunity for potential economic benefits of this magnitude, it is unlikely that any nuclear plant would be retired as result of the adoption of the cooling tower options considered by the EPA.

In addition, the EPA analyses ignore the possibility that fossil-fired facilities will be repowered instead of retired as a result of the adoption of any of the flow reduction technologies. The examples of the Reliant Astoria Repowering Project and the Bethlehem Energy Center in New York State are evidence that firms will seek to repower older, less efficient generating facilities and that such repowerings can include cooling towers as part of the repowered facility in place of once-through cooling. Such projects will provide significant environmental benefits in terms of reduced water usage and lowered air emissions and will offer substantial economic benefits for their owners.

Footnotes

17 EBA, at page B8-3.

18 We have similarly been unable to evaluate the analyses underlying the EPA claim that some fossil-fired units also would be retired as a result of these options.

19 Redacted Prefiled Testimony of Bruce E. Biewald in Vermont Public Service Board Docket No. 6545, dated January 7, 2002, at page 31, lines 16-18.

20 Ibid., at page 32, lines 1-5.

EPA Response

EPA disagrees with this comment. EPA's results with respect to early retirements of power plants, including nuclear plants, is based on the energy market modeling analysis conducted with the IPM. The IPM considers the net present value of future operations, both in the baseline and under section 316(b) policy options. If, as a result of compliance with a section 316(b) policy option, operation of the facility is no longer economical, the facility is predicted to shut down. The factors mentioned by the commenter (reduced O&M costs, low operating and fuel costs, and power updates and life extensions) are all taken into account by the IPM. However, a facility would still be predicted to retire in cases were compliance costs as a result of a policy option are high enough to offset these advantages.

EPA further notes that EPA's analyses did not ignore the possibility that fossil-fuel facilities will be repowered. The IPM includes a repowering option for both coal facilities and oil/gas facilities. In addition to compliance with the rule and retirement, repowering is one option that the IPM evaluates. It should be noted that Chapter B3 in support of the proposed rule (DCN 4-0002) erroneously stated that repowering in the IPM only consists of converting oil/gas capacity to combined-cycle capacity. This statement was corrected to also include coal facilities.

Economic impacts on consumers/households

Cost Estimates

Finding: The Costs of Complying with the alternative regulatory options that require cooling towers would be minor in the context of overall electricity costs to consumers.

As shown in Table 1 below, the compliance costs projected in the EBA would lead to very minor increases in the average cost of generating electricity at the affected facilities. In fact, these cost increases would average only 0.1 cents per kilowatt hour ("kwh") even under the All Cooling Towers Option (EBA Option 4), which would add cooling towers at 416 facilities. The average price of generating electricity at the affected facilities would increase by only 0.026 cents per kwh under the Waterbody/Capacity-Based Option (EBA Option 1).

[see hard copy for table]
Table 1 – Average Annual Costs per kwh of Alternative Regulatory Options Analyzed by EPA <FN 21>

It is not certain that in deregulated markets the owners of affected facilities could pass these cost increases along to their customers. But even if they could, the overall price paid by consumers for the electricity they use would reflect a blend of both the price of generating electricity at affected facilities and the price of generating electricity at non-affected facilities. Consequently, as shown in the last column of Table 1, the average price of electricity paid by consumers would increase by only 0.056 cents per kwh under the All Cooling Towers Option or by 0.015 cents per kwh under the Waterbody/Capacity-Based Option.

These average cost increases are extremely minor when compared to the average 8.47 cents per kilowatt hour paid by residential electricity consumers in 2000. <FN 22> For example, the 0.056 cents per kilowatt hour increase projected for the All Cooling Towers Option would represent only a 0.66 percent increase in an average residential customer bill. <FN 23> The 0.015 cents increase projected for the Waterbody/Capacity-Based Option would represent only a 0.18 percent increase in an average residential bill. <FN 24>

In other words, an average consumer who uses 500 kilowatt hours per month might see his/her bill increase by only 7.5 cents per month if the Waterbody/Capacity-Based Option were adopted. <FN 25> The average consumers' bill could increase by only 28 cents per month if the All Cooling Towers Option were adopted. <FN 26>

Footnotes

21 The annualized costs for each of the options shown in the middle column of Table 1 were taken from Tables B7-2, B7-7, B7-12 and B7-17 of the EBA. The individual cents per KWH costs shown in the right hand column were calculated by dividing each of these annual costs by the 2,300,000,000 of net generation forecast for affected facilities in Table A2-2 of the EBA.

22 Typical Electric Bills and Average Rates Report, Winter 2001, Edison Electric Institute, at page 188.

23 0.056 cents per kilowatt hour divided by 8.47 cents per kilowatt hour equals 0.66 percent.

24 0.015 cents per kilowatt hour divided by 8.47 cents per kilowatt hour equals 0.18 percent.

25 This 7.5 cents per month increase represents the 0.015 cents per KWH increase shown for this option in Table 2 multiplied by an average 500 KWH per month usage.

26 This 28 cents per month increase represents the 0.056 cents per KWH increase shown for this option in Table 2 multiplied by an average 500 KWH per month usage.

EPA Response

EPA agrees with the commenter's assessment of the uncertainties about the ability of affected facilities to pass on costs to their customers. See response to 087.004 and the preamble to the final rule for a discussion of EPA's decision not to promulgate a rule based on cooling water technologies.

Organization Synapse obo Riverkeeper, Inc.

Subject Matter Code 9.0

Costs

Finding: The Costs of Complying with the alternative regulatory options are significantly overstated.

Although the costs of complying with the alternative regulatory options that require the implementation of flow reduction technologies are extremely low, they are nevertheless overstated for the following reasons:

First, the capital costs of adding a cooling tower are annualized over a 30-year period even though the EPA has acknowledged that there is substantial evidence that cooling towers have service lives longer than 30 years. The EPA should annualize the capital costs of adding cooling towers over a period that is more likely to reflect the expected operating lives of those towers. Such an annualization over a period longer than 30 years would lower the annual compliance costs presented in the EBA for the All Cooling Towers, the Waterbody/Capacity-Based and Dry Cooling Options.

Second, the EPA notes that data from the Nuclear Regulatory Commission indicate that "recirculating cooling systems have lower condenser flow to MW ratios than once-through systems, regardless of age or other characteristics." <FN 27> However, the EPA nevertheless uses the baseline (i.e., once-through) system intake flow of affected plants to size the needed recirculating cooling towers and associated conduit systems. <FN 28> This assumption renders the affected facility recirculating systems modeled by EPA oversized and unnecessarily expensive. EPA instead should have used the Nuclear Regulatory Commission data to properly size the cooling system conversions.

Third, to calculate the capital costs of wet cooling towers, the EPA starts with the cost of a redwood tower with splash fill for all fossil-fuel plants. Such a cooling tower is slightly more expensive than a tower fabricated from fiberglass reinforced plastic. <FN 29> Further, EPA has acknowledged that it has learned from cooling tower vendors that fiberglass has become "relatively standard" for new facility installations. <FN 30> EPA should have used the cost of the more standard fiberglass material for new cooling towers at existing fossil-fired facilities.

Fourth, the equations used by EPA to quantify the capital cost of a new cooling tower produce cost estimates that "in almost all cases" exceeded the actual project costs, sometimes by as much as 25 percent of the actual costs. <FN 31> For this reason, EPA should revise its equations to more accurately reflect the actual costs of building a cooling tower. In the alternative, if the EPA decides to continue to use these equations without revision, it should not apply a 20 percent "retrofit factor" when quantifying the cost of adding a cooling tower at an existing facility. The combined use of both the existing equations and the 20 percent retrofit factor leads to unreasonably high estimates for the capital costs of adding a new cooling tower at an existing facility.

Fifth, the EPA assumed that in order to increase the efficiency of the recirculating cooling system affected facilities would elect to upgrade their condensers as part of cooling system conversions from once-through to recirculating systems. <FN 32> Although the costs of these condenser upgrades were included in the EPA's quantification of compliance costs, these costs do not reflect any reductions in condenser-related O&M costs that can be expected from upgrading to the new materials which are less susceptible to failure. Such material upgrades should lead to fewer tube leaks and, consequently, lower repair and repair outage-related costs.

Sixth, the EPA assumed that a range of 2,000 feet to 4,000 feet (depending on intake flow) of concrete-lined steel piping would be used for cooling water make-up water and blowdown. <FN 33> The EPA included these costs to account for conversion cases in which significant distances may exist between intake locations and cooling tower sites even though this was not necessarily true for the example cases reviewed by EPA. EPA should have used a range of piping length that is more typical of existing facilities instead of using a range that might only apply to a limited number of plants.

Seventh, the only intake structure technologies for which EPA develops costs are fine mesh traveling screens and fish handling equipment. The EPA notes that "fine mesh traveling screens tend to have higher costs, in the Agency's estimation than other similar technologies." <FN 34>   The EPA should identify these other viable intake structure compliance strategies, and compliance cost estimates should reflect the use of these strategies at facilities can be expected to use them.

Eighth, the EPA notes that it does not develop costs for certain compliance strategies that companies may employ in response to the new rule. <FN 35> Several of these compliance strategies are likely to be less costly than the strategies for which the EPA has developed costs. The EPA should cost out all applicable compliance strategies in order to develop an accurate assessment of each option's costs.

Ninth, as noted earlier, the EPA analyses do not reflect the repowering of coal-fired facilities to use combined-cycle technology. However, as we will discuss below, at least 15 coal-fired facilities have been repowered to combined-cycle technology or are planning to so repower in the near future. The costs of compliance under the All Cooling Towers, the Waterbody/Capacity-Based and Dry Cooling Options are overstated to the extent that they fail to reflect these repowerings because the costs of complying with any of these options would be lower for a repowered facility than for the original coal-fired plant.

Tenth, the energy penalties used by the EPA to develop the compliance costs are too high, as follows:

1. To calculate the cost of foregone electricity sales during the extended outage to connect a wet tower to an existing plant, EPA uses annual average electricity sales figures for the company and annual average wholesale prices. As the Agency notes, these outages are likely to occur during the off-peak seasons (spring and fall), when both electricity sales and wholesale prices are below annual average levels. <FN 36>   Thus, the use of annual average data will tend to overstate the cost of the extended outage. We believe that EPA should use electricity sales and wholesale price data from off-peak seasons to calculate this cost.

The EPA only quantified the avoided fuel costs from this one-month downtime. However, EPA also has noted that variable production costs other than fuel costs may be avoided during downtime. By only including fuel costs and ignoring the avoided variable production costs, EPA may have overstated the cost of the connection outage. <FN 37>

2. In calculating the energy penalty associated with reduced steam turbine efficiency, EPA calculates energy losses at 67-percent load operation for all in-scope facilities. <FN 38>   However, the EPA

notes that many power plants operate at very high load levels during most of their operating hours. <FN 39> In fact, a substantial number of the plants affected by this rule – especially large nuclear and coal-fired facilities – are used as baseload plants and operate at or near their maximum power levels during a very large percentage of their operating hours. Therefore, EPA should use a higher load level to calculate turbine efficiency losses due to cooling system conversions. As discussed at length in the EBA and the Technical Development Document, the use of such higher load levels would reduce the turbine losses that could be expected from the conversion to a recirculating cooling system.

On page 5-9 of the Technical Development Document, the Agency appears to confuse the concepts of a power plant's operating load level and its annual capacity factor. The Agency writes:

The average capacity factor for nuclear power plants in the U.S. has been improving steadily and recently has been reported to be approximately 89 percent. This suggests that for nuclear power plants, the majority appear to be operating near capacity most of the time. Therefore, the use of the energy penalty factors derived from the maximum load curves for nuclear power plants is reasonably valid. In 1998, utility coal plants operated at and average capacity of 69 percent (DOE 2000). Therefore the use of energy penalty values derived from the 67 percent load curves would appear to be more appropriate for fossil-fuel plants. <FN 40>

Operating loading is a description of how close to full load a plant is operating at a given moment. In contrast, a plant's capacity factor is a function of both the plant's load level during each hour and the number of hours operated. Thus, the 69 percent average capacity factor for fossil-fueled units does not indicate that these units tend to operate near 69 percent of full load. Most large fossil-fired steam plants operate at loadings above 69 percent during most of their hours of operation. The annual average capacity factor is brought down to 69 percent by forced and unforced outages – periods during which the plants are generating no electricity. <FN 41> (In fact, if one assumes a month per year of downtime on average for fossil units, then they must be operating at loadings well above 69 percent in order to achieve an average capacity factor of 69 percent.) Correcting this conceptual error illustrates why energy penalties for the in-scope units should be calculated at a loading well above 67 percent.

3. The EPA has acknowledged that energy penalties for the West were not available at the time that its analyses were finalized. The IPM analysis for plants located in California therefore used the U.S. average. This overstated the energy penalty for these facilities. <FN 42>

RFC: Effects of re-powering on intake flow

Repowering

Finding: There appears to be a contradiction between the definitions of "repowering" in the EBA and the Technical Development Document and the Federal Register Notice.

The EBA notes that "Repowering in the IPM consists of converting of oil/gas capacity to combined-cycle capacity." <FN 43> However, the Technical Development Document and the Federal Register Notice have a much broader definition of repowering. <FN 44> The EPA should clarify which definition is being used and should be consistent in the application of that definition. In addition, as noted earlier, the EPA also should consider facilities that are converting from coal to combined-cycle capacity within its definition of repowering.

EPA makes the following observations at page 2.38 of the Technical Development Document:

Because the Agency developed a cost estimating methodology that primarily utilizes design intake flow as the independent variable, the Agency examined the extent to which compliance costs would change if the repowering data summarized above were incorporated into the cost analysis of this rule. The Agency determined that projected compliance costs for facilities withdrawing from estuaries could be lower after incorporating the repowering changes. The primary reason for this is the fact that the majority of estuary repowering facilities would change from a steam cycle to a combined-cycle, thereby maintaining or decreasing their cooling water withdrawals (note that a combined-cycle facility will withdraw one-third of the cooling water of a comparably sized full steam facility). Therefore, the portion of compliance costs for regulatory options that included flow reduction requirements or technologies could significantly decrease if the Agency incorporated repowering changes into the analysis. As shown in Table 2-22 the majority of facilities projected to increase cooling water withdrawals due to the repowering changes use freshwater sources. In turn, the compliance costs for these facilities would increase if the Agency incorporated repowering for this proposal. <FN 45>

The EPA should explain in detail precisely how it evaluated and quantified the potential impact of repowering for potentially affected facilities and provide the underlying analyses and data. The EPA also needs to consider the potential impact of the repowering of oil, gas, and coal-fired facilities to combined-cycle technology on the costs of complying with the alternative regulatory options. This is especially important because the EPA acknowledges that the "the portion of compliance costs for regulatory options that included flow reduction requirements or technologies could significantly decrease if the Agency incorporated repowering changes into the analysis."

Footnotes

43 EBA at page B3-8, footnote no. 11.

44 Technical Development Document, at pages 2.36 and 2.37.

45 Technical Development Document, at page 2.38.

EPA Response

For a general discussion of repowering, see section II of the preamble to the final rule.

The Agency defines repowering as existing facilities either undertaking replacement of existing generating capacity or making additions to existing capacity. Under this final rule certain forms of repowering could be undertaken by an existing power generating facility that uses a cooling water intake structure and it would remain subject to regulation as a Phase II existing facility. For example, the following scenarios would be existing facilities under the rule:

- An existing power generating facility undergoes a modification of its process short of total replacement of the process and concurrently increases the design capacity of its existing cooling water intake structures;
- An existing power generating facility builds a new process for purposes of the same industrial operation and concurrently increases the design capacity of its existing cooling water intake structures;
- An existing power generating facility completely rebuilds its process but uses the existing cooling water intake structure with no increase in design capacity.

Thus, in most situations, repowering an existing power generating facility would be addressed under this rule. Ultimately, however, whether a facility is subject to Phase I or Phase 2 will be determined according to whether it meets the definition of "new facility" in §125.83.

EPA did consider conversion of existing coal capacity to new combined-cycle capacity as repowering. Comments regarding EPA's failure to consider the potential for the repowering of older, coal-fired facilities were due to a statement in the Economic and Analysis (EBA) in support of the proposed rule. At the time of the NODA and for the final rule, EPA has corrected the statement in the EBA to read, “Repowering in the IPM typically consists of the conversion of existing oil/gas or coal capacity to new combined-cycle capacity.” (See DCN 5-3002 and Chapter B3, DCN 6-0002)

EPA provided its repowering analysis at 66 FR 17134. There the Agency explained that it analyzed a proprietary database (NewGEN) for information on plants that planned to undertake repowering activities. (See also Technical Development Document for the Final Section 316(b) Phase II Existing Facilities Rule).

For the section 316(b) analysis, EPA did not use the IPM function that allows the model to pick among a set of compliance responses. As a result, there is no iterative process that would adjust the compliance response (and as a result the cost of compliance) if a facility chooses to repower. Repowering in the IPM typically consists of the conversion of existing oil/gas or coal capacity to new combined-cycle capacity. The modeling assumption is that each one MW of existing capacity is replaced by two MW of repowered capacity. This change in plant type and size might lead to a change in intake flow and potentially to different compliance requirements and costs. Since combined-cycle facilities require substantially less cooling water than other oil/gas or coal facilities, the effect of repowering is likely to be a reduction in cooling water requirements (even considering the doubling of the plant’s capacity). As a result, not allowing the model to adjust the compliance response or cost is likely to lead to a conservative estimate of compliance costs and potential economic impacts from the final rule. (See Chapter B3, Economic and Benefits Analysis for the Final Section316(b) Phase II Existing Facilities Rule; DCN 6-0002).

RFC: Effects of re-powering on intake flow

Finding: The EPA appears to have failed to consider the repowering of coal-fired facilities to use combined cycle technology.

Synapse has conducted a literature search to identify electric generating facilities that have been repowered or that are currently planned to be repowered in the near future. This literature search consisted of reviews of such public sources as state public utility commission websites, utility and non-utility generator websites, the EIA Form 767 database, and the UDI database.

We found that at least 16 coal-fired facilities have repowered or are currently proposing to repower. <FN 46> However, the EPA analyses appear to ignore such potential repowerings of coal-fired facilities. <FN 47> In fact, many of these repowerings involve conversion to combined-cycle technology.

Footnotes

46 Eleven of these repowerings were identified using publicly available information. The remaining four were identified from a confidential database.

47 "Repowering in the IPM consists of converting of oil/gas capacity to combined-cycle capacity." See the EBA at page B3-8, footnote no. 11.

Facility & firm-level costs/Econ. Practicability

The Cost-to-Revenue Measure

Finding: The cost-to-revenue analyses presented in the EBA appear to overstate the magnitude of compliance costs relative to facility-level and firm-level revenues.

Because many of the underlying calculations and data have been designated CBI it is impossible to evaluate the cost-to-revenues measures presented in the EBA. Nevertheless, there are several reasons why the cost-to-revenue discussions in Chapters B7 of the EBA (and the results presented in Tables B7-4, B7-5, B7-9, B7-10, B7-14, B7-15, B7-19, and B7-20 of the EBA) overstate the magnitude of compliance costs relative to revenues.

First, as discussed in detail above, the costs of complying with the alternative scenarios have been overstated. This overstatement directly distorts the cost-to-revenue measures presented in the EBA and inflates the magnitude of the compliance costs relative to revenues.

Second, it is unclear from the EBA and the materials provided by the EPA whether the analyses reflect any increases in facility-level and firm-level revenues as a result of the passing through to consumers of cost increases resulting from the implementation of the proposed Phase II rule or any of the alternative regulatory options. This omission would be critical because it is reasonable to expect that firms, rather than being forced to bear all of these costs themselves, could pass along to their customers a significant portion, if not all, of the costs they incur in meeting any new Phase II EPA requirements and, thereby, recover these costs through increased revenues.

Those firms located in states in which electricity generation has not yet been deregulated would have an opportunity to file a rate case to recover any increased costs resulted from cooling system modifications or conversions. Those firms located in states in which deregulated electricity markets exist may be able to recover any Phase II-related costs through increases in market prices.

For this reason, the EPA should model scenarios where some or all of the costs of implementing the proposed Phase II rule or the alternative regulatory options are recovered through increased revenues.

EPA Response

For a response to the comment on EPA's cost estimate for alternative scenarios, please refer to comment 316bEFR.087.005 in comment category 9.0.

EPA notes that the cost-to-revenue ratio was only one of several economic measures used in support of the proposed and final rules. The main measure of economic impact was the market model analysis using the IPM. This analysis explicitly considers the potential for increases in electricity prices and associated change in revenue for regulated entities as a result of the 316(b) regulation. Thus, this analysis incorporates the commenter's point that EPA should consider the possibility that some part of the cost of regulatory compliance will be passed onto consumers in the form of electricity price increases. Indeed, in its analysis of one of the NODA options, the waterbody/capacity-based option, EPA found that most facilities estimated to incur compliance costs would experience revenue increases as a result of the overall market effects of the regulatory option.

Subject Matter Code 21.05

Role of States and Tribes (alt./equiv. programs)

OPPD strongly believes that the EPA and States with program authority should build on the solid foundation of state experience with site-specific decision-making regarding section 316(b) of the Clean Water Act. While more rigor and consistency can be brought to the framework presently used by the states, the current approach contains a number of features that make it especially useful for making sound, scientifically credible decisions and which reflect progressive thought regarding how to approach environmental protection in the future.

EPA Response

EPA recognizes the effort on the part of some States to develop comprehensive 316(b) programs. As such, today's rule allows for the approval of State 316(b) programs that meet the requirements in 125.90(d).

Comment ID 316bEFR.088.002

Author Name Sonia S. Kim

Organization Omaha Public Power District

Subject Matter Code 7.01.03

Option 3--Site-specific determination

OPPD is encouraged that the proposed rule provides a solid initial foundation by recognizing the site-specific nature of the issue, providing several compliance options based on cost-benefit analyses, and, most important, rejects any mandate for the use of one specific technology (such as cooling towers) in a one-size-fits-all approach.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to section VII.E of the preamble for more information on why EPA rejected this alternative.

Comment ID 316bEFR.088.003

Subject Matter Code 17.06

Option: Site-specific determination of BTA

Author Name Sonia S. Kim

Organization Omaha Public Power District

Several aspects of the proposal must be improved in order to assure optimal, cost-effective, and administratively simple protection of the environment. To assure that environmental protections are effectively achieved, EPA should embrace a regulatory framework that allows states to equally and fairly consider all site-specific costs and benefits.

Specifically, EPA should endorse a rule that provides a framework for site-specific decision making, allowing a state to make the critical decisions about the kinds of controls to be established at a plant and does not arbitrarily reopen past decisions when a state finds them to be effective in minimizing adverse environmental impact. Both the cost-cost and cost-benefit test should be retained. While EPA suggests using the vague term “significantly greater than” as the decision criteria for deciding the acceptability of cost benefit tests, we suggest that when comparing differing policy options, the alternative having the greatest positive difference between benefits and costs is the best option and the basis on which such decisions should be made. A clear understanding of this important concept will ease the time associated with permit issuance, lessening the overall burden to permitting authorities in administering the final rule.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

A goal of today’s rule is to set national minimum performance standards that reflect the best technology available for minimizing adverse environmental impacts. Given that previous determinations of best technology available were not made in reference to the national performance standards, EPA believes that the Director should not rely entirely on historical determinations. EPA believes that these national requirements will promote more effective and consistent implementation of section 316(b) requirements, and ultimately minimize adverse environmental impacts associated with the use of cooling water intake structures by Phase II existing facilities.

For more information on the use of the term "significantly greater," please refer to the response to comment 316bEFR.006.003.

Comment ID 316bEFR.088.004

Author Name Sonia S. Kim

Organization Omaha Public Power District

Subject Matter Code 10.1

General: cost tests

Since many varied and efficient tools are available and are always being improved for implementing cost - benefit decisions, we encourage the Agency to explicitly state that alternative methods and approaches other than those expressly noted in the proposal are acceptable and encouraged. This will promote streamlined and innovative approaches that will lead to more efficient decision making.

EPA Response

This comment is not entirely clear. If the commenter is suggesting that EPA should provide flexibility within the site-specific compliance alternative, EPA believes that it has done so. Please see EPA's response to comment 316bEFR.004.004. Overall, EPA has provided a tremendous amount of flexibility in the rule, including five compliance alternatives, one of which enables any interested person to propose a technology for approval by the Director (see § 125.99(b)).

Comment ID 316bEFR.088.005

Subject Matter Code 18.02

RFC: Use of previous demonstration studies

Author Name Sonia S. Kim

Organization Omaha Public Power District

Moreover, the Agency should consider fortifying the proposal to encourage States to maintain, promote and refine existing programs that implement section 316(b) to include an alternative that accommodates facilities that have already demonstrated no adverse environmental impact. This would streamline the numerous NPDES permits each state must administer, reduce permit backlog and would maintain the integrity of state programs in this area. In many cases, environmentally protective and responsible decisions have already rendered in accordance with appropriate stakeholder input. To require these decisions to be re-evaluated and permits reissued is bureaucratic, unnecessary, costly and counterproductive since there, are additional water quality concerns that should be immediately addressed. Public Power facilities are particularly concerned about ways to minimize unnecessary and counter productive expenses since public power utilities are entities of local government.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule; however, existing data that is reflective of current conditions may be used to support the required studies. Please see response to comment 316bEFR.040.001 for details.

See also response to comment 316bEFR.034.005 for a discussion of the many streamlining efficiencies added to reduce burden in today's final rule.

Comment ID 316bEFR.088.006

Subject Matter Code 7.02

Performance standards

Author Name Sonia S. Kim

Organization Omaha Public Power District

The Agency should allow deployment of the technologies mentioned in the proposal as de facto compliance as long as they are properly operated and maintained. The administrative burden associated with demonstrating the effectiveness of already proven technologies is significant. Reducing the administrative burden associated with demonstrations associated with each permit is desirable. Since the technologies noted in the proposal are proven effective, then the administrative requirements associated with demonstrating performance should be waived. Where states and facilities determine that a site specific approach is warranted, these demonstration studies would still be required. This change, in particular, benefits both the state and the regulated industry and does not jeopardize environmental protection.

EPA Response

Under compliance alternatives 1(i), 1(ii), and 4, a facility, using any one of those alternatives, would be subject to fewer components of the Comprehensive Demonstration Requirements (see 125.95(b)).

Comment ID 316bEFR.088.007

Subject Matter Code 7.02

Performance standards

OPPD agrees with the threshold range that constitutes reductions in entrainment and not impingement, OPPD would like to bring to your attention, however, that the impingement performance standard of 80 to 95% reduction, although possibly achievable in most larger, clean freshwater stream segments or rivers, cannot be achieved with existing proven control technologies due to the amount of debris and situation that we experience on Missouri River.

EPA Response

EPA notes the commenter's support for the entrainment performance standard. In addition, EPA agrees that high debris loads in certain waterbodies (the Missouri River among them) present different challenges regarding the selection and deployment of design and construction technologies. EPA disagrees, however, with the commenter's assertion that existing technologies are incapable of meeting the impingement mortality performance standard in such waterbodies.

Compliance alternative 4 allows a facility to install and properly operate and maintain an approved technology, thus subjecting itself to a more streamlined compliance regimen. Today's rule approves cylindrical wedgewire screens for use by facilities sited on freshwater streams and rivers, among other criteria (see § 125.99(a) for more details on the specific criteria). EPA believes, based upon extensive research, that the majority of facilities with the appropriate site conditions, and that have installed and properly operate and maintain submerged cylindrical wedgewire screen technology, should be capable of meeting the performance standards set forth in § 125.94. For facilities that fail to meet performance standards through the approved design and technology alternative, the Director may amend the facility's permit to require the use of design and construction technologies, operational measures, and/or restoration measures, in order to meet the performance standards. For a discussion on the applicability of cylindrical wedgewire screens and their deployment in high-debris waterbodies, see Chapter 3 of the Technology Development Document.

Comment ID 316bEFR.088.008

Subject Matter Code 7.03

Available I&E technologies

Author Name Sonia S. Kim

Organization Omaha Public Power District

EPA based the presumptive performance standards on three technologies outlined in the proposed rule. Design and construction technologies such as fine and wide-mesh wedgewire screens, aquatic filter barrier systems, barrier nets, modified screens and fish return systems, fish diversion systems, fine mesh traveling screens, and fish return systems were outlined in the proposal. There are many technological strategies for the reduction in impingement and entrainment that were not included. It should be noted that state of the art technologies which may include other methods than those specifically listed may be used to achieve the applicable reduction rates associated with fish protection. It is recommended that research regarding existing or emerging technologies be further established, or that technologies be opened for further discussion. At this point, many reduction technologies are available, however the determination of the best or most economical, efficient, and cost effective methodologies is yet to be determined.

EPA Response

EPA agrees that there are many technological strategies, as well as operational and restoration measures, available to facilities to meet the requirements in today's rule. The discussion of certain technologies in the preamble to today's rule and supporting documentation does not preclude a facility from demonstrating that other, more innovative technologies would accomplish the desired results. EPA encourages the investigation of newer technologies and welcomes the distribution of any documentation that demonstrates its technologies.

EPA believes that the determination of which technologies are the most cost-effective is a process best left to the facility and its respective permitting authority. Today's rule does not make any such pre-determination.

RFC: Use of previous demonstration studies

Author Name Sonia S. Kim

Organization Omaha Public Power District

Research and analysis should not have to be conducted each time an NPDES permit is reissued. The concern is that the studies would be conducted on an ongoing basis throughout the lifetime of a permit if designated as a permit renewal requirement. It is true that historical records may have already been established and used as a basis for subsequent data or information forwarded to permitting agencies. It is believed that a less frequent monitoring or study period can be established for efficiency and validity of data as it changes over time and subject to the discretion of the State Director.

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to 316bEFR 041.126 for a discussion. Reduced monitoring requirements are at the discretion of the Director.

RFC: Use of previous demonstration studies

Author Name Sonia S. Kim

Organization Omaha Public Power District

Past research and studies should be allowed in order to establish a framework for determining if a utility has previously proved, with concurrence from regulatory agencies that current technologies at a site exhibit minimal or low impingement and entrainment occurrences as associated with levels in the proposed rule. For instance, OPPD has conducted previous studies which satisfied our State Administrator that mortality rates were already sufficiently low. Monitoring requirements, once mandated, have been deleted as unnecessary. Such prior reports with updated information subject to the discretion of the State Administrator should be allowed.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule; however, existing data that is reflective of current conditions may be used to support the required studies. Please see response to comment 316bEFR.040.001 for details.

Comment ID 316bEFR.088.013

Subject Matter Code 10.1

General: cost tests

Author Name Sonia S. Kim

Organization Omaha Public Power District

Previous cost estimates into modification technologies should be allowed to demonstrate that due to cost, it would not be feasible to construct, alter, or modify existing systems. Previous reports should be used to assist in the determination that once-through cooling systems are adequate for minimal adverse environmental impact and that the cost of retrofitting and installation of cooling towers may not be feasible at a site. Also, environmental disadvantages of cooling tower installations should be addressed for an objective assessment of alternatives.

EPA Response

Previous cost estimates may be used in estimating the compliance costs at a facility or for use in the cost-cost tests. The final rule requires the cost estimates to meet a particular standard for engineering cost estimates, but the age of the estimates is not defined as one of those criteria. The Agency notes that past cost analysis may not in all cases (as the commenter asserts) prove that modifications are infeasible.

RFC: Proposed use of restoration measures

Voluntary restoration measures were not readily defined in the proposed rule and perhaps that is appropriate. Such measures are likely numerous, and should be up to the discretion of the State regulatory agency and affected facility based on their unique knowledge of local environmental conditions and needs.

EPA Response

EPA agrees with the commenter that there are many types of restoration measures.

For a discussion of the roles and responsibilities of the permitting authority and the permit applicant, see EPA's response to comment 316bEFR.060.026.

RFC: Appropriateness of "significantly greater"

"Significantly Greater": The proposal provides for a site-specific determination of the "best technology available" if the costs of compliance at a site would be "significantly greater" than either the benefits of meeting the performance standards or the cost of what the agency considered. EPA must provide a clear definition of what is meant by "significantly greater." To maximize net benefits to society, economic theory would dictate that this should be interpreted to mean any cost benefit ratio greater that 1:1. This reflects the most cost-effective, performance-based outcome.

EPA Response

RFC: Use of previous demonstration studies

Author Name Tim Reeves

Organization Southern Illinois Power Coop

Application to Existing Facilities: The proposal should include a process for approving existing intake technologies as “best available” if it can be shown that the facility is not causing adverse environmental impact or the technologies have been deemed “best available” by the state. Such a process is reasonable since Section 316(b) has been in effect since 1972 and has been implemented case-by-case at many sites. There are many electric generating facilities for which there is already a high degree of confidence that the facility is not causing adverse environmental impact or that it has already installed the best technology available. In addition, if the facility has data indicating that the amount of entrainment and impingement is so small that there is no significant harm to the aquatic community or the environmental impact is of so little economic and environmental significance that the costs of a comprehensive 316(b) study would be significantly greater than its benefits, then there should be no need for either further studies or for additional intake technology.

EPA Response

Subject Matter Code 21.04

Determination of compliance

Compliance Assessment: Since there is such variability in biological systems, it is not practical to require the permittee to meet a specific numerical reduction in affected organisms. The proposed performance criteria should not be directly implemented as enforceable permit limitations. Rather, when the existing technology is not the “best available”, the permit should require the installation of technology identified collaboratively by the permittee and the state. Then compliance with the permit would be based on installation, operation and maintenance of the selected technology.

EPA Response

Please see EPA's response to comment 316bEFR.081.006.

Subject Matter Code 17.08

Option: UWAG's recommended approach

The Environmental Protection Agency (EPA) should adopt the UWAG site-specific approach and definition of adverse environmental impact. EPA should maintain in the regulations the highest flexibility in allowing for site-specific determinations of adverse environmental impact, and for voluntary restoration to meet best technology available (BTA) performance standards. The inclusion of a more flexible site-specific option and voluntary restoration will allow the permittee to cost-effectively protect the environment, which benefits all consumers of electricity.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Author Name David W. Kay

Organization Southern California Edison CO

Subject Matter Code 7.02

Performance standards

The proposed rule must be revised so the "calculation baseline" is not the only surrogate measure for the threshold of adverse environmental impact; the rule must provide for use of alternative performance standards that allow demonstrating that the existing intake structure is not significantly adversely impacting populations of aquatic life in the area.

For example, SCE's Clean Water Act Section 316(b) demonstration study for SONGS showed that with the present CWIS configuration, any individual of any age class among the target species examined would incur at most a 3% chance of being entrained (and presumably killed) in the CWIS. In other words, the adverse impact to marine life with the existing CWIS configuration is insignificant. Nevertheless, examination of seven additional CWIS technology retrofits showed that the incremental improvements in survival for all but one target species were less than 0.2%. Therefore, any technology retrofit would not result in any significant reduction in entrainment or impingement losses.

However, EPA's proposed numerical performance standards could require SCE to either install additional technology, implement restoration, or perform a cost/benefit analysis. While EPA's proposed performance standards may be achievable, undertaking any of these efforts to achieve those standards would be a waste of public and private resources given the knowledge that the current CWIS configuration causes no significant adverse environmental impact. EPA should therefore allow a permittee who has already made such a demonstration to be deemed in compliance with Section 316(b) if the authorized state permitting agency concurs.

EPA Response

The objective of section 316(b) includes population effects but is not limited to those effects. EPA has considered the consequences associated with the loss of large numbers of aquatic organisms, including impacts on the stocks of various species, loss of compensatory reserve due to the deaths of these organisms and the overall health of ecosystems. Given all of these considerations, EPA determined that there are multiple types of undesirable and unacceptable adverse environmental impacts which result from impingement and entrainment and which must be minimized. Today's rule, however, also authorizes site-specific determinations of Best Technology Available for minimizing adverse environmental impact based on cost-benefit determinations.

RFC: Proposed use of restoration measures

SCE supports restoration as a tool by the permittee to minimize adverse environmental impact. SCE believes, however, that restoration should be a voluntary compliance option.

EPA Response

For a discussion of the extent to which restoration measures are voluntary, see EPA's response to comment 316bEFR.060.022.

Comment ID 316bEFR.090.004

Author Name David W. Kay

Organization Southern California Edison CO

Subject Matter Code 21.09

Permit applications/implementation schedule

The proposed rule should make clear that time for agency review must be built into any schedule either prescribed by the rule itself or required by an NPDES permit condition. Permittees and their regulating agencies should be allowed to negotiate reasonable schedules for designing and implementing appropriate demonstration studies, as well as implementing any resulting technology or restoration commitments, without being subject to noncompliance enforcement or citizen lawsuits.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

EPA recognizes that installation of a technology or other means of reducing impingement mortality and/or entrainment at a facility may be a lengthy process. If a facility plans on installing a technology, the facility may demonstrate that it will select design and construction technologies, operational measures, and/or restoration measures that will in combination or alone, meet the performance requirements in 125.94, in its application. The facility could outline a possible installation timeline in its Proposal for Information Collection for review by the Director. The Director may approve an installation timeline for implementation of the design and construction technologies, operational measures, and/or restoration measures. For a discussion of ways of demonstrating compliance with today's rule, see the preamble to the final rule.

Comment ID 316bEFR.090.005

Subject Matter Code 18.02

RFC: Use of previous demonstration studies

Author Name David W. Kay

Organization Southern California Edison CO

Once a successful Section 316(b) demonstration is made, maintaining and operating the accepted technology for the life of the plant should be enough. At a minimum, there should be no reconsideration of Section 316(b) compliance for at least ten years, absent new evidence that conditions have so changed that the aquatic community is subject to new adverse impacts from the CWIS.

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. However, permit conditions will be reviewed at each permit cycle and adjustments, if any, will be made as appropriate. Please see response to 316bEFR 041.126 for a discussion.

Organization GE Aircraft Engines

Subject Matter Code 3.01

Definition: Existing Facility

As a business engaged in manufacturing and service operations, GEAE is particularly concerned that the Phase II proposed rule is drafted in such a manner as to potentially regulate facilities whose primary business activity is not related to the generation of electric power, as a result of the presence of cogeneration operations within such a manufacturing facility. GEAE recommends that the Agency clarify the final rule to make clear that facilities whose primary business activity is not power generation are not subject to this phase of the CWIS rule.

EPA Response

Subject Matter Code 3.06.01

Withdrawal threshold of 50 MGD

Author Name Karen W. Couch

Organization GE Aircraft Engines

In addition, GEAE is concerned that applicability determinations in the Phase II rule are proposed to be made on the basis of design, rather than actual, flows. GEAE urges the Agency to revise the rule to make clear that these rules do not apply where a permittee is willing to accept permit limitations that restrict its actual cooling water intake to below regulatory levels.

EPA Response

Please see response to comment 316bEFR.019.003.

Comment ID 316bEFR.091.003

Subject Matter Code 3.01

Definition: Existing Facility

Author Name Karen W. Couch
Organization GE Aircraft Engines

Applicability of the Phase II Rule Should be Limited to Facilities Whose Primary Business Activity is Electrical Power Generation

On Page 17135, Section IV of the proposal, EPA states, “Today’s rule does not apply to facilities whose primary business activity is not power generation, such as manufacturing facilities that produce electricity by cogeneration.” However this statement appears to be in conflict with provisions in the proposal that indicate the rule could apply to cogeneration facilities (see. e.g., applicability statement regarding cogeneration facilities at Page 17128, Section II, which states that “only that portion of the cooling water flow that is used in cogeneration process shall be considered when determining whether the 50 MGD and 25% criteria are met.”

The confusion resulting from the above statements should be clarified in the final rule by making clear that the Phase II rule applies only to facilities whose primary business activity is electric power generation. In particular, EPA should clarify that, where cogeneration units are located at a facility engaged in manufacturing, but the primary purpose of the power generation facility is to support the manufacturing business, the facility would not fall under Phase II.

This issue could be clearly resolved in the final rule by defining the primary business activity by Standard Industrial Classification (SIC) and/or North American Industry Classification System (NAICS) codes, and then limiting the applicable codes to those whose primary business is electric power generation (e.g. where the facilities primary SIC code does not begin with 49, the facility would not fall under Phase II).

EPA Response

See responses to 316bEFR050.002 and 316bEFR050.001.

Comment ID 316bEFR.091.004

Author Name Karen W. Couch

Organization GE Aircraft Engines

Subject Matter Code 3.06.01

Withdrawal threshold of 50 MGD

Applicability Determinations Should be Based Upon Permitted flow Limitations Rather Than Design Intake Capacity

The proposal sets a design intake flow capacity of 50 million gallons per day (MGD) as one of the triggers for applicability of Phase II. In many cases, however, actual intake flows are well below design capacity. This may occur for a variety of reasons, including physical limitations which effectively limit flows to less than design capacity (e.g., in a tidal water body intake structures are located such that they are out of the water during low tide), legal limitations (i.e., the facility may have accepted a permit that limits flow to a fraction of design capacity) or operational reasons (e.g., the intake in question may only be operated intermittently, or may be operated well below design capacity).

We strongly urge EPA to recognize the above limitations in setting applicability criteria. In particular, where the facility has accepted a permit limit that restricts cooling water flows to less than 50 MGD, EPA should use permitted capacity rather than design capacity to determine Phase II applicability. Because it is a legally enforceable limit, permitted capacity provides a more accurate index of the potential impact of the facility. In addition, this would give facilities an incentive to agree to restrictions of theft cooling water intake, thereby reducing the potential for impingement and entrainment.

The applicability criteria should also consider other limitations on flow. For example, under the proposed wording the presence of two pumps, each of 25 MGD capacity for the purposes of redundancy, would trigger rule applicability, when in fact only one pump is operated at a time and the second pump is in place only to back up the first pump should the first pump fail or require maintenance. Applicability is clearly not warranted in a case like this.

Similarly, pumps might have variable speed drives for the purpose of regulating water flow. The fact that the top capacity (highest rpm) might equate to 50 MGD and would result in rule applicability is not appropriate in cases where the pumps do not continuously operate at that top capacity. Another example would be an intake with a capacity of 50 MGD that is run infrequently. On a prorated basis, the daily withdrawal equivalent would be much lower than 50 MGD. The draft rule does address different performance standards for low capacity utilization, but does not consider low utilization in determining applicability.

Finally, the proposed rule also fails to recognize the relevance of intake design as a limiting factor in situations of changing water levels (such as tidal waters). As an example, in a tidal environment in which a CWIS is out of the water during certain lower tides and therefore unable to operate all day, this should be taken into account in determining applicability. A CWIS that has “design capacity” of 50 MGD, but which is out of the water during tides below half tide (equal to half the day), would in reality only be able to deliver 25 MGD. In such a case this facility clearly should not be subject to the rule.

EPA Response

Author Name Karen W. Couch
Organization GE Aircraft Engines

Subject Matter Code 3.06
RFC: Cooling water withdrawal thresholds of 25%

Only Cooling Water Used in Electric Power Generation Should be Considered in the Phase II Rule

The rule proposes, as an applicability criterion, that a facility must both generate and transmit electric power. The rule, however, does not clearly state that the cooling water being considered in calculating capacity is limited to cooling water involved in electric power generation. It is recommended that EPA more clearly define “cooling water”, and that this definition be restricted solely to cooling water related to electric power generation. Cooling water used for other cooling purposes should be specifically excluded in the calculation of capacity. This is consistent with the EPA’s stated intention that the rule apply only to facilities whose primary business is electric power generation.

EPA Response

In response to this comment and others like it, today’s rule addresses only those facilities whose primary activity is the generation and transmission of electric power. In Phase III, EPA expects to address existing facilities that use cooling water intake structures for other industrial purposes.

Subject Matter Code 3.05
Facilities not covered by today's proposal

Facilities Not Otherwise Subject to Phase II Should Not be Regulated Under This Rule on a Best Professional Judgment Basis

Proposed 40 CFR 125.9 (c) states that existing facilities not otherwise subject to this rule may be regulated under Phase II on a case-by-case, Best Professional Judgment (BPJ) basis. GEAE encourages EPA to omit this provision as it threatens to result in arbitrary overlaps between Phase II and Phase III facilities based on the judgment of individual permit writers and result in uncertainty, confusion, controversy and possible litigation. Further, EPA has provided no guidance or details concerning the underlying criteria upon which the BPJ provision would be implemented, preventing more detailed comment on this provision. Because facilities potentially subject to this provision will in all likelihood be subject to the CWIS Phase III rule in any event, there is no justification for incorporating this BPJ provision into this rule.

EPA Response

Other technology-based opt. under consideration

Alternative Means for Determination of Whether Performance Standards are Attained Should be Incorporated into the Rule

EPA seeks comments on other technology based options in VI.B, starting on page 17154. We do not believe all facilities should be required to meet performance standards for reducing impingement mortality and entrainment losses based solely on a reduction in intake flow to a level commensurate with that which can be attained by closed-cycle recirculating system. Numerous economic, land use, operational, safety, and other factors often make the consideration of closed-cycle cooling infeasible. Likewise, we do not believe this standard should be applied based on a specific water body type or proportion of water body flow withdrawn. Further, there should be broad allowance and flexibility to use innovative technologies, operational changes, and/or restoration to achieve mortality reduction.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161). Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

Subject Matter Code 21.09
Permit applications/implementation schedule

Permitting Issues Should be Taken into Consideration

EPA's intent to implement this rule through individual NPDES permits raises a series of issues. In many cases a considerable length of time (two to three years) will be required to propose a data collection plan, obtain approval for such plan, collect and analyze the data, use the data to determine performance status and evaluate potential technologies, and prepare a Best Technology Available (BTA) recommendation. Sufficient time for all of these steps, including the Agency approval steps, should be built into the permitting process, either through a schedule set out or suggested in the rulemaking itself, or as part of the individual NPDES permit. Where permittees have already submitted a renewal application when the final rule is issued, or their renewal application is due within two-three years, they should be "grandfathered" from the CWIS rule requirements until the next permit application; otherwise they will have to completely revamp their renewal application to incorporate these requirements, and considerable permitting delays would likely result. For facilities that do not have sufficient time to go through the entire process of gathering and analyzing data to support BTA recommendations before the renewal application is due, the permit could incorporate a reasonable compliance schedule for gathering the necessary data. Finally, EPA proposed rule indicates that at every permit renewal, a "comprehensive reevaluation" of the 316(b) demonstration is appropriate. GEAE believes that there is no need to repeat this very expensive and time-consuming analysis every five years; absent significant changes in plant operations or significant adverse changes to the populations at issue, the initial demonstration should not be reconsidered so long as the operating technology or other measures are being maintained.

EPA Response

See response to comments 316bEFR.021.008 and 316bEFR.035.019.

Organization GE Aircraft Engines

The Rule Should Provide for use of Relevant Existing Data

On page 17143 of the rule (first column), EPA indicates that "Owners and operators may use existing data for the Study as long as it reflects current conditions at the facility and in the water body from which the facility withdraws cooling water." We agree that the metric for data acceptability should not be its age, but its relevance. We recommend that available existing data be presumptively considered to be representative of current conditions, unless significant and documented changes have occurred in the watershed subsequent to its collection. Only where known or documented events have occurred since the data collection event(s) that have likely substantially altered the community of shellfish and finfish within the source water body should these data be discounted. To resolve questionable data sets, we suggest that EPA consider a small-scale supplemental data collection effort that could validate a subset of the historical sampling effort. This would provide a means to verify whether historical data are still generally representative of current conditions. Similar comparative methods have been used by the Federal Energy Regulatory Commission to meet hydroelectric relicensing data requirements

EPA Response

EPA agrees that existing historical data, as long as it reflects current conditions, should be available for use in completing studies. Please see response to comment 316bEFR.040.001 for details.

Performance standards

Author Name Karen W. Couch
Organization GE Aircraft Engines

EPA Should Clarify How Baseline Mortality and Impacts are to be Determined

The description of the calculation of baseline is confusing and unclear. Specifically, the description of the baseline calculation with respect to impingement does not provide sufficient detail to evaluate what constitutes a "shoreline intake with the capacity to support once-through cooling and no impingement mortality controls." This description does not address variations among facilities, such as design capacity, actual annual water usage, and site specific variables such as intake location relative to a specific water body and/or locations of fish and shellfish populations. The proposed regulations seem to suggest that the baseline may be estimated either by evaluating existing data for a nearby facility with no impingement or entrainment control technology, or by evaluating the abundance of organisms in the source water body in the vicinity of an intake structure potentially susceptible to impingement and/or entrainment.

It is suggested that the calculation of baseline be a function of the design capacity of the cooling water system, the annual usage of the system at full capacity, and the density of organisms in the zone of influence of the CWIS. Compliance with the performance criteria would then be based on the percentage reduction in impingement and entrainment from baseline (i.e., capacity) to actual use. This approach credits facilities that employ operational controls to operate at less than full design capacity, in addition to other technologies that may be employed to reduce impingement and entrainment from a worst case baseline impact.

We recommend that an equivalent-adults model be used on an annual basis to evaluate impingement reductions. Equivalent-adults per year, rather than fish per volume of water, more fairly evaluates the overall impact of a given facility on the environment. Impingement/entrainment reduction goals are in essence a mortality reduction goal. However, the biological necessity of this reduction at smaller facilities with minimal impacts is unclear. For example, facility A is found to impinge X number of larval fishes, which equate to Y number of equivalent adults. If the number of impinged adult equivalents is insignificant compared with other sources of mortality (e.g., predation, commercial fishing, recreational fishing, etc.) then reductions may have little or no benefit on a biological basis. In cases like this, stock-recruitment models could be used to assess the significance of impacts. They can evaluate whether the impacts could be readily off-set by the compensatory reserve of a given population (i.e., the capacity of the population to offset increased mortality).

EPA Response

For discussions on the basis for and implementation of the calculation baseline, please see response to comments 316bEFR.308.014 and 316bEFR.063.022, as well as the preamble to today's rule.

Subject Matter Code 21.03

Monitoring requirements

The Purpose of Compliance Monitoring Should be to Verify Proper Operation and Maintenance of the Appropriate Technologies

Since EPA's performance technologies are based on well-defined intake technologies that are in widespread use and that have been found to be effective (i.e. intake screens, etc.), the best way to assure compliance following installation of BTA is to ensure that the selected technologies are being installed, maintained and operated correctly in accordance with design. Compliance monitoring requirements that involve further studies to determine whether specific mortality reductions are in fact being achieved are very expensive and time consuming; in addition, given the complexity and variability of aquatic communities and the many variables involving in assessing potential impacts in a waterbody, they may generate misleading results. As currently proposed, compliance monitoring is therefore likely to generate large expenses, but produce little certainty or environmental benefit. Therefore, once BTA has been established, GEAE recommends that the focus of compliance monitoring be to document that the selected technologies have been implemented and are being properly maintained.

EPA Response

Please see EPA's responses to comments 316b.EFR.041.119 and 316bEFR.074.023.

EPA has included in today's final rule several alternatives for achieving compliance, including demonstrating compliance with a Technology Installation and Operation Plan in place of numeric performance requirements. Please see EPA's response to comment 316bEFR.017.003 for an explanation of what constitutes compliance with today's performance requirements. Also please see the final rule preamble section IX for a discussion of the Technology Installation and Operation Plan.

RFC: Appropriate spatial scale for restoration

Watershed Should be Defined Broadly

We recommend use of the USGS eight-digit hydrologic unit to define watershed relative to restoration opportunities. This scale of watershed allows flexibility but also helps to keep any restoration efforts relevant to facility-related impacts. However, we would encourage EPA not to limit permittees to this particular watershed area in all cases. It is important to allow for a situation where a permittee may need to go outside this hydrological unit to find a high benefit to cost ratio opportunity with a high potential for permanent success. We suggests that, if a permittee wishes to conduct restoration activities outside of this hydrologic unit, that EPA require permittees to provide written justification stating why the hydrological unit containing the facility does not afford a feasible restoration opportunity, and how a project outside of the hydrologic unit is relevant to the facility-related impacts. This provides obvious value for watersheds that affect coastal ecosystems where benefits in a broad reach of the shoreline could be expected to benefit the natural resources of the estuaries and the marine environment regardless of whether their precise location is in a single watershed.

EPA Response

For a discussion of the appropriate scale on which to conduct restoration measures and of the permitting authority's role, see EPA's response to comment 316bEFR.212.001 and 316bEFR.059.008.

Organization GE Aircraft Engines

Subject Matter Code 11.01
RFC: Proposed use of restoration measures

The Rule Should Encourage Consideration of Multiple Approaches to Meeting Performance Standards, Including Emphasis on Restoration Activities

Because of the tremendous variation that will be encountered in implementing these rules (every watershed will have unique characteristics, and each facility will also vary), the Phase II rule should provide for maximum flexibility in the approach to meeting performance standards for impingement and entrainment. This flexibility should include the potential for exclusive use of restoration actions as a method of compliance.

Pages 17146 through 17148 discuss the role of restoration in the Rule. We support the use of restoration to compensate for ongoing impacts and encourage EPA to allow a broad range of restoration measures that can be directly or indirectly linked to increases in the abundance of shellfish and/or finfish affected by CWIS. For example, restoration of nursery and refugia habitat, implementation of storm water control measures, removal of exotics or other undesirable species, watershed management programs, and the placement of land into conservation are steps that could be taken to ultimately improve the health of shelffish and finfish populations.

Restoration actions will provide benefits beyond those that can be directly linked to shellfish and finfish. For example, tidal wetland restoration would provide habitat for terrestrial and semiaquatic mammals and birds. Restoration activities will also likely reduce the level of environmental stress attributable to factors other than the facility (e.g., urban runoff). One of the long-term benefits of meeting performance standards through restoration will be that the restoration action will provide permanent value, regardless of facility operational status. For example, if a facility ceases to operate, the environment will benefit greatly because the facility-associated impact will cease and the restoration, which was conducted to offset the impact, will continue to provide ecological services. Allowing restoration to be used to meet performance standards will result in healthier ecosystems through time, with fewer environmental stressors.

EPA Response

EPA believes the requirements for restoration measures in the final rule offer permitting agencies and permit applicants substantial flexibility.

Restoration measures may be used in lieu of or as a supplement to design and construction technologies and operational measures.

All restoration measures must meet the requirements described in the final rule.

For a discussion of the ancillary benefits associated with restoration, see EPA's response to comment 316bEFR.032.011.

RFC: Performance/effectiveness of restoration

Use of the Habitat Equivalency Analysis Method to Determine Compensation for CWIS Impacts

We encourage EPA to address the use of natural resource economic models, such as the Habitat Equivalency Analysis (HEA) method, to demonstrate full compensation when restoration is used to offset impingement and/or entrainment impacts. Methods such as HEA can be used to show that the level of ecological service provided by the proposed restoration activity is equal to or greater than the ecological service loss associated with the amount of impingement and/or entertainment in excess of performance standards. This economic asset replacement model, which utilizes an ecological service-to-service approach, was developed by the US Department of the Interior and the National Oceanic and Atmospheric Administration. It is widely used and has been applied to many different habitat types. The method is supported by many Federal Agencies (NOAA, 1997; EPA/DOI, 1999) and in Federal Court Rulings (USA vs. M. Fisher et al. 1997) as a valid approach for determining compensation for environmental impacts. The origin of this approach is presented in the 1991 EPA commissioned paper entitled "Scientifically Defensible Compensation Ratios for Wetland Mitigation." The service-to-service approach has been used in many states (California, Texas, New Jersey, South Carolina, Virginia, Indiana, Louisiana, Florida, Oregon, Idaho, Alabama, Maryland, plus others). Several peer-reviewed journal articles and federal government reports discuss the merits of this approach (King and Adler, 1991; Unsworth and Bishop, 1994; NOAA, 1995; NOAA, 1997; NOAA, 1998; Fonseca, et al., 2000).

The HEA approach is effective in that its success is built around the participation and expertise of stakeholders. By using a team or consensus approach to define the assumptions and parameters of the model, stakeholders "own" the results from the model. The HEA approach also takes into account the changing value of a restoration action through time. As EPA indicates, the value of a restoration action will likely be manifested overtime, with the full level of ecological service not being realized for several years. HEA can be used to scale the size of the action accordingly to result in no net loss of ecological services through time.

EPA Response

EPA does not require in the final rule one particular approach to assessing the appropriate level of performance from a restoration measure. Habitat Equivalency Analysis (HEA) is one of a variety of methods that may offer some useful perspectives to permitting authorities, permit applicants, and the public.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

Any restoration measure must meet all of the requirements described in the final rule.

RFC: Definition of "adverse environmental impact"

DEFINITION OF ADVERSE ENVIRONMENTAL IMPACT

EPA should define "Adverse Environmental Impact" (AEI). The loss of a single fish or a single egg, or even a large number of them does not constitute an AEI. There are at least two reasons why even large losses of forage species may not damage an aquatic community or population. One is the large losses (especially of eggs and larvae) occur already in nature, and the Cooling Water Intake Structure (CWIS) loss may be insignificant compared to these other losses. There is also evidence entrainment mortality in once through cooling water systems is significantly lower than EPA's estimates. The other reason is fish populations have "compensatory" mechanisms that produce more or larger fish in response to the lower fish densities. Due to their size, larger water bodies such as the Great Lakes offer abundantly more opportunities for the natural compensatory process to replenish losses of the aquatic communities. An appropriate definition of AEI would recognize that (1) as a matter of basic biology, losses occur naturally even without a CWIS and have little or no effect on the vigor of the aquatic populations or community and (2) such losses often have little or no effect on the public's use and enjoyment of aquatic resources.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule. For more information regarding entrainment survival, please see the chapter, Entrainment Survival, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule.

Available I&E technologies

EPA's performance standards in this rule are based on certain specific intake technologies that EPA says are found to be effective (e.g., wedge wire screens, fine mesh fish screens, or aquatic fabric filter systems or a traveling screen with fish return systems). Applications of these systems are limited and have experienced inherent maintenance problems when used in certain situations. These systems are prone to pluggage, particularly from zebra mussels and are susceptible to adverse weather conditions (i.e., icing and storm damage).

EPA Response

In establishing the performance standards for today's final rule, EPA focused on the most widely-deployed and commercially-available technologies used to mitigate impingement and entrainment. EPA disagrees with the commenter's assertion that application of the systems evaluated as part of today's rule is limited. While no one technology is universally applicable, and all systems will experienced diminished performance if not properly maintained, EPA believes that today's rule maintains a desired flexibility for facilities to decide between any combination of design and construction technologies, operational measures, or restoration measures to meet today's requirements.

RFC: Proposed use of restoration measures

EPA must elevate its consideration of the use of site-specific alternatives to cooling towers, to meet the entrainment and impingement requirements in this rule. Alternative measures could include wetland construction and mitigation, fish restocking and relocation of intakes. The application of these alternatives or combinations of these alternatives versus the installation of cooling towers could provide a wide range of benefits for entire watershed ecosystems throughout the Great Lakes and other areas of the country. For example, constructed wetlands could be utilized for fish hatcheries and restocking programs. The trout and salmon populations in the Great Lakes are exclusively the result of stocking. Wetlands would establish breeding grounds in additional locations and in areas not affected by existing CWIS. We feel the use of these alternative measures would increase the variety and types of benefits and could offer long lasting solutions to the entrainment/impingement issues associated with traditional cooling towers and standard intake technologies.

EPA Response

Cooling towers are not required in the final rule.

In the final rule, EPA allows use of restoration measures to minimize or to help to minimize the adverse environmental impacts that derive from impingement and entrainment of aquatic organisms. Restoration measures must meet the requirements described in the final rule.

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

We also have several concerns with cooling towers, which are as follows:

-Cooling towers are consumptive water users. This is contrary to the nationwide movement to promote water conservation. This movement includes the Annex 2001 rule, which is attempting to reduce future uses of water from Lake Michigan. Water conservation is even part of new home construction codes in many communities. The codes regulate the use of low flow toilets and water conserving appliances.

-There are air pollution issues and energy penalties associated with cooling towers.

-Cooling towers cause icing problems with plant equipment and surrounding towns and industries. To prevent icing of equipment, cooling towers must be installed certain distances from electrical substations and must allow for wind drift. Cooling towers installed in operating facilities will encounter problems with existing substructure pipelines, underground electrical lines and natural gas lines. There can also be simple space limitations at existing facilities for retrofitted cooling towers. Two of our facilities have very limited property space and will encounter problems if required to install a cooling tower.

-Costs of cooling towers are high. Our experience indicates the initial capital cost of a cooling tower for a new 500 MW generating facility is in excess of twenty (20) million dollars and annual O&M costs are approximately $50,000.00.

-There is evidence that the mortality of aquatic organisms is one hundred (100) percent in the cooling tower recirculating water systems..

Subject Matter Code 3.05

Facilities not covered by today's proposal

BEST PROFESSIONAL JUDGMENT (BPJ)

The proposed Phase II rule contains a provision that is potentially the source of regulatory uncertainty. Proposed 40 CFR, Part 125.90(c) states: "Existing facilities that are not subject to this sub part (the Phase II rule) must meet requirements under Section 316(b) of the CWA determined by the Director on a case-by-case, best professional judgment (BPS) basis." This provision confuses the distinction between Phase II and Phase III facilities. It seems that EPA is directing permit writers to impose BPJ Section 316(b) conditions on Phase III facilities before the Phase III rule is promulgated and on Phase II facilities which fall below the applicability thresholds included in this rule. The benefits of the phased rulemaking addressing different types of facilities in different rules will be eliminated by including this provision in the Phase II rules. EPA claims that the authority for applying 316(b) BPJ interpretations already exists even though it has never included such a requirement in its regulations. If EPA believes that its rules have always allowed imposition of case-by-case requirements for cooling water intake structures, there is no need to modify the regulations now. We suggest the 125.90(c) section be deleted from this rule.

Permit applications/implementation schedule

125.92 COMPLIANCE SCHEDULES

This section simply states a facility “must comply with this subpart when an NPDES permit containing requirements consistent with this subpart is issued”. Time is needed to collect the required data and prepare the application. A large amount of biological data will have to be collected and analyzed. The calculation baseline required in the rule will have to be developed and reviewed. If changes in the intake are needed or alternative compliance measures are chosen, engineering studies and construction schedules will be required. If part of the solution is a restoration of a wetland or building a fish hatchery, time will be needed to complete these projects. Reasonable compliance schedules must be included by EPA in this regulation, particularly for facilities with administratively extended NPDES permits.

EPA Response

RFC: Use of previous demonstration studies

EPA's proposed rule also suggests "a comprehensive re-evaluation of the 316(b) demonstration must be completed every time a permit is renewed." Once a successful 316(b) demonstration is made, maintaining and operating the technology for the life of the plant should be enough, unless conditions have so changed that the aquatic community is threatened or significant changes have occurred in plant operations. Surely, Congress did not intend through the CWA to require electrical generating stations to redesign and rebuild their CWISs every five years.

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to 316bEFR 041.126 for a discussion.

Subject Matter Code 2.04

EPA's legal authority to:

125.94 (a) (1) and (2)

This section describes the three alternatives available to a Phase II existing facility to minimize adverse environmental impact. The first two alternatives state "operational measures" can be used to meet the requirements of this subpart and hence the requirements of Section 316(b) of the Clean Water Act. 316(b) states "Any standard established pursuant to Section 301 and section 306 of this Act and applicable to a point source shall require that the location, design, construction and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact." This definition does not include reference to "operational measures" as an option to meet the requirements of 316(b). In this proposed rule, EPA makes several references to the use of operational measures as a way to meet the 316(b) requirements. EPA does not have the legal authority, under Section 316(b) of the CWA, to regulate operation of cooling water intakes and with this subpart has bypassed due process of law. Curtailment of the operations of electrical generating facilities would have serious detrimental effects on local businesses with reduced power supplies and could impact the ability to meet requirements of other authorities for system reliability. We suggest EPA remove all "operational measures" phrases and references in this proposed rule.

Subject Matter Code 8.03
Proposed standards for Great Lakes

125.94(b) PERFORMANCE STANDARDS

This section contains the specific 316(b) requirements for the different types of U.S. water bodies. The requirements for the Great Lakes are more stringent than fresh water rivers, streams and other lakes. Facilities located on the Great Lakes must reduce entrainment as well as impingement of aquatic organisms. This additional requirement indicates EPA believes the Great Lakes are uniquely sensitive to entrainment and impingement. NiSource agrees the Great Lakes represent a unique resource deserving special protection. With regard to impingement and entrainment, EPA seems to be confusing uniqueness and sensitivity. We feel the Great Lakes are unique and have a unique fish population, but these fish are not uniquely sensitive. To the contrary, the fish communities in the Great Lakes are probably less sensitive to entrainment than in many other lakes and reservoirs.

The unique feature of the Great Lakes fish population is the presence of large numbers of both native and introduced salmonids. Although an unusual resource, the life history of these species indicate the opposite is true and that the population is more resilient than in more confined ecosystems.

The adults and juveniles of these coldwater species spend much of their time in the offshore cooler water. Thus, for most of the year, they are not vulnerable to impingement. It is important to note that trout and salmon populations in Great Lakes are exclusively the result of stocking. Thus, there are no trout, salmon eggs, or larvae to be entrained. This assessment is supported by data EPA provided in the 316(b) Phase I Rule. None of the 15 species most commonly impinged is a salmonid (Table 11-8 EEA). Only one salmonid (lake trout) appears in EPA's entrainment table (Table 11-6), it was at a single plant (out of 25 plants on Lake Michigan alone, Kelso and Milburn 1979), and it was entrained in low numbers.

Therefore, given the life history characteristics of the group of fishes of most concern in the Great Lakes (i.e., salmonids), no special level of concern is warranted. We feel the sampling requirements for the Great Lakes should be commensurate with potential sensitivity, and certainly no more stringent than those for lakes or reservoirs.

Among non-salmonids, most of the highly valued recreational Great Lakes fishes are also relatively insensitive based on life history characteristics. Besides salmonids, four species form the bulk of the Great Lakes sport catch: yellow perch, small mouth bass, northern pike, and walleye.

Yellow perch is of particular concern in Lake Michigan now because their population is currently very low. Yellow perch lay their eggs in long gelatinous strips, which greatly reduces the likelihood that their eggs will be entrained. Some yellow perch populations spawn well offshore, further reducing the likelihood of either entrainment or impingement losses.

Small mouth bass are nearshore nest builders. Upon hatching, the male guards the fry for a number of days. Because of this nest guarding, non-drifting behavior, smallmouth bass larvae are not frequently entrained, even where adult populations may be abundant (EA 1987).

Northern pike are primarily restricted to shallow embayments along the Great Lakes (which is not where the power plants are). They spawn in very shallow areas over dense aquatic vegetation. No intakes are located in any such areas. Walleye are uncommon in the open areas of the Great Lakes, except Lake Erie; thus, entrainment and impingement of walleye will generally not be an issue for Great Lakes power plants.

In summary, the fishes that make the Great Lakes unique (i.e., the salmonids) or constitute the nonsalmonid recreational fishery (i.e., yellow perch, smallmouth bass, northern pike, and walleye) are not at particular risk because of their life history characteristics. Therefore, increased levels of entrainment and impingement sampling are not warranted for Great Lakes intakes. Instead, the Great Lakes should be subject to the same requirements as smaller lakes and reservoirs and should not have to reduce entrainment.

Additionally, the size alone of the Great Lakes could effect entrainment and impingement of aquatic organisms. Fish simply have more room to exist and reproduce than in other smaller lakes and reservoirs. The location of CWISs also can reduce entrainment and impingement of aquatic organisms. Populations are lower in open sandy basins and intakes located in these areas of the Great Lakes would be less damaging to overall fish communities.

This section also lists specific entrainment and impingement reduction percentages for specific water bodies. For the Great Lakes, we must reduce entrainment and impingement of fish and shellfish by 80 to 95% to meet the requirements of this proposed rule. There is no allotment for the entrainment and impingement of nuisance species, particularly zebra mussels and round goby. Zebra mussels entered the Great Lakes in the ballast water of oceangoing ships several years ago. These mussels reproduce in great numbers and attach themselves to underwater structures in shallow areas. These colonies enter generating stations CWIS and cause major problems by plugging condensers, fire protection water systems, and other essential plant equipment. At this time, NiSource uses thermal treatment exclusively to control the zebra mussel population. To reduce entrainment and impingement mortality of zebra mussels by 80 to 90 percent would have serious effects on our operation. EPA should modify the rule language to exempt nuisance species from 316(b) entrainment/impingement requirements.

If the special entrainment reductions for the Great Lakes remain in the rule, EPA should consider replacing entrainment with entrainment mortality, as there is evidence that once through cooling water intake systems entrainment mortality rate is significantly less than EPA's estimates. In our future site-specific demonstrations, we plan to measure entrainment mortality to determine the effect our actual present intake systems have on aquatic organisms' mortality rates.

EPA Response

Please refer to the response to comment 316bEFR.025.013 for a discussion of the Great Lakes as sensitive waterbodies and the presence of nuisance species.

Please refer to the response to comment 316bEFR.041.086 for more information about species-specific comments.

Organization Associated Electric Cooperative, Inc.

Cooling Lakes. Constructed cooling lakes should be exempted from the regulations or specific regulatory consideration provided. AECI completed construction of the Thomas Hill Power Plant Unit 1 and the Thomas Hill Reservoir in 1966. Management of the reservoir and adjacent properties were turned over to the Missouri Department of Conservation for use as a managed public wildlife area with the reservoir developed as a valuable fishing area for the central area of Missouri. The Thomas Hill Reservoir was constructed for and continues to serve as the once through cooling water system for the power plant. Impingement studies conducted for the plant, with a shoreline intake structure, indicate that the number of fish impinged represents less than five percent of the total reservoir fish population. The fish population that exists in the reservoir represents an introduced fish population.

The proposed rule, at 125.95(b)(3)(ii), requires persons in their studies to determine the temporal/spatial characteristics of species in the vicinity of the intake structure. This term, vicinity of the intake structure, is not defined and, therefore, leads the person to believe you are looking at impacts in only the area of the intake structure, as opposed to the waterbody. This presents several issues for constructed cooling lakes: the population in the vicinity of the intake structure is not a natural population; and, there was no fish population before the lake was constructed.

Next, at 125.94(d) Restoration Measures. persons may mitigate impacts by increasing populations in the waterbody. In past studies it was demonstrated at the Thomas Hill Power Plant, as stated above, that the impingement impact was less than 5% of the reservoir fish population. Based on 125.95 we could not use this data as it represented the waterbody and not the vicinity of the intake structure. If there is no overall impact in the waterbody, what are you mitigating? Are we trying to populate species above that which is “balanced”?

Consideration should be provided in the rules for constructed cooling lakes that have introduced fish populations and are demonstrated to have limited impact by impingement. We recommend that EPA establish constructed cooling lakes a “closed-cycle recirculating system” and is, therefore, in compliance with the 316(b) rule if it can be demonstrated that the impingement rate is minimal, e.g. less than 10% of recreational important fish species.

RFC: Appropriateness of "significantly greater"

"Significantly Greater". The proposal provides for a site-specific determination of the "best technology available" if the costs of compliance at a site would be "significantly greater" than either the benefits of meeting the performance standards or the cost of what the agency considered. EPA must provide a clear definition of what is meant by "significantly greater." To maximize net benefits to society, economic theory would dictate that this should be interpreted to mean any cost benefit ratio greater that 1:1. This reflects the most cost-effective, performance-based outcome.

Organization Associated Electric Cooperative, Inc.

Application to Existing Facilities. The proposal should include a process for approving existing intake technologies as “best available” if it can be shown that the facility is not causing adverse environmental impact or the technologies have been deemed “best available” by the state. Such a process is reasonable since Section 316(b) has been in effect since 1972 and has been implemented case-by-case at many sites. There are many electric generating facilities for which there is already a high degree of confidence that the facility is not causing adverse environmental impact or that it has already installed the best technology available. In addition, if the facility has data indicating that the amount of entrainment and impingement is so small that there is no significant harm to the aquatic community or the environmental impact is of so little economic and environmental significance that the costs of a comprehensive 316(b) study would be significantly greater than its benefits, then there should be no need for either further studies or for additional intake technology.

Subject Matter Code 21.04

Determination of compliance

Compliance Assessment. Since there is such variability in biological systems, it is not practical to require the permittee to meet a specific numerical reduction in affected organisms. The proposed performance criteria should not be directly implemented as enforceable permit limitations. Rather, when the existing technology is not the “best available”, the permit should require the installation of technology identified collaboratively by the permittee and the state. Then compliance with the permit would be based on installation, operation and maintenance of the selected technology.

Option 3--Site-specific determination

Author Name Walter P. Bussells

Organization JEA

EPA should be complimented for considering a variety of alternative approaches to the regulation. JEA is encouraged that the EPA proposal-explicitly-recognizes that-alternative technology selection may be warranted based on site-specific factors that affect the technical practicability of meeting the proposed standards. Specifically, the EPA recognizes that there may be situations where the costs of meeting the proposed standards at a specific facility may be significantly higher than the costs considered by the EPA in establishing these standards. In those: instances the proposal provides the facility with the opportunity to justify an a1ternative technology selection.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Author Name Walter P. Bussells

Organization JEA

Subject Matter Code 10.07.02

RFC: Appropriateness of "significantly greater"

The EPA proposal explicitly recognizes that alternative technology selection may be warranted based on site-specific-factors that indicate that the costs of meeting the performance standards are not warranted by the projected benefits at that facility. This is potentially very good. The proposed rule allows facilities to select an alternative level of compliance where the costs of compliance with the EPA's performance levels would be significantly greater than the expected benefits of achieving these levels. This explicitly recognizes the site-specific variations in the waterbodies (with varying ecological conditions) and can help account for controls already in place at many facilities.

EPA Response

Supports rule. No response necessary.

Author Name Walter P. Bussells

Organization JEA

Subject Matter Code 7.01.03

Option 3--Site-specific determination

The EPA has chosen a flexible approach to compliance that allows facilities to meet the performance standards through a number of options, including creation or voluntary restoration of habitats and other non-traditional approaches. This approach allows for continued innovation in addressing the potential adverse environmental impacts associated with impingement and entrainment at power generating facilities. This also leaves significant discretion in determining how best to comply with the standards to state permitting authorities and facilities managers who have developed a great deal of expertise on these issues over the past 25 years. JEA has a good working relationship with the state and believes in deferring where possible, to the state regulators.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule. This rule preserves an important role for states.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

UMRA/Impacts on local governments

Criticism: the EPA has underestimated the impact on public power systems. JEA believes that the EPA should consider these impacts on local government. (See section titled Assessment of Unfunded Mandates Analysis on Public Power in the Comments submitted by the American Public Power Association).

JEA agrees with the APPA that the EPA should encourage states to implement the new 316(b) requirements by coordinating with states to ensure reliable grid operations.

JEA is very concerned with the unintended consequences of downtime in the utility industry when 316(b) requirements are implemented. If the EPA and states attempt to do these too quickly or at the same time, there may be electricity price spikes as public power generators purchase power from IOUs or other public power entities during a one to three month down time. The final rule should encourage state flexibility in setting sensible deadlines for 316(b) retrofits when the utility would -have scheduled outage, maintenance or have lower demand. The EPA's proposed-rule ignored this potential consequence that could be serious in a region (or watershed) where several utilities face NPDES permit renewal, imposition of 316(b) requirements, and planned outages in the same year. If not timed wisely, the region's customers could face unexpected utility bill increases - particularly during a peak use time such as mid summer or mid winter.

The EPA and states should take a common sense approach to new 316(b) requirements. This common sense approach would minimize potential cost spikes and energy disruptions and would avoid placing too high a demand on the few dozen consulting engineering firms that have considerable expertise in biological studies and the various intake technologies.

EPA Response

For a response to comments on potential impacts on public power systems, please refer to comment 316bEFR.028.008 in subject matter code 22.03.

Organization Xcel Energy

Subject Matter Code 7.01
RFC: Three-option framework for determining BTA

The EPA has chosen to address the cooling water intake issues by requiring fish protection technologies at the cooling water intake structures rather than requiring cooling towers at all Phase II facilities. Xcel Energy appreciates the Environmental Protection Agency's (EPA, The Agency) recognition that a solution to the 316(b) issue requires a flexible regulation that considers the highly variable nature of fish protection at intake structures. A national requirement for cooling towers at all facilities would have significant adverse implications for individual generating facilities and the industry as a whole despite the fact that minimal environmental benefit would be produced at many facilities.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

For a variety of reasons, EPA did not select a regulatory scheme based on the use of closed-cycle, recirculating cooling systems at all existing facilities. Please see Section VII.E in the preamble to the final rule for additional information.

Comment ID 316bEFR.097.002

Author Name Daniel J. Orr

Organization Xcel Energy

Subject Matter Code 17.08

Option: UWAG's recommended approach

Xcel Energy favors the implementation of 316(b) permitting via a site-specific permitting process. EPA has failed to demonstrate that impingement and entrainment are a universal problem at cooling water intake structures mandating nationally prescribed performance standards. A site-specific determination is the method that has been used by permitting agencies for the past 25+ years resulting in a significant body of expertise and legal precedent to guide the process. We have one significant concern with the two site-specific proposals put forward by EPA. Both of these proposals assume that adverse environmental impact is occurring at cooling water intake structures and therefore some mitigation is required unless cooling water use is the equivalent of closed cycle cooling. Xcel Energy feels the site-specific proposals offered by UWAG and PSEG offer better site-specific alternatives. The proposals include a definition of adverse environmental impact, which EPA has chosen not to define.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Comment ID 316bEFR.097.003

Author Name Daniel J. Orr

Organization Xcel Energy

Subject Matter Code 7.01

RFC: Three-option framework for determining BTA

Xcel Energy appreciates that EPA has recognized the variability inherent in providing fish protection at cooling water intakes in the preferred alternative they have chosen in the proposed regulation. We support the flexibility provided by allowing facilities to use a suite of options to meet the requirements. Permittees can choose to install intake technologies, implement operational modifications, or undertake restoration measures to meet the performance standards. In addition EPA offers a cost-cost or a cost-benefit test that allows facilities to demonstrate they qualify for reduced performance standards based on excessive costs of the prescribed methods.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

Comment ID 316bEFR.097.004

Author Name Daniel J. Orr

Organization Xcel Energy

Subject Matter Code 3.06.01

Withdrawal threshold of 50 MGD

Xcel Energy supports EPA's use of the design intake flow for applying the 50 MGD criteria but favors the use of actual intake flows for the 5% criteria for entrainment protection. The design flow is appropriate given the definition of existing facilities and the ability to modify them if no increase above the design flow is proposed. The 5% criteria though should be based on actual water use to avoid imposing costly entrainment protection based on possible water use.

EPA Response

Please see response to comment 316bEFR.019.003.

EPA disagrees with the commenter's suggestion to use actual intake flows rather than design flows for the 5% mean annual flow criterion for entrainment protection. Design intake flow is a fixed value set based on the design of the facility's operating system and the capacity of the circulating and other water intake pumps employed at the facility. This allows a clear and timely classification of facilities. The design intake flow does not change, except in those limited circumstances when a facility undergoes major modifications or expansion, whereas actual flows can vary significantly over sometimes short periods of time. EPA believes that an uncertain regulatory status is undesirable because it impedes both compliance by the permittee and regulatory oversight, as well as achievement of the overall environmental objectives. Further, using actual flow may result in the NPDES permit being more intrusive to facility operation than necessary since facility flow would be a permit condition and adjustments to flow would have to permissible under such conditions and applicable NPDES procedures. It also would require additional monitoring to confirm a facility's status, which imposes additional costs and information collection burdens, and it would require additional compliance monitoring and inspection methods and evaluation criteria, focusing on operational aspects of a facility.

Comment ID 316bEFR.097.005

Author Name Daniel J. Orr

Organization Xcel Energy

Subject Matter Code 3.04.01

RFC: Application to "unique" facilities

In addition, we feel that EPA has no legal basis to apply 316(b) regulations to facilities that have only general storm water permits as they have proposed to do. Xcel Energy also requests clarification on the permitting of intake structures that obtain their water from second parties not covered by 316(b) requirements. Requiring fish protection at one intake among a series of numerous intakes seems a little capricious.

EPA Response

See response to 316bEFR.035.001. The final rule specifies that use of a CWIS includes obtaining cooling water by any sort of contract or arrangement with an independent supplier (or multiple suppliers) of cooling water if the supplier or suppliers withdraw(s) water from waters of the United States and is not itself a point source. As indicated in the rule, this provision is intended to prevent circumvention of the final rule requirements by creating arrangements to receive cooling water from an entity that is not itself a point source.

Performance standards

Author Name Daniel J. Orr

Organization Xcel Energy

Xcel Energy requests clarification pertaining to the methodology to assess impingement mortality and entrainment reductions proposed by EPA. In particular, the relationship between impingement (and resulting impingement mortality) and entrainment complicates the assessment of the required percent reductions. EPA must clarify in the regulation how these reductions are to be measured and how to account for the proportionate increase in impingement (and likely mortality) caused by the implementation of entrainment protection at a cooling water intake. Based on several years of experience, the assessment of the survival of entrainable organisms when subjected to impingement is very difficult to accomplish with any degree of certainty.

EPA Response

Please see response to comment 316bEFR.063.005.

Comment ID 316bEFR.097.008

Subject Matter Code 21.09

Permit applications/implementation schedule

Author Name Daniel J. Orr

Organization Xcel Energy

Xcel Energy has a number of concerns regarding implementation of the proposed rule. In particular how the proposed study requirements fit into the NPDES permit renewal application requirements. The regulation requires completion of extensive studies prior to submitting an NPDES renewal application. There are also agency approvals necessary before proceeding to the next step in the evaluation. We have concerns with the permittees ability to complete the required studies especially if their permit application is due within three years after implementation of the regulation. EPA must clarify how the conditions of the regulation will be implemented especially in the first few years.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

Comment ID 316bEFR.097.009

Author Name Daniel J. Orr

Organization Xcel Energy

Subject Matter Code 21.04

Determination of compliance

EPA should also define what constitutes compliance with the regulation. Xcel Energy supports establishing compliance schedules in the newly issued NPDES permit. This would provide permittees with clear expectations on how to remain in compliance with their permit.

EPA Response

Please see EPA's response to comment 316bEFR.081.006.

Comment ID 316bEFR.097.010

Author Name Daniel J. Orr

Organization Xcel Energy

RFC: Use of previous demonstration studies

We also are concerned with the seemingly endless study requirements in the regulation. We feel that once compliance with the performance standards is demonstrated there is no need to revisit the studies with each subsequent NPDES permit application. Additional studies should be necessary only if changes are made at the facility that impact the cooling water intake operations or significant changes have occurred in the source water body ecosystem.

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to 316bEFR 041.126 for a discussion.

Comment ID 316bEFR.097.011

Author Name Daniel J. Orr

Organization Xcel Energy

Subject Matter Code 17.02

Option: Reduce capacity comm. with closed-cycle

Xcel Energy urges EPA not to adopt its alternate proposal to limit water use to that achieved by closed cycle cooling at any or all facilities. Imposition of a national performance standard is not justified based on the inherent variability of cooling water intake structures and the lack of a demonstrable universal impingement and entrainment problem. EPA has not accounted for several important issues in its analysis of the economics of the cooling towers option. Some of these ignored issues include; lack of physical space, availability of materials and manpower to meet the schedules and cost estimates, and the increased consumptive use of water in water-limited areas of the country.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to section VII.E of the preamble for more information on why EPA rejected this alternative.

Comment ID 316bEFR.097.012

Author Name Daniel J. Orr

Organization Xcel Energy

Subject Matter Code 17.02

Option: Reduce capacity comm. with closed-cycle

Xcel Energy supports the EPA's decision to not impose a national performance standard requiting facilities to meet closed-cycle cooling system water use limits at any or all facilities. The Agency has recognized and stated several times in the preamble to the proposed rule the highly variable nature of determining adequate fish protection at cooling water intake structures. Because of this need for flexibility, Xcel Energy supports the adoption of a site-specific determination option proposed by EPA in the Preamble to the proposed regulation. In the final Section 316(b) Rule for New Facilities EPA opted for a universal standard of cooling towers at all facilities. The agencies reasoning was that cooling towers could be more efficiently and cost effectively designed and installed at new facilities where there were no pre-existing conditions or limitations. The need for flexibility in a rule pertaining to existing facilities is critical to allow facility owners a range of options to meet the fish protection requirements.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to section VII.E of the preamble for more information on why EPA rejected this alternative.

Comment ID 316bEFR.097.013

Author Name Daniel J. Orr

Organization Xcel Energy

Subject Matter Code 17.06

Option: Site-specific determination of BTA

Xcel Energy prefers the choice of a site-specific permitting process as discussed by EPA in Section VI.C of the Preamble. The site-specific alternatives discussed offer more flexibility than EPA's preferred alternative permitting process. The Agency initially proposed Section 316(b) rules and guidance in the 1970s. Since that time, state permit writers and environmental protection agencies have made Section 316(b) decisions on a case-by-case basis. During the intervening years a substantial volume of research, administrative precedent, and case law have been developed pertaining to Section 316(b) implementation. Many state permitting agencies have developed 316(b) permitting procedures following the 1977 EPA Guidance Document that have been continuously refined and have functioned well over the years. In addition permittees have spent many years and significant resources conducting research and monitoring of previous 316(b) facility permitting decisions. It seems highly inefficient and wasteful not to better utilize this significant investment in the permitting process by parties from both sides of the issue.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b) determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact associated with cooling water intake structures.

The final rule provides for EPA approval of alternative State program requirements where such State NPDES requirements will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment that would otherwise be achieved under § 125.94. (see § 125.90(c)).

Comment ID 316bEFR.097.014

Author Name Daniel J. Orr
Organization Xcel Energy

Subject Matter Code 6.01
Overview of I & E effects on organisms

A site-specific approach is also supported by the fact that EPA has made no demonstration that impingement and entrainment losses are a universal problem creating adverse environmental impacts at all cooling water intake structures. EPA cites a few examples of facilities where there may have been impacts but in fact most are being or already have been addressed by the facility owners through the existing permitting process. Hundreds of other facilities have been sited under the existing permitting procedures where there has been a lack of demonstrable impact as a result of the cooling water intake structure. The Agency even recognized, in the Notice Of Data Availability (NODA) for the new facility rule, the highly variable nature of cooling water intake structure impacts citing, for example, the lower entrainment susceptibility of fresh-water riverine fish species.

EPA Response

Please see response to comment 316bEFR.025.018 for the discussion on the environmental impacts associated with cooling water intake structures. Today's final rule allows for a site-specific approach as one of the alternatives for meeting the requirements of § 125.94(a).

Organization Xcel Energy

Subject Matter Code 2.04.02

Apply 316(b) before a det. of impact/AEI

Xcel Energy has one concern with the two site-specific proposals outlined in the proposed regulation by EPA. Both of the proposed options for site-specific determinations (the Sample Site-Specific Rule and the 1977 Draft Guidance based alternative) assume that there will be adverse environmental impacts and that some mitigation or restoration will be required at all sites. This unsupported assumption also contributes to EPA's unwillingness to define adverse environmental impact The EPA proposals use the significantly greater than estimated benefits as the cost/benefit test but do not define how significantly greater would be interpreted.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Comment ID 316bEFR.097.016

Author Name Daniel J. Orr

Organization Xcel Energy

Subject Matter Code 17.08

Option: UWAG's recommended approach

Xcel Energy feels the site-specific proposals offered by UWAG and PSEG present a workable permitting process that insures protection of aquatic life. The proposed permitting procedures include a population-based definition of adverse environmental impact but do not assume that adverse environmental impact occurs at all sites. The UWAG process incorporates the use of the EPA's ecological risk assessment process (used successfully in many other federal and state permitting programs) to assess the potential and magnitude of adverse environmental impacts. The UWAG process also actively involves the various stakeholders in the impact evaluation procedures. As a result of the risk assessment evaluation the cost/benefit test produces a result that maximizes net benefits for selecting technology for minimizing adverse environmental impacts.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Comment ID 316bEFR.097.017

Author Name Daniel J. Orr
Organization Xcel Energy

Subject Matter Code 21.08
Burden on permitting agencies (general)

The Agency's reluctance to support a site-specific permitting process based on increased regulatory agency burden concerns Xcel Energy. While the burden placed on regulators is an issue to all involved in NPDES Permitting, the imposition of costly environmental requirements lacking any demonstrated benefits at numerous generating facilities contradicts this Administration's mandate for cost-effective regulation. Site-specific regulation, with accompanying Guidance from EPA based on nearly 30 years of experience, can produce an efficient permitting process.

EPA Response

EPA has included the site-specific determination of BTA in today's final rule in addition to four other compliance alternatives. Please see response to comment 316bEFR.019.014 for a discussion of site-specific considerations.

Subject Matter Code 7.01
RFC: Three-option framework for determining BTA

EPA's Preferred Alternative

Xcel Energy appreciates that EPA has recognized the variability in cooling water intake structures and the importance of site-specific determinations in the preferred permitting alternative The Agency has proposed. We support the proposals flexibility that allows facilities to meet the performance standards by using a combination of intake protection technology deployment, voluntary operational modifications or restoration measures, and possibly a trading program. By having a suite of measures to choose from facilities will be able to best accommodate individual facility conditions and most effectively meet the performance standards. In addition the preferred alternative recognizes the importance of developing environmentally protective but cost effective solutions to impingement and entrainment impacts through the use of a cost-cost and a cost-benefit test to determine if less restrictive protection measures are justified.

Xcel Energy supports the flexibility the proposed alternative offers to facilities attempting to evaluate the compliance options available to meet the impingement mortality and entrainment reduction performance standards proposed. We do however have some concerns with parts of the proposal. Specifically there needs to be additional clarification included in portions of the regulation.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

Comment ID 316bEFR.097.019

Author Name Daniel J. Orr

Organization Xcel Energy

Subject Matter Code 3.06.01

Withdrawal threshold of 50 MGD

Xcel Energy supports the use of a facility's design flow in the 50 MGD applicability criteria given the definition of existing facilities as including future modifications to the facility that do not increase the full design flow capacity of the intake structure. However, we feel the actual water use would be more appropriate in regard to the 5% of source water flow criteria affecting which performance standards the facility will have to meet A facility that has reduced its water use through operational modifications should not be penalized by having to meet the much more costly requirement of installing entrainment protection based on a potential for water use. If the facility decides, in the future, to expand its water use to the design flows (or actual flows above the 5% criteria) then it would have to meet the entrainment protection standards. Xcel Energy favors utilizing actual water (an average value over a given number of years) use as the determining criteria for the installation of entrainment protection.

EPA Response

Please see response to comment 316bEFR.019.003 and 316bEFR.097.004.

RFC: Application to "unique" facilities

EPA defines Phase II existing facilities as those that have or require an NPDES Permit to discharge pollutants including storm water. Xcel Energy is extremely concerned with the EPA proposal to include among Phase II existing facilities those facilities with only NPDES general storm water permits. We do not feel that EPA has the legal authority to indiscriminately expand the 316(b) program to unassociated areas of the NPDES permitting program. Facilities that do not have a regular NPDES permit likely have already taken steps to reduce their overall environmental impact. In addition, general storm water permits require the facility have a storm water pollution prevention plan in place to prevent contaminated runoff from leaving the site. There is no logical connection between a storm water discharge and a cooling water intake structure. There also are no provisions for regulating cooling water intake structures under general storm water permits. This would require permitting agencies to write individual storm water permits for these facilities further increasing the agency's permitting burden.

EPA Response

See response to 316bEFR.035.001. Although few facilities permitted only for storm water may be subject to this rule, there is no reason to believe that such facilities, as a result of storm water requirements, would have already addressed their cooling water intake structure impacts. In cases where 316(b) requirements are applied to facilities permitted only for storm water, Directors will follow all applicable and appropriate permit issuance or permit modification requirements.

RFC: Application to "unique" facilities

Xcel Energy has some concerns with the provision in the applicability criteria incorporating facilities that obtain their cooling water from second parties. We have facilities in western states that obtain their cooling water through extensive systems of canals that also serve numerous other water users of various types. It is not clear to us how cooling water intake structure regulations would be incorporated at one of multiple water users where the supplier is not subject to Section 316(b) regulation. Requiring an electric generating facility to install fish protection measures on its intake where a significant portion of the remaining water use is for irrigation (and consequent loss of all aquatic life) seems unreasonable in the extreme.

EPA Response

The comment does not provide sufficient information to respond regarding how such facilities are likely to be addressed under this rule and, even if such specific information was provided, the applicability of the criteria in section 125.91 of this final rule to a specific facility will be determined on a case-by-case basis, as is normal practice, to ensure consideration of all relevant factors. Nevertheless, numerous factors are relevant to the application of 125.91(c) to the general scenario described in the comment including, but not limited to, whether some or all of the canals are waters of the U.S., whether the supplier withdraws water through a cooling water intake structure from waters of the U.S., and whether the facility has a contract or arrangement with one or more independent suppliers. If these facilities meet the provisions of 125.91(c), EPA expects that the facilities, as purchasers or users of the water, would work with the independent supplier via contract or independent arrangement to ensure that the supplier meets 316(b) Phase II requirements, so that the purchasers could continue to do business with that supplier.

RFC: Definition of "adverse environmental impact"

Definition of Adverse Environmental Impact

EPA has chosen not to define adverse environmental impact in the current proposal but instead assumes that adverse environmental impact occurs at all cooling water intake structures. In essence EPA is saying that loss of individual organisms is adverse environmental impact. This concept is contradictory to modern fish management practices used by resource management agencies across the country. Fishing seasons and harvest limits are established to permit a controlled take but prevent harm to individual species or fish populations. These regulations are predicated on the concept that loss of individual organisms does not necessarily equal adverse environmental impact. Environmental impact is assessed at the species population or fish community levels rather than individual organism levels. In order to evaluate whether there is adverse environmental impact, and how to minimize it, EPA will need to either define adverse environmental impact or define what is not adverse environmental impact based on sound biological principles.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

Performance standards

Relationship Between Impingement Mortality and Entrainment

Xcel Energy has a number of concerns with the impingement and entrainment criteria proposed and the use of a “calculation baseline” to assess environmental impacts. Most facilities will be required to meet an 80 to 95% reduction in impingement mortality compared to the calculation baseline. A lesser number of facilities (depending on the type of water body on which they are located or based on their water use volume) will also have to meet a 60 to 90% reduction in entrainment from the calculation baseline. It is not clear in the proposed regulation how these two reductions will be measured when both impingement mortality reductions and entrainment protection are required especially since the regulation states that both reductions apply to “all life stages of fish and shellfish”. The issue is complicated by the fact that to reduce entrainment requires that impingement be increased by a similar magnitude likely increasing impingement mortality. Based on our experience it would be impossible to meet the impingement mortality reduction goals if entrainment protection is installed due to the sheer volume of organisms that will be impinged.

EPA Response

Please see response to comment 316bEFR.063.005.

EPA notes that consideration must be made when developing both an impingement mortality and entrainment reduction strategy. In some cases, the introduction of an entrainment control has resulted in an unintended increase in impingement losses. EPA also notes, however, that these situations can often be overcome with modifications and adjustments to the technology during the course of its deployment.

Subject Matter Code 7.03

Available I&E technologies

One method EPA lists for reducing entrainment is by the use of fine mesh screens. Xcel Energy operates the Prairie Island Generating Plant located on the Mississippi River downstream from Minneapolis-St. Paul. The plant employs a variable speed 3/8-inch mesh traveling screen system with a low-pressure screen wash and a low impact fish return. During the period from April through August the plant also installs 0.5 mm mesh screens that in effect all but eliminate entrainment of any fish life stages. Under certain conditions fine mesh screens may be capable of meeting the entrainment reduction stipulated in the rule and appear to return even the eggs and larval fish life stages to the river. However, the ability to assess the survival of the impinged organisms is another issue that needs to be addressed by EPA and those performing assessment sampling.

We have conducted screen survival studies for several years and have found highly variable results. Impingement survival is a function of the fish handling system, the volume of organisms in the water column, the species and life stages present, the volume of other organisms present, and the sampling induced mortality (Environmental Monitoring and Ecological Studies Program for the Prairie Island Nuclear Generating Report, 1988) (Summary reports of the screen survival studies and the sampling mortality studies are attached.). Overall impingement survival (without sampling mortality assessed) varied from 2.7 to 32.1 % depending upon the species and life stages present. We conducted sampling mortality assessments in an effort to get a better handle on some of the variability observed in the survival data (Environmental Monitoring and Ecological Studies Program for the Prairie Island Nuclear Generating Report, 1990). Results of the sampling mortality assessment revealed that sampling induced mortality could account for 73% of the mortality observed in impinged fish. Sampling mortality was related to the debris volume in the individual samples. Samples with high debris loads (generally zooplankton) suffered very high mortality due to the time required to process the samples. Based on our studies it will be nearly impossible to meet the specified impingement mortality reductions when entrainment protection is employed. EPA needs to clarify the methods that facilities will use to assess impingement mortality when entrainment reduction technologies are also required at a facility.

Another issue with the use of fine mesh screens is the O&M they require. The fine mesh screen panels need to be installed and removed at the appropriate times of the year. The fine mesh screens themselves are fairly fragile and need constant replacement as a result of damage from debris in the water column. When the zooplankton and other debris loading is heavy the screen surfaces can plug quickly increasing differential pressure across the screen face and creating additional mechanical wear on the screen drive mechanisms. Fine mesh screens may be capable of meeting the performance requirements but to do so they will require close operational attention and vigilant maintenance practices which both come at significant additional costs to the facility.

EPA Response

EPA agrees that fine mesh screens have shown promise under certain circumstances for reducing entrainment and require a diligent maintenance and repair regiment to ensure satisfactory performance. The commenter also notes, correctly in EPA's view, that fine mesh screens may not need to be deployed year-round but rather only during seasonal spawning or other high risk events.

EPA appreciates the ongoing evaluation of technologies such as fine-mesh screens that Xcel Energy and others have undertaken over past three decades and welcomes the submittal of any information that may be of value to other facilities.

Permit applications/implementation schedule

Implementation Issues

Xcel Energy has concerns with a number of significant issues with how the proposed rule would be implemented given the five-year NPDES permitting cycle. We feel additional clarification is needed in the regulation regarding how or in what time frame the conditions would be implemented following the regulation adoption. The draft states that the permittee must be in compliance with the regulation when issued a new permit following adoption of the regulation. Given the extensive pre-permitting study requirements and the numerous levels of regulatory review and approvals required by the proposed regulation this could be difficult or impossible to achieve. At the time the final regulation is published there will be facilities in various stages of the NPDES permitting process. Permit applications that are due in the two to three years following the effective date of the regulation will not have had time to design and conduct the required studies or to evaluate intake protection technologies. The comprehensive demonstration and impingement and entrainment studies described by EPA must be approved by the agency prior to initiation and could require at least two years to complete. Following completion of the environmental studies an engineering analysis to evaluate the technology, operational, or restoration options would likely take about another year and would also require agency review and approval prior to implementation. EPA should consider either establishing the effective regulation date several years after the regulation is finalized or allow permitting agencies to establish a compliance schedule in the initial permit requiring the facility to conduct the required studies and. to design and install the technology, if required, to meet the performance standards sometime within the life of the newly issued NPDES permit.

EPA Response

See response to comment 316bEFR.045.007.

Comment ID 316bEFR.097.026

Subject Matter Code 21.04
Determination of compliance

Author Name Daniel J. Orr
Organization Xcel Energy

Xcel Energy feels that EPA's draft proposal has not clearly defined what constitutes compliance with the regulation's requirements especially during the initial permitting cycle. This issue is important so that facilities will not be deemed out of compliance with their NPDES Permit during the study, design, installation, and evaluation phases of the mitigation process. Xcel Energy suggests that at least initial compliance be based on meeting steps established in a compliance schedule included in the NPDES Permit. EPA also should clarify when and how to deal with technologies that, for some reason, do not meet the performance standards so that additional measures are required. Xcel Energy would like to suggest that the subsequent permit renewal period be the appropriate time. This would allow the permittee access to data on what has and has not worked for other facilities.

EPA Response

EPA has included in today's final rule five alternatives for achieving compliance, and an option to demonstrate compliance with a Technology Installation and Operation Plan in place of numeric performance requirements. For a discussion of how compliance is to be determined, please see the preamble to the final rule and EPA's responses to comments 316bEFR.017.003 and 316bEFR.063.005. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble section IX for a discussion of the Technology Installation and Operation Plan.

RFC: Use of previous demonstration studies

Author Name Daniel J. Orr

Organization Xcel Energy

Xcel Energy urges the EPA to allow use of previously performed 316(b) studies to meet some of the study requirements of the proposed regulation. This would be appropriate where current facility and environmental conditions have not changed significantly since the studies were performed. Permittees and permit writers have invested time and resources in conducting and reviewing these studies and their efforts should not be overlooked.

EPA Response

EPA agrees that existing historical data, as long as it reflects current conditions, should be available for use in completing studies. Please see response to comment 316bEFR.040.001 for details.

Comment ID 316bEFR.097.028

Author Name Daniel J. Orr

Organization Xcel Energy

Subject Matter Code 18.02

RFC: Use of previous demonstration studies

Xcel Energy has serious reservations about the need for the seemingly continuous studies that will be required to demonstrate compliance with the regulation. EPA is requiring extensive studies be completed by permittees prior to submitting an NPDES Permit application. In addition there are compliance monitoring studies that are required following installation of fish protection technologies, operational modifications or restoration measures to assess effectiveness of the implemented technologies. In addition, it appears that EPA is requiring that follow-up studies be conducted prior to each subsequent permit renewal application for the facility. This requirement would result in nearly continuous studies being conducted at NPDES facilities adding substantial burden on the permittee as well as on the permitting agency to review the studies. EPA needs to add some clarification to this section of the proposal refining the subsequent study requirements to apply only when changes have occurred to the facility operations that may impact the function of the cooling water intake structure or significant improvements have occurred in the water quality of the source water body.

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to 316bEFR 041.126 for a discussion.

Comment ID 316bEFR.097.029

Author Name Daniel J. Orr
Organization Xcel Energy

Subject Matter Code 11.01
RFC: Proposed use of restoration measures

Xcel Energy also supports EPA's decision to allow restoration measures, alone or in concert with other technologies, to meet the performance standards. Xcel Energy also encourages EPA to provide flexibility in the use of restoration measures by allowing projects that may not be targeted at the specific cooling water intake structure impacts but never the less provide significant fisheries or aquatic wildlife related benefits. The use of restoration measures however, must be at the option of the facility not required a regulatory requirement. In some cases restoration measures may achieve greater gains in aquatic populations than intake technologies for similar cost. Use of habitat improvement or fish restoration programs would also lend themselves to an effective benefits trading program offering permittees yet another alternative to use in their efforts to meet the performance standards.

EPA Response

All restoration measures must meet the requirements described in the final rule.

For a discussion of the extent to which restoration measures are voluntary, see EPA's response to comment 316bEFR.060.022.

For a discussion of trading programs, see EPA's response to comment 316bEFR.074.020.

Comment ID 316bEFR.097.030

Subject Matter Code 17.02

Option: Reduce capacity comm. with closed-cycle

Xcel Energy has several serious concerns with EPA's alternative permitting strategy that would require facilities to meet an intake flow requirement the equivalent to that which would be used by a closed-cycle recirculating cooling system. This alternative would in effect require the installation of cooling towers at most Phase II facilities. This proposal ignores EPA's own admission that protection of organisms at cooling water intakes is highly variable. The proposal also fails to recognize that impingement and entrainment do not cause adverse environmental impacts universally.

Installation of cooling towers is not a viable option at many facilities where physical space to locate the towers is unavailable. This is especially true at many older metropolitan area plants that are surrounded by other facilities. The impacts of dealing with cooling tower plumes and subsequent fog and icing in metropolitan areas also needs to be considered.

Another issue EPA should consider in requiring universal installation of cooling towers is the availability of materials and manpower to undertake the extensive number of cooling tower installations during a limited period of time. Xcel Energy recently completed extensive maintenance to the towers at one facility and had difficulty finding an adequate number of skilled craftsmen to complete the project. The limited availability of materials and manpower caused by such a national mandate would result in significantly increased costs to get the work completed (if even possible) within the required time frame.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to section VII.E of the preamble for more information on why EPA rejected this alternative.

Comment ID 316bEFR.097.032

Author Name Daniel J. Orr

Organization Xcel Energy

Subject Matter Code 2.04.01

Require closed cycle cooling

Xcel Energy is also concerned with some other water use issues related to cooling towers that EPA seems to have overlooked. Although cooling towers reduce overall water appropriation by a facility they actually increase the consumptive water use (loss) due to evaporation losses from the towers. These water use changes could impact facilities in two ways. Once-through cooling systems return nearly all of the water appropriated back to the system for subsequent downstream uses so the net loss to the system is minimal. In areas of the country where water use is closely regulated, facilities may not be able to acquire water rights to account for the additional water required to meet the increased consumptive losses. This increase in consumptive water use could also be a significant issue at facilities that are constrained by instream flow requirements to protect aquatic life. This increased water loss could be especially pronounced during drought periods. Additionally, in states with prior appropriation water laws, failure to make use of your full water right results in forfeiture of that water volume not used. If facilities are required to reduce intake flows to the equivalent of closed-cycle flows they would not be able to utilize the full water rights and have to abandon them or try to sell them likely at reduced prices. The loss of those water rights would be considered a regulatory taking and would require compensation for the loss under the 5th Amendment.

EPA Response

In this final rule, performance standards are not based on cooling tower technology, however, one of five compliance alternatives is the reduction of flow commensurate with the use of cooling towers, since such a level of performance meets the rule performance standards. See preamble to the final rule, particularly sections III, VII, and VIII.

Subject Matter Code 10.1

General: cost tests

Economics and Benefits Assessments Issues

Xcel Energy feels that EPA has made some erroneous assumptions regarding the costs of technology installations and particularly on the cooling tower installation costs. From data we have seen the costs to install cooling towers is significantly higher than the cost used by EPA in their benefits analysis. In addition we feel EPA has over estimated the benefits attributed to the regulation in terms increased fishery production by overlooking entrainment survival. EEI and UWAG have spent considerable time and resources evaluating the benefits and costs used by EPA to justify this regulation. Their comments provide a detailed arid extensive analysis of the costs and benefits data and are fully supported by Xcel Energy.

EPA Response

EPA notes that the commenter's assertions regarding cooling tower retrofit costs reinforce and support the Agency's decision to not base the requirements of the final rule on this technology.

The Agency disagrees with the assertion that the Agency has overlooked the issue of entrainment survival. See response to comment 316b.EFR.306.516.

Definition: Existing Facility

Author Name Ted Bach

Organization South Carolina Chamber of Commerce

The applicability section of the rule should be revised to clarify that manufacturing facilities are not covered by the Phase II rule.

Section 125.1 of the proposed rule provides a description of what existing facilities are covered by the Phase II rule. Wording is contained in several sections of the preamble indicating that the Phase II rule does not apply to manufacturing facilities including this statement contained in section IV, “Today’s rule does not apply to facilities whose primary business activity is not power generation, such as manufacturing facilities that produce electricity by co-generation.” Under the proposed section 125.1, it is not clearly evident that power generation activities meeting the criteria stated in that section would be exempt from the rule if the power generation was owned or operated by, and used, solely for the support of the manufacturing facility. As discussed in the preamble, a provision stipulating that these facilities would be exempt from the Phase II rule should be added to the applicability section (125.1) of the rule.

EPA Response

See response to 316bEFR050.002.

Comment ID 316bEFR.098.002

Subject Matter Code 3.05

Facilities not covered by today's proposal

The provision requiring best professional judgment (BPJ) requirements for all existing CWIS not covered by the Phase II rule should be eliminated.

Section 125.90(c) requires that existing facilities not covered by the Phase II rule must meet 316(b) requirements as determined by the Director on a case-by-case, best professional judgment (BPJ) basis. Inclusion of this subpart is unnecessary and could be interpreted to mean that all existing CWIS not covered by the phase II rule require BPJ based requirements for their CWIS, regardless of their size, location, etc. In addition, since EPA is not providing any guidance on how to apply BPJ requirements to these CWIS, the provision will cause confusion and uncertainty for both the permit writers and the regulated facilities. Since the existing provisions of 316(b) already cover permitted facilities and a Phase III CWIS rule will be forthcoming, there is no need to include this provision.

EPA Response

See response to 316bEFR.063.021.

Comment ID 316bEFR.098.003

Author Name Ted Bach

Organization South Carolina Chamber of Commerce

Subject Matter Code 3.06.01

Withdrawal threshold of 50 MGD

Actual flow should be considered in the threshold for applicability.

A permittee whose actual CWIS flow is less than the 50 MGD threshold should be allowed to request exemption from the Phase II rule. Facilities may choose to operate at flow volumes below the design flow of the CWIS and should not be penalized for this voluntary flow reduction. If a facility chooses to select this option, EPA could institute maximum flow limits in the rule or individual permit to ensure that the threshold flow is not exceeded. Also, the facility would likely be covered under the Phase III CWIS rule thereby ensuring adequate protection.

EPA Response

Please see response to comment 316bEFR.019.003. In addition, EPA notes the commenter's suggestion that facilities that meet the 50 MGD total design intake flow threshold can be excluded from the rule if they agree to binding maximum flow limits. EPA did not adopt this approach because it is EPA's experience that facilities' average intakes are not constant, but rather fluctuate over time. In order to be protective, EPA chose to define the intake threshold based upon design capacity rather than actual cooling water use. Facilities with low capacity utilization rates; however, will be subject to less stringent requirements under § 125.94. Please see the final rule preamble for an explanation of the basis for today's final rule.

Author Name Ted Bach

Organization South Carolina Chamber of Commerce

Subject Matter Code 2.04.02

Apply 316(b) before a det. of impact/AEI

The proposed performance standard is based upon technology standards, which fail to consider if adverse environmental impact is occurring.

The proposed performance standards are based upon entrainment and impingement reductions that could be achieved if certain technologies are implemented. Although the proposed rule does not specific what technology must be used to meet the performance standard, the standard is technology based with an option to use restoration measures to supplement or replace implementation of technologies. The proposed rule with its performance standard, as well as the technology-based approaches under consideration, both ignore the fact that adverse environmental impact may not be occurring in all cases. Therefore both of these approaches may result in significant expenditures of resources that are unwarranted by site-specific conditions.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Comment ID 316bEFR.098.006

Subject Matter Code 7.02

Performance standards

Author Name Ted Bach

Organization South Carolina Chamber of Commerce

In addition, EPA states that the performance standard of reduction of impingement and entrainment is a “relatively easy and certain metric”. While impingement and entrainment studies may be relatively easy and certain, the performance standard being proposed requires the use of a “calculation baseline” from which the impingement and entrainment reductions are compared to demonstrate compliance. We believe that there is no scientifically sound manner to calculate that baseline where there is an existing CWIS in place, therefore the assessment of the performance standard can be seriously flawed.

EPA Response

For discussions on the basis for and implementation of the calculation baseline, please see response to comments 316bEFR.308.014 and 316bEFR.063.022, as well as the preamble to today's rule.

Author Name Ted Bach

Organization South Carolina Chamber of Commerce

Subject Matter Code 17.06

Option: Site-specific determination of BTA

A site-specific approach should be used to determine if adverse environmental impact (AEI) is being caused by an existing CWIS, and for determining the best technology available (BTA) to minimize the adverse impact if it is occurring.

EPA stated in its 1977 draft guidance document for evaluating adverse impact of CWIS that, “The environment-intake interactions in question are highly site-specific and the decision as to best technology available for intake design, location, construction, and capacity must be made on a case-by-case basis.” EPA also recognizes that there is major impact differences associated with CWIS based upon water body types (i.e., freshwater streams and rivers, lakes and reservoirs, tidal rivers and estuaries, and oceans). It should be obvious that there are also many other site-specific factors that affect potential CWIS impacts that cannot be dealt with in a prescriptive manner. EPA indicates that it is considering various site-specific based options for the Phase II rule. A site-specific based approach is the most appropriate method for determining BTA, and the most appropriate approach for determining AEI. If a site-specific based approach is implemented for the final Phase II rule, the applicability of that rule should not change from what is being proposed in the preamble to the proposed rule with the exception of comments presented above.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Comment ID 316bEFR.098.008

Subject Matter Code 10.07.03

RFC: Test: benefits should justify the costs

Site-specific process for determining the best technology available for minimizing adverse environmental impact and the role of costs and benefits

An evaluation of cost-effectiveness (i.e., the incremental cost to benefit) should definitively be a component of the analysis to determine best technology available (BTA) for minimizing adverse environmental impact (AEI). We also believe that a test based upon the “benefits should justify the cost” would be more appropriate than the “wholly disproportionate” cost-to-benefit test currently used, or the “significantly-greater” cost to benefit test proposed in the sample-site specific rule. EPA should not establish minimum standards by regulation for cost evaluation studies due to the complexities involved with a site-specific approach. EPA should develop guidance for conducting these types of studies and provide examples of a variety of methods that may be used at the option of the permittee.

EPA Response

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Please refer to the responses to comments 316bEFR.005.020 and 316bEFR.410.001 for a discussion of the application of the cost-benefit and cost-cost tests.

For more information on the use of the term "significantly greater," please refer to the response to comment 316bEFR.006.003.

Subject Matter Code 21.04

Determination of compliance

Author Name Ted Bach

Organization South Carolina Chamber of Commerce

Compliance Monitoring Issues

Once a facility and the permitting authority have agreed upon the appropriate BTA and it has been properly installed, operated, and maintained, the facility should be considered in compliance with the conditions of their permit. If compliance monitoring indicates that a performance standard or restoration/enhancement objectives are not being achieved, this should not be considered as noncompliance with the provisions of the permit. Because of the time and inherent variability involved with monitoring fish populations over multiple seasons, or the success or failure resulting from restoration/enhancement projects, we do not believe that re-opening of permits would be necessary except in extreme cases. Therefore, any modifications to 316(b) requirements should be dealt with during the normal permit renewal process.

EPA Response

Please see EPA's response to comment 316bEFR.081.006.

Comment ID 316bEFR.098.011

Author Name Ted Bach

Organization South Carolina Chamber of Commerce

Subject Matter Code 21.08

Burden on permitting agencies (general)

Burden to Regulatory Agencies from Site-Specific Decision Making

EPA has expressed concerns about the burden that will be placed upon regulatory agencies if a site-specific approach is adopted. The promulgation of new CWIS rules for existing facilities will place burdens on both permittees and the regulating authorities, regardless of the approach adopted. However, we believe that any burdens arising from a site-specific approach may be less than the potential costs of complying with a prescriptive performance standard. We also believe that greater environmental benefit will be achieved with the use of a site-specific approach. It is also likely that the use of a scientifically sound, site-specific approach will result in fewer legal challenges, thereby reducing some of the burden to the regulatory agencies that may occur under a prescriptive approach.

EPA Response

EPA has included the site-specific determination of BTA in today's final rule in addition to four other compliance alternatives. Please see response to comment 316bEFR.019.014 for a discussion of site-specific considerations.

Comment ID 316bEFR.098.012

Author Name Ted Bach

Organization South Carolina Chamber of Commerce

Subject Matter Code 18.02

RFC: Use of previous demonstration studies

EPA has also invited comment on whether the resource requirements of the site-specific approach serve as a disincentive to a comprehensive revisiting of section 316(b) permit conditions during each renewal, despite advances in technologies for reducing impingement mortality and entrainment. We believe that once a facility has installed BTA there is no need for a comprehensive review at each permit renewal. It is unlikely that possible advances in technologies for prevention of entrainment and impingement will improve to the point that would warrant retrofitting of technology during each five-year permit cycle, nor would it be practical to expect permittees to make expensive technology changes on such a frequent basis. A facility should only have to demonstrate during permit renewal that there are no significant changes in the operation of the permitted BTA, and that conditions in the water body are similar to those occurring during the original 316(b) demonstration. If comprehensive re-evaluations are deemed necessary, they should be conducted on a minimum of a ten-year cycle (every other permit renewal), which would reduce the burden to the permitting authority.

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. However, permit conditions will be reviewed at each permit cycle and adjustments, if any, will be made as appropriate. Please see response to 316bEFR 041.126 for a discussion.

Response to Public Comment

---National Pollutant Discharge Elimination System---
Regulations Addressing Cooling Water Intake Structures
for Phase II Existing Facilities

(40 CFR Parts 9, 122, 123, 124, and 125)

RFC: States to demonstrate comparable env. perf.?

[T]he State of Maryland believes that our existing 316(b) CWIS regulations have been and continue to be protective of the environment and the State's natural resources. For this reason, we suggest that the Phase II rule include the option of a State's existing regulations being accepted as satisfying 316b requirements. We strongly support a site-specific approach for determining BTA to minimize Adverse Environmental Impacts (AEI). We also believe that AEI should be considered at the species or ecosystem-effects levels and not simply on the numbers of organisms entrained and impinged.

EPA Response

Today's final rule allows States and Tribes to demonstrate alternative regulatory requirements (§ 125.90(c)) that will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment in the performance standards. Additionally, § 125.90(d) states that nothing in today's rule precludes a State or Interstate Agency from adopting or enforcing any requirement that is not less stringent than those required by Federal law. Today's rule does not preclude the consideration of environmental impacts at the species or ecosystem-effects level. For more information regarding the topic of environmental impact, please see the response to comment 316bEFR.025.018 and for more information regarding the definitions for adverse environmental impacts rejected by EPA, please see response to comment 316bEFR.011.041.

RFC: Cooling water withdrawal thresholds of 25%

Because the 50 MGD cut off is used to establish whether a facility should be covered under the Phase II or Phase III rule, the exact figure used for that cutoff is not of major concern. The 50 MGD withdrawal rate seems to be a reasonable criteria for separating the large, once-through cooling facilities from smaller cooling water users, as does the 25% cooling water use threshold.

EPA Response

EPA notes the comment. No response required.

Impacts of CWIS at ecosystem level (popn. vs. indiv.)

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Cumulative impacts of multiple intake structures in same watershed and in already impaired waterbody; effects of multiple intakes on fish stocks (V: 17136)

PPRP has evaluated cumulative effects of impingement and entrainment in Maryland. Because Maryland generating facilities have a rather broad geographical distribution, the biological populations exposed to the effects of these widespread plants are often distinct, with little or no intermingling. For example, species such as white perch and striped bass have tributary-specific stocks, such that impingement of white perch at the Morgantown facility on the Potomac River is of no biological consequence for white perch stocks in the vicinity of the Vienna facility on the Nanticoke River. Conversely, other species, such as Atlantic Menhaden (Brevortia tyrannus) may have a single stock that moves throughout the Chesapeake Bay. Thus, the total number of menhaden impinged at all of the power plants in Maryland is of potential relevance to the fate of the single menhaden stock. Maryland has tracked cumulative impingement losses across all power plants for species, such as menhaden, that may occur over a wide range of salinity regimes. However, in lieu of complicated and imprecise population modeling, the losses due to impingement were simply compared to other sources of menhaden loss to place them within a reasonable context. These comparisons showed that the cumulative magnitude of impingement of menhaden, as an example, is a small fraction of the commercial harvest of the species, and a small fraction of estimates of the amount of this species consumed by predators. On that basis, the state has concluded that the levels of impingement by Maryland's power plants do not represent a significant threat to this important resource species in the bay.

EPA Response

Please see response to comment 316bEFR.056.017 for the discussion regarding cumulative impacts associated with multiple intakes in a watershed. Also, please see the response to comment 316bEFR.025.018 for the discussion regarding the environmental impacts associated with cooling water intake structures.

Subject Matter Code 6.02

Impacts of multiple intake structures on watersheds

If an adverse cumulative impact to a watershed ecosystem is suspected or indicated, we recognize that considerable uncertainties may exist in the identification of individual contributors to the problem and the assignment of responsibility for ameliorating these impacts. Our research into this issue (Hochberg et al., 1993) has indicated that the lack of a regional land use or water quality management plan would make it difficult to sort out effects of power plants from other influences. In the absence of knowledge about other influences on the receiving water body or ecosystem, any assessment of cumulative impact and the effect of a single action (e.g., discharge permit approval) would be flawed. Minimizing the effects of power plants within a watershed would reduce the likelihood that such plants could contribute to environmental degradation. However, we believe that to require facility owners, and thus consumers, to incur substantial cost to do so when the benefits of such measures are unknown would be unreasonable. For this reason, Maryland has continued to support the concept of site- and facility-specific impact assessments, including those relating to cumulative impacts.

EPA Response

EPA agrees with this commenter that it is extremely difficult to separate the effects of any one factor causing stress on the environment when so many work concurrently. The intention of section 316(b) of the Clean Water Act is to minimize the adverse environmental impact of cooling water intakes structures specifically. Reducing impingement and entrainment will serve to aid in alleviating stress on nearby fisheries and prevent any hindrance these structures may be having on other programs that serve to reduce other types of stress. Please see the response to comment 316bEFR.025.018. The permitting authority should consider the cumulative impacts of multiple intakes in a watershed as part of its section 316(b) decisionmaking process because stricter controls may be necessary when more than one facility kills large numbers of individuals of the same species in the same watershed.

Organization State of Maryland Dept of Natural Resources

Subject Matter Code 6.02

Impacts of multiple intake structures on watersheds

With regard to Maryland's experience, cumulative impacts have been temporally addressed implicitly within the State through long-term monitoring of the status of important resource species. None of these diverse monitoring programs have suggested that an adverse cumulative impact to the State's fisheries have resulted from the effects of power plants operating in Maryland (Richkus and McLean, 2000; Ringger, 2000).

EPA Response

Please see the response to comment 316bEFR.099.004 by the same author.

Comment ID 316bEFR.099.006

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Subject Matter Code 6.02

Impacts of multiple intake structures on watersheds

With regard to use of watersheds as the basis for evaluating cumulative impacts of multiple facilities, cumulative impacts would only occur in circumstances where the multiple facilities are likely to be impacting the same ecosystem elements. For example, the effects of plants located on non-tidal waters in a watershed are unlikely to have impacts that would be cumulative to those of plants located on tidal portions of the same watershed (except with the possible exception of diadromous fish). We believe that cumulative impacts should be considered on the basis of affected resources and not simply on a watershed basis.

EPA Response

Please see the response to comment 316bEFR.099.004 by the same author. Diadromous species are exactly the type of species EPA believe need to be protected by considering the cumulative impact of multiple intakes in the same watershed. Multiple facilities located in the same watershed are more likely to be affecting the same population of a particular species. These types of impacts should be considered by the permit director as part of the 316(b) decisionmaking process. Please see response to comment 316b.EFR.099.004.

Impacts of CWIS at ecosystem level (popn. vs. indiv.)

Ecosystem level effects (food webs, nutrient-carbon-energy transfers, habitat alteration, species composition and biodiversity alteration) (V: 17137)

The diverse array of ecosystem level effects that are discussed in this portion of the proposed rule appear to be very speculative in nature, with minimal scientific support and citations. PPRP has conducted numerous studies of all ecosystem components at most of the generating facilities in Maryland over the past thirty years. We have recorded one clear ecosystem consequence of once-through cooling: benthic communities in the vicinity of power plant discharges tend to be enhanced (e.g., higher biomass densities), most likely due to increased availability of food in the form of planktonic organisms killed as a result of entrainment and settling out of the water column in the discharge area. This ecosystem response is restricted to a relatively small region, consisting of the immediate vicinity of the discharge plume. It is not inherently an adverse impact, since benthic organisms are an important food source for many of Chesapeake Bay's important resource species, such as blue crab and many fish species. From all other studies, no effects on other ecosystem elements have been noted, and no long term alterations in ecosystem structure or function have been observed that could be attributed to power plant operations (CEIR, 1986). Thus, we do not believe that existing data, information and literature support the occurrence of the speculative ecosystem level effects you describe.

EPA Response

Please see response to comment 316bEFR.207.015 for the discussion regarding impacts of cooling water intake structures at the individual versus population level.

This author has pointed out an ecosystem effect caused by the killing of many organisms via entrainment. Enhanced benthic communities in the vicinity of the discharge of power plants is clear evidence that the food chain of the ecosystem has been disrupted which may lead to long term alterations in ecosystem structure and functions. Entrainment of eggs and larvae has disintegrated these organisms so they are no longer a food source for larger predatory fish, but instead are only available as a food source for detritivores and other benthic (bottom-dwelling) organisms.

RFC: Directors set performance levels for a facility?

Require greatest possible reduction based on EPA's performance standard technologies or allow performance level decision to be made by the Director (VI..A.1.a: 17142)

The specification of a performance level, in the absence of knowledge of what the benefits of performing at that level may be, could place an undue burden on plant owners, the states, and consumers. We believe that the Director would be more likely to have the local knowledge needed to make a reasoned decision on what performance level would be acceptable. Thus, we strongly support having the Director assume responsibility for determining the appropriate performance level.

EPA Response

For a discussion on the methods of determining compliance please see response to comment 316bEFR.063.005 and the preamble to the final rule.

RFC: Restoration measures as supplement only?

Allow restoration measures only as a supplement to technology or operational measures (VI..A.5: 17146)

Designation of restoration measures only as supplements to technology or operational measures may be too restrictive. There may be circumstances in which the cost of technology or operational measures to achieve modest environmental gains is very high, in which case much greater benefit to the State's resources could result from use of those same funds purely for restoration or resource enhancement. Thus, Maryland would prefer to retain restoration on a case by case basis as an acceptable alternative to technology or operations measures and not just as a supplement.

EPA Response

For a discussion of the use of restoration measures as a supplement to technology, see EPA's response to comment 316bEFR.060.023.

RFC: Appropriate spatial scale for restoration

Appropriate spatial scale for restoration measures: waterbody, watershed, State boundary (VI..A.5: 17146)

We believe it is reasonable to implement restoration measures within the same ecosystem and watershed within which the generating facility is located. This would be the most direct means of ensuring that the ecosystem and stakeholders with interest in the ecosystem (e.g., residents, fishermen) would be compensated for whatever impacts the generating facility may be having, even if that compensation is out-of-kind. An example within Maryland of such acceptable and beneficial restoration is PEPCO funding of anadromous fish migration blockages in the Patuxent River watershed as mitigation for entrainment (discussed in detail in comment 9 below).

EPA Response

For a discussion of the appropriate scale on which to conduct restoration measures, see EPA's response to comment 316bEFR.212.001.

Role of Restoration

How to measure "substantially similar performance" of restoration measures; methods to reduce uncertainty of restoration activities; margins of safety for restoration measures, basis for safety margins, appropriate authority to establish; how to consider additional environmental benefits to fish and shellfish in restoration projects; role of restoration in addressing CWIS impacts and alternative approaches (VI..A.5: 17147, 17148)

We believe that mitigation can play a valuable role in resolution of 316(b) issues on a site-specific basis. We use the term mitigation here to refer to something aside from alternative intake technologies or operating strategies which might be used to minimize impacts of cooling water intakes. The mitigation we refer to takes the form of some alternative measure which can compensate for resource losses in some other way.

Empirical studies of entrainment at Chalk Point (formerly owned by Potomac Electric Power Company or PEPCo, now Mirant) indicated the potential for significant losses of forage species (bay anchovy, naked goby, silversides) in the Patuxent River estuary. Such losses can inhibit the successful completion of the life cycles of other important species that use the Patuxent as a spawning and nursery area (MMES 1985). Based on field studies, PEPCo concluded (Loos and Perry, 1989) that the reduction in anchovy recruitment for the Patuxent was 4% and that entrainment mortality could cause a reduction in forage fish biomass of about 3,000 to 15,000 pounds (dry weight). These estimates were based on field measurements of population size in the Patuxent and entrainment by Chalk Point. An independent analysis conducted by the state of the same data indicated that loss of bay anchovy in the estuary due to entrainment was approximately 14 to 51% (most probably 20 to 30%) annually (Versar, 1989). PEPCo (Loos and Perry, 1989) calculated the value of the entrainment losses at $150,000 per year (1989 dollars) based on its loss estimates. PEPCo also calculated the cost of BTA alternatives (cooling towers and wedgewire screens) as ranging from $10,000,000 to $288,000,000 (1989 dollars). According to PEPCo, the alternatives evaluated varied in effectiveness in reducing entrainment from almost none to 100%. Maryland negotiated a mitigation plan in discussions with PEPCo. This plan was developed as a result of a number of factors, including the fact that there was a substantial difference between the cost of requiring BTA (such as cooling towers) and the environmental benefits. There was also substantial uncertainty regarding the magnitude of benefits and the nature of the impacted species. The negotiated settlement resulted in an NPDES permit requirement that PEPCo spend $200,000 per year on striped bass aquaculture or other species as requested by the Maryland Department of Natural Resources (DNR), and $50,000 per year for aquaculture of yellow perch or other species as agreed upon by DNR. This permit condition contemplated the production of 200,000 striped bass and 50,000 yellow perch per year. The permit additionally required PEPCo to provide $100,000 per year to the state for environmental education or for projects to remove obstructions to anadromous fish.

We believe a sound decision was made based on the success of this mitigation program. In this case, this program included creating a fish hatchery for potentially impacted fisheries and provision of funds for removal of obstructions to migratory fishes on tributaries, by removing dams or providing fish passage facilities. Results of the hatchery and stocking program resulted in the production and release of 3.5 million juvenile striped bass to date, the total estimated weight of which exceeded the estimated weight of forage fish lost from entrainment at Chalk Point. At the end of 1997, 750,000 shad had also been produced; this species is currently the focus of fishery restoration efforts in Maryland. Each of these benefits is directly related to the enhancement of the State's fisheries. However, no specific "valuation" approach was used to arrive at the enhancement objectives; the agreement on numbers of fish to be reared and amount of funds to be used for passage enhancement were based on technical expertise of agency staff and PEPCo staff and consultants, and targeted the State's resource management objectives.

We believe that a critical component of the regulation is to assure the provision of substantial flexibility to allow States to direct restoration and enhancement measures to their most pressing resource management needs. Placing rigid, restrictive criteria within the regulation would impose constraints on regulators that may not result in the greatest benefits to resources of concern and the resources of the states that are impacted.

EPA Response

For a discussion of the role and implementation of restoration measures in the final rule, see EPA's response to comment 316bEFR.081.007.

The final rule does not require a specific valuation approach to determine appropriate restoration measures. For specific requirements for restoration measures addressing species other than those impinged and/or entrained by a facility's cooling water intake structure, see section 125.95 in the final rule. EPA believes that the requirements for restoration measures in the final rule are important for ensuring a restoration measure addresses those adverse environmental impacts that derive from a cooling water intake structure.

Comment ID 316bEFR.099.014

Subject Matter Code 12.02

RFC: Monitoring frequencies

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Narrative criteria sufficient to support various BTA approaches to minimize AEI; require specific, minimum monitoring frequencies and consider uncertainty in I&E estimates; require 2 years of monitoring, at least once per month for 24 hours for I and biweekly for 24 hours for E during critical periods; require more frequent sampling to assess diel, seasonal and annual variation in I&E losses; less frequent monitoring for compliance, depending on technologies implemented (VI..A.6.a: 17148, 17149)

EPA notes the difficulties that are encountered in monitoring CWIS impacts, and Maryland's experience supports EPAs views on this issue. Because of the great diversity of natural conditions that could impact the accuracy and precision of estimates of CWIS impacts, we believe that it may be more appropriate to specify monitoring goals (e.g., certain levels of precision or documentation of impacts during a spawning season) and allow permittees to propose the means of achieving those goals. This would provide the flexibility needed to design monitoring programs that take into account site-specific environmental conditions. Setting any specific minimum sampling frequencies runs the risk of either "overkill" or insufficient sampling. Sampling designs can be reviewed by the Director to determine if they are sufficient to meet the objectives of the regulation.

EPA Response

Comment ID 316bEFR.099.015

Subject Matter Code 12.03

RFC: Entrainment vs. entrainment mortality

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Approaches to estimate entrainment mortality for compliance with performance standard; studies documenting entrainment survival rates (VI..A.7: 17149); review of quality of entrainment survival studies and inclusion of entrainment mortality and survival estimates in benefits assessment (VI..A.8.a.(3).b: 17150)

Maryland is aware of many of the entrainment survival studies conducted at facilities throughout the country in the 1970s and 1980s. One point to be made regarding these studies is that it is the nature of the power plant's cooling system rather than the nature of the CWIS that primarily determines the extent of entrainment mortality. Due to the diverse nature of these studies and the high degree of variability in some of the results, Maryland has in the past taken a conservative approach in our assessment of entrainment by assuming 100% mortality of all entrained organisms. We took this approach because the objective of our assessment was to determine whether the direct effects of entrainment might result in significant impact to the designated RIS species or ecosystem function. As we described earlier, most of our assessments lead us to conclude that entrainment effects did not result in significant impacts. The potential for substantial survival of entrained organisms becomes significant when the total number of organisms lost to entrainment is the focus of an assessment (e.g., in determining the economic value of entrainment losses). In such circumstances, we believe it appropriate to take into consideration the fact that all entrained organisms may not be killed. However, the onus is clearly on the permitee to provide scientifically valid support for such a position.

EPA Response

Please see response to comment 316bEFR.305.001 with regard to entrainment-based performance standards. Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis. Please see the response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule.

Subject Matter Code 10.02.03

Use of Replacement Costs (HRC and hatchery-based)

Appropriate methodology for benefits assessment (VI..A.8.a: 17149)

The procedure defined in Maryland regulations for determining BTA for impingement employs a very simple cost/benefit evaluation. The value of fish killed due to impingement is calculated using the dollar values of the affected species that are also included in Maryland regulation. The American Fisheries Society (AFS) has issued and regularly updates a listing of fish species and their dollar value, and these values are commonly used throughout the country in assessing dollar value damages in cases of environmental perturbations that result in fish kills (e.g., spills of toxic compounds). We believe there is thus precedence for use of the AFS fish values for calculating benefits of BTA. We believe that there is a high degree of uncertainty and controversy with regard to the many methods that have been developed to estimate non-use values of living resources, and thus do not strongly support their use in this regulation. However, we have not conducted a detailed review of the economic valuation procedures used by EPA in developing this Phase II rule.

EPA Response

EPA agrees that there is precedence for using American Fishery Society (AFS) fish values for approximating forage benefits under the rule. Note that replacement costs based on fish stocking are used routinely to monetize the damages associated with fish kills, including fish losses resulting from impingement and entrainment (e.g., by the Maryland Power Plant Program). While all parties acknowledge that these hatchery-based replacement “costs” are not true “benefits values” per se, in the absence of information on public values, these are accepted and used as the only available alternative for monetizing damages. In fact, in its publication presenting estimates of fish replacement costs, the American Fisheries Society states that such costs can be considered a “proxy for value.”

However, in the analyses for the NODA and the final rule, EPA has chosen to use the preferred foregone production method. In this method losses among forage species are translated into foregone production among harvested species that are impinged and entrained using an assumed trophic transfer ratio, and then translates foregone production among these harvested species to foregone yield. Further information on the methods EPA used to estimate forage losses is provided in the regional study document prepared for the analysis for the final Phase II rule. See Chapter A5: Methods Used to Evaluate I&E.

Please also note that for the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. See Chapters A12, Non-use Meta-analysis Methodology, and A9, Economic Benefit Categories and Valuation Methods of the final Phase II Regional Studies Document (DCN # XX).

Subject Matter Code 14.0

5% Flow Threshold in Rivers

Adequacy of 5% flow threshold in rivers or alternative of: 5% of spawning season flow, 10-15% of mean annual or spawning season flow, or 25% of the 7Q10, species-specific flow threshold (VI..A.11: 17151)

This issue is only potentially applicable in Maryland to the two plants located on the riverine portion of the Potomac River (Dickerson and R.P. Smith). For the Dickerson facility, 5% of the spawning season flow is 614 cfs in May, based on USGS Point of Rocks flow data; 10-15% of the mean annual flow is 951-1427 cfs; 25% of the 7Q10 is 215 cfs. Based on these flow ranges, the Dickerson facility could be subjected to entrainment reduction requirements depending on which criterion is chosen (maximum plant intake flow is about 400 mgd or about 620 cfs). Yet entrainment data collected at that facility has lead Maryland to conclude that no significant impacts result from entrainment. Any of these criteria are by their very nature arbitrary. For this reason, Maryland believes that it is more reasonable to consider the magnitude of entrainment and how that entrainment might affect a fish community rather than using an arbitrary flow cutoff percentage.

EPA Response

EPA believes it has presented ample evidence demonstrating a significant decrease in the level of entrainment when intake flow is minimized in relation to the flow of the source waterbody. The documents DCN# 2-013L-R15 and 2-013J support the proposition that flow is related to entrainment. EPA believes the intake capacity standard established under today's final rule provides an appropriate level of protection.

RFC: States to demonstrate comparable env. perf.?

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Allow State to demonstrate adoption of alternative regulatory requirements with comparable environmental performance in I&E reduction within a watershed (VI..A.11: 17151)

The State of Maryland believes its regulations are protective of its natural resources and would like the opportunity to demonstrate that its regulations are of comparable environmental performance. However, it is not at all clear how a state would be able to make such a demonstration short of re-evaluating all of its facilities. EPA needs to provide clear and reasonable guidance to states on how they may make this demonstration if they desire to do so. Such guidance must be economically reasonable for the state to implement.

EPA Response

Today's final rule allows States and Tribes to demonstrate alternative regulatory requirements (§ 125.90(c)) that will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment in the performance standards. EPA will review and approve a State's alternative regulatory requirements. EPA has left the decision on whether to attempt to make this demonstration to the discretion of the State. Such a demonstration may require re-evaluating all of its facilities. EPA does not see this as economically unreasonable because each facility should be re-evaluated with each permit cycle (every 5 years). Also as with any new rule, existing State section 316(b) determinations must be revisited to determine compliance with the new requirements.

Comment ID 316bEFR.099.020

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Subject Matter Code 15.0

State or Tribal Alternative Requirements

Appropriate definition of watershed for achievement of comparable environmental performance (VI.A.11: 17151); use of USGS 8-digit hydrologic unit as maximum geographic scale for alternative requirements; appropriate watershed scale definition and boundary of watershed units at State boundary unless adjoining states jointly propose alternative requirements (VI.A.11: 17152)

We addressed this issue under item 2 above. As we noted there with regard to use of watersheds as the basis for evaluating cumulative impacts of multiple facilities, cumulative impacts within a watershed would only occur in circumstances where the multiple facilities are likely to be impacting the same ecosystem elements. For example, the effects of plants located on non-tidal waters in a watershed are unlikely to have impacts that would be cumulative to those of plants located on tidal portions of the same watershed (except with the possible exception of diadromous fish). We believe that impacts should be considered on the basis of affected resources and not simply on a watershed basis. Thus, the scale to be used in defining a watershed is less relevant than the geographical distribution of the affected resource entities relative to the locations of the power plants. In cases, where affected resource stocks cross state boundaries, it would be reasonable to consider cumulative impacts of facilities located in adjacent states.

EPA Response

Today's final rule maintains the prerogative of a permitted State to demonstrate to the Administrator that it has adopted alternative requirements which will result in reductions in impingement mortality and entrainment comparable to those that would be achieved under § 125.94.

EPA has deferred a formal definition of "watershed" to the Director for the purposes of today's final rule. Because of the potentially numerous variables that interact in various waterbodies, EPA believes the Director will be best suited to make a determination of an appropriate watershed boundary for his or her constituency.

Please see response to comment 316bEFR.002.016.

RFC: Incorp. costs/benefits without burden on Dir.

Minimum standards for Comprehensive Cost Evaluation Study; cost-benefits of meeting performance requirements and estimates of burden to regulatory agencies (VI.A.12: 17153)

Maryland concurs that EPA should establish minimum standards for cost evaluation, to ensure a “level playing field” for all facilities that wish to pursue this alternative within the regulation. Provision of guidance for conducting such an evaluation may alleviate some of the burden on the Director who would be required to review such evaluations. The more specific the guidance, the less burden imposed on the Director.

EPA Response

EPA agrees and has provided additional information on the Comprehensive Cost Evaluation Study in the final rule. See discussion regarding site-specific compliance alternative in the preamble to the final rule and the regulatory language for detailed information.

Comment ID 316bEFR.099.022

Subject Matter Code 16.01

RFC: Regulating limited capacity facilities

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Adequacy of capacity utilization threshold (15%); facilities operating at less than 15% capacity utilization required to implement BTA only for impingement and not entrainment (VI.A.14: 17154)

Maryland concurs with the use of the capacity utilization threshold within the regulation for the purpose stated. We also believe that the 15% threshold is not unreasonable, although, as with many of the thresholds established, it is arbitrary. Given it's arbitrary nature, it may be appropriate to provide to the permitee an opportunity to demonstrate that even at a somewhat higher utilization they should only be required to implement BTA for impingement.

EPA Response

The Agency disagrees that the 15 percent threshold for capacity utilization rates is arbitrary as the commenter asserts. The Agency provides the reasonable basis for the capacity utilization threshold at DCN 6-3586. Therefore, the Agency does not agree with the commenter's request that higher utilization rates thresholds be implemented. See response to comment 316b.EFR.041.238.

Role of States and Tribes (alt./equiv. programs)

Inclusion of regulations on impacts to local water resources other than I&E (VI..B: 17154)

This question appears to contemplate water use restrictions where evaporative losses can have a significant impact, e.g. in rivers and lakes. Maryland's regulations already include provisions for considering water losses at power plants within its water appropriations permit system. If EPA chooses to include such regulations in its 316(b) rule, it should permit states with existing regulations for this issue to adopt its own regulations as an alternative.

EPA Response

If a State 316(b) program is approved according to 125.90(c) of today's rule, a State will have flexibility to address evaporative losses as best suits the local environment.

Subject Matter Code 17.05

Option: I&E reduction without regard to WB type

Intake capacity commensurate with close-cycle cooling systems based on waterbody type (VI.B.1,2: 17155); based on waterbody type and proportion of waterbody flow (VI.B.1,2: 17156)

Maryland supports EPA in not proposing the option of requiring intake capacity commensurate with close-cycle cooling systems based on waterbody type. Our evaluations of major estuarine power plants in Maryland, such as Calvert Cliffs, indicate that all estuarine facilities do not cause significant impacts as a result of entrainment. Thus, this option could impose significant costs on plant owners and customers without generating any environmental benefits. Maryland does not support the option that brings in the proportion of water body flow as a decision factor. The threshold value specified (>1% of flow) is arbitrary and has no scientific support. States should be given the flexibility to consider the significance of ecological and resource impacts in imposing BTA rather than being automatically required to impose requirements that are based only on an arbitrary threshold value.

EPA Response

EPA agrees that requiring intake capacity commensurate with close-cycle cooling systems based on waterbody type was not the optimal approach, and has not chosen that approach in today's final rule. For EPA's rationale for rejecting that compliance framework, please refer to the final rule preamble in the section entitled Intake Capacity Commensurate with Closed-Cycle, Recirculating Cooling Systems Based on Waterbody Type, and also, Intake Capacity Commensurate with Closed-Cycle, Recirculating Cooling System Based on Waterbody Type and Proportion of Waterbody Flow.

RFC: Definition of "adverse environmental impact"

Various definitions of Adverse Environmental Impact, including that any I&E is adverse, or use a threshold approach (VI.C.5: 17162-17164)

As we noted earlier, Maryland regulations consider CWIS impact at the level of RIS or ecosystem function. We believe that this is a scientifically and valid basis for determining if adverse impact is occurring. We disagree that the numerical magnitude of organisms entrained and impinged is, by itself, indicative of adverse environmental impact.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

Comment ID 316bEFR.099.027

Subject Matter Code 18.02

RFC: Use of previous demonstration studies

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Use of previous 316(b) demonstrations for AEI and BTA and criteria for current adequacy (VI.C.5.b(4): 17165)

Maryland strongly supports the use of prior 316(b) studies for demonstrations of AEI and BTA, but is in agreement with several of the caveats that EPA presents. Most importantly, we concur that results of prior studies are only valid and useful if the basic nature and composition of the source water body ecosystem has not changed substantially. If there have been major shifts in biological communities and major changes in relative species abundances, it is appropriate that the permitee be required to collect and submit data representative of current conditions.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule; however, existing data that is reflective of current conditions may be used to support the required studies. Please see response to comment 316bEFR.040.001 for details.

Comment ID 316bEFR.099.028

RFC: Role for fish & wildlife agencies for site-specific

Appropriateness of cost-effectiveness evaluation of CWIS technology or other measures to determine BTA for minimizing AEI (VI.C.5.c(3): 17165)

We believe that the use of an incremental cost-benefit assessment as a procedure for establishing BTA is reasonable. As suggested by PSEG, the costs of a series of potential BTA technologies would be estimated concurrently with the incremental environmental benefits that would result from implemention of those technologies. It appears that a requirement for such a sequential assessment may place a substantial burden on both the permitee as well as the Director, since the validity of each of the cost estimates would have to be evaluated. This may be a procedure that could be included as guidance, rather than being incorporated into the regulation itself.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161). Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

Please refer to the responses to comments 316bEFR.005.020 and 316bEFR.410.001 for a discussion of the application of the cost-benefit and cost-cost tests. Also see 316bEFR.345.003.

EPA disagrees that a large percentage of facilities will opt for a site-specific determination of BTA. Please refer to the response to comment 316bEFR.202.002 for more information.

Comment ID 316bEFR.099.029

Subject Matter Code 11.0

Role of Restoration

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Permit voluntary restoration or enhancement measures to be included for compliance (VI.C.5.d: 17166)

As we indicated in item 6, above, we believe that restoration or enhancement measures should not be considered to be only supplemental to BTA determination. Thus we are supportive of voluntary measures being accounted for in permitting decisions, to the extent that they are consistent with, and supportive of, a state's resource management goals and objectives.

EPA Response

Under the final rule, facilities may use restoration measures either in lieu of or as a supplement to design and construction technologies and/or operational measures that reduce impingement mortality and entrainment.

For a discussion of the extent to which restoration measures are voluntary, see EPA's response to comment 316bEFR.060.022.

A restoration measure may be designed to be consistent with and supportive of state resource management goals and objectives provided that the measures also meet the requirements for restoration measures described in the final rule, including those in sections 125.94 and 125.95.

Organization State of Maryland Dept of Natural Resources

Subject Matter Code 21.08

Burden on permitting agencies (general)

Burden of implementing site-specific 316(b) rules on permitting agencies (VI.C.6:17167)

Maryland agrees that a site-specific approach does pose a substantial burden on the agencies with responsibility for reviewing and approving 316b applications. Because PPRP is unique within the country (e.g., a small surcharge on electric bills provides funding for the evaluation of power plant impacts), we recognize that many other states may not have comparable technical and financial resources to be applied for that purpose. However, as we have noted above, we strongly believe that a site-specific approach to 316b implementation is the most cost-effective means of maximizing benefits to our citizens from this new rule. Our suggestion to EPA for minimizing the burdens to other states would be to develop guidance documents for implementation of the rule that are clear and detailed, so that the information to be presented to the agencies is relatively standardized and done in a manner that enhances the likelihood that the findings are applicable, and technically sound.

EPA Response

EPA has included the site-specific determination of BTA in today's final rule in addition to four other compliance alternatives. Please see response to comment 316bEFR.019.014 for a discussion of site-specific considerations. In addition, EPA agrees with the commenter on the need for guidance and plans to develop guidance on implementation for today's final rule.

Comment ID 316bEFR.099.031

Organization State of Maryland Dept of Natural Resources

Subject Matter Code 21.01.04

Comprehensive demonstration study (7 parts)

Comprehensive Demonstration Study: specify particular submission time frame; require approval by Director (VII.B.4.a:17175)

We believe that approval of the demonstration study by the Director is very important, so we do not support removing that requirement. It appears reasonable to establish specific time frames for submission, but, given the substantial uncertainties that surround environmental studies, it is also reasonable to provide substantial flexibility to the Director in enforcing compliance with those time frames.

EPA Response

EPA agrees that with the commenter's statement that the approval of the Comprehensive Demonstration Study (CDS) by the Director is a crucial part of ensuring proper implementation of 316(b) requirements. EPA also agrees that the Director must have flexibility in establishing time frames for submittal of the CDS components. Please see 316bEFR.075.093 for a discussion of what to do in the instance that a facility needs additional time to complete studies.

Comment ID 316bEFR.099.032

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Subject Matter Code 21.05

Role of States and Tribes (alt./equiv. programs)

State alternative regulatory requirements that are “functionally equivalent” and EPA decision criteria for evaluating them; role of restoration and habitat enhancement projects in these (VII..F: 17180)

As we have stated above and in prior submittals to EPA, Maryland believes that its existing 316b regulations have successfully protected our State’s aquatic resources and ecosystems. Thus, we strongly support including in the Phase II rule an allowance for accepting a State’s existing 316b regulations. However, the suggestion in this proposed rule is that the state would have to demonstrate that implementation of their regulations are “functionally equivalent” to implementation of 125.94. As we have noted above, Maryland considers adverse environmental impact at the RIS or ecosystem effects level, as opposed to 125.94 which encompasses total entrainment and impingement mortality caused by the plant. Thus, Maryland’s regulations may be determined by EPA to not be “functionally equivalent” to the regulation proposed in 125.94. We are very supportive of the incorporation of restoration and habitat enhancement as acceptable elements of state regulations.

EPA Response

Under 125.90(c) of today's final rule, EPA allows any State/Tribe to demonstrate to the Administrator that it has adopted alternative regulatory requirements that will result in environmental performance within each relevant watershed that is comparable to the reductions in impingement mortality and entrainment that will be achieved under § 125.94. A State program would be evaluated at the watershed level, not the facility level, such that if reductions in impingement mortality and entrainment at the watershed level are expected to be similar to that which would be achieved under § 125.94, the program may be considered as functionally equivalent.

Performance standards

Definition of what constitutes entrainment vs. impingement

By definition, organisms that pass through a traveling screen and enter the cooling system are entrained, while those too large to pass through the screen are impinged on the screen. Thus, the size of the mesh on the traveling screen has bearing on what is entrained and what is impinged. A 3/8" mesh traveling screen is the conventional separation between the two. EPA should consider specifying the mesh size that would represent the standard for distinguishing between entrainment and impingement.

EPA Response

EPA has modified the definition of calculation baseline to include 3/8-inch mesh traveling screens to aid facilities in distinguishing between "entrainable" and "impingeable".

Comment ID 316bEFR.099.034

Subject Matter Code 11.0

Role of Restoration

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Use of out-of-kind mitigation

While restoration and enhancement is addressed at various points in the proposed rule, out-of-kind mitigation is not explicitly addressed. We have made the point under item 9, above, that a State should be allowed the flexibility to identify the enhancement or restoration measures that would provide the greatest benefit to their constituents, even if those measures represent out-of-kind mitigation. We describe the Chalk Point permit agreement above, in which striped bass and American shad juveniles were raised and released as mitigation for entrainment losses.

EPA Response

"Out-of-kind" restoration measures are permitted in the final rule insofar as they adhere to the general requirements for restoration, including those in sections 125.94 and 125.95. EPA believes the inclusion of the option to use restoration measures in the final rule provides permitting authorities and permit applicants with additional compliance flexibility.

Subject Matter Code 21.09

Permit applications/implementation schedule

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Frequency of detailed permit evaluations

While the standard NPDES permit renewal period is 5 years, in most instances ecosystems do not change substantially over such a short time period. Thus, it may be reasonable to require a detailed 316b reassessment perhaps only every third permit renewal, unless there is reason to believe there is a substantial change in the affected ecosystem or that plant operations are likely to be causing some significant impact.

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. See response to comment 316bEFR 041.126 for a discussion.

Comment ID 316bEFR.099.036

Subject Matter Code 12.02.01

RFC: Uncertainty in I&E mortality estimates

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Quantifying impingement

In many instances, large episodes of impingement occur as a result of already impaired or dead fish accumulating on intake screens. Such situations have occurred where large number of fish such as menhaden accumulate in small confined areas and die as a result of lack of oxygen, and are then drawn into intake screens. Similar situations sometimes occur where unusually cold water immobilizes fish, such as alewife on the Great Lakes. EPA should specify in their guidance documents some means of accounting for such pre-impingement mortality in assessing the need for BTA.

EPA Response

Please see EPA's response to comment 316bEFR.306.116 for an explanation of EPA's position on factoring naturally dead or moribund organisms. For EPA's position on upset or bypass provisions for episodic impingement mortality and/or entrainment events, please refer to the preamble and EPA's response to comment 316bEFR.034.017.

Comment ID 316bEFR.099.037

Subject Matter Code 7.02

Performance standards

Author Name R. McLean

Organization State of Maryland Dept of Natural Resources

Performance ranges vs. a single compliance target and performance baseline

We find the presentation of a range of performance targets somewhat confusing, and do not see that the provision of a range has any ecological significance. We understand that the range presented arises from information available on the efficacy of available intake technologies. However, if the range is based on performance of technologies, perhaps it would be more appropriate just to specify acceptable technologies and not attempt to specify a reduction target. Even in this circumstance, however, the intended reduction only has meaning when a baseline for comparison is established. While the proposed rule indicates what is considered to be a baseline (e.g., a shoreline intake with no protective screening), no guidance is presented on how to use existing or new data to extrapolate what baseline impacts might be. This is a critical missing element in the proposed rule, since compliance with the rule will have to be based on comparison of monitoring results after a BTA determination is made with these projected baseline values.

EPA Response

Please see response to comment 316bEFR.307.064.

For discussions on the basis for and implementation of the calculation baseline, please see response to comments 316bEFR.308.014 and 316bEFR.063.022, as well as the preamble to today's rule.

Subject Matter Code 22.03

Other regulatory requirements

Background

The Proposed Rule would affect 19 existing power plants in California. These power plants are listed in the Enclosure. Of these 19 facilities, nine draw water from the Pacific Ocean. The others draw water from bays, harbors, deltas, and estuaries. Environmental factors have affected the aquatic populations in these water bodies. These factors include pollution, reduction of freshwater inflows, loss of wetland habitat, invasive species, overfishing, thermal discharges and water intakes.

California recently deregulated its electrical utilities and required its privately owned utilities to sell their power plants to other companies. The purpose of this was to separate the delivery of power from the generation of power. The privately owned utilities complied with this requirement and sold their power plants, except for two nuclear power plants, the San Onofre Nuclear Generating Station and the Diablo Canyon Nuclear Power Plant. The new owners have been modernizing the power plants by adding new combined cycle units or replacing existing simple cycle units with combined cycle units Projects of this type have been completed at Huntington Beach, are under construction at Moss Landing, have been approved at Contra Costa, and are under review at Potrero, Morro Bay, and El Segundo. The modernization will most likely continue until all the old single cycle units, except for the nuclear units, are replaced.

The modernization projects are being reviewed by the California Energy, Conservation and Development Commission (California Energy Commission) and the Regional Boards. To complete these reviews, the agencies have required biological studies to be completed to evaluate the impacts of the cooling water intake structures. These projects have been controversial. For various reasons, including the effects of the cooling water intakes, the public has expressed concerns about the continued use of the sites for power generation.

Federal Clean Water Act (CWA) section 316(b) studies were completed for California's power plants in the early 1980s. In some cases, the Regional Boards have required that these studies be revised if the new studies showed that modifications of the intake structures would be effective in reducing impingement and entrainment, the Regional Boards mandated the modifications.

Our experience is that existing technologies for once-through cooling water systems are good at preventing impingement but are poor at preventing entrainment, the effect of which is a challenge to model since the effect concerns impacts on complex biological systems. A parameter that the Central Coast Regional Board has been using for analyzing the effect is the proportional loss of larval productivity caused by entrainment. The proportional loss is determined by comparing the number of larvae entrained to the number of larvae in the source water. The method assumes that larval mortality through the cooling water system is 100 percent and that ecological systems do not compensate for the loss in productivity in a positive way. If this method is used, a once-through cooling water system located in a small bay or harbor will be shown to have a greater impact than a system located in an ocean. Exceptions for ocean intakes may occur when the intake is located in a small cove or an area of highly productive habitat.

California has an environmental review law called the California Environmental Quality Act (CEQA) that requires environmental review for projects, such as power plant modifications. In general, CEQA requires that for each significant impact identified in an environmental impact report (EIR), the EIR must discuss feasible measures to avoid or substantially reduce the project's significant environmental effect. CEQA gives public agencies in California the authority to require feasible changes in any or all activities involved in a project to substantially lessen or avoid significant effects on the environment. This authority, however, is not unlimited, and there must be a clear nexus between the impact and the proposed mitigation. Under CEQA, the California Energy Commission is the lead agency for review of power plant modifications and has its own environmental review process.

California brought new power plants on line last year, and, at this time, it has enough power generation capacity to meet its energy needs. (These new plants do not have water intakes.) It does not, however, have a surplus of power generation capacity, and some power plants recently approved for construction are not initiating construction because of uncertainty in California's energy markets. Hence, any rule that requires an extended down time for plant modifications in the near future could create energy supply problems in California.

EPA Response

Today's rule provides facilities with several options for complying with the requirements such that EPA does not expect that extended downtime will be needed by facilities.

Comment ID 316bEFR.100.002

Subject Matter Code 3.01

Definition: Existing Facility

Author Name Celeste Canti

Organization State Water Reources Control Board

Under the definition in the Proposed Rule, additional units or units that replace existing units would be classified as existing facilities. Although site constraints may prevent the installation of recirculating cooling water towers on these new units, for other upgrades the cost of constructing a recirculating cooling water tower may be equivalent to the cost of constructing a recirculating cooling water tower at a new facility. USEPA should consider this in developing its standards. The issue is whether existing facilities should always be “grandfathered” into the lower standard of the existing facility rule or whether they should be placed into the higher standard of the new facility rule as existing units are replaced.

EPA Response

See response to 316bEFR.064.002. As indicated in section II of the preamble to the final rule and the referenced response, changes at existing facilities are not always "grandfathered" and regulated as existing facilities. Such changes can be regulated as new facilities, depending on what they are. EPA notes that the Agency's national cost estimates indicate that it is more expensive (and more difficult) to retrofit close-cycle cooling towers at existing facilities than to install them at new facilities.

Comment ID 316bEFR.100.003

Subject Matter Code 7.02
Performance standards

Author Name Celeste Canti
Organization State Water Reources Control Board

The proposed rule lists performance standards that a power plant must meet. For a power plant that generates more than 15 percent of its maximum capacity, the standards are:

-An 80 to 95 percent reduction in impingement from what would occur if the power plant had no facilities to reduce impingement (i.e., an onshore intake with a trash rack) and

-A 60 to 90 percent reduction in entrainment from what would occur if the power plant had no facilities to reduce entrainment.

The Proposed Rule is unclear as to how to measure the required reduction in impingement and entrainment. Do you measure the reduction by counting the organisms impinged and entrained? Do you weigh the organisms impinged and entrained? If so, do you use dry weight or wet weight? Do you have to measure the reduction for each life stage, or do you lump all life stages together and use a combined count or weight?

EPA Response

Please see response to comment 316bEFR.063.005.

Comment ID 316bEFR.100.004

Author Name Celeste Canti

Organization State Water Reources Control Board

Subject Matter Code 7.03

Available I&E technologies

The technologies available to meet the required reduction in entrainment are unproven. Table 5-1 in the development document shows three technologies that can meet a 60 to 90 percent reduction in entrainment. These are the Gunderboom aquatic filter barrier, fine mesh traveling screen, and fine mesh wedgewire screen. The Gunderboom aquatic filter barrier has only been used at one facility; it may be susceptible to biofouling; and it may not work in conditions of heavy currents or wave action. Fine mesh traveling screens have had limited seasonal applications and require frequent maintenance, especially in marine environments. Wedgewire screens are more suitable for closed-cycle make-up intakes because the large size of the screens limits their applicability.

EPA Response

EPA disagrees with the commenter's assertion and maintains that the technologies forming the basis for the entrainment reduction range contained in the performance standards of today's rule are economically practicable for Phase II facilities considered as a group. A facility may opt for any combination of design and construction technologies, operational measures, or restoration measures to reduce entrainment as required by today's rule. Site-specific requirements are also available based on cost-cost or cost-benefit considerations.

EPA does not agree with the commenter's assertion that wedgewire screens are more suitable for closed-cycle make-up intakes; closed-cycle facilities do not necessarily withdraw small volumes of water. Wedgewire screens are typically limited in their application by debris loads in the source water, ambient current, and through-screen velocity. Larger-volume intakes may require more screen assemblies than would a smaller-volume intake. In these cases, the limiting factor may be the availability of sufficient space to locate the structures.

EPA agrees with the commenter's assertion that fine mesh screens require frequent maintenance and are typically deployed on a seasonal basis. EPA does not agree that this makes the technology limited in its applicability. While maintenance requirements for fine mesh screens may be greater than for standard wide mesh systems, EPA does not believe that an increased maintenance demand makes it an undesirable or economically-unfeasible option to reduce entrainment. Seasonal deployments of this technology may, in fact, be the desired option. Because entrainment events are typically associated with spawning seasons, fine mesh screens may not need to be deployed year-round. As with all design and construction technologies, the optimal deployment scenario must be tailored to the waterbody conditions and intake structure configuration unique to each individual facility.

EPA agrees that the aquatic filter barrier technology (Gunderboom) has only been deployed and evaluated at a limited number of facilities. Initial studies have shown promise to reduce both entrainment and impingement under certain waterbody conditions. It is too soon to make any determination in this rule as to the broad applicability of this technology.

Comment ID 316bEFR.100.005

Author Name Celeste Canti

Organization State Water Reources Control Board

Subject Matter Code 7.01.03

Option 3--Site-specific determination

Because of the uncertainty of the available entrainment reduction technologies, applicants will most likely decide not to install them and instead will request site-specific determinations or will propose restoration measures as an alternative to meeting the performance standards Otherwise, the owners would risk violating their NPDES permits and being subject to fines and requirements to modify or replace their entrainment reduction facilities.

EPA Response

EPA recognizes that it can be difficult to demonstrate compliance with the national performance standards, e.g., because of variability in the ambient conditions. Therefore, EPA has authorized facilities, with the approval of the Director, to demonstrate compliance using a TIOP.

RFC: Three-option framework for determining BTA

In situations where once-through cooling is being allowed, SWRCB supports a process in which the applicant is required to evaluate alternative technologies for impingement and entrainment reduction and to select the most effective available technology for the site. This selection would be subject to approval from the permitting authority.

EPA Response

EPA agrees that the permitting authority has a central role in the selection of the most effective intake technology. The final rule contains five compliance alternatives from which a permittee may choose. For a discussion of these alternatives and the methods for determining compliance, please refer to the preamble to the final rule.

Comment ID 316bEFR.100.007

Author Name Celeste Canti

Organization State Water Reources Control Board

Subject Matter Code 7.01.03

Option 3--Site-specific determination

As an alternative to meeting the performance standards, the Proposed Rule allows a site-specific determination to be made when:

-The cost to comply with the performance standards would be significantly greater than the costs considered by USEPA when developing the performance standards; or

-The costs to comply with the performance standards would be significantly greater than the benefits.

Our experience is that it is difficult to obtain agreement on costs or benefits. The result is a long series of arguments involving dueling cost/benefit analyses. Cost estimates vary widely between estimates generated by the applicant and those generated by independent consultants. Estimates of biological impacts are even more variable, and the applicant often asserts that there will be no net impact. Even if agreement could be obtained on the benefits to a biological community of meeting the performance standards, agreeing on the monetary value on this benefit would still be difficult. If USEPA decides to adopt this portion of the Proposed Rule, we request that the Proposed Rule require the applicant to fund an independent analysis.

EPA Response

EPA does not believe that a large percentage of facilities will opt for a site-specific determination of BTA, reducing the risk of a protracted debate over the cost-cost or cost-benefit test. Please refer to the response to comment 316bEFR.202.002 for more information.

EPA also believes that the burden of proof lies with the permittee. This is reflected in the choice of words used in the rule language and in the preamble. For example, the rule may say "you [the facility] must demonstrate to the Director" when stating a requirement.

RFC: Appropriateness of "wholly disproportionate"

We also request that "wholly disproportionate" be substituted for "significantly greater" to ensure that site-specific determinations will only be used in unusual circumstances. A rule that requires cost/benefit analyses for most decisions will be difficult to administer.

EPA Response

See response to 316bEFR.006.003. This rule does not require a site-specific determination of best technology available for every Phase II existing facility. Rather, it provides five compliance alternatives, including the ability of facility to seek a site-specific determination of best technology available based on the facility's demonstration, that its compliance costs would be significantly greater than the costs determined by the Administrator in establishing the final rule performance standards, or if its costs of compliance are significantly greater than the benefits of complying with the performance standards at the facility. Given the diversity among Phase II existing facilities, different compliance alternatives are likely to be most cost-effective for different facilities. Given this fact, and the fact that implementing a site-specific determination of best technology available is a potentially more involved process than other available compliance alternatives, EPA expects that the overall rule will not be unreasonably difficult to administer. Costs and benefits have been considered as appropriate in 316(b) decisions made to date, and EPA has included reasonable criteria in the rule to guide this process.

RFC: Proposed use of restoration measures

Author Name Celeste Canti

Organization State Water Reources Control Board

In lieu of or in combination with impingement and entrainment reduction technologies the Proposed Rule allows the use of restoration measures as an alternative to meeting the performance standards. Under the Proposed Rule, the applicant must demonstrate that the restoration measures will maintain fish and shellfish within the water body, including the community structure and function, to a level comparable to those that will result if the performance measures were met.

Although restoration efforts may create a net benefit, it may be unrealistic to expect the restoration effort to restore the original structures to the aquatic community. A cooling water intake structure will affect each aquatic species differently. Therefore, it may be difficult to demonstrate that the original community structure and function is being maintained.

EPA Response

Restoration measures must meet the requirements described in the final rule.

Comment ID 316bEFR.100.010

Author Name Celeste Canti

Organization State Water Reources Control Board

Subject Matter Code 11.02

RFC: Restoration measures as supplement only?

In cases where the cost of complying with the best technology available requirements would be wholly out of proportion to the benefits, it may be preferable to use a less effective technology combined with restoration measures. The emphasis of the Proposed Rule, however, should be the installation of facilities to minimize impingement and entrainment.

EPA Response

For a discussion of the use of restoration measures as a supplement to technology, see EPA's response to comment 316bEFR.060.023.

Comment ID 316bEFR.100.011

Organization State Water Reources Control Board

Subject Matter Code 21.01.04

Comprehensive demonstration study (7 parts)

The Proposed Rule requires the applicant to complete a comprehensive demonstration study at least 180 days before the existing permit expires. As proposed, the comprehensive demonstration study must include:

-A proposal for information collection;
-Source water flow information;
-An impingement and entrainment characterization study;
-A design and construction technology plan;
-Information to support proposed restoration measures;
-Information to support a site-specific determination of best technology available for minimizing adverse environmental impact, and
-A verification monitoring plan

The proposal for information collection should be submitted at least two years before the submittal of the other portions of the comprehensive demonstration study to allow time to review the proposal and complete necessary monitoring.

For the design and construction technology plan, it is not clear as to how to calculate the baseline rate of impingement and entrainment. Rates for impingement and entrainment are site specific, and the only way to accurately characterize them would be to dismantle the existing technology and to measure the subsequent rate of impingement and entrainment. Since the baseline rates will later be used for the purpose of determining compliance, both applicants and regulatory agencies will probably not find estimated rates based on other sites to be acceptable.

EPA Response

Please see the preamble to today's rule and EPA’s response to comment 316bEFR.034.013 for an explanation of the calculation baseline.

Option: Reduce capacity comm. with closed-cycle

It is possible that an existing facility could operate an intake structure servicing a recirculating cooling water system and meet all of the applicability criteria, including the 50 MGD threshold. Since reduction of intake capacity commensurate with operation of a closed-cycle, recirculating system is a performance standard for demonstrating minimal adverse impact (proposed 40 CFR l25.94 (b)(1)), the applicability criteria (proposed §125.91) should simply "screen out" such systems (i.e., recirculating cooling systems). Also, if the cooling water withdrawn by a power producing facility is makeup to a recirculating system, the performance standard is met and there is no need for facility owner/operator to furnish all the detailed permit application information specified in proposed §122.21 and §125.95.

EPA Response

EPA agrees that facilities with closed-cycle, recirculating cooling systems meet the performance standards and are subject to fewer application requirements. Please refer to § 125.94(a)(1) for more information.

Comment ID 316bEFR.101.002

Performance standards

Author Name D.W. Coleman

Organization Energy Northwest

Under another performance standard the facility must reduce impingement mortality by 80 to 95 percent of the calculation baseline (§125.94(b)(2)). The calculation baseline assumes a shoreline intake structure with no impingement controls. This could be interpreted as no trash racks, screens, and other devices against which fish and shellfish can be entrapped. This is problematic because, for this case, there could be no baseline impingement for measuring improvements.

EPA Response

Monitoring requirements

EPA is soliciting comments on appropriate monitoring frequencies for demonstrating compliance with impingement and entrainment standards. We believe it is not appropriate to specific monitoring frequencies in regulation. There are too many variables of location, design, and operation that must be factored into a monitoring program. Offshore intakes in locations exposed to swift currents have special safety considerations, particularly in cold weather regions. Collecting 24-hour samples once per month over two years (EPA suggestion at 67 FR 17149) constitutes excessive exposure in many situations. These elements need to be negotiated with the permitting authority on a case-by-case basis.

EPA Response

EPA's legal authority to:

Author Name Gary Aydell

Organization Louisiana Dept of Environmental Quality

EPA should not promulgate guidelines for cooling water intake structures. When facilities build intake structures located in waters of the US, they are required to obtain permits from the Corps of Engineers (COE) - either under Section 404 of the Clean Water Act (CWA) or Section 10 of the Rivers and Harbors Act. On a case-by-case basis, the COE can prepare an environmental impact statement for those projects expected to have negative environmental impacts. It is redundant for both the COE and EPA to regulate the same activity. This is a waste of federal and state dollars. EPA should seek to have the CWA amended to remove the requirements of 316(b).

EPA Response

The U.S. Army Corp of Engineers implements section 404 of the CWA in conjunction with EPA, whereas in this rulemaking, EPA is implementing section 316(b) of the CWA. These sections have different requirements and different environmental objectives.

Organization Louisiana Dept of Environmental Quality

Subject Matter Code MISC

Miscellaneous comment

Regulating the use of ground water has become a major issue with the Louisiana Legislature. New legislation has been passed to regulate the withdrawal of ground water. Some facilities are making efforts to convert from ground water to surface water. These 316(b) regulations will hinder efforts to reduce ground water withdrawals. As proposed, the requirements on intake structures will encourage existing facilities to covert from surface water to ground water for cooling purposes and will discourage facilities that are willing to converting from ground water to surface water. Whenever adequate surface water is available, it is better to use surface water and conserve ground water for potable water usage.

EPA Response

Today's final rule implements section 316(b) of the Clean Water Act. Ground water issues are beyond the scope of this rulemaking. While what Louisiana Dept of Environmental Quality asserts may be true, no one has demonstrated to EPA that conversions from surface water to ground water have become an issue. The facilities regulated under the Phase II final rule are large facilities that withdraw at least 50 million gallons per day of water. EPA believes that it is highly unlikely that such facilities would be able to pump ground water at this rate. Furthermore, water rights issues are beyond the purview of the section 316(b).

Author Name Gary Aydell

Organization Louisiana Dept of Environmental Quality

Subject Matter Code 21.08

Burden on permitting agencies (general)

In our opinion EPA vastly under estimated the resources necessary for the agency to implement the 316(b) requirements for new sources and Louisiana has no reason to believe EPA has done anything differently for Phase II. Throughout the proposed regulations, reference is made to site-specific determination of best technology available, restoration measures, comprehensive demonstration study, etc. being submitted to the Director for approval. The states and EPA already have a backlog of major and minor permits to issue or re-issue. Where will the states and/or EPA get the resources to review all the submittals required by these new regulations? Louisiana made a similar comment on the proposed 316(b) regulations for new facilities. Well, Louisiana currently has a new facility applying for a new permit under the 316(b) regulations and the staff time to review and evaluate the submittals is enormous. Existing permit writers do not have the experience to review the biological data being submitted. We are having to depend on personnel from our standards section to assist in evaluating the biological data and our engineering section to review some of the design information associated with the intake screen.

EPA Response

EPA appreciates the lack of resources at some State agencies and plans to provide guidance concerning implementation of today's final rule. In addition, EPA has added many efficiencies to the final rule to streamline study requirements and speed permitting. See response to comment 316bEFR.034.005 and response to comment 316bEFR.064.016.

Comment ID 316bEFR.201.004

Author Name Gary Aydell

Organization Louisiana Dept of Environmental Quality

Subject Matter Code 8.01

Proposed standards for FW rivers and streams

There should be some correlation between the criteria for the intake structures and the size of the rivers. The Mississippi River has a 7Q10 flow rate of 141,955 cfs or 9.2 X 1010 GPD and a harmonic mean flow rate of 366,748 cfs or 2.4 X 1011 GPD. One of the larger cooling water intakes on the Mississippi River uses 1040 MGD. The 1040 MGD represents 1% of the Mississippi River's 7Q10 flow rate and 0.4% of the harmonic mean flow rate of the Mississippi River. On the other hand, 2 MGD is more than the critical flow of some of the rivers in Louisiana. Therefore, it is not appropriate to apply the same requirements for all size rivers.

EPA Response

EPA disagrees that the final rule applies the same requirements to all freshwater rivers. Facilities withdrawing greater than 5% of the mean annual flow from freshwater rivers and streams (and having a capacity utilization rate greater than 15%) are required to meet both impingement and entrainment requirements. Facilities withdrawing less than 5% of the mean annual flow are subject to impingement requirements only. EPA acknowledges that intakes are located on waterbodies of varying sizes and therefore pursued an approach based on the percentage of the waterbody withdrawn rather than a fixed intake threshold to determine which facilities would be required to meet both impingement and entrainment requirements.

Apply 316(b) before a det. of impact/AEI

It appears a large amount of information will be necessary for an existing discharger to justify the continued use of once-through cooling water. As stated in comment #3, a large amount of staff time will be required to evaluate this information. The proposed regulations require the existing facilities to submit information to 'document' justification to continue the use of once-through cooling water. This is like saying they are 'quilty until proven innocent'. The regulations should be changed so that the facilities could continue to use once-through cooling water unless EPA or the state determines that the use of once-through cooling water is having a negative impact on the waterbody.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Author Name Gary Aydell

Organization Louisiana Dept of Environmental Quality

Subject Matter Code 6.08

Non-aquatic impacts

Zebra muscles have become a significant problem along the Mississippi River in Louisiana and it is expected to spread to other waterbodies in the state. It has been reported that one method to combat the accumulation of zebra muscles is to maintain a velocity in piping and intake structures of 15-17 ft/sec. If these velocities aren't maintained and zebra muscles accumulate inside intake structures and piping, additional chemicals will be needed to combat the accumulation of zebra muscles. Consideration should be given for exemptions from the requirements when appropriate to control nuisance organisms.

EPA Response

The Agency makes no requirements in the final rule regarding either intake or "inside-the-pipe" velocities. The final rule includes a provision that allows for consideration of invasive species in the calculation of the reduction standards. As such, the commenter's request for flexibility in this matter is met. In addition, as the commenter states, utilizing extreme intake velocities is but "one method" to combat zebra mussels. The Agency notes that no facility responding to the 316(b) survey reported intake velocities approaching 15 to 17 ft/sec. The median intake velocity reported by existing facilities within the scope of this rule is 1.5 ft / sec. Nonetheless, the Agency estimated the costs of controlling zebra mussels in locations such as the Mississippi River in Louisiana (through materials selection on retrofitted intake structures) in the final rule's analysis. See the Technical Development Document for further information on the costs developed to support the final rule and the inclusion of zebra mussel mitigation costs for these technologies.

RFC: Appropriate spatial scale for restoration

The proposed regulations say that 'restoration measures' must be in the same waterbody. The regulations should allow for restoration measures in other waterbodies. Along the Mississippi River the federal government and the state have spent millions of dollars to divert water from the Mississippi River to adjacent waterbodies and estuaries. The state has been negotiating with some existing facilities to divert some of their once-through, non-contact cooling water to the natural drainage (away from the Mississippi River) to enhance the adjacent waterbodies. Thus, the enhancement (or restoration measures) will not be in the same waterbody.

EPA Response

For a discussion of the appropriate scale on which to conduct restoration measures, see EPA's response to comment 316bEFR.212.001.

General Statement of Opposition

As articulated throughout the enclosed comment document, the Department has a number of concerns regarding the proposed rule. One significant concern is that the proposed rule substantially weakens the 316(b) review process employed over the past 25 years, without any offsetting benefit in efficiency or predictability.

EPA Response

No response is required, as this comment summarizes the author's comments. Each issue is addressed individually in subsequent responses.

Comment ID 316bEFR.202.002

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 7.01

RFC: Three-option framework for determining BTA

EPA had committed to simplifying the 316(b) process and making it more predictable and consistent, by minimizing the need for the resource-intensive case-by-case BTA evaluations that we have been doing for 25 years. The proposed rule does nothing to address these goals. Instead, it will perpetuate the need for case-by-case evaluations in most cases, because the most attractive option for most facilities will be to avoid the performance standards by seeking a site-specific BTA determination.

EPA Response

EPA acknowledges the substantial burden associated with a site-specific permitting process for both permittees and regulators. To alleviate this burden, EPA has crafted this final rule to include compliance alternatives that greatly reduce the effort required by both parties during the permitting process. For example, a permittee can demonstrate to the Director that its current cooling water intake structure configuration meets the applicable performance standards (see § 125.94(a)(2)) or demonstrate to the Director that it has installed is properly operating and maintaining a rule-specified approved design and construction technology (see § 125.94(a)(4)). Facilities with closed-cycle recirculating cooling and facilities with a design through-screen velocity of 0.5 ft/sec or less (see § 125.94(a)(1)) also meet some or all of the performance standards. These compliance alternatives meet the performance standards, generally without the permitting burden associated with the site-specific compliance option. As such, EPA does not expect inordinate numbers of facilities to seek a site-specific determination of best technology available.

Additionally, EPA expects some facilities to opt to conduct a Technology Installation and Operation Plan (TIOP), as described under § 125.95 and in section IX of the preamble.

Comment ID 316bEFR.202.003

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 7.01.03

Option 3--Site-specific determination

Case-by-case evaluations under the proposed rule will be far less environmentally protective than the evaluations the states currently conduct. Currently, a facility must demonstrate that the costs of reducing impingement and entrainment impacts are "wholly disproportionate" to the benefits. EPA has proposed to weaken that standard, allowing a facility to avoid meeting performance standards if the costs are merely "significantly greater" than the benefits, or if the costs are "significantly greater" than what EPA estimated in developing the rule. This is especially problematic when the EPA has acknowledged that its estimate of compliance costs is shaky at best. Time constraints prevented the EPA from running an economic model to obtain cost data for the regulatory option included in the proposed rule.

EPA Response

Under this final rule, EPA has established national performance standards for the reduction of impingement mortality and, when appropriate, entrainment (see § 125.94). These performance standards reflect the best technology available for minimizing adverse environmental impacts determined on a national categorical basis.

Today's rule also preserves each State's right to adopt or enforce more stringent requirements.

For more information on the use of the term "significantly greater," please refer to the response to comment 316bEFR.006.003.

Comment ID 316bEFR.202.004

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 7.01.03

Option 3--Site-specific determination

Another significant concern with the site-specific option is that it is likely that a facility will contend that there are no cost-effective fish protection technology alternatives and will then argue that it is justified in doing nothing to minimize impingement and entrainment effects. The Department is also concerned that the regulated community will use this alternative as a means to declare that they have no adverse impact and investigation and/or implementation of fish protection alternatives is unnecessary. The permittee would then devote resources into disproving it has an impact where that effort could be better spent in developing a technological solution to minimize impingement and entrainment effects. The rule, therefore, is likely to result in protracted dialogue between the permittee and the regulatory agency, undue and wasted effort, and delayed implementation of the required improvements.

EPA Response

This rule does not require a determination of whether an adverse environmental impact is occurring as a preliminary step in implementing 316(b). Please refer to the response to comment 316BEFR.313.001 for more information on EPA's position on minimum impacts at existing facilities.

Author Name Bradley M. Campbell
Organization NJ Dept of Environmental Protection

Subject Matter Code 22.01
Executive Orders (except EO 13211)

The Department is concerned that in proposing this rule, the EPA has disregarded state interests protected by a Presidential Executive Order (Executive Order 13132) on federalism. The rule, as proposed, differs greatly from what the EPA had submitted to the Office of Management and Budget in December 2001. Most importantly, the draft submitted to the OMB included the site-specific alternative as narrow exception to be used sparingly, to a freely available alternative to complying with performance standards. The proposed rule implicates federalism because it affects the policymaking discretion of the States in a manner that is not mandated by federal statute.

The expansion of the site-specific alternative from an exception (as contained in the December 2001 draft) to a freely available third regulatory option imposes an enormous additional administrative burden on the States with a commensurate increase in direct implementation costs, and no additional funding.

EPA Response

EPA has followed Executive Order 13132 regarding federalism and concluded that this rule does not have federalism implications.

Comment ID 316bEFR.202.006

Use cost-benefit tests

The imposition of a formal cost/benefit analysis as a central focus of the regulation is not mandated (or even authorized) by Section 316(b) of the Clean Water Act or by any other federal law.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Comment ID 316bEFR.202.007

Author Name Bradley M. Campbell
Organization NJ Dept of Environmental Protection

Subject Matter Code 18.01
RFC: Definition of "adverse environmental impact"

Use of Term Adverse Environmental Impact

General Comment, Several Locations

The Department suggests replacement of the term "minimizing adverse environmental impact" with the term "minimizing impingement and entrainment effects" wherever possible. It is the Department's current policy to consider the death of any fish at or through a cooling water intake to be an "adverse impact" which must be minimized under Section 316(b). This position makes sense and simplifies an already complex analysis.

A debate regarding whether or not an adverse impact is occurring is not a productive use of time or resources. The Department is concerned that use of the term "adverse environmental impact" will contribute to the debate between the regulated community and regulatory agencies concerning whether or not an adverse environmental impact is occurring instead of on ways to minimize impingement and entrainment effects. This debate could last for years and include discussions regarding the population measure of a given fish species, let alone many fish species. The results of biological population studies and modeling can be very subjective because it is difficult to identify, measure, and attribute the impact of each of the many variables (what's happening on a coast wide basis, or what's happening with the climate) affecting populations of each of the impacted species. Rather than engage in this kind of biological debate, time and resources would be better spent focusing on the magnitude of the impingement and entrainment losses in relation to the costs and benefits of implementing various technologies to avoid or minimize the impact. This focus is appropriate for Section 316(b) which the Department feels is a technology-driven provision.

The Department is hereby requesting that the term "minimizing adverse environmental impact" be replaced with the term "minimizing impingement and entrainment effects" at the following locations in the proposed regulation:

122.21(r) (ii)	125.94(a)	125.94(e)	125.98(b)(1)(iii)
125.90(a)	125.94(a)(3)	125.94(f)	
125.90(b)	125.94(c)(2)	125.95(b)(6)	
125.94	125.94(c)(3)	125.94(b)(6)(ii)	

While it is suggested that the term "minimizing adverse environmental impact" be replaced with the term "minimizing impingement and entrainment effects" in all the above referenced locations, it is particularly important that these changes be made wherever the site-specific alternative is specified. Given that requests for consideration under the site-specific alternative are inherently subject to consideration of site-specific factors and hence site-specific decision-making, it is particularly important that the regulation language be clear as to its intent in minimizing impingement and entrainment effects. Therefore, it is critical that this language substitution be made at the following locations:

122.21(r)(ii)   125.95(b)(6)
125.94(c)(2)   125.94(b)(6)(ii)
125.94(c)(3)   125.98(b)(1)(iii)

Additional detail concerning this issue is included in Comment 6 below.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule. See also preamble to the final rule.

Submittal of required information

122.21(r)(2)(iii), Locational Maps

It is not clear what is meant by the term "locational maps". This should be clarified to indicate whether this means a locational map of the facility; locational map of the cooling water intake structure; or some other meaning.

EPA Response

Locational maps are required with respect to the source water physical data. Maps showing the location of the source water body with respect to the geographic surroundings are required.

Comment ID 316bEFR.202.010

Author Name Bradley M. Campbell
Organization NJ Dept of Environmental Protection

Subject Matter Code 21.01.03
Cooling water system description

122.21(r)(5)(i), Phase II Existing Facility Cooling Water System Data

This item should be expanded as follows:

(i) A narrative description of the operation of each of your cooling water systems, relationship to cooling water intake structures, proportion of the design intake flow that is used in the system, number of days of the year in operation and seasonal changes, if applicable, <ADD: and a listing of other cooling water intake structures on the same watershed within a ten mile radius.>

A listing of other nearby cooling water intake structures would be helpful for the regulatory agency for many reasons including, but not limited to: understanding the species of concern, identifying other Section 316(b) data that may already be available, and in identifying other intake protection technologies that may have been researched and/or implemented to address the species of concern.

[see hard copy for insert/strikeout text]

EPA Response

EPA has determined that it will not request from facilities a listing of cooling water intake structures located in their watersheds. Because permitting Directors will receive permit applications from each facility in their jurisdictions, and each applicant must name his or her facility's intake waterbody and locale, EPA did not feel it was necessary to include that additional requirement. EPA believes that requiring facilities to submit information that the Director will already have access to would be redundant.

Subject Matter Code 3.01
Definition: Existing Facility

Clear Applicability

125.91 (a)-(d), What is a "Phase II Existing Facility" subject to this subpart?

The Department supports the language and criteria described in this section. It is imperative that the applicability of Section 316(b) be unambiguous and straightforward to ensure that State agencies can utilize their resources focusing as to how to minimize impingement and entrainment as opposed to debating as to when Section 316(b) applies. The Department supports these specific criteria and finds them reasonable in ensuring that existing facilities that are likely to have an impact will be addressed. The Department is particularly supportive of the threshold of 50 million gallons per day as it provides a clear boundary and, as noted by US EPA, addresses 99.04% of water withdrawn yet covers 539 of 942 plants (57%). These criteria will help ensure that regulatory agencies focus on the largest impacts.

EPA Response

Supports rule, particularly 50 MGD threshold. No response necessary.

Author Name Bradley M. Campbell
Organization NJ Dept of Environmental Protection

Subject Matter Code 3.02
Definition: Cooling Water Intake Structure

125.91(c), Source of Cooling Water

The Department would like to make specific mention of its support for the language in this section which states "Use of cooling water does not include obtaining cooling water from a public water system or use of treated effluent that otherwise would be discharged to a water of the U.S." The Department has an active reuse program (i.e. recycling and/or reuse of treated effluent to be used as a water source for other purposes such as cooling water) and interprets this language to encourage reuse practices. Specifically, the Department interprets this language to mean that if reuse water is used, this water will not be counted towards the twenty-five percent water withdrawal threshold cited as eligibility criteria under 125.91. The Department also supports this same philosophy that is articulated in the definition of cooling water at 125.83.

EPA Response

Comment supports excluding from cooling water use obtaining cooling water from a public water system or use of treated effluent. It also supports excluding from the 25 percent threshold cooling water used in a manufacturing process before or after use for cooling. Both provisions have been retained in the final rule. EPA agrees that reuse consistent with § 125.91(d) would not be considered cooling water use or counted towards the 25 percent threshold in § 125.91(a)(4).

Permit applications/implementation schedule

Use of Compliance Schedules

125.92, When must I comply with this subpart?

As discussed further in Comment 6B, the Department has concerns about the feasibility of complying with the performance standards in 125.94(b). As such the Department feels it is imperative that the issue of compliance schedules be addressed. Although the Department does have concerns regarding the feasibility of achieving performance standards in the short-term, the Department supports performance standards and suggests that incentives in the form of flexibility be offered to those facilities, which choose to comply with them. As such, the Department is suggesting that the language in 125.92 be expanded as follows:

(a) You must comply with this subpart when an NPDES permit containing requirements consistent with this subpart is issued to you. <ADD: Regulatory authorities can incorporate compliance schedules into a NPDES permit in order to implement and/or study fish protection technologies to meet the performance standards at 125.94(b). >

It should be noted that the Department has specifically mentioned 125.94(b), but has not identified 125.94(c). The Department does not agree that this same flexibility regarding compliance schedules should be offered to facilities that choose the site-specific alternative as identified under 125.94(c).

RFC: Definition of "adverse environmental impact"

Lack of Definition of Adverse Environmental Impact, Inclusion of Definition for "Significantly Greater"

125.93, What special definitions apply to this subpart?

The Department notes that the term "adverse environmental impact" has not been defined in this section. The Department suggests that this section be modified to include a definition where "adverse environmental impact" should be defined as "any impingement or entrainment of aquatic organisms". This is the same definition that the Department currently uses in applying its Section 316(b) policy for existing facilities. The Department considers the death of any fish at or through a cooling water intake to be an "adverse impact" which must be minimized under Section 316(b). This position makes sense and simplifies an already complex analysis as described above in Comment 1.

Although the above referenced definition would be the Department's first choice, another alternative would be to simply not define "adverse environmental impact" as has been done in the proposed rule. The Department supports this lack of definition as well.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

RFC: Appropriateness of "significantly greater"

The Department suggests definition of the term "significantly greater" with either a number or a range. The Department suggests a range of 6 to 7 where at least $6 or $7 of costs must outweigh $1 of benefits in order for a permitting agency to disregard a particular technology.

EPA Response

See responses to 316bEFR.006.003 and 018.009.

Comment ID 316bEFR.202.016

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 10.07.02

RFC: Appropriateness of "significantly greater"

The Department suggests replacement of the term "significantly greater" in 125.94(c) with the term "wholly disproportionate" as described later in Comment 6G and Comment 19. The term "significantly greater" can be interpreted as being less stringent than the term "wholly disproportionate". Since "wholly disproportionate" is used in applying the Department's Section 316(b) policies based on case law, the Department has determined that use of "significantly greater" would be applying a less stringent standard which is inconsistent with the intent and philosophy of 40 CFR 122.44(l). If replacement of this term is incorporated, "wholly disproportionate" should be defined in this section as a range of at least 6 to 7 (or greater) as described above.

EPA Response

Site-Specific Alternative

125.94, How will requirements reflecting best technology available for minimizing adverse environmental impact be established for my Phase II existing facility?

The Department has numerous comments/suggestions regarding this section. As such, the Department has reiterated a portion of the rule, including suggested deletions and additions, and summarized its concerns below in individual comments.

125.94 How will requirements reflecting best technology available for minimizing <STRIKE: adverse environmental impact> <ADD: impingement and entrainment effects> be established for my Phase II existing facility?

(a) You may choose one of the following three alternatives for establishing best technology available for minimizing <STRIKE: adverse environmental impact> <ADD: impingement and entrainment effects> at your site.

(1) You may demonstrate to the Director that your existing design and construction technologies, operational measures, and/or restoration measures meet the performance standards specified in paragraph (b) of this section;

(2) You may demonstrate to the Director that you have selected design and construction technologies, operational measures, and/or restoration measures that will, in combination with any existing design and construction technologies, operational measures, and/or restoration measures, meet the performance standards specified in paragraph (b) of this section; or

(3) You may demonstrate to the Director that a site-specific determination of best technology available for minimizing <STRIKE: adverse environmental impact> <ADD: impingement and entrainment effects> is appropriate for your site in accordance with paragraph (c) of this section.

Compliance Schedules

As stated above in Comment 4, it is important to be clear on the issue of compliance schedules. The Department has determined that compliance schedules are appropriate in order to implement the performance standards at 125.94(b), particularly in the short-term.

(1) You must reduce your intake capacity to a level commensurate with the use of a closed-cycle, recirculating cooling system; or

(2) You must reduce impingement mortality <ADD: (initial mortality)> of all life stages of <ADD: representative important species (including> fish and shellfish) by 80 to 95 percent from the calculation baseline if <STRIKE: your facility has a capacity utilization rate less than 15 percent> your facility's design intake flow is 5 percent or less of the mean annual flow from a freshwater river or stream; or

(3) You must reduce impingement mortality <ADD: (initial mortality)> of all life stages of <ADD: representative important species (including> fish and shellfish) by 80 to 95 percent from the calculation baseline, and you must reduce entrainment of all life stages of <ADD: representative important species (including> fish and shellfish) by 60 to 90 percent from the calculation baseline if your facility <STRIKE: has a capacity utilization rate of 15 percent or greater and> withdraws cooling water from a tidal river or estuary, from an ocean, from one of the Great Lakes, or your facility's design intake flow is greater than 5 percent of the mean annual flow of a freshwater river or stream; or

<ADD: (4) You must meet the performance standards cited in (b)(1), (b)(2), or (b)(3) above if your facility has a capacity utilization rate of 10 percent or less. As an alternative the facility can: (a) accept a permit condition restricting operations to an average capacity factor of 10% over any three calendar years; (b) accept a permit condition restricting operations to a capacity factor of no more than 20% in any calendar year; (c) accept a permit condition that imposes seasonal restrictions as reasonably necessary to protect aquatic life; or (d) accept a permit condition requiring cessation of the use of once-through cooling no later than the expiration date of the permit.>

Author Name Bradley M. Campbell
Organization NJ Dept of Environmental Protection

Subject Matter Code 12.02.01
RFC: Uncertainty in I&E mortality estimates

Performance Standards

Impingement mortality should be clarified to state "initial mortality". Reducing initial mortality will address the bulk of the mortality associated with impingement in many cases. Latent mortality is much more difficult to control and site-specific factors could cause the results to vary results tremendously. In establishing latent mortality, aquatic organisms are held in a laboratory environment in an effort to represent how many fish suffer from mortality after being released to the receiving water. Because a laboratory environment is very different from a receiving water environment, it is questionable whether latent mortality studies represent "real world" latent mortality.

EPA Response

Please see EPA's responses to comments 316bEFR.099.036 and 316bEFR.074.023.

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 16.01

RFC: Regulating limited capacity facilities

The Department does not agree with the capacity utilization rate of fifteen percent or less as a threshold for not requiring entrainment measures. Instead, the Department suggests a capacity utilization rate of ten percent or less as a threshold for alternate measures which is consistent with the definition of a peaking unit at 40 CFR 72.2 as contained in Federal Air Regulations. The Department also does not agree that facilities with low capacity utilization rates should be exempt from meeting performance standards. In many cases a facility that is operated as a peaking unit is an older facility. Older facilities can have substantial withdrawal rate volumes and hence significant impingement and entrainment effects on aquatic life during biologically critical times of the year even if the facility is operated infrequently. The Department suggests that these facilities be required to meet performance standards at 125.94(b). As an alternative, the Department suggests that these facilities be given the option to: (a) accept a permit condition restricting operations to an average capacity factor of ten percent over any three calendar years; (b) accept a permit condition restricting operations to a capacity factor of no more than twenty percent in any calendar year; (c) accept a permit condition that imposes seasonal restrictions as reasonably necessary to protect aquatic life; or (d) accept a permit condition requiring cessation of the use of once-through cooling no later than the expiration date of the permit.

EPA Response

The Agency has defined the capacity utilization rate threshold based on an analysis of the facilities within the scope of this final rule, and not based on federal air regulations. The definition of a "peaking unit" under the Federal Air regulations is not relevant to the cooling water intake of a power plant. The Agency notes that other commenters attempted to use the same logic (i.e., basing the capacity utilization rate on a definition of a peaking unit) to justify a rate higher than 15 percent. See DCN 6-3586 for the Agency's analysis of cooling water intake flows and capacity utilization of plants within the scope of the rule. See also preamble to the final rule.

The Agency cannot accept the suggestion that facilities be required to cease using once-through cooling at the expiration of their current permits. For the Agency's discussion of the rejection of the cooling tower retrofit options see section VII.E of the preamble to the final rule.

The Agency notes that seasonal (or strategic) restriction on cooling water intake flow can be a condition of a permit if that is part of the means by which a facility will attempt to meet the entrainment reduction standards. In addition, in the case where significant local issues justify standards more stringent than those imposed by this final rule, the Director may have the authority under state or other federal laws to require such seasonal restrictions in addition to the requirements of this final rule.

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 7.02

Performance standards

The Department emphatically supports the concept of performance measures. The Department views Section 316(b) as a technology driven provision and finds performance measures to be in line with this approach. The Department also finds it reasonable to set such measures as a range of values rather than a discrete value given the natural variability of impingement and entrainment effects. The Department finds the proposed performance measures stringent, but reasonable so long as flexibility is given to regulatory authorities in applying them. Given the stringent nature of these standards, particularly for entrainment, the Department has concerns about requiring such performance measures immediately. Although there are some impingement control technologies that can come close to or attain the impingement control performance measures specified in the rule at some sites, the same can not be said for entrainment at this time even at the lower range of 60% reduction. The Department is confident that promulgation of this rule in final form will generate research and development that will benefit the science of fish protection technologies for both impingement and entrainment. However, this research and development can take several years to complete, and developing something in a laboratory setting is very different from applying something at a particular site.

EPA Response

EPA agrees that facilities should have time to design, install and optimize technologies to achieve the requirements of this rule. Today's rule reflects this.

Comment ID 316bEFR.202.024

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 7.03

Available I&E technologies

In addition, given the development of behavioral technologies such as light and sound, it is critical that caution be exercised in applying these technologies at individual sites. There is always the risk that these technologies can cause more harm than good given attraction potential and the many confounding factors present in an aquatic environment. It is critical that time be given to develop and study these technologies before they are implemented and the regulated community is subject to compliance with such performance measures. Clarification on the issue of compliance schedules as noted above in Comments 4 and 6B will help to alleviate this concern.

(4) (5)If your facility withdraws cooling water from a lake (other than one of the Great Lakes) or reservoir:

(i) You must reduce impingement mortality <ADD: (initial mortality)> of all life stages of <ADD: representative important species (including> fish and shellfish) by 80 to 95 percent from the calculation baseline; and
(ii) If you propose to increase your facility's design intake flow, your increased flow must not disrupt the natural thermal stratification or turnover pattern (where present) of the source water, except in cases where the disruption is determined by any Federal, State or Tribal fish or wildlife management agency(ies) to be beneficial to the management of fisheries.

[see hard copy for insert/strikeout text]

EPA Response

EPA agrees that behavioral barriers, such as the light and sound deterrents mentioned by the commenter, can be effective under certain circumstances, but has not based the performance standards of today's final rule on any data evaluated for these technologies because of the limited study data detailing their effectiveness. EPA does not believe, however, that these technologies should be excluded from the options available to facilities in meeting the requirements of today's final rule.

For a discussion of compliance issues, see the preamble to the final rule.

Subject Matter Code 7.01.03

Option 3--Site-specific determination

Site-Specific Determination

Regarding deletion of the phrase “would be significantly greater than the costs considered by the Administrator when establishing such performance standards”, please refer to Comment 6F below.

The Department has many concerns regarding (c)(1) above including the fact that this alternative will be extremely resource intensive for the permitting agencies. However, the Department’s biggest concern is that the regulated community will find that there are no fish protection technology alternatives for which the costs are not significantly greater than the benefits and will then argue that “doing nothing” to minimize impingement and entrainment is the only cost-effective alternative. The Department is also concerned that the regulated community will use this alternative as a means to declare they have no adverse impact and investigation and/or implementation of fish protection alternatives is unnecessary. The permittee would then devote time and energy into disproving that it has an impact where that time and energy could be better spent in developing a technological solution to minimize impingement and entrainment effects.

One way to dissuade the regulated community against this alternative would be to make clear that the burden is on the person requesting the alternative requirement to demonstrate that alternative requirements should be imposed. In addition, the permittee should have to include a detailed cost/benefit analyses along with its application under this alternative. Inclusion of these suggested changes will help to address some of these concerns.

The Department also suggests that incentives be given to persuade the regulated community to comply with the performance standards instead of this alternative. As discussed in Comment 4, clarifying that compliance schedules are acceptable may work to make compliance with the performance standards more reasonable for the regulated community.

<STRIKE: (2) If data specific to your facility indicate that your costs would be significantly greater than those considered by the Administrator in establishing the applicable performance standards, the Director shall make a site-specific determination of best technology available for minimizing adverse environmental impact that is based on less costly design and construction technologies, operational measures, and/or restoration measures to the extent justified by the significantly greater cost. The Director’s site-specific determination may conclude that design and construction technologies, operational measures, and/or restoration measures in addition to those already in place are not justified because of significantly greater costs.>

[see hard copy for insert/strikeout text]

EPA Response

Please refer to the response to comment 316BEFR.202.004.

EPA disagrees that a large percentage of facilities will opt for a site-specific determination of BTA. Please refer to the response to comment 316bEFR.202.002 for more information.

EPA agrees that the burden of proof lies with the permittee. This is reflected in the choice of words used in the rule language and in the preamble. For example, the rule may say “you [the facility] must demonstrate to the Director” when stating a requirement. By implication, the burden of proof lies with the permittee.

For more information on the use of the term "significantly greater," please refer to the response to comment 316bEFR.006.003.

For information on compliance schedules, please refer to sections VII, VIII and IX of the preamble.

Comment ID 316bEFR.202.027

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 10.07.02

RFC: Appropriateness of "significantly greater"

Costs Considered by Administrator

The Department does not agree that facilities should be able to qualify for the site-specific alternative strictly based on the rationale that a facility's costs would be significantly greater than those considered by the Administrator in establishing the applicable performance standards. The costs of compliance with the performance standards will vary greatly site by site and costs developed on a national basis are almost certain to be different than costs incurred by a particular facility. Certainly, the waterbodies and locations of facilities are extremely diverse on a regional basis, where this is even more profound on a national basis.

Fish protection technologies are almost certain to evolve if regulatory agencies consistently require facilities to meet and/or study ways to achieve the performance standards. As a result, costs will decrease. So, the costs of fish protection technologies developed at the time of the rule-making may be biased high. It would be unfair to the permitting agencies to allow facilities "a way out" of complying with the performance standards in five, ten or twenty years based on outdated costing information. Based on these reasons, the Department suggests deletion of this alternative.

(3) (2) <STRIKE: If data specific to your facility indicate> <ADD: If a facility is able to present data and analysis that prove> that your costs would be <STRIKE: significantly greater than> <ADD: wholly disproportionate to> the benefits of complying with such performance standards at your facility, <ADD: any interested person can request that> the Director shall make a site-specific determination of best technology available for minimizing <STRIKE: adverse environmental impact> <ADD: impingement and entrainment effects. that is based on less costly design and construction technologies, operational measures, and/or restoration measures to the extent justified by the <STRIKE: significantly greater> <ADD: wholly disproportionate> costs. The Director's site-specific determination may conclude that design and construction technologies, operational measures, and /or restoration measures in addition to those already in place are not justified because the costs would be <STRIKE: significantly greater than> <ADD: wholly disproportionate to. the benefits at your facility.

[see hard copy for insert/strikeout text]

EPA Response

See response to 316bEFR.006.003. EPA notes that if costs do indeed decrease over time, as the comment suggests, existing facilities would have a more difficult time meeting the rule threshold for a site-specific determination of BTA.

Comment ID 316bEFR.202.028

Author Name Bradley M. Campbell
Organization NJ Dept of Environmental Protection

Subject Matter Code 21.08
Burden on permitting agencies (general)

Burden of Proof

It should be clear in the rule that the facility bears the burden to show that costs would be wholly disproportionate to the benefits of complying with performance standards. The regulatory agency is not in possession of the facility's data and economic expertise to make this showing. Where a facility is essentially applying to have a relaxed standard apply to them, the burden should be placed firmly on their shoulders to show that they qualify for consideration under the site-specific alternative. Inclusion of the phrase "If a facility is able to present data and analysis that prove" and "any interested person can request that the Director make a site-specific determination of best technology available" will help make clear that the burden is on the person requesting the alternative requirement to demonstrate that alternative requirements should be imposed. This is consistent with the intent of Comment 6-E.

EPA Response

EPA agrees with the commenter that the burden of proof is upon the facility to demonstrate that it qualifies for site-specific performance requirements and has clarified the rule language accordingly.

Comment ID 316bEFR.202.029

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 11.01

RFC: Proposed use of restoration measures

Restoration Measures

125.94(d), Restoration Measures

First and foremost, the Department considers Section 316(b) to be a technology driven provision. Any technology for which the costs are not wholly disproportionate to the benefits must be either required and/or studied for existing cooling water intake structures. However, in the event that fish protection technologies are not currently available to meet the performance measures at 125.94(b) at a particular site, the Department supports mitigation measures to minimize impingement/entrainment losses. There is no debate that wetlands aid in producing fish and therefore help mitigate the effects of a facility's impingement and entrainment losses. This is especially important since shrinking open space and lost wetlands have become a critical environmental issue. In addition, since entrainment technologies are still evolving and wetlands aid in producing early life stages of fish, restoration is clearly a good idea in the short term. The Department supports the inclusion of restoration measures as part of Section 316(b) rules. However, this support is conditional on the premise that all technological options are carefully considered first and mitigation is not required as a substitute for technology.

To ensure that this concern is addressed, the Department suggests that 125.94(d) be changed as follows:

(d) Restoration Measures. In lieu of, or in combination with, reducing impingement mortality and entrainment by implementing design and construction technologies or operational measures to comply with the performance standards specified in paragraph (b) of this section or the Director's determination pursuant to paragraph (c) of this section, you may, with the Director's approval, employ restoration measures that will result in increases in fish and shellfish in the watershed. <ADD: Restoration measures can only be implemented after all appropriate intake protection technologies have been considered.> You must demonstrate to the Director that you are maintaining the fish and shellfish within the waterbody, including community structure and function, to a level comparable to those that would result if you were to employ design and construction technologies or operational measures to meet that portion of the requirements of paragraphs (b) or (c) of this section that you are meeting through restoration. Your demonstration must address species that the Director, in consultation with Federal, State, and Tribal fish and wildlife management agencies with responsibility for fisheries and wildlife potentially affected by your cooling water intake structure, identifies as species of concern.

The Department prefers the restoration and/or preservation of wetlands to fish stocking. Fish stocking presents the risk of the introduction of disease and does nothing to remedy the problem of loss of aquatic habitat. Restoration and/or preservation of wetlands has the added benefit of enhancing fish production as well as creating and/or preserving habitat for those fish to live in. The Department also supports the installation of fish ladders as a mitigative measure to allow migratory fish to be re-introduced to historical spawning runs.

[see hard copy for insert/strikeout text]

EPA Response

For a discussion of the requirement in the final rule to consider technologies before choosing restoration measures, see EPA's response to comment 316bEFR.033.005. EPA does not want to preclude the use of restoration measures when they can achieve the environmental requirements of the final rule in a more cost-effective, more feasible, or more environmentally beneficial manner than design and construction technologies and operational measures.

The final rule gives permitting authorities the flexibility to make determinations on the feasibility of restoration measures on a site-specific, case-by-case basis. Permitting authorities should consider the net environmental benefits of any proposed restoration measure.

Comprehensive demonstration study (7 parts)

Application Information

125.95, As an owner or operator of a Phase II existing facility, what must I collect and submit when I apply for my reissued NPDES permit?

The Department supports the information referenced in items (a) and (b). The items referenced in this section are comprehensive and cover all relevant information. The Department also supports the fact that the information identified in item (b) must be submitted with a renewal application, which will help by ensuring that the necessary information is submitted without delay and that a consistent timeframe is applied to all facilities.

However, the Department has a few comments/suggestions regarding particular portions of this section which are reiterated below:

(3) Impingement Mortality and Entrainment Characterization Study

(i) – (ii) No changes suggested

(iii) Documentation of the current impingement mortality <ADD: (initial mortality)> and entrainment of all life stages of <ADD: representative important species (including> fish and shellfish) at your facility and an estimate of impingement mortality and entrainment under the calculation baseline. The documentation may include historical data that are representative of the current operation of your facility and of biological conditions at the site. Impingement mortality and entrainment samples to support the calculations required in paragraph (b)(4)(iii) and (b)(5)(ii) of this section must be collected during periods of representative operational flows for the cooling water intake structure and the flows associated with the samples must be documented.

(iv) No changes suggested

Any time comprehensive information (such as a characterization study) is required pertaining to impingement and entrainment it is important that it be clarified that “initial impingement mortality” and “representative important species” be focused on.

EPA Response

EPA appreciates the New Jersey Department of Environmental Protection’s support of EPA’s application requirements. EPA disagrees, however, that it should change the language in the final rule to specify the terms “representative important species” and “initial impingement mortality.” Please see the preamble to today's rule and EPA’s responses to comments 316bEFR.017.003 and 316bEFR.063.005 for an explanation of how compliance is to be determined.

Available I&E technologies

(4) Design and Construction Technology Plan

…The plan must explain the technologies and operational measures you have in place or have selected to meet the requirements in 125.94 (Examples of potentially appropriate technologies may include, but are not limited to, wedgewire screens, fine mesh screens, fish handling and return systems, barrier nets, aquatic filter barrier systems, <ADD: sound deterrents>, and enlargement of the cooling water intake structure opening to reduce velocity.). Examples of potentially appropriate operational measures may include, but are not limited to, seasonal shutdowns or reductions in flow, and continuous operations of screens.)….

Sound deterrents are a new but proven technology in some circumstances and for some species (e.g. alosids) which shows a lot of promise for in-situ applications. As such, this technology should be mentioned in this example.

[see hard copy for insert/strikeout text]

EPA Response

EPA agrees that behavioral barriers, such as the sound deterrents mentioned by the commenter, can be effective under certain circumstances, but has not based the performance standards of today's final rule on any data evaluated for these technologies because of the limited study data detailing their effectiveness. EPA does not believe, however, that these technologies should be excluded from the options available to facilities in meeting the requirements of today's final rule.

Comment ID 316bEFR.202.033

Subject Matter Code 7.02

Performance standards

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

The Department supports specific mention of operational measures such as seasonal shutdowns and a reduction in flow as a means to minimize impingement and entrainment effects. The Department also supports the mention of a reduction in flow for facilities that recirculate a portion of their flow as stated later in 125.95(b)(4)(iii). A flow limit or mandatory reduction in flow is an effective way to minimize impingement and entrainment effects with little to no construction costs. This is important for existing facilities, particularly for those that have a limited life and it is not practical to invest significant capital in upgrades.

EPA Response

EPA agrees with the commenter. A discussion of operational measures, including seasonal flow reductions, can be found in the Technology Development Document for today's final rule.

RFC: Proposed use of restoration measures

(5) Information to Support Proposed Restoration Measures

(i) No suggested change

(ii) A <STRIKE: quantification> <ADD: demonstration> of the combined benefits from implementing design and construction technologies, operational measures and/or restoration measures and the proportion of the benefits that can be attributed to each. This <STRIKE: quantification> <ADD: demonstration> must include: the percent reduction in impingement mortality and entrainment that would be achieved through the use of any design and construction technologies or operational measures that you have selected (i.e., the benefits you would achieve through impingement and entrainment reduction); a demonstration of the benefits that could be attributed to the restoration measures you have selected <ADD: (can be quantified as a range)>; and a demonstration that the combined benefits of the design and construction technology(ies), operational measures, and/or restoration measures will maintain fish and shellfish at a level comparable to that which would be achieved under 125.94. If it is not possible to demonstrate quantitatively that restoration measures such as creation of new habitats to serve as spawning or nursery areas or establishment of riparian buffers will achieve comparable performance, you may make a qualitative demonstration that such measures will maintain fish and shellfish in the waterbody at a level substantially similar to that which would be achieved under 125.94.

As discussed previously in Comment 7, the Department supports restoration measures after all feasible technological measures have been considered. However, the benefits of restoration measures are extremely complex to quantify. The Department is concerned that the language in this section will deter permittees from pursuing restoration measures. As such, the Department has included minor changes to reflect that benefits from restoration are not discrete values but rather would be more appropriately expressed as a range.

(iii) – (v) No suggested changes.

[see hard copy for insert/strikeout text]

EPA Response

EPA agrees with the commenter that the benefits of restoration measures can be complex to quantify. However, EPA believes there are multiple aspects of every restoration measures that can be quantified. This quantitative analysis provides useful and important insight into the proper design, assessment, and implementation of restoration measures. Under the final rule, EPA requires quantitative analysis as part of the Restoration Plan.

Summary of Rule and Differences from EPA's 1977 Draft Guidance

On page 17124 the following is stated:

Today, EPA proposes a national framework that would establish certain minimum requirements for the location, design, capacity, and construction of cooling water intake structures for large cooling water intake structures at Phase II existing facilities. In doing so, the Agency is proposing to revise the approach adopted in the 1977 draft guidance which was based on the judgment that "[t]he decision as to best technology available for intake design location, construction and capacity must be made on a case-by-case basis." Other important differences from the 1977 draft guidance include today's proposed definition of a "cooling water intake structure." Today's proposal also would establish a cost-benefit test that is different from the "wholly disproportionate" cost-benefit test that has been in use since the 1970s.

As described above in Comment 6E, the Department is very concerned about 125.94(c)(1). In fact, the Department anticipates that the majority of permittees will choose this option as it does not appear to be in their best interest to choose the significantly more stringent options under 125.94(b) or (c). In fact, the Department considers the option under 125.94(c)(1) to be essentially the same as the 1977 draft guidance. In addition, as discussed in Comment 5, it is the Department's opinion that the "significantly greater than" test is weaker than the "wholly disproportionate" test so 125.94(c)(1) could be viewed as less stringent than current case law.

EPA Response

EPA disagrees that a large percentage of facilities will opt for a site-specific determination of BTA. Please refer to the response to comment 316bEFR.202.002 for more information.

Please refer to the response to comment 316bEFR.202.003 for a discussion of how today's rule is no less stringent than the previous BPJ implementation of 316(b).

For more information on the use of the term "significantly greater," please refer to the response to comment 316bEFR.006.003.

Subject Matter Code 3.01

Definition: Existing Facility

Definition of an Existing Facility – Exception for Some Facilities

On page 17128 the following is stated:

… Finally, under the proposed definition, any facility constructed in place of a facility that commenced construction before January 17, 2002, would remain defined as an existing facility if the newly constructed facility uses an existing cooling water intake structure whose design intake flow is not increased to accommodate the intake of additional cooling water.

Under this proposed rule certain forms of repowering could be undertaken by an existing power generating facility that uses a cooling water intake structure and it would remain subject to regulation as a Phase II existing facility. For example, the following scenarios would be existing facilities under the proposed rule:

-An existing power generating facility undergoes a modification of its process short of total replacement of the process and concurrently increases the design capacity of its existing cooling water intake structures;

-An existing power generating facility builds a new process for purposes of the same industrial operation and concurrently increases the design capacity of its existing cooling water intake structures.

The two bulleted items above appear to be in conflict with the statement "…any facility constructed in place of a facility that commenced construction before January 17, 2002, would remain defined as an existing facility if the newly constructed facility uses an existing cooling water intake structure whose design intake flow is not increased to accommodate the intake of additional cooling water." In both bulleted items, the design capacity of the existing cooling water intake structure has been increased; therefore, it seems appropriate that these facilities would be covered under the eligibility criteria for new sources for Section 316(b) rules. It is not clear what portion of the regulation is being referred to by "certain forms of repowering could be undertaken by an existing power generating facility that uses and cooling water intake structure and it would remain subject to regulation as a Phase II existing facility". In fact, after reading the regulation, this exception was still not clear. Perhaps this issue could be further clarified.

EPA Response

See response to 316bEFR.064.002. The items are not in conflict. Under the final rule, a modification to an existing facility that does not totally replace the process or production equipment, or the addition of unit that is not substantially independent of the existing facility, could remain existing facilities even if a new or expanded cooling water intake is installed. See, definition of existing facility at 40 CFR 125.93. Also see, 125.83. The discussion in section II of the preamble clarifies this definition and the issue of repowering under this definition.

Subject Matter Code 3.04

Applicability to facilities subject to NPDES permit

Implementation of Measures in a NPDES Permit

On page 17129 the following is stated:

Based on the Agency's review of potential Phase II existing facilities that employ cooling water intake structures, the Agency anticipates that most existing power generating facilities that would be subject to this rule will control the intake structure that supplies them with cooling water, and discharge some combination of their cooling water, wastewater, and storm water to a water of the U.S. through a point source regulated by an NPDES permit. In this scenario, the requirements for the cooling water intake structure would be specified in the facility's NPDES permit. In the event that a Phase II existing facility's only NPDES permit is a general permit for storm water discharges, the Agency anticipates that the Director would write an individual NPDES permit containing requirements for the facility's cooling water intake structure. The Agency invites comment on this approach for applying cooling water intake structure requirements to the facility. Alternatively, requirements applicable to cooling water intake structures could be incorporated into general permits.

Any facility that has a cooling water intake structure that meets the criteria of 125.91 should be subject to intake protection technology requirements regardless of whether or not they have a NPDES permit. In fact, the Department does not interpret the criteria at 125.91, 125,92 or 125.93 as meaning that you are required to have a NPDES permit to be within the scope of the rule. Based on the flow chart included as "Appendix I – Section 316(b) Phase II Existing Facility Rule Framework" it appears that a facility is out of scope of the rule if they are not required to have a NPDES permit. This issue should be clarified to describe EPA's intent.

Nonetheless, the Department recognizes that the NPDES permit is the regulatory mechanism for which intake protection technology requirements will be implemented. If requirements are deemed necessary for regulating cooling water intake structures, it is feasible to incorporate site-specific intake protection technology requirements as an individual NPDES permit for that site, even if the only NPDES permit for that site is a general stormwater permit.

With respect to the statement "Alternatively, requirements applicable to cooling water intake structures could be incorporated into general permits", the Department is not clear as to whether this is intended to seek comment on incorporating intake protection technology requirements into a general permit (e.g. stormwater general permit) or if it is intended to seek comment on the appropriateness of issuing a general permit for regulating intake protection technologies.

If it is the former, it would be appropriate to incorporate intake protection technology requirements as a separate individual NPDES permit for that site as opposed to incorporating such complex requirements into the comparatively simpler general permit. Incorporation of individual requirements into a general permit defeats the goal of the general permit in keeping the conditions streamlined and simple. It would be preferable to keep the two regulatory mechanisms separate.

If it is the latter, the Department disagrees with the concept that a general permit could be issued to incorporate Section 316(b) conditions. By definition, a general permit prescribes a set of conditions for a number of facilities deemed eligible under those conditions. Establishment of appropriate cooling water intake structure technologies is dependent on numerous site-specific factors, where the regulatory authority should have oversight over any such choice. A general permit that prescribes a set of standard conditions will simply not work as it has the potential to eliminate the regulatory oversight of the permitting agency. It could also cause a problem in prescribing a "one size fits all" mentality for intake protection technologies which is simply not appropriate.

EPA Response

Section 125.91 of the final rule contains criteria that indicate which facilities constitute Phase II existing facilities subject to Part 125, Subpart J. Under this section, the first criterion provides that an existing facility must be a point source. As the comment acknowledges, the rule also provides under 125.90(a) that the requirements specified under section 316(b) are implemented through NPDES permits. This is the case given that 316(b) requirements are linked to standards established pursuant to CWA sections 301 and 306, and such requirements are only applicable to point sources through NPDES permits (see, CWA sec. 402(a)). Finally, the rule does not specify the type of permit (individual or general) to be used to implement these requirements. Such determinations remain with the Director and will be made based on applicable regulations and implementation considerations. Also see the response to 316bEFR.035.001.

Option 3--Site-specific determination

Concerns Regarding Site-Specific Alternative

On page 17140 the following is stated:

A facility may use one of the three different methods for establishing the best technology available for minimizing adverse environmental impact. Under the first method, a facility would demonstrate to the Director issuing the permit that the facility's existing design and construction technologies, operational measures, and/or restoration measures already meet the national minimum performance requirements that EPA is proposing.

Under the second method, a facility would select design and construction technology, operational measures, restoration measures or some combination thereof. The facility would then demonstrate to the Director that its selected approach would meet the performance requirements EPA is proposing.

Under the third method, a facility would calculate its cost of complying with the presumptive performance requirements and compare those costs either to the compliance costs EPA estimated in the analysis for this proposed rule or to a site-specific determination of the benefits of meeting the presumptive performance requirements. If the facility's costs are significantly greater than EPA's estimated costs or site-specific benefits, the facility would qualify for a site-specific determination of best technology available.

The Agency discusses each of these three methods for compliance and the proposed presumptive minimum performance requirements in greater detail below. EPA invites comments on all aspects of this proposed regulatory framework as well as the alternative regulatory approaches discussed later in this section.

The Department has many concerns regarding this third method. Please refer to Comments 6B, 6C, 6D, 6E, 6F, and 6G.

EPA Response

No response is required, as the referenced comments are addressed individually in separate responses.

Performance standards

Implementation of Performance Standards

On page 17142 the following is stated:

In specifying a range, EPA anticipates that facilities will select technologies or operational measures to achieve the greatest cost-effective reduction possible (within today's proposed performance range) based on conditions found at their site, and that Directors will review the facility's application to ensure that appropriate alternatives were considered. EPA also expects that some facilities may be able to meet these performance requirements by selecting and implementing a suite (i.e. more than one) of technologies and operational measures and/or, as discussed below, by undertaking restoration measures. EPA invites comment on whether the Agency should establish regulatory requirements to ensure that facilities achieve the greatest possible reduction (within the proposed ranges) that can be achieved at their site using the technologies on which the performance standards are based. EPA also invites comment on whether EPA should leave decisions about appropriate performance levels for a facility to the Director, provided that the facility will achieve performance that is no lower than the bottom of the performance ranges in today's proposal.

As discussed in Comment 6C, the Department emphatically supports a range of performance measures given the highly site-specific nature of selecting appropriate intake protection technologies. In addition, utmost flexibility should be given to facilities that choose to comply with performance standards. The Department also agrees that a suite of technologies may be feasible and appropriate in many circumstances. Given the above as well as the fact that intake protection technologies are still evolving, the Department believes that "EPA should leave decisions about appropriate performance levels for a facility to the Director, provided that the facility will achieve performance that is no lower than the bottom of the performance ranges in today's proposal."

EPA Response

EPA agrees with the commenter and believes that today's final rule maintains the desired flexibility for both the permitee and permitting authority in determining the most cost-effective means by which the rule's requirements can be met.

Comment ID 316bEFR.202.044

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 7.02

Performance standards

Compliance with Performance Standards

On page 17143 the following is stated:

If compliance monitoring determines that the design and construction, operating measures, or restoration measures prescribed by the permit have been properly installed and were properly operated and maintained, but were not achieving compliance with the applicable performance standards, the Director could modify permit requirements consistent with existing NPDES program regulations (e.g. 40 CFR 122.62, 122.63, and 122.41) and the provisions of this proposal. In the meantime, the facility would be considered in compliance with its permit as long as it was satisfying all permit conditions. EPA solicits comment on whether the proposed regulation should specify that proper design, installation, operation and maintenance would satisfy the terms of the permit until the permit is reissued pursuant to a revised Design and Construction Technology Plan. If EPA were to adopt this approach, EPA would specify in the regulations that the Director should require as a permit condition the proper design, installation, operation and maintenance of design and construction technologies and operational measures rather than compliance with performance standards.

As discussed in Comments 4 and 16, utmost flexibility should be given to those facilities that choose to comply with the performance standards. Given the many site-specific factors that affect biological populations from year to year (i.e. weather patterns, climate changes, fishing regulations), compliance with performance standards can fluctuate greatly. As stated in Comment 6C, these factors help to justify the appropriateness of specifying performance standards as a range of values as opposed to discrete point source values. In sum, the Department agrees that permittees should be considered to be in compliance with their permit so long as design and construction, operating measures or restoration measures prescribed by the permit have been achieved.

EPA Response

EPA believes that today's final rule maintains the desired flexibility for both the permittee and permitting authority. The Technology Installation and Operation Plan (TIOP) allows a facility to select a suite of design and construction technologies, operational measures, and/or restoration measures and request that the implementation of the TIOP be considered the means of determining compliance with today's rule. This option is available to the permittee with the approval of the Director for the first two permit cycles.

EPA has deferred to the Director the determination of the proper method by which compliance with the rule is to be measured. EPA believes the Director is best suited to address the variable situations that may arise on a site-specific basis, such as those discussed by the commenter.

Author Name Bradley M. Campbell
Organization NJ Dept of Environmental Protection

Subject Matter Code 7.01.03
Option 3--Site-specific determination

Site-Specific Determination

On page 17143 the following is stated:

How could a Phase II Existing Qualify for a Site-Specific Determination of Best Technology Available for Minimizing Adverse Environmental Impact?

…To be eligible to pursue this approach, the facility must first demonstrate to the Director either: (1) that its costs of compliance with the applicable performance standards specified in §125.94 (b) would be significantly greater than the costs considered by the Administrator in establishing such performance standards; or (2) that the facility's costs would be significantly greater than the benefits of complying with the performance standards at the facility's site. A discussion of applying the cost test us provided in section VI.A.2 of this proposed rule. A discussion of applying the test in which costs are compared to benefits is provided in Section VI.A.8.

Please refer to Comment 6F concerning item (1) in this cite and Comments 5 and 6G concerning the use of the term "wholly disproportionate".

EPA Response

For more information on the use of the term "significantly greater," please refer to the response to comment 316bEFR.006.003.

EPA agrees that the burden of proof lies with the permittee. This is reflected in the choice of words used in the rule language and in the preamble. For example, the rule may say "you [the facility] must demonstrate to the Director" when stating a requirement.

Comment ID 316bEFR.202.046

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 10.07.02

RFC: Appropriateness of "significantly greater"

Use of Lower Cost Threshold in Rule

On page 17146 the following is stated:

EPA believes it is appropriate to set a lower cost threshold in this rule to avoid economically impracticable impacts on energy prices, production costs, and energy production that could occur if large numbers of Phase II existing facilities incurred costs that are more than significantly greater that but not wholly disproportionate to the costs in EPA's record. EPA invites comment on whether a "significantly greater" cost test is appropriate for evaluating requests for alternative requirements by Phase II existing facilities.

Similarly, on page 17146 the following is stated:

EPA invites comment on whether the standards proposed today might allow for backsliding by facilities that have technologies or operational measures in place that are more effective than in today's proposal. EPA invites comment on approaches EPA might adopt to ensure that backsliding from more effective technologies does not occur.

The Department vehemently opposes this weaker cost test as contained in the proposed regulation as discussed previously in Comment 5. The Department also agrees that inclusion of this weaker cost test would almost certainly result in backsliding from current policies and practice and is therefore in violation of 40 CFR 122.44(l).

The Department and other regulatory agencies have been waiting for regulations regarding Section 316(b) for over twenty-five years. Inclusion of the site-specific alternative as well as the inclusion of the "significantly greater" cost test as opposed to the "wholly disproportionate" cost test (as described in current case law) is a sore disappointment to regulatory agencies. Intake protection technologies have evolved tremendously since enactment of the Clean Water Act in 1972. As a result, the Department does not agree that inclusion of the stronger "wholly disproportionate" cost test would necessarily result in a negative economic impact on energy prices, production costs, and energy production. In fact, a strong Section 316(b) regulation would help in advancing the science of intake protection technologies and in creating new research and jobs.

EPA Response

EPA basis for the site-specific provisions of the final rule are discussed in the preamble to the final rule, including but not limited to section VII. Regarding backsliding, this rule does not alter the existing backsliding regulations. See response to 316bEFR.021.013.

Comment ID 316bEFR.202.047

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 2.04.04

Use cost-benefit tests

Beyond opposing a weaker cost-benefit analysis, it is the Department's position that a formal cost-benefit analysis is not permitted pursuant to the Section 316(b) as it has been interpreted for the past three decades. This issue was long ago analyzed by the EPA Administrator:

Unlike Sections 301 and 304, Section 316(b) determines what the benefits to be achieved are and directs the Agency to require use of "best technology available" to achieve them. There is nothing in Section 316(b) indicating that a cost/benefit analysis should be done, whereas with regard to "best practicable control technology currently available" and "best available technology economically achievable" Congress added express qualifiers to the law indicating a requirement for cost/benefit analysis. Indeed, but for one bit of legislative history, there would be no indication that Congress intended costs to be considered under Section 316(b) at all. I find, therefore, that insofar as the RA's decision may have implied the requirement of a cost/benefit analysis under Section 316(b), it was incorrect.

However, the RA may have meant only that some consideration ought to be given to costs in determining the degree of minimization to be required. I agree that this is so--otherwise the effect would be to require cooling towers at every plant that could afford to install them, regardless of whether or not any significant degree of entrainment or entrapment was anticipated. I do not believe that it is reasonable to interpret Section 316(b) as requiring use of technology whose cost is wholly disproportionate to the environmental benefit to be gained.

IMO Public Service Company of New Hampshire, et al. (Seabrook Station, Units 1 and 2) National Pollutant Discharge Elimination System Permit, 1977 WL 22370 (E.P.A.), 1 E.A.D. 337 (1977).

Since the Seabrook ruling, the wholly disproportionate test has been consistently limited in scope and function due to its marginal statutory basis. It must be stressed, however, that this test is a limited one, for the Administrator in the same decision rejected the notion that a full cost/benefit analysis is required under Section 316(b). In re Central Hudson Gas and Electric Corporation, et al. Opinion No. 63 July 29, 1977, 1977 WL 28250 *8 (E.P.A.G.C.). Considering the marginal statutory authority for considering costs in a 316(b) determination and the rejection of a full cost/benefit analysis in the 30 year history of applying this statute, it is the Department's position that EPA lacks statutory authority to promulgate the third regulatory option under the current rule because it distorts the prior limited and informal "wholly disproportionate test" into a formal cost/benefit analysis which will now be the crux of the rule.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

RFC: Appropriate spatial scale for restoration

Spatial Scale of Restoration Measures

On page 17146 the following is stated:

EPA specifically invites comment on whether restoration measures should be allowed only as a supplement to technologies or operational measures. EPA also seeks comment on the most appropriate spatial scale under which restoration efforts should be allowed - should restoration measures be limited to the waterbody at which a facility's intakes are sited, or should they be implemented on a broader scale, such as at the watershed or State boundary level.

As described in Comment 7, all technological options must be carefully considered first, and mitigation should not be required as a substitute for technology. However, in the event that fish protection technologies are not currently available to meet the performance standards at 125.94(b), the Department supports mitigation measures to minimize impingement/entrainment losses.

With regard to the spatial scale under which restoration efforts should be allowed, the Department suggests that the spatial scale be defined at the watershed level. Although it is true that it would be easier for regulatory agencies to monitor and control restored lands within that regulatory agency's boundary, aquatic life do not necessarily respect state boundary lines. As a result, it should not be a requirement that restored lands must stay within state boundary lines. In addition, there may be a parcel of ecologically productive or potentially ecologically productive land within the watershed in a different state. It would be unfortunate if there was indeed a requirement for lands chosen for restoration to stay within the same state. Using a broader spatial scale of a watershed will also help to ensure that ecologically productive lands within that watershed can be considered for restoration.

EPA Response

For a discussion of the consideration of technologies before choosing restoration measures, see EPA's responses to comments 316bEFR.033.005 and 316bEFR.202.029.

For a discussion of the appropriate scale on which to conduct restoration measures, see EPA's response to comment 316bEFR.212.001.

RFC: Performance/effectiveness of restoration

Measure of Success of Restoration Measures

On page 17147 the following is stated:

EPA seeks comment on how it may measure the success or failure of restoration activities given the high degree of uncertainty associated with many areas of this developing science and that many of these activities do not produce measurable results for many months or years after they are implemented. For these reasons, EPA requests comment on whether to require that a facility using restoration measures restore more fish and shellfish than the number subjected to impingement mortality or entertainment. EPA believes that restoring or mitigating above the level that reflects best technology available for minimizing adverse environmental impact (e.g. restocking higher numbers of fish than those impinged or entrained by facility intakes or restoring aquatic system acreages at ratios greater than one-to-one) would help build a margin of safety, particularly when the uncertainties associated with a particular restoration activity are known to be high.

The Department agrees that there is uncertainty associated with producing a certain number of fish by way of wetlands restoration. Therefore, instead of requiring a permittee to produce a particular number of fish, permittees should be required to restore a discrete number of wetlands. The amount of wetlands to be restored should be based on the amount of losses due to impingement and entrainment. Conservative assumptions should be used to account for uncertainties in developing this value of land acreage.

One alternative in establishing the number of acres to be restored would be to consider the amount of plant growth necessary to sustain the biomass lost by the facility's intake operations. Specifically, wetlands production can be estimated by the aggregated food chain model. This can be related directly to the estimated biomass lost by the facility's intake operations. This loss can be used to estimate the wetlands restoration acreage required to adequately minimize the effects of the intake losses by increasing the population of those species. The food chain model estimates the production of fish biomass per acre based on the biological conversion for wetland plant productivity through the food chain to the fish species at issue. Primary productivity per acre of wetland per year and food chain transfer conversion factors can be derived from published, peer-reviewed scientific literature and can be employed in this calculation using information specific to the watershed, where available. Conservative assumptions should be incorporated into these calculations.

The plan for restoration should be established in a Management Plan which should have regulatory oversight. Definitive goals for vegetative and hydrological success criteria could be established in any such Plan with periodic deadlines to assess the successes and/or failures of the restoration.

The Department agrees that the benefits of restoration projects can take months or even many years to realize. However, this should not be a deterrent. If these lands are deeded for conservation in perpetuity, the benefits of ecological production from these lands will be realized for many, many years.

As discussed in Comment 7, the Department prefers the restoration and/or preservation of wetlands to fish stocking as fish stocking does not remedy the problem of continued losses of fish habitat.

EPA Response

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

EPA agrees that some restoration measures, such as habitat restoration, may have strong ancillary benefits and encourages permit applicants and permitting authorities to consider the net benefits of a restoration measure. For a discussion of the ancillary benefits from restoration measures, see EPA's response to comment 316bEFR.032.011.

Any restoration measure must meet all of the requirements described in the final rule.

RFC: Consideration of additional env. Benefits

Other Environmental Benefits of Restoration Projects

On page 17148 the following is stated:

Habitat restoration measures may provide important benefits beyond direct effects on fish and shellfish numbers, such as flood control, habitat for other wildlife species, pollution reduction, and recreation. EPA requests comment on whether and how additional environmental benefits should also be considered in determining appropriate fish and shellfish rates for restoration projects.

Because the goal of habitat restoration measures required under Section 316(b) would be to minimize the losses due to impingement and entrainment from an intake structure, the focus and rationale for any required habitat restoration should be strictly fish production. The Department agrees that there are numerous other benefits to restoration measures for other species, including people. However, these benefits are ancillary and including them as a basis for habitat restoration would complicate the issue and not serve the original purpose to increase fish populations.

EPA Response

Any restoration measure must meet all the requirements described in the final rule.

For a discussion of the ancillary benefits associated with restoration measures, see EPA's response to comment 316bEFR.032.011.

RFC: Habitat conservation as part of restoration

Conservation of Existing Habitats

On page 17148 the following is stated:

In some cases, conservation of existing, functional habitats - particularly conservation of habitats that are vulnerable to human encroachment and other anthropogenic impacts - may be desirable as part of a facility's restoration effort. In the case of conservation, the functionality of the habitat would not be compromised, therefore eliminating much of the uncertainty associated with measuring the success of other restoration efforts such as habitat enhancement or creation. However, because conserved habitat is already contributing to the relative productivity and diversity of an aquatic system, conservation measures would not necessarily ensure a net benefit to the waterbody or watershed of concern. EPA seeks comment on whether habitat conservation would be an appropriate component of a facility's restoration efforts.

The loss of wetlands has become a critical environmental issue. Conservation of existing, functional habitats would be desirable as part of a facility's restoration efforts considering the continued threat of development to wetlands and adjacent upland buffers. However, the Department agrees that conservation of already productive wetlands may not increase fish populations as much as restoration of former or degraded wetlands. As such, conservation of existing wetlands should count towards a facility's required number of acreage; however, it should count as a lesser value. For example, three acres of wetlands that are conserved can be considered equivalent to one acre of wetlands that is restored. Therefore, if a facility is required to restore 1000 acres of wetlands, the conservation of 3000 acres of existing wetlands could be considered to be in compliance with this requirement. Other combinations that could be used to meet the 1000 acre requirement in this example would be the restoration of 500 acres of former wetlands coupled with the conservation of 1500 acres of existing wetlands.

EPA Response

Any restoration measure must meet all of the requirements described in the final rule.

For a discussion of the roles and responsibilities of the permitting authority in determining the appropriate level of performance to meet the requirements of the final, see EPA's response to comment 316bEFR.060.026.

RFC: Monitoring frequencies

Minimum Elements of Impingement Mortality and Entrainment Characterization Study

On page 17148 the following is stated:

What are the Minimum Elements of Impingement Mortality and Entrainment Characterization Study?

EPA invites comment on whether it should set specific, minimum monitoring frequencies and/or whether it should specify requirements for ensuring appropriate consideration of uncertainty in the impingement mortality and entrainment estimates.

Similarly, on page 17149 the following is stated:

EPA invites comment on including minimum sampling frequencies and durations as follows: for at least two years following the initial permit issuance, impingement samples must be collected at least once per month over a 24 hour period and entertainment samples must be collected at least biweekly over a 24 hour period during the primary period of reproduction, larval recruitment and peak abundance. These samples would need to be collected when the cooling water intake structure is in operation.

Given that many sites do not conduct ongoing impingement and entrainment monitoring, inclusion of a minimum impingement and entrainment sampling frequency for representative important species would be helpful. In fact, any facility that has chosen to comply with 125.94(c) should be required to conduct impingement and entrainment monitoring for representative important species for the life of the permit at a minimum frequency of once per month for impingement and once per month for entrainment. If the facility has agreed to comply with the performance standards at 125.94(b), then it would be more appropriate to tailor impingement and entrainment monitoring to the intake protection technologies chosen for that site. For example, if upgraded traveling screens with fish buckets is the chosen technology (where the focus of such technology is impingement), than increased impingement monitoring for representative important species to monitor the efficacy of upgraded screens would be appropriate. On the contrary, if wedgewire screens are the chosen technology (where the focus of such technology is entrainment), than increased entrainment monitoring for representative important species to monitor the efficacy of wedgewire screens would be appropriate.

Benefit Estimation Methodology

Quantification of Benefits

On page 17149 the following is stated:

EPA believes that a rigorous environmental and economic analysis should be performed when a facility seeks a site-specific determination of best technology available due to significantly greater cost as compared to the benefits of compliance with the applicable performance standards. EPA invites comment on which of these methodologies, or any other, is the most appropriate for determining a fair estimate of the benefits that would occur should the Phase II existing facility implement technology to comply with the applicable performance standards. In addition, EPA invites comment on whether narrative benefits assessments should supplement these methodologies to properly account for those benefits which cannot be quantified and monetized.

The Department agrees that a rigorous economic analysis should be required for any facility that seeks a site-specific determination of BTA. Again, the burden to provide and justify this analysis should clearly belong to the facility. The Department has reviewed the three options for a benefits assessment (i.e. (1) Quantified and Monetized Baseline Impingement and Entrainment Losses; (2) Random Utility Model; (3) Contingent Valuation Approach).

The Department recommends use of (1) Quantified and Monetized Baseline Impingement and Entrainment Losses coupled with (2) Random Utility Model to provide an estimate of benefits. With respect to the use of supplementing these estimates with narrative benefit assessments, the Department is not sure how narrative values would be of use in the analysis. It would be preferable to quantify benefits to the best extent practicable instead of using narrative benefits. If narrative benefits are not given a value, then it is assumed that their value would be assumed to be zero in the analysis.

EPA Response

EPA agrees that accurate valuation of benefits is critical for any facility that seeks a site-specific determination of BTA. EPA further agrees that it is appropriate to use quantified and monetized baseline impingement and entrainment losses and use the Random Utility Model approach to estimating recreational fishing benefits in estimating site-specific benefits of BTA. EPA also agrees that it would "be preferable to quantify benefits to the best extent practicable." The Agency, however, disagrees that if a value cannot be assigned for some ecological benefits then their value would be assumed to be zero in the analysis. Ignoring ecological values that are difficult to value could result in serious misallocation of resources. The Agency notes that the EPA's Guidelines for Preparing Economic Analyses, United States EPA (EPA 240-R-00-003, DCN #6-1931) recommend using narrative benefit assessment when estimation of quantified and monetized benefits is not feasible.

RFC: Entrainment vs. entrainment mortality

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Conservation of Entrainment Mortality and Survival

On page 17150 the following is stated:

EPA requests comment on whether it is appropriate to allow consideration of entertainment mortality and survival in benefit estimates, and if so, should EPA set minimum data quality objectives and standards for a study of entertainment mortality and survival used to support a site-specific determination of best technology available for minimizing adverse environmental impact. EPA may decide to specify such data quality objectives and standards either in the final rule language or through guidance.

The Department has determined that it is appropriate to allow consideration of entrainment mortality and survival in benefit estimates. However, site-specific factors are quite variable which may make it difficult for EPA to set minimum data quality objectives and standards for a study of entrainment mortality and survival.

EPA Response

Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis.

More Stringent Requirements

More Stringent Requirements than Performance Standards

On page 17150 the following is stated:

Proposed 125.94 (e) provides that the Director could establish more stringent requirements relating to the location, design, construction, or capacity of a cooling water intake structure at a Phase II existing facility than those that would be required based on the proposed performance standards in the rule (125.94 (b)), or based on the proposed site-specific determination of best technology allowed under the rule (125.94 (c)), where compliance with the proposed requirements of 125.94(b) or (c) would not meet the requirements of applicable tribal, state or other federal law.

Although the Department has determined that the performance standards cited in 125.94(b) are stringent and protective in most circumstances, inclusion of 125.94(e) is also helpful, particularly if intake protection technologies continue to evolve in the future.

EPA Response

Today's rule recognizes a State's authority to adopt more stringent requirements.

Organization NJ Dept of Environmental Protection

Subject Matter Code 13.0

More Stringent Requirements

Assessing Benefits of Impaired Waterbodies

On page 17151 the following is stated:

EPA also notes that States have designated many waterbodies for the propagation of fish and shellfish that are not attaining such uses due to pollution, and that, in these waters, aquatic communities may be significantly stressed or under-populated. EPA also believes that in some waterbodies, heavy fishing pressures have greatly altered and reduced aquatic communities. EPA anticipates that studies valuing the monetized benefits of reducing impingement and entrainment may not identify significant site-specific benefits in such areas and, should one or more permit applicants request site-specific determinations of less-costly best technology available for minimizing adverse environmental impact, a State may not have authority to deny such requests. EPA requests comment on whether recovery of aquatic communities in such waterbodies might be delayed by use of the significantly greater cost-to-benefit test proposed today. EPA request comment on an regulatory alternative that would explicitly allow the Director to require more stringent technologies or measures where not doing so would delay recovery of an aquatic species or community that fish and wildlife agencies are taking active measures to restore, such as imposing significant harvesting restrictions.

The Department agrees that studies valuing the monetized benefits of reducing impingement and entrainment may not identify significant site-specific benefits in areas subjected to heavy fishing pressures or other negative impacts. In fact, an important part of the benefits equation includes societal benefits which are difficult to quantify as a monetary value since societal benefits are based on intrinsic values. On the other hand, it is much easier to quantify another part of the benefits equation namely the value of fish lost for species which have a market value. It is easy to establish a benefit value for these fish as known market prices are available.

With respect to impaired waterbodies as described in this excerpt of the preamble, the Department is concerned that the use of site-specific assessments for impaired waterbodies will result in intake protection technologies not being deemed cost-effective. This will be due in part to the fact that benefits will be severely understated as fish may not be available in great numbers at the time of the cost/benefit analysis. In addition, societal benefits of having an increase in fish in the waterbody will be difficult to quantify. Therefore, benefits are sure to be understated for such a waterbody. In addition, as stated in this excerpt, the cause of the impairment could be a result of many factors such as fishing pressures, water pollution etc.; however, losses from the cooling water intake structure(s) may very well have contributed to this impairment. It seems inappropriate that an analysis for a cooling water intake structure on an impaired waterbody is likely to result in understated benefits which could in turn result in no technologies being cost-effective and therefore being implemented. This lack of action will only continue to contribute towards the impairment.

Based on the above, it is extremely important that impaired waterbodies are given special treatment in the rule. In sum, the Department is in support of an regulatory alternative that would explicitly allow the Director to require more stringent technologies or measures for waterbodies in which fish and wildlife agencies are taking active measures to restore.

RFC: 5% threshold and supporting documents

Discussion of 5% Threshold in Freshwater Rivers

On page 17151 the following is stated:

10. Discussion of the 5% Flow Threshold in Freshwater Rivers

…EPA believes that it is unacceptable to impact more than 5% of the organisms within the area of an intake structure. Hence, if the facility withdraws more than 5% of the mean annual flow of a freshwater river or stream, the facility would be required to reduce entrainment by 60-90 %…

EPA also requests comment on the following alternative withdrawal thresholds for triggering the requirement for entertainment controls: (1) 5% of the mean flow measured during the spawning season, (to be determined by the average of flows during the spawning season, but remaining applicable to non-spawning time periods); (2) 10% or 15% of the mean annual or spawning season flow; (3) 25% of the 7Q10; and (4) a species-specific flow threshold that would use minimum flow requirements of a representative species to determine allowable withdrawals from the waterbody.

The Department supports the 5% flow threshold for freshwater rivers as it finds it reasonable. Items (2) and (3) are too lenient whereas item (4) is far too site-specific. Item (4) would result in debate with permittees, review time for regulatory agencies; and delays in implementing intake protection technologies.

EPA Response

EPA notes the comment and has retained the provision in today's final rule.

Comment ID 316bEFR.202.059

Author Name Bradley M. Campbell
Organization NJ Dept of Environmental Protection

Subject Matter Code 15.01
RFC: State or Tribal alts. achieve comparable perf.

Requirements at a Watershed Level

On page 17151 the following is stated:

In 125.90, today's proposal includes an alternative where an authorized State or Tribe may choose to demonstrate to the Administrator that it has adopted alternative regulatory requirements that will result in environmental performance within a watershed that is comparable to the reductions in impingement mortality and entrainment that would otherwise by achieved under 125.94. If a State or Tribe can successfully make this demonstration, the Administrator is to approve the State or Tribe's alternative regulatory requirements.

EPA is proposing that such alternative requirements achieve comparable performance at the watershed level, rather than at larger geographic scales or at the individual facility-level, to allow States and Tribes greater flexibility and, potentially, greater efficiency in efforts to prevent or compensate for impingement mortality and entrainment losses, while still coordinating those effects within defined ecological boundaries where the increased impacts are directly offset by controls or restoration efforts…

As discussed in Comment 2 and Comment 28, it is important to keep a real-world perspective in applying impingement and entrainment. However, imposing requirements at the watershed level sounds far too complex and would likely result in delays in implementation of intake protection technologies. There are far too many site-specific factors in establishing impingement and entrainment controls for each facility, never mind on a watershed basis. For example, completely different species and life stages could reside at two facilities within the same watershed. In sum, the Department is opposed to alternative requirements on a watershed level instead of the individual facility level.

EPA Response

Please see response to comment 316bEFR.099.020.

Subject Matter Code 7.01.03

Option 3--Site-specific determination

Site-Specific Approach Provides an Important Safety Valve

On pages 17152 and 17153 the following is stated:

The Agency anticipates that the inclusion of a site-specific cost to benefit test will continue to be of concern to local regulatory entities and the regulated community in light of the associated burden on permit writers…

However, EPA believes it important to have a site-specific option in the rule to cover cases of exceptionally high costs and/or minimal benefits…EPA anticipates that many, if not most, facilities will choose to comply with the presumptive standards, but believes that for those facilities with exceptionally high costs or exceptionally low benefits, the site-specific provisions provide an important "safety valve".

EPA invites comment on whether the Agency should establish minimum standards for a Comprehensive Cost Evaluation Study and on whether such standards should be established by regulation or as guidance only. EPA also invites comment on the above discussion of the burden that reviewing site-specific cost studies poses for permitting authorities and on its belief that site-specific provisions to address cases of unusually high costs or unusually low benefits are necessary.

As stated previously, the Department is concerned that the inclusion of a site-specific cost/ benefit test will result in a huge burden on the permitting authority.

The Department strongly disagrees with EPA's contention that "many, if not most facilities will choose to comply with the presumptive standards". In fact, the Department questions why any facility would choose to comply with the performance standards when they have the option to comply with the site-specific option. The performance standards are very stringent, and while the Department supports such standards, compliance with such will pose a technological struggle for some years to come. These standards are particularly stringent with respect to entrainment as there are few proven entrainment technologies that can easily be retrofitted to an existing facility. Addressing the issue of compliance schedules would help bridge this gap regarding performance standards. If EPA must include a site-specific option, than the Department suggests that it be made clear that the burden is on the applicant to demonstrate the appropriateness of this option.

The Department agrees that minimum standards for a cost evaluation study would be helpful, although it is suggested that these standards be established as guidance, not regulation.

EPA Response

EPA disagrees that a large percentage of facilities will opt for a site-specific determination of BTA. Please refer to the response to comment 316bEFR.202.002 for more information.

For information on the timing of attaining the performance standards, e.g., through a TIOP, please refer to the preamble to the final rule.

Burden on permitting agencies (general)

Burden to Resource Agencies

On page 17153 the following is stated:

…To reissue a permit to the Salem Nuclear Generating Station, the New Jersey Department of Environmental Protection recently reviewed and reconsidered a 36-volume permit application supported by 137 volumes of technical and reference materials. The facility filed its application in 1994; NJDEP made its decision in 2001.…

EPA is correct in stating that the original filing contained 137 volumes of technical and reference materials (additional reference materials were later filed). The voluminous nature of the permit application for this facility is a good example of the burden associated with a site-specific Section 316(b) decision. If the site-specific alternative included as 125.94(c) is indeed included in final regulation, then voluminous permit applications are likely for other facilities that apply to be covered under the site-specific alternative. Again, this concern supports the improvements to the site-specific alternative as described previously in Comment 6.

EPA Response

EPA included a site-specific determination of BTA in today's final rule with four other compliance alternatives to provide maximum flexibility for the facility and speed permitting where possible. Please see response to comment 316bEFR.019.014 for additional discussion.

Comment ID 316bEFR.202.062

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 4.01

Source data used by EPA

The Department would also like to comment on a mistake in this particular cite. The 36 volume permit application referenced above was filed in March 1999, not 1994. The June 2001 final NJPDES permit decision was in response to the March 1999 filing. This 2001 permit decision renewed the previous permit decision, which was issued in 1994.

EPA Response

EPA appreciates the clarification. Regardless of the specifics of the citation, EPA agrees with the New Jersey Department of Environmental Protection that the voluminous nature of the permit application for Salem is a good example of the burden associated with a site-specific determination of best technology available.

Author Name Bradley M. Campbell
Organization NJ Dept of Environmental Protection

Subject Matter Code 16.01
RFC: Regulating limited capacity facilities

Capacity Utilization

On page 17153 the following is stated with respect to capacity utilization:

In § 125.94(b)(2), the Agency proposes standards for reducing impingement mortality but not entrainment when a facility operates less then 15 percent of the available operating time over the course of several years. Fifteen percent capacity utilization corresponds to facility operation for roughly 55 days in a year (that is, less then two months). The Agency refers to this differentiation between facilities based on their operating time as a capacity utilization cut-off. The Agency's record demonstrates that facilities operating at capacity utilization factors of less then 15 percent are generally facilities of significant age, including the oldest facilities within the scope of the rule.

Similarly, on page 17154 the following is stated:

...EPA invites comment on its proposed approach to regulating Phase II existing facilities with limited capacity utilization. EPA specifically invites comment on the above alternate thresholds for using capacity utilization to establish performance standard that address impingement mortality but not entrainment....

Please refer to Comment 6C regarding concerns about capacity utilization.

Author Name Bradley M. Campbell
Organization NJ Dept of Environmental Protection

Subject Matter Code 4.01.03
Information provided to EPA by stakeholders

Consumption of Water

On page 17157 the following is stated:

The Nuclear Regulatory Commission estimates that a steam-electric plant utilizing a once-through cooling system would consume approximately 40 percent less water than a comparably sized plant equipped with recirculating wet cooling towers because a wet cooling tower uses a small amount of water many times and evaporates most of this water to provide its cooling (which can sometimes be seen as a white vapor plume).

Perhaps an error was made here. A once-through cooling system consumes more water than a comparably sized plant equipped with recirculating wet cooling towers.

EPA Response

EPA believes the statement to be correct. In this context, the term "consume" means to entirely remove from the surface waterbody. The comparison done by the NRC illustrates that a once-through system returns all of the water taken in, less some evaporative losses in the heated discharge. Alternatively, a cooling tower removes or consumptively uses a proportionately higher volume of water during the evaporative cooling process in the cooling tower, despite taking in a significantly smaller volume of water as compared to a once-through cooling system. Please refer to DCN 3-3074 in the Phase I docket (W-00-03) for the full document.

Subject Matter Code 17.06

Option: Site-specific determination of BTA

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Site-Specific Based Options

On page 17159, the following is stated under item C. entitled "Site-Specific Based Options Under Consideration":

EPA also invites comment on site-specific approaches for determining the best technology available for minimizing adverse environmental impact at existing facilities. In general, a site-specific option is a formal process for determining the best technology available for minimizing adverse environmental impact at particular facilities that focuses on the site-specific interactions between cooling water intakes and the affected environment and the costs of implementing controls. This approach would be based on the view that the location of each power plant and the associated intake structure design, construction, and capacity are unique, and that the optimal combination of measures to reflect best technology available for minimizing adverse environmental impact must be determined on a case-by-case basis.

As stated previously, the Department is opposed to 125.94(c)(1) of the proposed regulation language. As can be expected, the Department is also imposed to the Site-Specific Alternative Sample Rule Language included here as it is a less stringent variation of the option proposed in 125.94(c)1. The Department has many specific concerns regarding the sample regulation language for this option as noted below in Comments 37 - 40.

EPA Response

While EPA rejected a purely site-specific approach, EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees that a large percentage of facilities will opt for a site-specific determination of BTA. Please refer to the response to comment 316bEFR.202.002 for more information.

No further response is required, as the issues raised in this comment are addressed in individual responses.

Subject Matter Code 17.06.01
Sample site-specific rule (p.17159-61)

Site-Specific Alternative Sample Rule - Burden of Proof

On page 17160 the following is stated:

(a)(1) Except as provided in paragraph (1)(2) of this section, an owner or operator of an existing facility covered by this subpart must conduct a baseline biological survey and provide any other information specified in § 125.97 that the Director concludes is necessary for determining the magnitude of any adverse environmental impact occurring at the facility.

The Department interprets this language to mean that the burden of proof is on the permitting agency for the Site Specific Alternative Sample Rule language. This will be extremely resource intensive for the permitting agency and, as a result, will result in less (if any) protection overall. Again, the Department is concerned that no facility will ever agree that they are causing an "adverse environmental impact". If they contend that they are not causing an "adverse environmental impact" then they will not be agreeable to implementing intake protection technologies.

EPA Response

EPA did not adopt the sample site-specific rule language in the proposed rule. While EPA rejected a purely site-specific approach, EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA agrees that the burden of proof lies with the permittee. This is reflected in the choice of words used in the rule language and in the preamble. For example, the rule may say "you [the facility] must demonstrate to the Director" when stating a requirement.

Sample site-specific rule (p.17159-61)

Site-Specific Alternative Sample Rule - Criteria for Determination of Adverse Environmental Impact

On page 17160 the following is included as sample rule language for the Site Specific Alternative:

(c) In determining the best technology available for minimizing adverse environmental impact at an existing facility, the Director shall:

(1) Minimize impingement mortality for fish and shellfish;
(2) Minimize entrainment mortality for entrainable life stages of fish and shellfish;
(3) Take into account non-aquatic environmental impacts, including energy requirements, and impacts on local air quality or water resources; and
(4) Not require any technologies for location, design, construction or capacity or operational and/or restoration measures the costs of which would be significantly greater than the estimated benefits of such technology or measures.

These criteria, as contained in the Site-Specific Alternative Sample Rule language, are extremely subjective, broad and vague. But perhaps a bigger concern is the fact that the burden of proof is on the permitting agency. Given that this language is requiring definition of intake protection technology measures at the site, it is more appropriate and reasonable to require the facility to provide information regarding these criteria. The facility will have far more familiarity with their site, biological considerations, biological studies etc. than the permitting agency.

EPA Response

EPA did not adopt the sample site-specific rule language in the proposed rule. While EPA rejected a purely site-specific approach, EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA agrees that the burden of proof lies with the permittee. This is reflected in the choice of words used in the rule language and in the preamble. For example, the rule may say "you [the facility] must demonstrate to the Director" when stating a requirement.

Sample site-specific rule (p.17159-61)

Site-Specific Alternative Sample Rule - Restoration Measures

On page 17160 the following is stated as sample rule language for the Site-Specific Alternative:

125.95 As an owner or operator of an existing facility, may I undertake restoration measures to mitigate adverse environmental impact?

(a) An owner or operator of an existing facility may undertake restoration measures (such as habitat improvement and fish stocking) that will mitigate adverse environmental impact from the facility's cooling water intake structure.

(b) In determining whether adverse environmental impact is minimized, the Director must take into account any voluntary restoration measures.

As discussed in Comment 7, restoration measures should only be considered after all technological alternatives have been considered. The decision to allow restoration measures should be up to the permitting agency as discussed later in Comment 53.

With respect to this sample language, the Department has many concerns regarding such. The tone of this language can be interpreted to mean that a facility can voluntarily choose to undertake restoration measures without any oversight from the permitting authority. The permitting authority would then be required to take into consideration any restoration measures that the permittee incorporated without having any say in the appropriateness of such measures. In sum, the Department strongly opposes this language.

EPA Response

EPA did not adopt the sample site-specific rule language in the proposed rule. While EPA rejected a purely site-specific approach, EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

For information on the role of restoration, please refer to the preamble to the final rule.

Sample site-specific rule (p.17159-61)

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Site-Specific Alternative Sample Rule - Monitoring

On page 17161 the following is stated:

125.98 As an owner or operator of an existing facility, must I perform monitoring?

(b) The Director may require modifications of the monitoring program proposed by the owner or operator based on, but not limited to, consideration of the following factors:

(1) Whether or not the facility has been determined to cause adverse environmental impacts under 125.100...

This language is very disconcerting. According to such, the Director can modify and/or eliminate a monitoring program if it determines that the facility does not cause an averse environmental impact. As stated previously it is unlikely that any facility would not object to a finding that it is causing an adverse environmental impact. As a result, facilities will expect to be alleviated from any monitoring obligation. The permitting authority will then have no basis for requiring any intake protection technologies and will actually not even be given the opportunity to understand the magnitude of any impingement and entrainment effects since no data could be collected. In sum, this language is a recipe for the permittee to “do nothing”.

EPA Response

EPA did not adopt the sample site-specific rule language in the proposed rule. While EPA rejected a purely site-specific approach, EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Option: Site-specific based 1977 Draft Guidance

EPA's 1977 Section 316(b) Draft Guidance

On page 17161 the following is stated regarding "Site-Specific Alternative Based on EPA's 1977 Draft Guidance:

The 1977 Section 316(b) Draft Guidance states, "The environmental-intake interactions in question are highly site-specific and the decision as to best technology available for intake design, location, construction, and capacity must be made on a case-by-case basis." Section 316(b) Draft Guidance, U.S. EPA, 1977, p.4).

Similarly, on page 17161 the following is stated:

Although the Draft Guidance describes the information to be developed, key factors to be considered, and a process for supporting section 316(b) determinations, it does not establish national standards for best technologies available to minimize adverse environmental impact. Rather, the guidance leaves the decision on the appropriate location, design, capacity, and construction of each facility to the permitting authority. Under this framework, the Director determines whether appropriate studies have been performed and whether a given facility has minimized adverse environmental impact.

Intake protection technologies have evolved tremendously since 1977. As such, the direction in these excerpts is clearly outdated where current times call for national performance standards as those contained in 125.94(b). The inclusion of national performance standards will help to ensure that facilities are given a goal and site-specific factors can be considered in deciding how to get to that goal. As stated numerous times throughout this document, the Department is strongly opposed to a site-specific alternative as written.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Option: PSEG site-specific alternative

PSEG Approach for Determination of Adverse Environmental Impact

On page 17162 the following is stated:

Under PSEG's recommended approach, permitting authorities would have the authority to continue to place emphasis on the factors they believe are most relevant to a given situation. For example, when long-term data are available that meet appropriate data quality standards, and when analyses using appropriate techniques such as models that already have been developed to allow population-level analysis of the potential for adverse environmental impact, permit writers would focus on those adverse environmental impact factors related to population-level impacts.

As stated in Comment 1, the Department believes it most appropriate to define adverse environmental impact as “any impingement or entrainment”. This is in direct contrast to a population level impact approach. Populations level impacts are very difficult to quantify given the many confounding factors that affect populations. Instead this effort should be focused on the magnitude of the impingement and entrainment effects caused by the facility and technological measures that can be implemented to minimize that impact. In sum, the Department does not agree with PSEG’s recommended approach.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA has chosen not to define the term "adverse environmental impact" in the final rule. Please refer to section VIII of the preamble to the final rule for more information.

Subject Matter Code 18.01

RFC: Definition of "adverse environmental impact"

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Options for Definition of Adverse Environmental Impact

In an effort to promote discussion concerning a definition of Adverse Environmental Impact, the following options are described on pages 17162 and 17163:

(1) EPA's 1977 Definition of Adverse Environmental Impact and Examples of its Current Use

In EPA's 1977 Draft Guidance, adverse environmental impact is defines as follows:

Adverse environmental impact means the adverse aquatic environmental impact that occurs whenever there will be entrainment or impingement damage as a result of the operation of a specific cooling water intake structure. The critical question is the magnitude of any adverse impact which should be estimated both in terms of short term and long term impact with respect to (1) absolute damage (number of fish impinged or percentage of larvae entrained on a monthly or yearly basis); (2) percentage damage (percentage of fish or larvae in existing populations which will be impinged or entrained, respectively); (3) absolute and percentage damage to any endangered species; (4) absolute and percentage damage to any critical aquatic organism; (5) absolute and percentage damage to commercially valuable and/or sport species yield; and (6) whether the impact would endanger (jeopardize) the protection and propagation of a balanced population of shellfish and fish in and on the body of water from which the cooling water is withdrawn (long term impact).

Over the past 25 years, permitting agencies have interpreted this definition in a variety of ways. Some agencies consider the absolute number of organisms subjected to impingement and entrainment by facility cooling water intakes. Permitting authorities that evaluate adverse environmental impact by enumerating losses of numbers of fish individuals find this approach removes much of the uncertainty associated with evaluating effects to species at higher organizational levels such as populations, communities, or ecosystems. Other permitting authorities have focused on evaluating effects on populations in determining whether an adverse environmental impact is occurring.

(2) An Alternative Definition

EPA solicits comment on an alternative definition of "adverse environmental impact" as follows:

Adverse environmental impact means one or more of the following: entrainment and impingement of significant numbers of a critical aquatic organisms or percentages of aquatic populations; adverse impacts to threatened, endangered or other protected species, or their designated critical habitat; significant losses to populations, including reductions of indigenous species populations, commercial fishery stocks, and recreational fisheries; and stresses to overall communities or ecosystems as evidenced by reductions in diversity or other changes in system structure of function.

(3) Discussion of UWAG Recommendation for Determining Adverse Environmental Impact

UWAG offers the following definition:

Adverse environmental impact is a reduction in one or more representative indicator species (RIS) that (1) creates an unacceptable risk to a population's ability to sustain itself, to support reasonably anticipated commercial or recreational harvests, or to perform its normal ecological function and (2) is attributable to operation of the cooling water intake structure.

The Department strongly opposes all three of these definitions. Inclusion of any of these definitions presents a danger in that facilities will contend that they “are not causing an adverse environmental impact” and therefore should not be required to implement intake protection technologies. As discussed in Comment 5, adverse environmental impact should be defined as “any impingement or entrainment effects” and, as a second choice adverse environmental impact should be left undefined in final rule.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

Comment ID 316bEFR.202.073

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 18.01.01

UWAG definition of "adverse environmental impact"

UWAG Locational Criteria

In a discussion of the UWAG approach, the following critereon is included as one of several factors under the heading Physical Criteria on page 17163:

Locational Criterion: An existing cooling water intake structure would be considered not to create a risk of adverse environmental impact if it withdraws water from a zone of a water body that does not support aquatic life due to anoxia or other reasons, such as lack of habitat, or water quality conditions.

According to UWAG's description, this is one of several protective decision criteria that should be considered in trying to eliminate the risk of adverse environmental impact. Specifically, a waterbody that does not support aquatic life would be considered to not create a risk of adverse environmental impact. However, this decision criteria begs the question "is the lack of aquatic life due in part to the cooling water intake structure"? Given this potential cause, it seems inappropriate that a lack of aquatic life in a waterbody would be considered a criteria for adverse environmental impact.

EPA Response

EPA agrees with this commenter. The lack of aquatic life in a waterbody should not automatically exempt a cooling water intake structure from provisions of any part of the Clean Water Act. The operation of the cooling water intake structure, or the facility in general, may be the reason for the lack of aquatic life. The reason for the lack of aquatic life should be investigated before any decisions are made.

Comment ID 316bEFR.202.074

Author Name Bradley M. Campbell
Organization NJ Dept of Environmental Protection

Subject Matter Code 18.01.01
UWAG definition of "adverse environmental impact"

UWAG Biological Criteria

In a discussion of the UWAG approach, the following critereon is included as one of several factors under the heading Biological Criteria on page 17163:

Percent Population Loss Criterion: On freshwater rivers, lakes (other than the Great Lakes), and reservoirs, a facility would be considered not to create a risk of adverse environmental impact if the cooling water intake structure causes the combines loss, for entrainment and impingement, of (1) no more than 1% of the population of any harvested RIS and (2) no more then 5% if the population of any non-harvested RIS, with fractional losses summed over life stages for the entire lake, reservoir, or river reach included in the evaluation.

As discussed in Comment 1, a population measure of a given fish species, let alone many fish species, could result in a debate for years. The results of biological population studies and modeling can be very subjective because it is difficult to identify, measure, and attribute the impact of each of the many variables affecting populations of each of the impacted species. Given this potential for unending debate, the Department has determined that this critereon is infeasible and unpractical.

EPA Response

EPA agrees with this commenter. It is extremely difficult to identify, measure, and attribute the impact of each of the many factors affecting populations of each of the impacted species. Please see the response to comment 316bEFR.002.019 for the discussion on the definitions EPA rejected for adverse environmental impact in this rulemaking.

Questions for Definition of Adverse Environmental Impact

To summarize the discussion on the determination of adverse environmental impact, the following summary is included on page 17164:

(4) Questions for Comment on the Determination of Adverse Environmental Impact

(a) EPA invites public comment on all aspects of the foregoing approaches to defining adverse environmental impact and for making the preliminary determination on adverse environmental impact, and on which approach should be included if the Agency adopts a site-specific approach for the final rule.

(b) Should the final rule adopt the 1977 Draft Guidance approach to defining adverse environmental impact as any entrainment or impingement damage caused by a cooling water intake structure?

© Should the final rule state that any impingement and entrainment is an adverse environmental impact and focus site-specific assessment on whether that impact is minimized by technologies already in place or potential changes in technology? Alternatively, should the final rule define adverse environmental impact in terms of population-level or community-level effects?

(d) Should EPA adopt an approach that makes more explicit use of threshold determinations of whether adverse environmental impact is occurring. If so, should EPA adopt any or all of the conservative decision criteria suggested by UWAG in a final rule?

(e) Should the structured risk assessment decision process that UWAG recommends for determining adverse environmental impact be adopted?

The Department has determined that the first part of option (c) is the only feasible alternative in order to allow permitting agencies the authority to require technological solutions to minimize impingement and entrainment effects. The Department strongly supports the inclusion of a statement that "any impingement and entrainment is an adverse environmental impact" so that the focus of the site-specific assessment can be a determination as to whether or not that impact is minimized by technologies already in place or if it can be addressed by potential changes in technology.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

Comment ID 316bEFR.202.076

Author Name Bradley M. Campbell
Organization NJ Dept of Environmental Protection

Subject Matter Code 18.02
RFC: Use of previous demonstration studies

Use of Previous Section 316(b) Determinations and Section 316(b) Demonstration Studies

On page 17164 the following is stated with respect to the use of previous Section 316(b) demonstration studies:

Under PSEG's approach, if a cooling water intake structure at an existing facility has previously been determined to employ best technology available based upon a diligent review of a section 316(b) demonstration that was conducted in conformance with the 1977 EPA Guidance, then the existing would continue to be determined to employ best technology available for the next permit cycle.

Similarly, on page 17165 the following is stated with respect to the use of previous demonstration studies:

EPA invites public comment on whether a final rule should permit the use of a previous section 316(b) demonstration for determining whether there is adverse environmental impact and the best technology available for minimizing adverse environmental impact. If such a provision is included in the final rule, what criteria or conditions should be included to ensure that the previously conducted demonstration is an adequate basis for section 316(b) decisions?

Although the Department is not opposed to the consideration of a previously conducted section 316(b) demonstration in rendering a decision on best technology available, this is a completely different issue than consideration of a section 316(b) determination as discussed in the first excerpt of this comment. In fact, the Department questions why this excerpt has been included under the heading “PSEG Recommendation for Using Previous Demonstration Studies” since the content of the excerpt concerns a section 316(b) determination not demonstration. Any Section 316(b) determination up until promulgation of final rule for Phase II existing facilities would have been rendered without rules and guidance. Instead permitting agencies had to rely on the plain language of the Clean Water Act and relevant case law since draft EPA guidance documents were never finalized. Once rules are promulgated, permitting authorities will be required to use them in guiding any future Section 316(b) determinations. In sum, the Department does not necessarily find it appropriate to simply “roll over” a prior Section 316(b) determination. However, the factors and site-specific information included in that determination should certainly be considered in any future Section 316(b) determination as they may still be relevant.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today’s final rule; however, existing data that is reflective of current conditions may be used to support the required studies. Please see response to comment 316bEFR.040.001 for details.

UWAG approach for determining site-specific BTA

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

UWAG Recommendation for Rejecting Technologies

Under the UWAG recommendation for a process on page 17165 the following is stated:

Facilities then would calculate the net benefits for each technology and rank them by cost-effectiveness. Those with marginal costs greater than marginal benefits would be rejected. The technology with the greatest net benefit would be the "best" technology for the site.

Although the Department agrees with the general approach of ranking technologies by their cost-effectiveness, the Department disagrees that “those with marginal costs greater than marginal benefits” should be rejected. This would mean that any technology for which the costs are greater than the benefits would be dismissed (i.e. $1 or greater of costs as compared to $1 of benefits). This directly contrasts the wholly disproportionate standard articulated in case law. Again, the Department can not help but to assume that it is unlikely that any technologies would be deemed cost-effective and therefore implemented if this direction is incorporated into final rule. This is particularly magnified by the fact that benefits are often understated due to the difficult nature of quantifying such.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161). Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

Please refer to the responses to comments 316bEFR.005.020 and 316bEFR.410.001 for a discussion of the application of the cost-benefit and cost-cost tests.

Subject Matter Code 7.01.03

Option 3--Site-specific determination

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Burden Associated with Site-Specific Determination

On page 17167 the following is stated:

The site-specific decision-making process requires each regulated facility to develop, submit, and refine studies that characterize or estimate potential adverse environmental impact. Although some approaches allow facilities to use existing studies in renewal applications, States must still conduct evaluations to ascertain the continued validity of these studies and assess existing conditions in the water body. Such studies can be resource intensive and require the support of a multidisciplinary team. A Director's determinations as to whether the appropriate studies have been performed and whether a given facility has minimized adverse environmental impact have often been subject to challenges that can take significant periods of time to resolve and can impose significant resource demands on permitting agencies, the public, and the permit applicant.

...Because of workload concerns, some States have requested that EPA adopt regulations that set clear requirements specifying standards of performance, monitoring and compliance.

The Department wholeheartedly supports the promulgation of regulations that set clear requirements with respect to performance standards as discussed in Comment 6C.

The Department agrees with EPA in its recognition of the burdens associated with the above excerpt for the site-specific decision making process. As discussed in Comment 6 as well as elsewhere through this document, the Department opposes the site-specific option unless significant improvements are made.

EPA Response

EPA disagrees that a large percentage of facilities will opt for a site-specific determination of BTA. Please refer to the response to comment 316bEFR.202.002 for more information.

The commenter cross-references several of its own comments. Please refer to the responses to these comments for detailed responses to the issues raised.

Comment ID 316bEFR.202.080

Subject Matter Code 11.1

RFC: Discretionary restoration approach

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Restoration Approaches

Regarding the issue of restoration approaches being considered, the following language is included on page 17169:

In the existing facilities rule, EPA is proposing to allow restoration as one means of satisfying the compliance requirements for any one of the three alternatives in 125.94(a). The demonstration a facility would make to show that the restoration measures provide comparable performance to design and construct technologies and/or operational measures would be similar to the demonstration that a facility would make under Track II in the new facility rule.

This language continues in itemizing options regarding restoration which are as follows:

(1) Discretionary Restoration Approaches
(2) Mandatory Restoration Approach
(3) Restoration Banking

The Department supports the use of restoration as part of implementing Section 316(b); however, as discussed in Comment 7, restoration should not be a substitute for technology. Nonetheless, the Department supports "Discretionary Restoration Approaches" over "Mandatory Restoration Approaches". Based on the descriptions of each in the preamble, the Department has determined that "Discretionary Restoration Approaches" are more likely to ensure that the permitting authority has control as to whether or not this option is considered and is only considered after all feasible technological options have been exhausted.

EPA Response

For a discussion of the extent to which restoration measures are voluntary in the final rule, see EPA's response to comment 316bEFR.060.022.

For a discussion of the requirement to consider design and construction technologies and operational measures before deciding to implement restoration measures, see EPA's responses to comments 316bEFR.033.005 and 316bEFR.202.029.

For a discussion of the role of the permitting authority in determining the appropriate level of performance to meet the requirements of the final rule, see EPA's response to comments 316bEFR.060.026 and 316bEFR.212.001.

Comment ID 316bEFR.202.081

Subject Matter Code 11.12

RFC: Restoration banking

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Regarding Restoration Banking, while the Department agrees that this option may reduce the burden on the permit applicant and cuold potentially result in more wetlands being restored, the Department is concerned that proper regulatory oversight is maintained with this option. The Department is not entirely satisfied that this concern has been addressed, based on the preamble language, and therefore does not support the concept of restoration banking.

EPA Response

In the final rule, EPA allows use of restoration to minimize or to help to minimize adverse environmental impacts that derive from impingement and entrainment of aquatic organisms. Restoration measures must meet the requirements described in the final rule.

For a discussion of trading programs, see the preamble to the final rule.

Subject Matter Code 20.01

RFC: Should EPA include impingement trading?

Restoration Trading

On page 17170 the following is stated:

EPA seeks comment on whether a section 316(b) trading program would generally afford greater watershed protection by increasing the number of facilities meeting the performance standard and whether consideration of credit purchases should be mandatory prior to the Director setting alternative requirements.

The Department does not agree with this option. Section 316(b) is already complex and this option would only add to that complexity as it introduces interrelationships. In addition, trading presents many unique challenges for permitting agencies as recognized by EPA. The Department has determined that the end result of this option would be less protection overall since some facilities will implement measures while other facilities will not. Instead, all facilities should implement any feasible technologies where restoration can account for any gaps.

Although the Department's first choice is to not include a restoration trading options for existing or new facilities, its second choice would be to allow voluntary adoption of trading.

EPA Response

Please see response to comment 316bEFR.034.027 regarding the role of trading in today's final rule. Please see response to comment 316bEFR.018.029 regarding trading restoration.

Organization NJ Dept of Environmental Protection

Subject Matter Code 21.01.04
Comprehensive demonstration study (7 parts)

Design and Construction Technology Plan

On page 17176 the following is stated to describe the Design and Construction Technology Plan:

If you choose to use existing and/or proposed design and construction technologies or operational measures in whole or in part to meet the requirements of 125.94, proposed 125.95(b)(4) would require that you develop and submit a Design and Construction Technology Plan with your application that demonstrates that your facility has selected and would implement the design and construction technologies necessary to reduce impingement mortality and/or entrainment to the levels required. The Agency recognizes that selection of the specific technology or group of technologies for your site would depend on individual facility and waterbody conditions.

The Department supports the requirement to submit a Design and Construction Technology Plan. Submission of these plans will be used to support performance standards. In addition to the Department's position that compliance with performance standards should be encouraged, the Department is confident that submission of these plans will advance the knowledge and science of intake protection technologies. Specifically, upon review of these plans, permitting authorities will better understand the efficacy and applicability of the intake protection technologies that are the subject of the plans.

EPA Response

EPA appreciates the support of the New Jersey Department of Environmental Protection.

RFC: Appropriateness of "significantly greater"

EPA's Cost Estimates

On page 17181 the following is stated with respect to the costs evaluated as part of the Economic Analysis:

Section VIII.A.1 below presents the analysis of national costs associated with the proposed section 316(b) Phase II Rule. Section VIII.A.2. presents a discussion of their impact analysis of the proposed rules at the market level and for facilities subject to this rule.

1. Costs

EPA estimates that facilities subject to this proposed rule will incur annualized post-tax compliance costs of approximately 178 million. These costs include one-time technology costs of complying with the rule, annual operating and maintenance costs, and permitting costs (including initial permit costs, annual monitoring costs, and repermitting costs)....

As discussed in Comment 6F, it is inappropriate to allow a facility to be eligible for the site-specific option based on its determination that a facility's costs would be significantly greater than those considered by the Administrator in establishing the performance standards. The Department is unclear as to whether a facility is expected to compare its costs with those determined by the Administrator that are articulated in this section. If this is the case, then this comparison is simply not appropriate. The cost data included in this section is not detailed enough and many many assumptions were made. In addition, the Department notes that the scenario included in the proposed rule did not contain accurate cost data as parts of the analysis could not be completed. As stated by EPA on page 17181:

Because of limited time after final definition of the rule as proposed herein, EPA was unable to rerun the IPM model with an analytical option that completely matches the proposed rule's specifications.

Again, the Department suggests that this criteria as contained in 125.94(c)(1) be deleted as stated in Comment 6F.

EPA Response

EPA has discussed the basis for the site-specific provisions of the rule, as well as how it can be implemented, in the preamble to the final rule. (See section VII and IX). In addition, the rule itself includes criteria that address the cost tests. See, 125.94(a)(5)(i).

Data Issues

Underestimates of Benefits

On page 17192 the following is stated regarding the concern that EPA's estimates of impingement and entrainment losses and benefits are probably underestimates:

EPA's estimates of fish losses due to impingement and entrainment, and of the benefits of the proposed regulations, are subject to considerable uncertainties. As a result, the Agency's benefits estimates could be either over- or under-estimated. However, because of the many factors omitted from the analysis (typically because of data limitations) and the manner in which several key uncertainties were addressed, EPA believes that its analysis is likely to lead to a potentially significant underestimate of baseline losses and, therefore lead to understated estimates of regulatory benefits.

Several of the key factors that are likely to lead EPA's analysis to underestimate benefits include:

-EPA's analysis is based on facility-provided biological monitoring data. These facility-furnished data typically focus on a subset of the fish species impacted by impingement and entrainment, resulting in an underestimate of the total magnitude of losses.

-Industry biological studies often lack a consistent methodology for monitoring impingement and entrainment. Thus, there are often substantial uncertainties and potential biases in the impingement and entrainment estimates. Comparison of results between studies is therefore very difficult and sometimes impossible, even among facilities that impinge and entrain the same species.

-The facility-derived biological monitoring data often pertain to conditions existing many years ago (e.g. the available biological monitoring often was conducted by the facilities 20 or more years ago, before activities under the Clean Water Act had improved aquatic conditions). In those locations where water quality was relatively degraded at the time of monitoring relative to current conditions, the numbers and diversity of fish are likely to have been depressed during the monitoring period, resulting in low impingement and entrainment. In most of the nation's waters, current water quality and fishery levels have improved, so that current impingement and entrainment losses are likely to be greater than available estimates for depressed populations.

The Department agrees that difficulties in quantification of all these factors leads to underestimates of benefits. The Department would also like to specifically note the fact that impingement and entrainment data collected at a time when water quality was comparatively worse than current conditions will result in underestimated benefits as part of the cost/benefit analysis for intake protection technologies. In other words, if a cost/benefit analysis is performed for certain intake protection technologies using outdated impingement and entrainment data, any benefits to reduced impingement and entrainment effects will be underestimated as there are less fish available to be "protected" by the use of the intake protection technologies. Therefore, the use of outdated impingement and entrainment data could directly result in underestimated benefits and hence the rejection of an appropriate intake protection technology. This concern further supports the inclusion of minimum impingement and entrainment monitoring requirements as discussed in Comment 24.

EPA Response

EPA agrees with the commenter that facility-furnished data typically focus on a subset of the fish species impacted by impingement and entrainment, resulting in an underestimate of the total magnitude of losses.

EPA also agrees that industry biological studies often lack a consistent methodology for monitoring impingement and entrainment, resulting in substantial uncertainties and potential biases in the impingement and entrainment estimates. EPA agrees that this makes comparison of results between studies very difficult and sometimes impossible, even among facilities that impinge and entrain the same species.

EPA agrees with the commenter that in those locations where water quality was relatively degraded at the time of monitoring relative to current conditions, the numbers and diversity of fish are likely to have been depressed during the monitoring period, resulting in low impingement and entrainment. As a result, old data may underestimate current I&E rates in places were fish abundances, and therefore I&E rates, have increased.

EPA also agrees that if a cost/benefit analysis is performed for certain intake protection technologies using outdated impingement and entrainment data, any benefits to reduce impingement and entrainment effects will be underestimated as there are less fish available to be “protected” by the use of the intake protection technologies. Therefore, the use of outdated impingement and entrainment data could directly result in underestimated benefits and hence the rejection of an appropriate intake protection technology. For this reason, monitoring of current I&E is required as part of the determination of this rule.

Use of Data in Delaware Case Study

On page 17193 the following is stated:

EPA also examined the estimated economic value of the losses from impingement and entrainment. The estimated cumulative impact of impingement and entrainment at the 12 cooling water intake structures located in the Delaware case study area was based on data available for the Salem facility and than extrapolated to the other facilities on the basis of flow.

Given the varying levels of salinity, variation in species and life stages at different locations, different intake structure configurations, as well as many other site-specific factors, the Department questions whether extrapolation of Salem's data is scientifically appropriate and accurate in establishing impingement and entrainment effects for other Delaware Estuary dischargers. EPA's justification for this assumption should be further clarified.

The Department would also like to further comment on the appropriateness of the use of Salem's biological data. From a national perspective, Salem is unique in that it has extensive historical impingement and entrainment data, ongoing impingement and entrainment data collection (with minimum frequencies defined in its 1994 and 2001 New Jersey Pollutant Discharge Elimination System permits), a comprehensive loss analysis; several Section 316(b) demonstrations; and technological studies regarding alternate intake protection technologies. As was illustrated in the table entitled "Estimated Distribution of Number of Facilities Having Conducted an Environmental Technology Study by Industry Group", which was distributed by EPA at the May 23, 2001 EPA "Technical Experts Panel for Section 316(b)", only 61.5% of traditional utilities have any discrete or on-going impingement and entrainment data sets; Section 316(b) demonstrations; or technological studies.

Despite the fact that Salem's data is more comprehensive than most facilities, there was still some concern regarding the accuracy of the point estimates of impingement and entrainment data, particularly with respect to entrainment. In the June 14, 2000 report prepared by the Department's consultant, ESSA Technologies Ltd., to provide its findings on certain components of Salem's March 1999 application, the following is stated:

In order to complete the analysis of the loss of fish due to entrainment and impingement at the station, the investigators made a careful and substantial effort to fill gaps in the data and to adjust for known biases. Significant data engineering for entrainment losses had to occur before analyses could proceed. They should be commended for their efforts.

Significant, however, was the extensive interpolation and extrapolation of entrainment data required to complete the historical sampling period. There was also a high degree of process error (bias) in the sampling methodology with which the investigators have had to cope. We believe that the variance in the entrainment data warrant an uncertainty analysis to accompany the single-averaged point estimate approach taken in the analyses.

Again, the Department requests that EPA further justify the appropriateness of extrapolating Salem's data to other facilities.

EPA Response

EPA agrees with the commenter that there are site-specific conditions that influence I&E rates for individual facilities. However, it was not EPA's intent to develop precise I&E estimates for individual facilities for its 316b Phase 2 benefits analysis. Rather, the goal was to develop an estimate of the magnitude of I&E for the over 550 facilities nationwide that are in scope of the rule. Because I&E data are not available for most of these facilities, EPA, by necessity, had to extrapolate I&E rates from facilities with data to facilities without data. EPA took great care in this procedure to extrapolate among similar facilities within the same ecological region.

For the final analysis of I&E for the mid-Atlantic region, EPA extrapolated I&E from 6 facilities in different parts of the region Calvert Cliffs, Indian River, Chalk Point, Morgantown, Indian Point, and Salem) to capture a range of conditions within the region. For a discussion of EPA's extrapolation procedure for its final analysis, please see Chapter A5 of the Regional Analysis Document (DCN #6-0003) and EPA's response to Comment 316bEFR.041.041. EPA's analysis of the mid-Atlantic region is presented in Part D of the Regional Analysis Document.

RFC: Definition of "adverse environmental impact"

Use of Individual Loss Data Versus Population Effects Data

As stated numerous times through this document, the Department defines losses at the individual level. As a result of this policy, it is the Department's position that the best starting point to understanding any facility's effects on a receiving waterbody is to refer to impingement and entrainment data sets. These numbers reflect the direct effects at the intake structure due to impingement and entrainment. An assessment of these effects is integral to defining alternatives to minimize these losses. Impingement and entrainment data sets feed directly into the overall impingement and entrainment losses. Specifically, these impingement and entrainment data sets are extrapolated to be representative of actual operating flow conditions and are then used in choosing appropriate intake protection technologies and their associated cost/benefit ratios.

To further illustrate the importance of defining adverse environmental impact at the individual level, the Department would again like to use the example of the Salem facility in describing the many ways losses can be defined in addition to impingement and entrainment losses. Despite the fact that the Department defines losses at the individual level and because of a lack of regulations from EPA in determining whether an adverse environmental refers to losses at the individual level versus a population level, PSEG provided loss estimates in its 1999 application for the Salem facility in the following ways:

-Impingement and entrainment losses - expressed in losses (number of fish) and densities (number/million m3)

-Conditional Mortality Rates (CMR's) – CMR values provide a conservative estimate of the percentage reduction in the Delaware portion of the young-of-the year populations due to Salem's operations without taking into account compensation or the portion of the population that resides outside the study area within the Delaware River.

-Base Case Losses - impingement and entrainment losses were calculated for a consistent set of operating conditions and losses were converted to age 1
equivalent recruits. The alternate intake protection technologies were defined in terms of base case losses.

-Production Foregone - estimates the total reduction in future growth (measured in units of biomass) attributable to organisms killed as a result of impingement and entrainment at the station. This analysis was included for the forage fish bay anchovy and for non-RIS forage species and this analysis fed into the cost/benefit assessment.

-Spawning Stock Biomass per Recruit (SSBPR) – this model considers the reproductive capacities of organisms entrained and impinged by estimating the fractional change in reproductive capacity of a given species as a result of plant operations.

-Equilibrium Spawner Recruit Analysis (ESRA) – this model is used to understand long-term (equilibrium) impacts by calculating the population consequences of base-case conditional mortality rates for entrainment and impingement.

As illustrated by this example, a lack of definition for adverse environmental impact will result in facility's providing complex data analyses where the building block for any such analyses is impingement and entrainment data. The review of these analyses is extremely time-consuming and resource intensive for the permitting agency. In addition the question of the actual losses due to the facility becomes extremely complex and can lead to great debate, which is an unproductive use of effort. Again, it is the Department's position that the focus should be on the direct effects of the facility, namely individual impingement and entrainment losses, and ways in which to minimize those losses with intake protection technologies.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

Executive Orders (except EO 13211)

Federalism Implications

On pages 17214 to 17216, EPA set forth its understanding of the requirements of Executive Order 13132 regarding federalism and the steps taken by EPA in furtherance of same. On page 17215 the following is stated:

Under section 6 of Executive Order 13132, EPA may not issue a regulation that has federalism implications, that imposes substantial direct compliance costs, and that is not required by statute unless the Federal government provides the funds necessary to pay the direct compliance costs incurred by State and local governments or EPA consults with STATE and local officials early in the process of developing the proposed regulation.

It is the Department's position that Federal government has not complied with the substance or the spirit of Executive Order 13132. The Department disagrees with EPA's assertions that this rule (1) has no federalism implications, (2) does not impose substantial direct compliance costs on state regulating agencies and (3) is required by statute. To the contrary, this regulation does implicate federalism policies because it affects the policymaking discretion of the States. Moreover, the expansion of the site-specific alternative from an exception, to be granted at the discretion of the permitting authority, to a freely available third regulatory option eliminates all of the gains in administrative simplicity which were anticipated to be reaped from the relatively simple performance standards, and thus, imposes an enormous additional administrative burden on the States with a commensurate increase in direct implementatione costs. Finally, the imposition of formal cost/benefit analysis as a central focus of the regulation is not required by Section 316(b) of the Clean Water Act. Beyond being not "required" by statute, it is the Department's position that the cost/benefit analysis imposed by the "site-specific" alternative is not authorized by 316(b) as discussed in Comment 6F above.

EPA Response

EPA has followed Executive Order 13132 regarding federalism and concluded that this rule does not have federalism implications.

Comment ID 316bEFR.202.092

Author Name Bradley M. Campbell

Organization NJ Dept of Environmental Protection

Subject Matter Code 22.0

Administrative Requirements

Notwithstanding its claim that the federalism issues protected by OE 13132 are not implicated in this rulemaking, EPA asserts that it has provided sufficient opportunity for review and comment by State and local agencies to satisfy the requirements of OE 13132. However, the significantly less stringent changes made to this regulation subsequent to the December 28, 2001 submission of the EPA draft to the Office of Management and Budget were not subject to any comment or input from State or local agencies. OE 13132 appoints the Office of Management and Budget as the gatekeeper of agency responsiveness to OE 13132. It makes a mockery of the substance and intent of the OE 13132 to allow the gatekeeper to ignore the mandates of the executive order and require changes, which violate federalism policies.

EPA Response

EPA has followed Executive Order 13132 regarding federalism and concluded that this rule does not have federalism implications.

Burden on permitting agencies (general)

IDEM is concerned with the additional burden a site-specific approach described in the proposed rule could have to our existing NPDES permit program. It is apparent that significant resources will be required to effectively implement the proposed regulation. Most states are currently working hard to process NPDES renewal applications in a timely way and to effectively implement other provisions of the NPDES program. Also, most states face significant budget constraints. It is not apparent that U.S. EPA has considered the costs and burden of implementing the proposed regulation on existing state NPDES programs.

IDEM is aware that some site-specific review may be needed while permitting existing facilities. However, EPA must not require implementation of cooling water intake regulations in a vacuum without considering other requirements, timing and needs of the NPDES program. The establishment of a regulatory framework that presupposes a level of available resources without proper consideration of the ability to effectively implement its provisions will not be successful.

EPA Response

EPA did greatly consider the costs and burden of implementing today's final rule and has provided maximum flexibility for both facilities and Directors through the four compliance alternatives in 125.94(b) and the site-specific determination of BTA. Please see response to comment 316bEFR.034.005 for a discussion of the efficiencies added to the final rule.

EPA is also sensitive to the resource limitations of some States. Because of the multiple compliance alternatives and the availability of the Technology Installation and Operation Plan as discussed at 125.94(e), EPA believes that most facilities will not seek compliance via a site-specific determination of BTA. Only a handful of facilities are expected to pursue the site-specific determination of BTA.

EPA has outlined possible timing requirements in the preamble to today's final rule. Please see response to comment 316bEFR.034.066 for a discussion on timing of application studies.

RFC: Three-option framework for determining BTA

IDEM supports an approach that gives the permit writer a clear option for requiring technologies that are proven in their efficacy under particular conditions EPA could provide technical guidance on technologies available and their efficacy under certain conditions and provide permit writers with clear criteria for considering these different technologies given the conditions at the facility.

EPA Response

Please refer to the preamble for a discussion of the framework of today's rule, which includes a compliance alternative for preapproved technologies. EPA notes that facilities using approved design and construction technologies (such as a wedge-wire screen in certain freshwater river environments) may demonstrate compliance with the rule under § 125.94(a)(4) or may request that the Director approve additional technologies under § 125.99(b).

With respect to the choice of intake technologies for a particular facility or type of facility in the final rule, there are several resources permit writers may consult for information. First, EPA has provided a database with numerous studies that illustrates the effectiveness of various intake technologies (see DCN 5-4420 in OW-2002-0049, the docket for the Phase II NODA). Second, the final rule also includes provisions for verification monitoring (see § 125.95), allowing the Director to monitor the effectiveness of a selected technology. Lastly, as stated in the Phase II Information Collection Request for the final rule (DCN 6-0001 in OW-2002-0049, the docket for today's final rule), EPA assumed that some facilities would conduct pilot studies to evaluate the potential effectiveness of intake technologies. The results of such a study may help guide the selection of the most effective intake technology.

Use cost-benefit tests

Our basic concern with EPA's current proposal is this: EPA's proposal threatens to turn a technology-based regime into a cost-benefit regime, without any support for this transformation in the statutory language, structure, or history.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Comment ID 316bEFR.204.002

Author Name Thomas McGarity

Organization Center for Progressive Regulation

Subject Matter Code 22.0

Administrative Requirements

Further, the motivation for this sea change in statutory interpretation appears to have come from an agency, the Office of Information and Regulatory Affairs (OIRA), within the Office of Management and Budget (OMB), which is not charged with implementing and interpreting the Clean Water Act and which is, it appears, engaged in a pattern of holding closed-door meetings with industry representatives on pending rules, followed by "recommendations" to EPA to weaken the rules under consideration. OIRA's influence on this and other rulemakings, and in particular its closed-door sessions with private parties, have caused misinterpretations of the Clean Water Act and, more generally, violate both the spirit and the letter of the Administrative Procedure Act.

EPA Response

EPA has coordinated with OIRA in accordance with Executive Order 12866 and will complete any associated docketing requirements. EPA's final decisions with respect to this rule were made pursuant to, and consistent with the Clean Water Act. EPA has complied with all Administrative Procedure Act requirements regarding ex parte contacts during an informal rulemaking.

Comment ID 316bEFR.204.003

Author Name Thomas McGarity

Organization Center for Progressive Regulation

Subject Matter Code 2.04.04

Use cost-benefit tests

Statutory interpretation: EPA's reliance on formal cost-benefit analysis, including the agency's proposed differentiation of standards according to the quality of the receiving waters affected, is a misinterpretation of the Clean Water Act. Changes to EPA's proposal made after review by OIRA suggest that EPA's new reliance on formal cost-benefit analysis in setting technology-based standards under the Clean Water Act is a result of OIRA's influence. It thus appears that EPA is ceding its interpretive authority under the Clean Water Act to OIRA, which violates Congress's intent that EPA be responsible for implementation of the Clean Water Act.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Subject Matter Code 22.0

Administrative Requirements

Author Name Thomas McGarity

Organization Center for Progressive Regulation

Administrative process. While OIRA was reviewing EPA's initial proposal for CWIS's, and insisting on numerous and extensive changes in EPA's proposal that greatly relaxed the requirements of EPA's initial proposal, top OIRA officials met with numerous representatives of the energy businesses affected by this proceeding. Yet neither EPA nor OIRA has made available all of the documents that passed between EPA and OIRA concerning EPA's proposal. Moreover, EPA's preamble does not explain whether and how EPA's initial proposal was changed as a consequence of OIRA review and/or OIRA's contacts with industry representatives. As things stand now, the existing public record invites the unfortunate conclusion that the changes made to EPA's proposal between the time when EPA submitted the proposal for OIRA review and when the agency offered a significantly changed proposal for public comment were influenced by ex parte contacts between high-level OIRA officials and industry representatives, contacts undocumented and unexplained in EPA's preamble.

EPA Response

EPA has coordinated with OIRA in accordance with Executive Order 12866 and will complete any associated docketing requirements. EPA's final decisions with respect to this rule were made pursuant to, and consistent with the Clean Water Act. EPA has complied with all Administrative Procedure Act requirements regarding ex parte contacts during an informal rulemaking.

Comment ID 316bEFR.204.005

Author Name Thomas McGarity

Organization Center for Progressive Regulation

Subject Matter Code 22.0

Administrative Requirements

We believe that these errors of statutory interpretation and the appearance (and perhaps reality) of secret industry influence on EPA's proposal will make this rulemaking proceeding exceedingly vulnerable to judicial invalidation. We also believe, as scholars of environmental law and the administrative process, that the substance and process of this rulemaking reflect an exceedingly problematic turn of events both for environmental regulation and, more generally, for open and impartial administrative proceedings. See Sidney A. Shapiro, Two Cheers for HBO: The Problem of the Nonpublic Record, 54 Admin. L. Rev. 853 (2002). We strongly urge EPA to respond to the comments below by changing the proposal in the ways we suggest and by making public the documents and any other records that shed light on the reasons why the rule was changed so substantially at OIRA's behest.

EPA Response

EPA has coordinated with OIRA in accordance with Executive Order 12866 and will complete any associated docketing requirements. EPA's final decisions with respect to this rule were made pursuant to, and consistent with the Clean Water Act. EPA has complied with all Administrative Procedure Act requirements regarding ex parte contacts during an informal rulemaking.

Comment ID 316bEFR.204.006

Author Name Thomas McGarity

Organization Center for Progressive Regulation

Subject Matter Code 2.04.04

Use cost-benefit tests

EPA's proposal transforms technology-based regulation into cost-benefit regulation, with no support in the statute for doing so.

Section 316(b) is not a cost-benefit provision. It does not even mention economic costs, in contrast to other technology-based provisions of the Clean Water Act, which explicitly allow EPA to consider costs. See, e.g., 33 U.S.C. §§ 1314(b)(1)(B), 1314(b)(2)(B), 1314(b)(3), 1316(b)(1)(B). The contrast between the explicit mention of costs in other statutory provisions and the absence of such language in section 316(b) is striking evidence that cost-benefit analysis is not permitted under section 316(b). See Whitman v. American Trucking Associates, 531 U.S. 457, 468 (2001) (faced with similar interpretive question under Clean Air Act, Justice Scalia rejected the argument that costs should be considered, remarking on the importance of the issue and observing that Congress does not "hide elephants in mouseholes"). Moreover, even the consideration of costs that has been undertaken under other provisions of the statute is not as rigid and hyper-quantified as the cost-benefit balancing EPA proposes to undertake here. For example, EPA's longstanding practice under other provisions of the Clean Water Act has not, in contrast to the approach undertaken here, featured relaxation of regulatory requirements based on a comparison of monetized costs to monetized benefits.

In lacking any reference to consideration of costs, section 316(b) contrasts strikingly not only with other provisions of the Clean Water Act, but with provisions of other statutes that do contemplate formal cost-benefit analysis. The Safe Drinking Water Act, for example, specifically directs EPA to undertake cost-benefit analysis and to consider willingness-to-pay in undertaking that analysis. See 42 U.S.C. § 300g-1(b)(3)(C)(iii). No such language appears in section 316(b). It is more than a little awkward, therefore, that EPA cites to the Safe Drinking Water Act as a possible source for the cost-benefit standard under the Clean Water Act – as if they were somehow the same statute! See National Pollutant Discharge Elimination System—Proposed Regulations to Establish Requirements for Cooling Water Intake Structures at Phase II Existing Facilities, 67 Fed. Reg. 17122, 17166 (April 9, 2002). They are not.

EPA Response

Author Name Thomas McGarity

Organization Center for Progressive Regulation

Subject Matter Code 21.08

Burden on permitting agencies (general)

Moreover, EPA itself recognizes the significant administrative burdens that will be imposed on state and federal permitting agencies as a result of individualized cost-benefit assessments for CWIS regulation. Indeed, these burdens were one reason why EPA did not choose site-specific cost-benefit as a lead option in its original proposal. See OMB Review Draft for the Proposed Section 316(b) Rule for Large Cooling Water Intake Structures at Existing Power Generating Facilities, USEPA Docket W-00-32, DCN# 4-4005, at 93 (December 28, 2001). At the behest of OIRA, however, EPA elevated site-specific cost-benefit analysis to a lead option. EPA should explain the basis for this change of heart. Mere reference to OIRA's desires, of course, will not be an adequate statement of EPA's basis and purpose for this rule, as OIRA is not the agency charged with implementing and interpreting the Clean Water Act. Motor Vehicle Manufacturers Assoc. v. State Farm Mutual Automobile Ins. Co., 463 U.S. 29, 56 (1983) (an "agency must examine the relevant data and articulate a ‘rational connection between the facts found and the choice made'").

EPA Response

Please refer to the final rule preamble for an explanation of EPA's decision to include a site-specific option.

Author Name Thomas McGarity

Organization Center for Progressive Regulation

Subject Matter Code 8.0

Waterbody Type

EPA also errs, as part of its new emphasis on cost-benefit balancing, in proposing to vary regulatory requirements according to the nature and quality of the water bodies affected by individual CWISs. Section 316(b) requires that effluent standards demand the "best technology available for minimizing adverse environmental impact." Once a technology is identified as available and as the best for minimizing adverse environmental impact, EPA should not relax regulations under section 316(b) based on the nature of the water bodies affected. Such an approach runs counter to EPA's longstanding approach to the technology-based requirements of the Clean Water Act. See, e.g., Weyerhaeuser v. Costle, 590 F.2d 1011, 1035 (D.C. Cir. 1978) (rejecting site-specific variances from best available technology standards). EPA's new approach also runs counter to the history and purpose of the Act itself, which was significantly amended in 1972 precisely because the previous water-quality-based approach had been, in Senate Muskie's words, "inadequate in every vital respect." A Legislative History of the Water Pollution Control Act of 1972, vol. 2, at 1253 (1973). Finally, and perhaps most tellingly, EPA's focus on site-specific water quality under section 316(b) is undermined by the subsection immediately preceding section 316(b) – section 316(a) – which provides explicitly for the kind of site-specific analysis EPA has endorsed here. The lack of such site-specific emphasis in section 316(a) evinces congressional intent that section 316(a) not turn on site-specific determinations.

EPA Response

EPA disagrees with this analysis. EPA sees no relevance to the commenter's reference to 316(a), which relates to thermal discharges. In any case, section 316(b) specifically directs EPA to consider waterbody characteristics and environmental effects when choosing a BTA. Nowhere does 316(b) specify that EPA must adopt a single national categorical standard or technology.

Definition: Existing Facility

In another reflection of its misunderstanding of section 316(b), EPA proposes very different requirements for existing facilities than it has required for new facilities in its Phase I rules. Section 316(b) does not, however, distinguish between new and existing facilities; its requirements apply equally to all facilities. Other sections of the Clean Water Act, in contrast, draw a clear distinction between new and existing facilities. Compare, e,g., 33 U.S.C. § 1311 (referring to existing sources) with 33 U.S.C. § 1316 (referring to new sources). The lack of such a distinction in section 316(b) is telling evidence that the same requirements should apply to both kinds of facilities. EPA thus errs in drawing such a large distinction between new and existing facilities for purposes of this proposed rule.

To be sure, section 316(b) does refer to provisions of the Clean Water Act (sections 301 and 306) that distinguish between new and existing facilities. However, nothing in section 316(b) says that the requirements of section 316(b) are the same as those under sections 301 and 306. Moreover, if this were the case, then EPA's use of site-specific, formal cost-benefit analysis, and its emphasis on the condition of the affected waters in setting regulatory requirements, would be even more suspect, as these regulatory approaches have not historically been adopted under sections 301 and 306.

EPA Response

As the comment notes, section 316(b) requires that "...standards established pursuant to..." sections 301 and 306 of the CWA must require that the location, design, construction and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact. Given the wording of section 316(b), as well as its reference to both existing and new facility standards, the Agency believes it is well within its authority to make reasonable distinctions in determining both best technologies for existing versus new facilities, as well as to make reasonable distinctions in determining which technologies are available to existing versus new facilities. Such distinctions are based on documented differences between the two categories of facilities with regard to their respective ability to address issues such as intake location, intake design, the availability of space for specific technologies, secondary environmental effects (e.g., plumes, fogging, icing, etc.), operational delays associated with retrofitting, energy impacts, costs, and cost-effectiveness.

RFC: EPA rationale to not require closed-cycle

EPA makes a half-hearted attempt to justify its distinction between new and existing facilities, arguing that more flexibility is needed for existing sources and that energy impacts would be unacceptable if the same requirements were to apply to both kinds of sources. 67 Fed. Reg. at 17140-41, 17146. The best evidence against these claims are EPA's own words, in the original proposal it sent to OIRA for review in December 2001. There, EPA found that 59 existing sources, at least, could be subject to much more stringent standards than it now proposes imposing, despite the supposedly reduced flexibility of such existing facilities. See OMB Review Draft for the Proposed Section 316(b) Rule for Large Cooling Water Intake Structures at Existing Power Generating Facilities, USEPA Docket W-00-32, DCN# 4-4005, at 77-78 (December 28, 2001). In the current proposal, which followed OIRA's review and OIRA's closed-door meetings with industry representatives, EPA has softened the requirements for these facilities. However, EPA does not elaborate upon its reasons for having done so. Even under its own, mistaken view of the proper interpretation of the Clean Water Act – according to which cost-benefit analysis is the criterion for regulatory choice – EPA does not adequately explain why the costs of requiring closed-cycle cooling at any or even all facilities covered by this proceeding are not worth the benefits. EPA vaguely suggests that the costs are "unacceptable." The agency also recognizes, however, that the benefits of closed-cycle cooling would reach at least almost $1.5 billion, 67 Fed. Reg. at 17168, without even accounting for the numerous and multifarious unquantified benefits conferred by regulation of CWISs. See 67 Fed. Reg. at 17190-93. EPA cannot simply declare that the costs are unacceptable; it must explain why it believes them to be so.

EPA Response

The costs of converting to recirculating wet cooling towers for a portion of or the entirety of the existing facilities within the scope of the rule are unacceptable, in the Agency's view (see the preamble to the final rule). Additionally, EPA based its decision on the uncertainty relating to the engineering feasibility, the potential for extended connection outages, and the lack of historical engineering precedent for cooling tower retrofit projects (with only one known case at a power plant of the size of the typical facility within the scope of the rule). The Agency can and did consider a wide range of factors into its determination that the societal "costs" of mandated cooling tower retrofit are "unacceptable," especially when compared to the relatively inexpensive and beneficial societal impacts of the preferred final rule requirements. See section VII.E of the preamble to the final rule.

One fact influencing this conclusion came to the Agency, literally, on the eleventh hour prior to proposal. This fact, was the real-life construction downtime data from the Palisades Nuclear plant cooling tower conversion, which the Agency requested from the facility far in advance of the proposal, only to receive it on the day before the proposal was signed. Prior to this point, the Agency had in hand data from two small power plant conversions that indicated connection outages could be quite short. However, the 10 month outage at Palisades was so far in excess of the Agency's previous estimates (1 month net outages at all plants retrofitting to closed-cycle) that this served to reinforce the Agency's findings of the costs of retrofitting being high to unacceptable. Hence, the Agency did not have the opportunity to include this important piece of evidence in its proposal submission to OIRA nor did it have opportunity to fully flesh this fact out in the analyses supporting the proposed rule and retrofitting cooling towers. Therefore, the Agency re-analyzed some proposal regulatory options for the Notice of Data Availability (68 FR 13525).

Use cost-benefit tests

We strongly support Congress' choice of technology-based standards to implement the Clean Water Act. Although this approach has been criticized by those who favor a cost-benefit approach, the academic literature has long recognized the important advantages of this approach to environmental protection as compared to the cost-benefit approach that OIRA has attempted to smuggle into EPA's decisionmaking. See, e.g., Sidney A. Shapiro & Thomas O. McGarity: The Rationale for Technology-Based Regulation, 1991 Duke L.J. 729; Thomas O. McGarity, Media-Quality, Technology, and Cost-Benefit Balancing Strategies for Health and Environmental Regulation, 46 Law & Comp. Probs. 159 (Summer 1983).

EPA's transformation of technology-based regulation into cost-benefit regulation, along with its inadequate explanation of its regulatory choices under the new cost-benefit regime, is made all the more troubling, as we next explain, by the obvious and undue influence of OIRA, and perhaps even industry representatives, in leading to EPA's regulatory change of heart.

EPA Response

EPA has coordinated with OIRA in accordance with Executive Order 12866 and will complete any associated docketing requirements. EPA's final decisions with respect to this rule were made pursuant to, and consistent with the Clean Water Act. EPA has complied with all Administrative Procedure Act requirements regarding ex parte contacts during an informal rulemaking.

Administrative Requirements

EPA and OIRA should make available any and all documents pertaining to OIRA's review of EPA's initial proposal for this rule, and EPA should explain why it changed its proposal so significantly at OIRA's behest. EPA should also explain whether and how private industry representatives with whom OIRA officials met during OIRA's review of this rule affected OIRA's and/or EPA's perspective on this rule.

Even a cursory comparison of EPA's original proposal, sent to OIRA in December 2001, and the proposal EPA published in April, reveals that OIRA insisted on numerous and extensive changes in EPA's proposal. EPA should explain why it made these changes. EPA's December 2001 proposal was made by the expert agency, charged with implementing and interpreting the relevant statute, after plenary agency review. Changes made at the behest of OIRA at this point should be explained in the administrative record. This is particularly so in this case, where OIRA met with numerous industry representatives while undertaking its review of this rule.

While EPA's initial proposal was under review at OIRA, high-level OIRA officials met with representatives from the following industry groups: TXU, Cinergy, PSEG, Progress Energy, Edison Electric Institute, TECO Energy Inc., Constellation Energy Group, Allegheny Energy, Minnesota Power, and Mirant Corporation. See "Meeting Record Regarding: Meeting with the Administrator of OIRA to Discuss 316(b) Existing Facilities Rule," available at http://www.whitehouse.gov/omb/oira/2040/meetings/87.html. All of these are businesses in the energy sector. (We have used the abbreviated designations used by OIRA on its web site; we think it most likely that "TXU" is TXU Energy, "PSEG" is Public Service Enterprise Group, and "EEI" is Edison Electric Institute.)

Several weeks after this meeting, OIRA concluded its review of EPA's proposal. OIRA's review ultimately produced substantial changes in EPA's proposed rule. EPA itself has documented the changes that occurred at OMB's behest. See Section 316(b) Phase II Proposed Rule Summary of Major Changes During Interagency Review, USEPA W-00-32 DCN 4-4019, (May 23, 2002) (documenting that over thirty major changes, i.e. the vast majority, were made "at the suggestion or recommendation" of OIRA). EPA has not stated, however, whether any information, opinions, or documents that might have been supplied by the energy industry representatives who enjoyed an ex parte meeting with OIRA officials led to the changes in EPA's proposal. Yet EPA officials were present at the meeting with industry representatives. (See meeting record, available at http://www.whitehouse.gov/omb/oira/2040/meetings/87.html (listing EPA employees Stephanie Dangle, Geoff Grubbs, David Gravallese, and Tom Gibson as attendees).) EPA thus should explain what influence, if any, its ex parte contacts with industry representatives had on its current proposal.

In addition, EPA should make public any documents that passed between EPA and OIRA during this review. OIRA so far has refused to make public all such documents, citing a Reagan-era policy on nondisclosure of OIRA-review-related documents. See Letter from Donald R. Arbuckle, Deputy Administrator, OIRA, to Reed Super, Senior Attorney, Riverkeeper (June 20, 2002)). EPA should also make public any written or oral communications that passed between private groups and individuals and EPA or OIRA during OIRA's review. See Shapiro, supra, at 855 ("The legitimacy of rulemaking relies on public knowledge of private contacts with agency and White House officials even if any agency can successfully defend its rule against legal attacks on the basis on publicly available information.")

Without this disclosure, OIRA's early and intense involvement in EPA rulemaking would allow OIRA to undo the procedural strictures of the Administrative Procedure Act: a "private" notice and comment period, open to select members of affected groups, would precede the "public" notice and comment period contemplated by the APA. The D.C. Circuit has warned of such secrecy "frustrating" the APA, since the final rule would not be "based (in part or whole) on any information or data which has not been placed in the docket...." Sierra Club v. Costle, 657 F.2d 298, 403 (D.C. Cir. 1981), quoting Administrative Procedure Act, 42 U.S.C. §7607(d)(6)(C). The court also expressed the same concern in United Steelworkers of America v. Marshall, 647 F.2d 1189 (D.C.Cir.1980) (partially rev'd on unrelated grounds, United Steelworkers of America v. Dole, 1990 WL 488981 (D.C. Cir. 1990)), requiring disclosure of any ex parte communications "that may have influenced the agency decisionmaking." 647 F.2d at 1237-38. Surely these principles cannot be circumvented by the simple expedient of having private industry representatives meet in OIRA's offices rather than in EPA's.

EPA Response

EPA has coordinated with OIRA in accordance with Executive Order 12866 and will complete any associated docketing requirements. EPA's final decisions with respect to this rule were made pursuant to, and consistent with the Clean Water Act. EPA has complied with all Administrative Procedure Act requirements regarding ex parte contacts during an informal rulemaking.

Commercial Fishing Benefits

Producer Surplus of Commercial Landings:

Producer surplus in concept is "the difference between the market price a producer can obtain for a good or service and the actual cost of producing that unit of the commodity" (p. A9-2, footnote 1). Chapter A9 concludes that producer surplus is 40% to 70% of commercially landed fish values (p. A9-5). This may be true in fisheries for which fishing effort is near optimal levels, i.e., those for which long run marginal fishing costs (for the industry) approximate long run marginal fishery revenue. However, producer surplus is likely much smaller in overcapitalized fisheries, for which fishing costs (and usually fishing effort) exceed optimal levels. For instance, in his estimates of the demand and supply of all U.S. lake whitefish landings, Ghanbari (1977) estimated that the ratio of producer surplus to landed value was .29. This is lower than those of EPA's other citations. Further, using data from Pattinson and Talhelm (1978) on costs reported by whitefish fishing firms in Michigan's Green Bay, Ghanbari also estimated that producer surplus for whitefish fishing in those Michigan waters was only 3% of current revenue. Finally, using a surplus production analysis of Michigan's Green Bay whitefish fishery, Ghanbari estimated that at optimal effort (much lower than the then-current effort), producer surplus would be 40% to 66% of total revenue. Husin (1984) found similar results. In his surplus production analysis, using Pattinson and Talhelm (1978) cost data, he estimated that producer surplus for all of Michigan's 1982 whitefish fishery was 15%, but could have increased to 45% at optimal effort. (See further discussion in Talhelm 1988). These studies show that overcapitalization was common in Michigan's Great Lakes fisheries at the time, reducing producer surplus levels considerably below optimal levels. They also imply that the ratio of producer surplus to revenue may vary considerably over time. Michigan's fisheries have changed drastically since 1982, and recent levels of producer surplus apparently have not been estimated. Judging by reports in the fisheries literature and in the news media of stock depletion in many Great Lakes and saltwater commercial fish stocks, excess effort is common. In such cases, producer surplus will commonly be lower than EPA's estimated 40% to 70% of landed value, and could be as low as zero. An upper estimate of 40% would be more realistic for Great Lakes fisheries. EPA's related rule of thumb, a .22 ratio between producer surplus and total economic surplus for commercial landings, is similarly flawed, though there apparently are no alternative empirical estimates of this ratio for Great Lakes commercial fisheries.

EPA Response

For the cost-benefit analysis of the EPA assumed that producer surplus in the commercial fishing sector ranges from 0% to 40%. The 22% rule of thumb was not used.

For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits, please see the response to comment 316bEFR.005.029.

Subject Matter Code 10.02.04
Valuing Forage Species (incl non-use and non-landed)

Existence and other Nonuse Values:

In the economic literature, the term "existence" has been used in several contexts, ranging from the literal existence or not of a species or habitat (or the risk of extinction), to the possible loss of "integrity" of an ecosystem. I&E losses rarely threaten the existence or integrity of a species or habitat; they generally only impact a very small percentage of highly viable populations. Yet the proposed EPA rules assign existence values to these species (as part of non-use values). The relationship between the value of the risk of extinction and the value of a trivial population reduction has not been adequately addressed in the economics literature. Clearly, the pure survival value of organisms and unique ecosystems can be large and socially important. People felt violated when they heard that Prince William Sound's ecological integrity was threatened by a large oil spill, and when they heard that Lake Erie was "dying." People might also feel violated, but to a much lesser degree, when they hear about I&E losses where species/ecosystem integrity is not threatened, but it is not clear whether this is even a form of existence value. Further, people may feel similarly violated by fish removals by sport and commercial fisheries, but society generally considers both practices acceptable. One can validly argue that marginal losses of non-threatened species have zero impact on existence values. One can also argue that option value (another nonuse value) is also zero because all impacts are easily reversible in a relatively short time frame. Therefore, EPA's assumption that existence and other non-use values are 50% of recreational values (p. A9-10) is quite arbitrary, as EPA acknowledges, and EPA has cited no scientific basis for any loss of non-use values in non-threatening removals such as via I&E. Appropriately, EPA has agreed to "revisit the body of research on this topic…" New research is particularly needed to determine whether existence values and other nonuse values are impacted at all by marginal removals of non-threatened species.

EPA Response

In the cost-benefit analyses for the NODA and for the final Section 316(b) Phase II rule, EPA did not use the 50% rule-of-thumb to estimate non-use benefits. For EPA's response to comments on the use of the 50% rule-of-thumb to estimate non-use benefits, please refer to EPA's response to comment #316bEFR.005.034.

Please also refer to EPA's response to comments on the HRC methods (316bEFR.005.035) and the SRP methods (316bEFR.005.006); the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003); and to EPA's Guidelines for Preparing Economic Analyses (EPA 240-R-00-003).

For further discussion of the topic of conditions under which nonuse values may or may not apply, and the issues associated with applying stated preference techniques to estimate such values more reliably, please see response to comment 316bEFR.306.105.

Subject Matter Code 10.01
Ecological Evaluation Methodology

Negative Values of Nuisance Species:

Some fish and other aquatic organisms can have negative economic values. Several exotic species in the Great Lakes are considered to have negative values, including the sea lamprey, the round goby, the Eurasian ruffe, the spiny water flea and the zebra mussel. For instance, the Great Lakes Fishery Commission spends millions of dollars annually to reduce sea lamprey populations in U.S. Great Lakes waters. Any I&E reduction in sea lamprey would be welcomed and encouraged. The potential benefits of reducing the negative impacts of nuisance species should be explicitly considered in the EPA rules, but there is no evidence that they have been considered.

EPA Response

EPA is not aware of any I&E studies that have documented I&E of large numbers of “nuisance” species. EPA has not estimated benefit values for problem species.

Subject Matter Code 10.02.03

Use of Replacement Costs (HRC and hatchery-based)

Replacement Costs:

Chapter A11's second sentence states that "the HRC [habitat-based replacement cost] method can be used to value a broad range of ecological and human service losses associated with I&E of aquatic species…." Chapter A11 later repeatedly states that HRC estimates the "values" of services lost due to I&E. These statements are incorrect under conventional uses of the term "value" in economics. HRC is actually an estimate of the cost of one of several methods of avoiding the loss of services (e.g., sport fishing) by replacing lost organisms or their equivalents, not the value of the services that would be lost if the removed organisms were not replaced. Chapter A11 apparently acknowledges that on page A11-3, stating that HRC is "a proxy for the value of resources lost to I&E" [emphasis added], but goes on to incorrectly state that HRC estimates the values of the services lost. HRC could be greater than or less than the actual value of the lost services because HRC depends in part on the market value of coastal property and the cost of modifying the property to produce the desirable organisms. It is illogical to assume that such costs have any relationship to the value of sport fishing, commercial fishing, or other services that might otherwise be lost to I&E.

EPA Response

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule.

Please see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method. Please also see EPA's response to comment #316bEFR.005.035.

Comment ID 316bEFR.205.005

Subject Matter Code 10.03.07.01

J.R. Whiting

Author Name Dr. Daniel Talhelm

Organization Consumers Energy Co.

Case Study: Consumers Energy Company's J.R. Whiting Power Plant

EPA's case study applying the benefits transfer methods in Chapter A9 to the Consumers Energy Company's J.R. Whiting power plant (Chapter H4) has several erroneous assumptions and apparent miscalculations, nearly all of which exaggerate the estimated economic losses attributable to the plant's I&E. EPA's estimated total I&E values in this case study are roughly 3 times higher than those that EPA would have derived if it had applied the methods outlined in Chapter A9 but used more appropriate data and assumptions. Issues include:

-misallocating species between recreational and commercial fisheries (Table H4-1),

-arbitrarily assigning some of the highest recreational values per fish to species least preferred by anglers (Tables H4-5 and -6), and

-apparently miscalculating (overestimating) average commercial prices for Lake Erie fish (Tables H4-7 and –8).

Misallocating Species: Table H4-1 purportedly allocates the impacts of the Whiting facility on non-forage species between recreational and commercial fisheries in proportion to "the landings in each fishery" (p. H4-1). A footnote to the table explains that "accurate recreational landings data for Lake Erie have not yet been located, so EPA applied a 50/50 split for species both commercially and recreationally harvested." Michigan, Ohio, Pennsylvania and New York all regularly estimate Lake Erie sport catch by species. EPA's Chapter H1 even cites Michigan's estimates of sport catch for Lake Erie. Similar data are also available from the Lake Erie Committee of the Great Lakes Fishery Commission (GLFC). Apparently, EPA did not contact the state resource agencies or the GLFC regarding this information. Even if "accurate" estimates were not available from those sources, approximations are available from the respective professional fisheries biologists in those states that are considerably more accurate than EPA's arbitrary 50/50 split. Several allocations in H4-1 clearly are inaccurate:

-White perch: Lake Erie anglers commonly catch white perch when available, though they are generally sought only by a small segment of anglers. The NMFS website cited on p. A9-4 as EPA's source of commercial fisheries prices lists the commercial catch of white perch in the 1990s as 120,000 to 1,021,000 pounds per year, so it is clearly both a commercial and recreational fish. If angler catch data were unavailable a 50/50 allocation would be more appropriate than EPA's 100% recreational. The Great Lakes white perch commercial harvest has generally exceeded the Great Lakes white bass catch, so it is unclear why EPA allocated white bass 50/50 and white perch 100% to recreational harvest.

-Yellow perch: Yellow perch are highly sought after by Lake Erie anglers, but also are a popular food fish. Data from the same NMFS website show that large numbers of perch (500,000 to over 1,000,000 pounds) have been harvested annually and sold commercially from Lake Erie's U.S. waters (though none from Michigan) during EPA's baseline period (the 1990's decade). A 50/50 allocation would be reasonable if sport catch data were unavailable, but EPA unaccountably assigned all perch to the recreational fishery.

Recreational Values for Fish Species: EPA assigned some of the highest recreational values per fish to species least preferred by anglers (Tables H4-5 and -6). White bass, channel catfish and perhaps walleye are over-valued relative to the others. Recreational valuation studies generally study the more popular species. Those found in Lake Erie are yellow perch, smallmouth bass, walleye and bluegills, crappie and sunfish, though smallmouth and bluegills are not valued in this case study. Of the four species, walleye are valued disproportionately higher. However, walleye are the most sought after species by anglers with expensive boats and equipment—an indicator of high recreational value—so perhaps a higher value is justified. Relatively few benefits transfer data are available for the other species. EPA apparently arbitrarily picked values for them, because no other explanation is available.

The difficulty with benefits transfer procedures is that unscientific judgments must often be made because the available studies may not evaluate the species needing to be valued, or the study values may be based on entirely different conditions, such as different fishing conditions, different size fish, or different availability of substitute kinds of angling. EPA cites only four studies as references for benefits transfer (Table H4-4). Further, the national studies by Charbonneau and Hay (1978), and the Idaho study of Sorg, et al. (1985) likely represent conditions quite different from those of Lake Erie. Finally, the upper value listed for Boyle, et al. (1998), exceeds the supposedly broader range of values listed for the same study in Table A9-2, with no explanation from EPA. Unscientific judgments such as these by EPA cannot be conclusively refuted. However, common knowledge of the relative popularity of various Lake Erie species and the wide availability of several species and fishing modes along the Lake Erie shoreline suggests the following:

-White bass are popular only with limited segments of the angling population though they are readily available in season. Thus they probably have lower values than indicated in the tables. Judging by the typical fishing modes observed, anglers apparently spend relatively little per fish caught to fish for white bass — which is an indicator of a lower economic value. A more accurate range of values would probably be $1.00 to $3.37 per fish.

-While channel catfish are considered a game species (as well as a commercial species), they should probably be valued less than smallmouth bass ($1.58 to $5.32 in Table I4-5) as the latter is a more preferred species, judging by expenditures as indicated by angling mode. Channel catfish are roughly comparable to crappie in terms of apparent angler preference, so its lower value should probably be around $1.50, rather than EPA's $2.64.

-Walleye values probably are appropriately the highest on these lists, but nevertheless may be too high because there are probably more substitute kinds of angling available in the Lake Erie area than in the two areas used for the benefits transfer estimates cited in Table H4-4 (Idaho for Sorg, et al., 1985, and nationally for Charbonneau and Hay, 1978). This would suggest slightly lower values, perhaps $4.00 to $7.00.

Table 1. Comparison of commercial fish values.

Species Values estimated by Re-source

	Econometrics using EPA stated methods	EPA values from Tables H4-7 and H4-8
Brown bullhead	$0.246	$0.33
Carp	$0.104	$0.16
Channel catfish	$0.442	$0.76
Freshwater drum	$0.119	$0.21
Gizzard shad	$0.041	$0.15
Suckers	$0.067	$0.17
White bass	$0.978	$0.98

Commercial Fishery Prices: EPA states that "a ten year average (1990-1999) of the market values [from NMFS data on its website] were used to even out inter-annual fluctuations, and where a facility's surrounding watershed boundaries were included in multiple states, an average of the states' market values were used. All values are stated in 2000 dollars" (p. A9-5). Surely in the case of the Whiting facility, the appropriate watershed is the U.S. waters of Lake Erie, implying the use of catch and harvest values for Lake Erie fisheries from the Great Lakes data published on the NMFS website for the 1990-1999 period. For purposes of this review, H4-7 and H4-8 were recalculated using the catch and harvest values for Lake Erie fisheries for the 1990-1999 period listed in the Great Lakes data published on the NMFS website. All landed values were first converted to 2000 dollars using the U.S. Consumer Price Index, 1982-84 = 100 series. Table 1 lists the results and compares them to EPA values from Tables H4-7 and H4-8. All EPA values are higher than those calculated using the procedures stated by EPA, except the white bass value was about the same.

Recalculating Total Valuation of J.R. Whiting's I&E: EPA's Table H4-13 summarizes its estimates of the values attributable to I&E at Whiting. However, our examination of the application of the valuation methodologies has shown that many of these estimates are erroneous. We approximate the correct values using procedures described in EPA's Chapter A9. For expository purposes these approximations follow Chapter A9's guidelines even though we have earlier shown that some of those are flawed.

1. Though at least two EPA allocations between sport and commercial harvest are inappropriate, to simplify the remainder of this critique we have not estimated the impacts of more appropriate catch allocations on total I&E valuation. Changing the harvest assump-tions would alter many of the subsequent calculations, thus adding to their complexity, but would not help explain the validity of this point.

2. Commercial: Using the landed values from NMFS data (Table 1, above), the losses in Tables H4-7 and H4-8 are $38,456 and $5,164, respectively, implying total commercial fisheries losses of $78,516 to $137,403, or about one-third the $254,340 and $445,095 es-timated by EPA (right-hand column of Table H4-13).

3. Recreational: Reducing the values of channel catfish and white bass to more appropriate levels (to $1.5 to $5.02 and $1.00 to $3.37 per fish, respectively) lowers the estimated recreational values substantially, to about $8,031 to $23,586.

4. Forage: EPA estimates retained without comment.

5. Nonuse values are still assumed to be 50% of the (now lower) recreational values, following

Chapter A9's guidelines for expository purposes despite their flaws.

6. Aggregate: The aggregate total values attributable to I&E, using procedures described in EPA's Chapter A9 but with more appropriate data (except harvest allocations), are about $90,000 to $200,000 (Table 2). EPA case study estimates are about 3 times higher.

These findings should also be appropriately reflected in the conclusions presented in Chapter I6: Benefits Analysis for the J.R. Whiting Facility, and Chapter I7: Conclusions.

[see hard copy for table]

EPA Response

In the first portion of his comments, Dr. Talhelm summarizes EPA's methods to estimate fishery benefits for the proposed Phase II rule. Dr. Talhelm's main comments are summarized in the six points that conclude the comments. EPA responds to each of these in turn below.

1) At proposal EPA did not identify a data source that would provide recreational landings data that would be adequate to calculate useful % commercial and % recreational values. Thus, EPA relied on the expert opinion of several local fisheries biologists to determine these commercial/recreational values.
For the final rule, EPA collected recreational harvest information from state agencies in the Great Lakes region. While these data provided valuable input into the recreational benefits analysis, it was not sufficiently detailed to determine % commercial and % recreational values. However, based on comments from Dr. Talhelm and other commenters, EPA did review the commercial landings data and made two changes. Because there is a documented Great Lakes commercial harvest of white perch and yellow perch, EPA agrees that a 100% recreational assumption is inappropriate. For the analysis for the final rule a 50% commercial and 50% recreational assumption was made for both species.

2) Based on comments by Dr. Talhelm and others, EPA reviewed and modified many of the methods used to estimate commercial fishing benefits and losses. For details on EPA's response to comments on the commercial fishing methods please refer to the response to comment 316bEFR.005.029. See also the Regional Study Document prepared for the final rule, Chapter A10: Methods for Estimating Commercial Fishing Benefits.

3) EPA also reviewed and modified the methods used to estimate recreational fishing benefits and losses. In its analysis for the final rule, EPA no longer uses a benefits transfer approach to estimate recreational losses and benefits. Rather, EPA has developed a random utility model (RUM) to estimate benefits for each region. For further detail on the new methods please refer to the Regional Analysis Document (DCN # 6-0003, Chapter A11: Estimating Benefits with a Random Utility Model (RUM) and Chapter G4 of the Great Lakes RUM model.

4) In its analysis for the final rule, EPA did not use hatchery replacement costs to estimate non-use benefits.

5) In its analysis for the final rule, EPA did not use the 50% rule-of-thumb to estimate non-use benefits.

6) This comment is noted, but it does not provide specifics requiring a response from EPA.

Overview of I & E effects on organisms

COOLING WATER INTAKE STRUCTURES AND THEIR ENORMOUS IMPACTS ON FISH AND AQUATIC LIFE.

Every year, electric generating facilities kill the overwhelming majority of organisms in the more than 70 trillion gallons they withdraw from U.S. waters for cooling. This staggering mortality – trillions of fish, shellfish, plankton and other species, including some that are endangered or threatened – has harmed aquatic, coastal and marine ecosystems for decades, and has contributed to the collapse of some fisheries.

This excessive mortality occurs both despite and as result of the facilities' attempts to filter extraneous materials including fish from the cooling water stream. Aquatic organisms too small to be screened out are drawn through the cooling system and are killed by "entrainment." <FN 3> Larger organisms become trapped on intake screens and are killed or injured by "impingement." <FN 4>

Data on fish mortality from cooling water intake structures (abbreviated as "CWIS") are far from comprehensive and most likely understate impacts. Nevertheless, generators and government agencies, including EPA, have documented massive fish kills by power plants for decades in the U.S. and Europe. As just a few examples of this waste:

-The Brayton Point Station in Somerset, Massachusetts on Mt. Hope Bay in the northeastern reach of Narragansett Bay killed between 7 million and 164.5 million menhaden and river herring each day in the summer of 1971 by entrainment;

-the Millstone Point Nuclear Power Station on Niantic Bay in Waterford Connecticut killed 36 million menhaden and blueback herring during a sixteen day period in 1972 by entrainment; and

-the Connecticut Yankee Plant on the Connecticut River in Haddam Neck, Connecticut killed 179 million fish larvae were per year from 1969-70. <FN 5>

The same EPA document also reported enormous impingement death tolls at power plants, such as:

-The Surry Power Station on the James River, Virginia destroyed 6 million river herring by impingement from October-December, 1972;

-the Millstone Point Plant's intake screens on Niantic Bay killed more than 2 million fish during the late summer and early fall of 1971;

-the Indian Point Electric Generating Station on Haverstraw Bay on the Hudson River in Buchanan, New York killed 1.3 million white perch and striped bass during one 9-1/2 week period from 1969-1970, with a predicted impingement death toll of 6.5 million fish per year; and

-the P.H. Robinson Plant in Galveston Bay, Texas impinged 7,191,785 menhaden, anchovy and croaker in one year from 1969-70. <FN 6>

In the preamble to the Phase II Proposal, EPA provided further examples of devastating impacts associated with impingement and entrainment at individual steam electric generating facilities:

-The Brunswick nuclear plant on the Cape Fear estuarine system in North Carolina, has entrained as much as 3-4 billion individual fish and shellfish at early life stages annually. Studies there have predicted an associated 15-35 percent reduction in populations, which may be altered beyond recovery; <FN 7>

-On Florida's Gulf Coast, the Crystal River power plant seriously reduces forage species and recreational and commercial landings (e.g., 23 tons per year); <FN 8>

-On Lake Michigan, the D.C. Cook nuclear plant killed one million fish during a three-week study period. <FN 9>

-On New York's Hudson River, entrainment at five power plants (Indian Point, Bowline, Roseton, Lovett and Danskammer) predicted year-class reductions of up to 79 percent, depending on fish species. The generators' 2000 analysis of three of these plants completed in predicted year-class reductions of up to 20 percent for striped bass, 25 percent for bay anchovy, and 43 percent for Atlantic tomcod, even without assuming 100 percent entrainment mortality. These losses could seriously deplete any reserve or compensatory capacity needed to survive unfavorable environmental conditions. <FN 10>

-The Brayton Point facility in Somerset, Massachusetts withdraws 1.3 billions gallons per day from Mt. Hope Bay and has apparently caused an 87 percent reduction in finfish abundance since a 50 percent increase in its cooling water withdrawal in 1985. <FN 11>

-At the San Onofre Nuclear Generating Station on the Southern California coast, in a normal (non-El Niño) year, 121 tons of midwater fish are entrained, causing a 34-70 percent decline in Pacific Ocean fish populations within 3 kilometers; <FN 12>

-The Pittsburg and Contra Costa Plants in the San Francisco Bay Delta in northern California can impinge and entrain more than 300,000 endangered and threatened species per year, including Delta smelt, Sacramento splittail, Chinook salmon, steelhead trout. <FN 13>

-More than 1,300 endangered sea turtles entered enclosed cooling water intake structure canals at the St. Lucie plant in Florida, resulting in mortality over a 9-year period. <FN 14>

The massive toll on U.S. ecosystems and fisheries has aggrieved commercial and recreational fishermen and other citizens who value these natural resources. Environmental advocates around the country have devoted substantial time and energy monitoring and fighting these impacts in the thirty years since Congress enacted the Clean Water Act.

For example, on New York's Hudson River, environmental groups and fishermen's organizations, including Riverkeeper, Inc., the Hudson River Fishermen's Association, (Riverkeeper's predecessor), the Natural Resources Defense Council, and Scenic Hudson, Inc., have been fighting for more than 30 years to reduce the massive entrainment and impingement at the River's six large once-through plants. Decades of fish kills from these facilities, including reductions in some year classes up to an estimated 79 percent, has sapped the recovery of one of the most valuable estuaries on the eastern seaboard, once a word-class fishery.

Similarly, the Brayton Point Power Station in Somerset, Massachusetts has obliterated the fisheries of Mount Hope Bay, which forms the northeast arm of Narragansett Bay. Mount Hope Bay, a federally designated essential fish habitat and a critical spawning and nursery area for many marine species, had a long history as a productive fishing ground for flounder, lobster, and shellfish. The Bay's legendary fishing productivity crashed in the mid-1980's, after the power plant increase in cooling water withdrawals approximately 45 percent. Environmental organizations, such as Save the Bay and its Narragansett Baykeeper and the Conservation Law Foundation, and Rhode Island public agencies including the state Attorney General and Department of Environmental Management, have fought for years to force the plant to reduce its water withdrawals to restore the ecological health of Mount Hope Bay.

The Salem Nuclear Generating Station, in Salem County, New Jersey approximately 30 miles southwest of Philadelphia, withdraws over than 3 billion gallons per day, more cooling water than any facility in the country, from Delaware Bay. A study commissioned by the New Jersey Department of Environmental Protection estimated that the Salem cooling water intake annually kills 375,000 white perch, 281,746 herrings (alewife & blueback), 305,000 spot, 61,100 Atlantic croaker, and 3,239 striped bass, 842,000,000 bay anchovy and 1,120,000 weakfish – four times as many bay anchovy and weakfish each year than are commercially caught in the Delaware Estuary. <FN 15> The Delaware Riverkeeper Network and the American Littoral Society have been fighting for years to cause Salem to reduce its massive death toll.

Similarly large aquatic mortality tolls have occur at numerous other locations around the country, including but not limited to the Big Bend plant in Tampa, Florida, the Duke Energy Plants in Morro Bay and Moss Landing, California, the Portero Plant in San Francisco Bay, many plants on the Great Lakes, and a great many others where environmental advocates continue to devote substantial time and energy to monitoring and fighting these impacts.

EPA also has placed in the docket for the Phase II Proposal a large collection other studies of fish mortality by entrainment and impingement at cooling water intake structures. <FN 16> In all, EPA currently has a database of impingement and entrainment data from more than 100 different facilities, ranging from the relatively small Palisades Plant in Michigan, which takes in 19.7 million gallons per day (mgd), to the nation's largest user of cooling water, the Salem Nuclear Plant in New Jersey which withdraws more than 3 billion gallons per day. <FN 17> EPA acknowledges that even the massive reported death tolls fail to account for the full extent of mortality to aquatic organisms:

Studies like those described … may provide only a partial picture of the severity of environmental impact associated with cooling water intake structures. ….[T]he methodologies for evaluating adverse environmental impact used in the 1970s and 1980s, when most section 316(b) evaluations were performed, were often inconsistent and incomplete… <FN 18>

Footnotes

3 Entrainment occurs when relatively small fish and shellfish organisms, eggs, and larvae are drawn through the cooling water intake structure into the plant's cooling system, pass through its heat exchanger, and are discharged out of the facility.

As entrained organisms pass through the cooling system they are subject to mechanical, thermal, and toxic stress including physical impacts in the pumps and condenser tubing, pressure changes caused by diversion of the cooling water into the plant or by the hydraulic effects of the condensers, sheer stress, thermal shock in the condenser and discharge tunnel, and chemical toxemia induced by antifouling agents such as chlorine. Few, if any, entrained organisms survive. 67 Fed. Reg. at 17136; see also U.S. EPA, Guidance for Evaluating the Adverse Impact of Cooling Water Intake Structures on the Aquatic Environment: Section 316(b), P.L. 92-500, p. 1 (1977) (hereinafter “1977 EPA Guidance Manual”).

4 Impingement occurs when fish and other aquatic organisms become trapped on screening devices or other barriers installed at the entrance of the intake structure to prevent debris from entering the facility's cooling system. Impingement is caused by the force of water passing through the intake structure and can result in starvation and exhaustion (when organisms are trapped against an intake screen), asphyxiation (when organisms are forced against an intake screen or other barrier at the entrance to the cooling water intake structure by velocity forces that prevent proper gill movement or when organisms are removed from the water for prolonged periods of time), and descaling (when organisms are removed from an intake screen by a wash system). 67 Fed. Reg. at 17136; see also 1977 EPA Guidance Manual, p. 1.

CLOSED-CYCLE COOLING IS AN AVAILABLE TECHNOLOGY WHICH WOULD DRASTICALLY REDUCE FISH KILLS DUE TO ONCE THROUGH COOLING

The enormous aquatic mortality caused by power plants intakes is almost entirely unnecessary. Readily available, affordable and common technology can eliminate more than 90% of the impact for those facilities using "once through cooling," which requires extremely large quantities of water because it does not recirculate any. The water simply transfers the waste heat to the receiving waterbody by its flow. "Closed-cycle" cooling, in contrast, substantially recirculates cooling water because it uses a cooling tower transfer heat to the atmosphere by evaporation and convection.

As a result closed-cycle cooling systems use dramatically less water than once-though cooling systems, and thereby impinge and entrain a fraction of the aquatic organisms. The precise volume of water withdrawn by closed cycle systems depends on the size of the plant, type of electricity generation technology, and the source water salinity. On fresh water, closed-cycle systems generally reduce water usage by about 95% over once through cooling. That is, a plant which would extract 1 billion gallons per day (1000 mgd) of water if cooled by a once-through system, will require only about 5% of that amount or 50 mgd if cooled by an evaporative cooling tower instead. <FN 19>

Footnotes

19 Where State water quality standards limit chloride to a maximum increase of 10 percent over background and therefore require a 1.1 cycle of concentration (as opposed to 2.0) , closed-cycle cooling may reduce intake volume by a still significant 70%, rather than 95% or more. EPA Phase II Technical Development Document ("Phase II TDD") at p. 4-1.

Dry Cooling

“Dry” closed-cycle (also known as air-cooled) systems are also available to reduce impacts even further. Dry-cooling uses radiator-type coils to transfer heat to air by convection. These systems recirculate virtually all their water. As a result, plants that use dry cooling have no visible plume or thermal discharge to waterways, and have much smaller water requirements. Hybrid cooling systems use both wet sections and dry sections in order to abate evaporation plumes present caused by wet cooling towers.

Ex. facilities converted to closed-cycle

Author Name Reed Super

Organization Riverkeeper

Both the wet and dry closed-cycle cooling has been standard power plant technology for decades. As EPA reported last year, 100% of the utility and nonutility combined-cycle plants built in the last 20 years have a closed-cycle recirculating cooling system and 88% of the coal-fired facilities built in the last 10 years have closed-cycle cooling. 66 Fed. Reg. at 28855-28856 (May 25, 2001). Existing facilities of various sizes and fuel types, including the 821 MW Palisades Nuclear Plant in Michigan; the 490 MW coal-fired Canadys Steam Plant in South Carolina, the 346 MW Jefferies Coal Plant also in South Carolina, and Unit 7 of the 751 MW gas-fired Pittsburg Power Plant in Contra Costa County, California, have retrofit closed-cycle cooling over the last 30 years. <FN 20>

Purpose of Rule (General, incl. bckgrd., history)

CWA SECTION 316(B) REQUIRES BEST TECHNOLOGY AVAILABLE

Section 316(b) of the 1972 Federal Water Pollution Control Act amendments ("Clean Water Act," "CWA" or the "Act") <FN 21> provides:

Cooling water intake structures

Any standard established pursuant to [Section 301 or Section 306 of the Act] and applicable to a point source must require that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact. <FN 22>

Congress enacted the requirement in response to a number of well-profiled fish kills at power plants in the early 1970s. <FN 23> In fact, during debate over the Clean Water Act, Senator Buckley cited with approval two newspaper articles reporting a decision of the Atomic Energy Commission (AEC) to require Consolidated Edison to install closed cycle cooling at Indian Point. <FN 24> The articles noted that the plants withdrew massive amounts of water from the Hudson River, entraining thousands of organisms per minute, and that the AEC had ordered Con Ed to stop removing such large volumes of water from the River and to install cooling towers in order to abate these massive fish kills. <FN 25>

Organization Riverkeeper

Subject Matter Code 17.03.03
Benefits of reduced intake capacity

Technology years ago advanced to the point where impacts on waters of the U.S. from cooling water intake structures at existing power plants can be drastically reduced, as was both anticipated and required by the Clean Water Act. <FN 32> Aquatic and other environmental impacts from closed-cycle cooled stations are negligible. By reducing cooling water intake volume and fish kills by more than an order of magnitude, closed-cycle cooling clearly represents the best capacity technology available for minimizing adverse environmental impact, and the key component of the BTA determination. EPA has no discretion to disregard such an effective and proven technology in determining BTA.

Subject Matter Code 2.03
Purpose of Rule (General, incl. bckgrd., history)

HISTORY OF CWIS REGULATION

EPA has established effluent limitations under CWA Section 301 for existing sources in each of the industry categories which are major users of cooling water. <FN 33> However, none of these standards address cooling water intake structures. Unlike other sources of degradation to aquatic ecosystems controlled under the 1972 Clean Water Act amendments (such as discharges of pollutants), cooling water intake structures have uniquely avoided nationally uniform limitations. Instead, regulation of cooling water intake structures has long been relegated to ad hoc determination by individual permit writers exercising best professional judgment.

In 1976, EPA chose to promulgate a single regulation under Clean Water Act section 316(b), codified at 40 C.F.R. Part 402 <FN 34> and applicable to all categories of point sources, rather than include a section 316(b) provision within all individual effluent limitations guidelines and new source performance standards under sections 301 and 306.

The operative section of the 1976 regulation, provided in full:

The information contained in the Development Document <FN 35> shall be considered in determining whether the location, design, construction and capacity of a cooling water intake structure of a point source subject to standards established under section 301 or 306 reflect the best technology available for minimizing adverse environmental impact. <FN 36>

In 1977, the United States Court of Appeals for the Fourth Circuit remanded the regulation back to EPA because EPA had violated the Administrative Procedure Act by failing to either publish the Development Document in the Federal Register or properly incorporate it by reference. <FN 37> As a result, the court did not address the validity of the regulation on substantive grounds. EPA subsequently withdrew the regulation, <FN 38> and although it reserved space in the Code of Federal Regulations, had not promulgated or proposed a new cooling water intake structure regulation until its December 18, 2001 publication of the Phase I new facility rule. The present proposal is EPA's first proposed rule for new facilities since the 1976 regulation was set aside and then withdrawn in 1979.

In the absence of federal regulations, section 316(b) determinations have typically involved individualized ecological assessment and determination of best technology available for each proposed or renewed cooling water intake structure. This lack of categorical standards has resulted in uneven and conflicting regulation as well as enormous, unnecessary aquatic mortality, which runs contrary to the goals of the Clean Water Act and the direct mandate of section 316(b). The individualized assessments have typically relied on narrow and inaccurately applied population models, and have ignored other impacts on ecosystem health.

For 30 years, industry has used the threat of litigation and a variety of dubious interpretations of section 316(b) to avoid the imposition of BTA. A favorite strategy of industry is to threaten state permitting agencies with litigation in order to obtain a compromise settlement for limited mitigation or data gathering and study, rather than installing best technology. Even with extensive data collection, there has been continued disagreement among industry, permitting agencies, and environmental groups over ecological impacts.

The multiplicity of these individual determinations and the combination of ecological and mathematical/statistical expertise necessary to determine the complex population dynamics for individual species has granted industry a critical strategic advantage because of superior resources in these proceedings. This advantage is a key component in industry's strategy to avoid national technology based regulations. Industry's most common analytical tools in these individualized technical determinations are density-dependent models of fisheries populations. Cooling water users have for decades used arguments based on density-dependence to justify the destruction of large numbers of fish and crustaceans via impingement and entrainment at their CWISs. In many critical cases, mathematical models of density dependent compensation these models have been misapplied. As just one example, industry has misapplied commonly-used Ricker curves, originally developed for salmonid fisheries with intense competition for spawning space, is misapplied to the entrainment of other species which lack such intense competition. <FN 39> More fundamentally, typical compensation analysis relies on an ecologically baseless concept of "surplus production" which dismisses the ecological value of the tens of millions of fish which are a critical base of the food chain whether or not they grow to adulthood – even though their predators may be populated at far below their historic values.

On January 19, 1993, Riverkeeper, Inc. <FN 40> and a coalition of individuals and environmental organizations sued EPA in the United States District Court for the Southern District of New York, to obtain an order directing EPA to promulgate new cooling water intake regulations. Riverkeeper, Inc., et al v. Whitman, U.S.D.C., S.D.N.Y., Case No. 93 Civ 0314 (AGS). <FN 41> In 1995, plaintiffs and EPA agreed to a consent decree which among other things set forth a timetable by which EPA would take final action on regulations to implement Section 316(b). <FN 42> Under the consent decree entered by the court in 1995, EPA was required to propose regulations implementing Section 316(b) for all facilities no later than July 2, 1999, and to take final action with respect to the regulations no later than August 13, 2001.

EPA subsequently moved to amend the Consent Decree, claiming it was unable to meet the deadlines. <FN 43> Although the court found that EPA's "explanations for its previous delays do not justify modification of the Consent Decree," it extended the proposal deadline, on the ground that "the public interest does require that the Decree be modified to enable EPA to produce a sound Regulation." <FN 44> Pursuant to an amended consent decree entered by the Court in October 2000, EPA is now required to promulgate 316(b) regulations in three phases according to the following schedule:

Phase I (new facilities)
-final rule due 11-9-01

Phase II (existing large power plants)
-draft rule due 2-28-02
-final rule due 8-23-03

Phase III (existing small power plants and other facilities)

-draft rule due 6-15-03
-final rule due 12-15-04

As required by the amended consent decree, EPA Administrator Christine Whitman signed the final Phase I regulation for new facilities on November 9, 2001 and the Federal Register published it on December 18, 2001. <FN 45> Both industry and environmental stakeholders, including Riverkeeper and other signatories to this comment have challenged the Phase I regulation on various grounds in distinct but consolidated cases, Riverkeeper, et al; Utility Water Act Group, et al, v. USEPA, U.S. Court of Appeals for the Second Circuit, Case No. 02-4005(L).

Administrative Requirements

THE PROPOSED PHASE II REGULATION.

On December 28, 2001, after years of research by its Office of Science and Technology, EPA submitted its draft proposal to the White House's Office of Management and Budget (OMB) for interagency review. EPA's original draft regulation would have required closed-cycle cooling for 59 of the largest plants on tidal rivers, estuaries and oceans. This compromise proposal fell far short of a closed-cycle requirement on all major power plants, but it would have at least minimized the impact on the most ecologically productive waterbodies.

However, antiregulatory ideologues in OMB's Office of Information and Regulatory Affairs (OIRA) forced EPA to abandon its carefully chosen option and remove any closed-cycle requirements. The agencies relied on cost-benefit analyses which systematically belittle the value of aquatic ecosystems. Even using this drastic underestimate, the calculated benefits of the EPA original proposal would have exceeded costs to retrofit the most destructive facilities by an ample 3 to 2 margin. Nevertheless, in direct contravention to the Congressional "best technology available" mandate in the Clean Water Act, OIRA rejected any use of cooling towers and compelled the least cost alternative. OIRA's action also violated Executive Order (E.O. 12866), which prohibits regulatory economic analyses from dictating a result contrary to statutory requirements.

EPA formally proposed the Phase II Proposal on February 28, 2002 and published it in the Federal Register on April 9, 2002 pursuant to the amended consent decree in Riverkeeper v. Whitman. The Phase II Proposal sets unreasonably low standards and then provides applicants the opportunity to avoid meeting those standards.

EPA Response

Subject Matter Code 17.02

Option: Reduce capacity comm. with closed-cycle

Specifically, EPA's proposal fails to require closed-cycle cooling (which reduces fish kills by approximately 95%) as "best technology" for any of the 550 large power plants in the country, but instead sets a performance standard based loosely on the protection offered by a variety of cheaper, less effective, less reliable mechanisms. This weak mandate would allow existing plants to kill 20 to 1000 times more fish per megawatt than new plants, and continue to decimate aquatic life in U.S. waterways indefinitely.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to section VII.E of the preamble for more information on why EPA rejected this alternative.

RFC: Appropriateness of and tests for variance

The proposal also allows power companies to avoid the weak technology standard by pleading special economic circumstances, or arguing that the local ecosystem does not merit protection. Specifically, the variance test for permit-writers to apply is two-fold: whether a facility' costs (a) are significantly greater than EPA's estimated costs; (the "economic variance") or (b) are significantly greater than the monetized benefits (the "ecological variance").

EPA Response

See response to 316bEFR.033.004.

Organization Riverkeeper

Subject Matter Code 17.06

Option: Site-specific determination of BTA

Instead of setting a protective, technology based standard, the rule would adopt and codify many of the site-specific arguments which permittees typically use to avoid closed-cycle cooling requirements. Since even environmentally sympathetic regulators lack the resources needed to rebut, or in most cases fully evaluate, these arguments, the rule will allow applicants to continue to obstruct and delay needed technology upgrades.

EPA Response

Please refer to the response to comment 316bEFR.206.027 for information about the regulatory approach for the final rule.

EPA also disagrees that today's final rule is less stringent than the previous implementation of 316(b). Please refer to the response to comment 316bEFR.202.003.

Organization Riverkeeper

Subject Matter Code 2.04.04
Use cost-benefit tests

EPA's failure to require sufficiently protective technology is based in large part on relatively minor cost variations between the cooling system technologies, and wholly incomplete benefits estimates. Significantly, the proposal was based on a completely new, and unauthorized approach to the costs of cooling intake technologies. EPA has always contended "that there should be some reasonable relationship between the cost of cooling water intake structure control and the environmental benefits associated with its use." <FN 46> Based on a statement by one Congressman in the 1972 legislative history, EPA has long interpreted BTA to mean "best technology available commercially at an economically practicable cost." In so doing, EPA claimed to be implementing "congressional concern that the application of best technology available should not impose an impractical and unbearable burden." <FN 47> EPA has traditionally measured economic practicability by applying the "wholly disproportionate test" to compare the benefits of cooling water intake technology against marginal cost to the ratepayer, i.e., the incremental electricity cost. Under EPA's traditional wholly disproportionate cost test, a cooling water intake structure technology would not be deemed to reflect BTA if the incremental costs of requiring the use of that technology are wholly disproportionate to the environmental benefits to be gained through its use.

RFC: Cost-benefit in proposed provision 124.95

In its Phase I rule for new facilities published December 18, 2001, EPA established the first minimum national standards for cooling water intake structures. The rule includes two new cost tests. First, EPA examined the proposed national standards to determine whether they are "economically practicable." The test used was to compare annualized post-tax compliance costs with revenues on facility, firm and national (industry) levels. Second, EPA established a test for permit-writers to use when determining whether to grant a variance from the minimum national standards. This test utilizes a wholly disproportionate test, but compares the individual facility's compliance costs to the compliance costs estimated by EPA in the rule. If a facility's costs will be wholly out of proportion to the EPA costs, the permit-writer can include weaker standards. <FN 48>

In the Phase II proposal for existing facilities, EPA changed its cost test approach once again. As in Phase I, EPA used the cost/revenue test to determine whether the proposed option is economically practicable on a facility and firm level. But EPA's proposed option was selected (and the cooling tower options were rejected) using a rigid cost-benefit decision-making criterion. Under this criterion, also known as "maximize net benefits," EPA even rejected a regulatory alternative where the total benefits exceeded the total costs by a 3:2 margin. Furthermore, because of EPA's ecological variance – which allows an individual facility to demonstrate that the costs of installing technology at its site will outweigh benefits – permit writers will be required to engage in the same kind of wholly inappropriate cost/benefit analysis on a local level.

Footnotes

48 40 CFR § 125.94(c) [proposed].

EPA Response

The commenter's summary of cost analyses for the Phase I final rule for new facilities is generally accurate. In setting national standards, EPA also considered the ratio of initial compliance costs to the construction cost of a new plant.

Regarding the Phase II rule, EPA notes that the cost-to-revenue ratio is not the main measure used to assess economic practicability. It is only one of several measures used. See EPA's response to Comment ID 316bEFR.005.021 for discussion on EPA's use of cost-to-revenue test to determine economic practicability.

EPA did not use "maximize net benefit" in the final rule. See EPA's response to Comment ID 316EFR005.020 for additional information. EPA notes that the approach to benefit cost analysis of the final rule is consistent with principles outlined in the EPA's Guidelines for Preparing Economic Analyses, US EPA (EPA 240-R-00-003).

See preamble to the final rule for a discussion of why the cooling tower options were rejected.

See preamble to the final rule for a discussion on the cost benefit test.

Subject Matter Code 2.04.05

Implement a site-specific alternative

Finally, EPA is requesting comment on a wide array of alternative approaches to establishing BTA limitations, many of which have been suggested by the electric generating industry. These case-by-case, site-specific, multi-tiered approaches contravene the Act's mandate for uniform, national standards and would significantly prejudice the efforts of state regulators and local officials and advocates, who – facing the extensive resources of the power industry – would be required to prove the need and reasonable cost of best technology in the permit proceeding for each new power plant.

EPA Response

EPA disagrees. Today's rule in general, and the site-specific option in particular, will not impose a significant burden on states, tribes, local governments, environmental advocates, or the public. There is sufficient flexibility in the final rule that EPA expects facilities will use the site-specific compliance options infrequently.

Define BTA as anything less than closed cycle

THE CLEAN WATER ACT REQUIRES TECHNOLOGY-BASED AND TECHNOLOGY-FORCING STANDARDS TO RATCHET DOWN POLLUTION.

Congress enacted the Clean Water Act <FN 49> (CWA) in 1972 to “restore and maintain the chemical, physical, and biological integrity of the Nation’s waters.” 33 U.S.C. § 1251(a). The CWA establishes a comprehensive regulatory program requiring all dischargers, including power plants, to obtain National Pollutant Discharge Elimination System (NPDES) permits for point source discharges. 33 U.S.C § 1311. The permits contain standards, which are established by EPA through a system of technology-based limitations, supplemented by water-quality related limitations, which protect specific bodies of water. <FN 50> 33 U.S.C. § 1312. The NPDES permit takes the applicable effluent limitations and other standards and turns them into the obligations borne by the individual polluting entity. NRDC v. EPA, 822 F.2d 104, 110 (D.C. Cir. 1987).

The intended effect of the Clean Water Act permit and effluent limitation process is to gradually reduce pollution and adverse environmental impact to the point of elimination. Indeed, Congress set a “national goal that the discharge of pollutants into the navigable waters be eliminated by 1985.” 33 U.S.C. § 1251(a)(1). Congress understood that compliance with the Act would have economic consequences to industry and, accordingly, adopted a phase-in compliance scheme. That scheme uses increasingly more stringent effluent limitation guidelines and NPDES permits to ratchet surface water pollution down to zero. As explained by the court in NRDC v. EPA:

[T]he [Clean Water Act’s] regulatory scheme is structured around a series of increasingly stringent technology-based standards (beginning with the implementation of the best “practicable” technology (BPT) and progressing toward implementation of pollution controls to the full extent of the best technology which would become available (BAT). New sources would, again, be subject to the most stringent technology-based standards of all, namely “new source performance standards”. … [T]he most salient characteristic of this statutory scheme, articulated time and again by its architects and embedded in the statutory language, is that it is technology-forcing.… The essential purpose of this series of progressively more demanding technology-based standards was not only to stimulate but to press development of new, more efficient and effective technologies. This policy is expressed as a statutory mandate, not simply as a goal.

NRDC v. EPA, 822 F.2d 104, 123 (D.C. Cir. 1987) (emphasis added).

Congress’s plan to eliminate surface water impairment requires that NPDES permits be made more stringent over time. Thus, it devised a three-phase implementation plan:

-For permits issued before EPA had completed the limitation guidelines, EPA was to use its “best professional judgment” (BPJ). <FN 51>

-By 1976, industries had to use the “best practicable technology” (BPT). <FN 52> Later, amendments to the Act extended the deadline for use of BPT to 1979.

-By 1981, industries had to use the “best available technology” (BAT), a much more stringent standard. <FN 53>

CWA section 316(b) requires NPDES standards for cooling water intake structures. <FN 54> Like sections 301, 304 and 306 of the Act, section 316(b) mandates a best technology standard. Congress used the locution, “best technology available” (BTA), which is unique in the Clean Water Act, but is substantially similar to the Section 301 “best available technology” (BAT) standard. On its face, it is stricter than the Section 301(b) requirement to impose the “best technology available economically achievable” (BAT) <FN 55> because its spare and direct mandate contains no explicit cost component and does it require the consideration of the other factors relevant to BAT. <FN 56> Given the practically identical language and the application of the Phase II Proposal only to existing sources, the BTA requirement is as least as stringent, and possibly more stringent, than the section 301 BAT standard.

Footnotes

49 33 U.S.C. §§ 1251-1387. The CWA is officially known as the Federal Water Pollution Control Act. It was amended in 1977 and 1987.

50 “Whenever a technology-based effluent limitation is insufficient to make a particular body of water fit for the uses for which it is needed, EPA is to devise a water-quality based limitation that will be sufficient to the task.” 33 U.S.C. § 1312(a); see also NRDC v. EPA, 822 F.2d 104, 111 (D.C. Cir. 1987).

51 “Best professional judgment” (BPJ): Where EPA has not yet promulgated national effluent standards for a particular category of point sources, the permit writer must use, on a case-by-case basis, his or her best professional judgment to impose “such conditions as the permit writer determines are necessary to carry out the provisions of the Clean Water Act.” 33 U.S.C. § 1342(a)(1)(B); NRDC v. EPA, 863 F.2d 1420, 1424 (9th Cir. 1988).

52 “Best practicable technology” (BPT): BPT represents the “average of the best existing performance by plants . . . within each industrial category.” Kennecott v. EPA, 780 F.2d 445, 448 (4th Circ.1985).

53 33 U.S.C. § 1311(b) (2) (A), (C), (D) and (F). BAT uses “the optimally operating plant, the pilot plant which acts as a beacon to show what is possible.” Kennecott v. EPA, 780 F. 2d 445, 448 (4th Cir. 1985). For new sources, the strictest standard, “best available demonstrated control technology” (BACT) is required. 33 U.S.C. § 1316.

54 “Any standard established pursuant to [Section 301 or Section 306 of the Act] and applicable to a point source must require that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact.” 33 U.S.C. § 1326(b).

55 CWA § 301(b)(2)(A); 33 U.S.C. § 1311(b)(2)(A).

56 “Factors relating to the assessment of best available technology shall take into account the age of equipment and facilities involved, the process employed, the engineering aspects of the application of various types of control techniques, process changes, the cost of achieving such effluent reduction, non-water quality environmental impact (including energy requirements), and such other factors as the Administrator deems appropriate.” 33 U.S.C.§ 1314(b)(2)(B)

Subject Matter Code 2.0
Legal Authority and Purpose of Today's Proposal

CLOSED-CYCLE COOLING REDUCES WATER WITHDRAWALS AND FISH KILLS BY AN ORDER OF MAGNITUDE OR GREATER AND IS THEREFORE NECESSARY TO MINIMIZE IMPACT.

1. Capacity is the Critical Factor in Minimizing Adverse Environmental Impact.

CWA section 316(b) requires minimization of adverse environmental impact (AEI):

the location, design, construction, and capacity of cooling water intake structures [must] reflect the best technology available for minimizing adverse environmental impact. <FN 57>

The amount of water withdrawn by an intake is directly related to – and is the critical determinant of – the extent of adverse environmental impact. Consequently, section 316(b) requires a minimization of intake capacity.

Overview of I & E effects on organisms

On November, 9, 2000, Riverkeeper submitted to EPA a report prepared by Drs. Peter A. Henderson and Richard M. Seaby of Pisces Conservation, Ltd., that reviewed and evaluated the ecological basis for the proposed Phase I regulation. <FN 58> Drs. Henderson and Seaby reviewed literature and data on cooling water intakes from many power plants in freshwater, marine and estuarine water bodies in the U.S. and Great Britain, and concluded that there is a direct relationship between the volume of water pumped and the number of fish impinged and entrained. <FN 59> The following regression equations summarize the average correlation for all of the plants studied:

I = 0.023(G+340.25)1.844

E = 1.816(G+340.25)1.658

where "I" represents the number of fish impinged per year, "E" is the number of fish entrained per year, and "G" is gallons of water per second. <FN 60> The power function indicates a particularly sensitive relationship: increases in water withdrawal will result in a greater proportional increase in entrainment and impingement mortality.

As the Pisces Report explains:

It is impossible to remove any significant volume of water from a lake, reservoir, river or the ocean without also removing some of the organisms that are living within it. When water is extracted from healthy natural waters, to an over-riding degree the number of organisms killed be they fish, crustaceans or members of the plankton increases with the volume of water pumped. <FN 61>

As Drs. Henderson and Seaby explain in the Pisces Phase I Report, mathematical analysis of data from a large number of U.S. and European power plants show "no appreciable difference in overall catch rate over a wide range of habitats and geographical position." <FN 62> As such, "pumping rate is considerably more important than locality and intake configuration in determining the number of fish either entrained or impinged." <FN 63> Indeed, EPA agrees that impingement and entrainment levels are directly related to the volume of water withdrawn.

Benefits of reduced intake capacity

Closed-Cycle Cooling Minimizes Capacity and Fish Kills.

The difference in capacity between once-through cooling systems and closed-cycle cooling systems is enormous. “Once-through” cooling systems take water from a local body of water, use it to absorb heat from the facility (in the case of electric power plants, from the steam condensers), and discharge it back at an elevated temperature. In a once-through system none of the cooling water is recirculated and extremely large volumes are required.

Once-through systems generally consume on the order of hundreds of millions or billions of gallons of water per day. The Salem Generating Station in New Jersey uses more than 3.3 billion gallons of water per day. Each reactor at the Indian Point facility in New York uses more than 1.4 billion gallons per day. Once-through systems at modern combined-cycle fossil fuel plants will use somewhat less water, but the volumes for large plants of that type are still in the hundreds of millions of gallons per day (mgd).

“Closed-cycle” cooling, in contrast, involves significant or complete recirculation of cooling water. The volume of water used by either of the two primary types of closed-cycle systems is dramatically lower than for once-through cooling. In closed-cycle wet cooling systems (i.e., evaporative cooling towers), cooling water is circulated through cooling towers to transfer heat to the atmosphere by evaporation, and is then recirculated through the plant to absorb heat. In closed-cycle dry-cooling systems (a.k.a. air cooling) radiator-type coils are used to transfer heat to air passing over the coils. In dry systems, there is no water evaporation and virtually all water is recirculated. As a result, plants that use dry cooling have no visible plume and have much smaller water requirements. Plants with dry cooling systems have no thermal discharge to watersheds, only to air, and need to add additional water only occasionally for periodic system maintenance and cleaning. Where steam plume abatement is desirable, hybrid cooling systems are available that use both wet sections and dry sections.

The precise volume of water withdrawn by any of these systems depends on the size of the plant and the type of electricity generation technology. Generally, the higher the output of a power plant, the more cooling water is required. <FN 64> Most critical for BTA purposes, however, is that water requirements for the different cooling system categories vary by orders of magnitude.

The differences in both capacity and mortality between once-through cooling and closed-cycle cooling are particularly dramatic. Closed-cycle systems generally require only 2-5% as much water as once-through cooling systems. That is, a plant which would extract 1 billion gallons per day (1000 mgd) of water if cooled by a once-through system, will require only about 2-5% of that amount or 20 to 50 mgd if cooled by an evaporative cooling tower instead. Retrofitting evaporative cooling towers on a power plant that currently uses once-through cooling will therefore reduce water usage by approximately 95-98%. The reduction in water use from saline sources may in some circumstances be lower, but is still highly significant, at 70% or more, depending on the extent to which State water quality standards limit chloride increases.

Most significantly, this dramatic reduction in intake volume will directly reduce the mortality of aquatic organisms by a correspondingly large amount. Thus, power plants which currently slaughter billions of larval fish will generally destroy less than 5% (and possibly as little as 2%) of that total.

Footnotes

64 Section 3 of the Pisces Phase I Report contains regression functions to describe the relationship between power output and cooling water requirements.

Documented facility examples of CWIS impacts

As just one example of the massive reduction on fish deaths from converting to closed-cycle cooling, in early 2002, the Albany Steam Station on the Hudson River received approvals from New York State to repower the once-through, steam-cycle plant and convert to closed-cycle cooling. The Bethlehem Energy Center project, as it is known, will convert the existing 400 MW oil-burning facility to a 750 MW combined-cycle natural gas facility. The project will reduce Hudson River water withdrawals dramatically, by 98-99%, from the current 500 mgd to a maximum of about 8 mgd. (It will also reduce air pollution rates by 98-99%). The plant's owner, PSEG Power New York, Inc., has estimated that the reduction in intake capacity will reduce entrainment by 98-99% from the current annual totals of 420 million eggs, 460 million yolk-sac larvae, 210 million post yolk-sac larvae, and 130,000 juveniles. <FN 65>

Organization Riverkeeper

Subject Matter Code 17.03.03

Benefits of reduced intake capacity

Retrofitting to closed-cycle cooling drastically reduces water usage and fish kills through impingement and entrainment. This ratcheting down of impacts is exactly what was contemplated by Congress when it established the NPDES permitting system and the technology-based limitation requiring best technology available.

EPA Response

See response to comment 316b.EFR.404.034 The commenter apparently alludes to Section 301(b)(2)(B), which requires EPA to establish effluent limitations that result in "reasonable further progress toward the national goal of eliminating the discharge of pollutants." While this is indeed the overarching goal of section 301, EPA also notes that such effluent limitations must be based on the best available technology economically achievable, which in turn is based on the factors in section 304(b). In other words, the amount of "ratcheting down" those effluent limitations guidelines accomplish is directly affected by what EPA judges to be BAT. The "reasonable further progress" is always defined in terms of that BAT. EPA believes the same principle holds true for 316(b) by virtue of its reference to section 301 as the similarities in terminology.

Author Name Reed Super
Organization Riverkeeper

Subject Matter Code 7.03
Available I&E technologies

All Other Technologies Are Significantly Less Effective.

While other technologies exist to reduce entrainment and impingement, none of them afford anywhere near the level effectiveness and reliability of closed-cycle cooling. Such technologies include: Ristroph screens and fish return systems; wedgewire screens; fine mesh traveling screens; barrier nets; louver screens; angled screens; velocity caps; porous dikes; behavioral barriers; variable speed pumps; and microfiltration.

As the Pisces Phase II Report, submitted with these Comments details, these technologies vary in their effectiveness, but none of them come close to achieving the effectiveness and reliability of closed-cycle cooling. Indeed, EPA acknowledges the superiority of cooling towers in reducing impingement and entrainment:

The only technology effectiveness that is certain is reductions in impingement and entrainment with cooling towers. <FN 66>

As a result, these technologies cannot be considered as BTA or as substitutes form closed-cycle cooling technology. They can, of course, be considered as supplements which when used in conjunction with closed-cycle cooling may offer additional environmental protection and further reduce impact.

Footnotes

66 67 Fed. Reg. 17192.

EPA Response

EPA did not select a regulatory scheme based on the use of closed-cycle, recirculating cooling systems at all existing facilities based on its generally high costs (due to conversions), the fact that other technologies approach the performance of this option, and other considerations. Although closed-cycle, recirculating cooling water systems serve as the basis for requirements applied to Phase I new facilities, for Phase II existing facilities, a national requirement to retrofit existing systems is not the most cost-effective approach for existing facilities. EPA estimates that the capital costs for individual high-flow plants (i.e., greater than 2 billion gallons per day) to convert to wet towers generally ranged from $130 to $200 million, with annual operating costs in the range of $4 to $20 million. For purposes of general comparison, EPA estimated that capital and installation costs for cooling towers under the Phase I rule would range from approximately $170,000 to $12.6 million, depending on flow. At proposal, EPA estimated that the total social cost of compliance for this option would be approximately $3.5 billion per year.

Moreover, EPA had serious concerns about the short term energy implications of many facilities converting to this technology within a short period of time (i.e., within ten years of promulgation of this rule), and the potential for supply disruptions that it would entail. At proposal, EPA estimated annual benefits (in $2001) for this option at $87 million per year for impingement reductions and $1.1

billion per year for entrainment reductions. Retrofitting an existing facility requires special consideration of various factors, including the adequacy of space to accommodate a cooling tower, approval and special conditions to locate such technology, potential redesign of intake, piping and cooling system components, often unique construction concerns, and secondary effects, such as formation of plumes or excessive noise. New facilities generally do not encounter costs associated with these factors.

EPA also considered several points made by commenters in rejecting this option. Some commenters asserted that, for many existing facilities, it is not spatially feasible to replace a once-through system with a closed-cycle cooling water system. Commenters asserted that this is especially true at many older metropolitan area plants that are surrounded by other facilities. They also noted that certain facilities with closed-cycle, recirculating cooling systems often need to address the impacts of cooling tower plumes, and subsequent fog and icing in metropolitan areas, and noise abatement. Commenters also asserted that the costs of retrofitting and operating such systems at facilities which do not now have them is disproportionate to the potential benefits derived, particularly given the similarity in the level of protection provided under this option (all facilities required to reduce flow commensurate with a closed-cycle, recirculating system) and the final rule. Finally, they also stated that the need for flexibility in a rule pertaining to existing facilities is critical to allow facility owners a range of options to meet the fish protection requirements. EPA does not agree that in all cases the costs of a retrofitting a closed-cycle cooling water system is disproportionate to the benefits derived. Nevertheless, EPA recognizes that these concerns can have merit for some facilities and that the validity and extent of such concerns often must be assessed on a case-by-case basis.

EPA further compared the efficacy of closed-cycle, recirculating cooling systems with that estimated for design and construction technologies. Although not identical, the ranges of impingement and entrainment reduction is similar under both options, such that the reductions estimated for the design and construction technologies, particularly when optimized, approach those estimated for closed-cycle, recirculating cooling systems. Therefore, the use of design and construction technologies as the basis for this rule is supported since they can approach towers at less cost with fewer implementation problems. EPA considered this similarity in efficacy, along with the economic practicability and availability of each type of technology, in determining that closed-cycle, recirculating cooling systems are not the required technology for all Phase II existing facilities.

Sample facilities/technologies

In particular, one technology, the microfiltration device known as Gunderboom, is an experimental technology that cannot be considered as any component of a national BTA standard, certainly not in lieu of cooling towers. The only locations where Gunderboom has been tested are on the Hudson River at the Lovett Station Unit 3 and in an in-situ experiment in Bowline Pond conducted by Riverkeeper. Analysis of the monitoring reports of Gunderboom deployment at Lovett reports indicates that even after anchoring problems were corrected, the effectiveness of the filter fabric began to decline soon after deployment, and the material was ineffective after 5 to 6 weeks of use. The failure of the Gunderboom fabric at Lovett was likely related to biofouling, which blocks water flow through the material, thereby causing water and aquatic biota to overtop, tunnel under and/or rip through the fabric. As a result, the 80% exclusion rate (or even a 60% exclusion rate) hoped for by EPA is highly speculative and cannot in practice be achieved. Such success rate has never been achieved at Lovett or anywhere else. If anything, the Lovett reports demonstrate that Gunderboom material will foul and fail within a month or two of deployment.

As the Pisces Phase II Report explains. Gunderboom has never been proven to be effective at Lovett, except for very limited periods of time:

The only microfiltration system considered is the Gunderboom and the report makes it clear that the only data available come from the observations at Lovett GS. It is concluded that 'Entrainment reductions up to 82 percent were observed for eggs and larvae and these levels have been maintained for extended month-to-month periods during 1999 through 2001.'

This statement is a clear exaggeration of the observed effectiveness of the Gunderboom at Lovett GS. Overtopping, tunneling and rips have been observed during testing. For example, in the Lovett evaluation report for 1999 it is stated that "the divers documented a substantial gap along the bottom of the boom. The gap extended along the bottom of the boom for approximately 3 m and ranged in depth from 0.5 to 0.6 m".

It is clear in Table 2 of the Lovett 2000 report (above [in Pisces report]) that there was a gradual increase in entrainment through time. Further, there was also a series of events between May and August 2000 that resulted in short-term total failures. The efficiency of the Gunderboom was assessed by comparing the level of entrainment at unit 3 (protected by a Gunderboom) to that at unit 4 (unprotected). Thus a ratio above 1 for the number of fish entrained at unit 3 to unit 4 shows that the boom was offering no protection. To achieve 82% effectiveness or better the ratio would need to be smaller than 0.18. As shown in the figure below this level of efficiency was only achieved for a short period during May 2000. It is therefore incorrect to conclude that it was achieved for extended month-to-month periods during 1999 through 2001. In fact from late July 2000 the Gunderboom was completely ineffective at reducing entrainment. <FN 67>

Because Riverkeeper suspected that the declining efficiency of Gunderboom has was related to biofouling, we commissioned original research on Gunderboom fabric with intervenor funds in the New York State Article X power plant siting proceeding for the proposed Bowline 3 facility (Case

No. 99-F-1164). <FN 68> The in situ experiment conducted in Bowline Pond by Pisces Conservation, with assistance from Carpenter Environmental Associates, demonstrated that when exposed to the Hudson River environment during the spawning season, the permeability of Gunderboom material progressively declines as a result of the growth of a biological community on the surface. <FN 69> In fact, after 29 days in the water, Gunderboom material which was subjected to an airburst cleaning system (as proposed for BEC) had only 4% of the permeability remaining, as compared to clean material. <FN 70> Fouling of the filter fabric can result in at least three biological problems: (1) fouling of the surface might reduce the area through which water can flow leading to velocity ‘hot spots’ where delicate animals may be pinned or pulled through the mesh; (2) increased flow resistance causes water to force another path across or around the barrier; and (3) establishment of a predatory community adapted to feed on any small animals drawn close to the fabric. <FN 71>

Because Gunderboom is an experimental technology, and has not been shown to be an effective substitute for closed-cycle cooling, it cannot be considered BTA.

EPA Response

Today's rule maintains the flexibility for a facility to determine the most appropriate design and construction technologies, operational measures, and/or restoration measures suitable to its location that can best achieve requirements of today's rule.

The Gunderboom technology has demonstrated promise in reducing impingement and entrainment. EPA agrees that the technology is relatively new to the market and is still undergoing modifications and improvements but does not agree with the commenters assertion that Gunderboom should be excluded from BTA determinations. EPA has left the determination of BTA (in compliance alternatives 2 and 3) up to the Director on a site-specific basis. If the Gunderboom can be shown to reliably meet the requirements in today's rule, it should be eligible for consideration as BTA.

Ex. facilities converted to closed-cycle

CLOSED-CYCLE COOLING IS AVAILABLE AND AFFORDABLE FOR EXISTING FACILITIES, AND WILL NOT ADVERSELY AFFECT ENERGY SUPPLY, RELIABILITY OR PRICES.

1. Closed-Cycle Cooling Is Virtually Ubiquitous For Modern Power Plants, and Has Been Retrofit on Numerous Older Plants.

Closed-cycle cooling is available technology for both new and existing facilities. For new plants, it is overwhelmingly the standard technology. In conjunction with the Phase I regulation for new facilities, EPA reported that 100% of the utility and nonutility combined-cycle plants built in the last 20 years have a closed-cycle recirculating cooling system. <FN 72> For coal-fired facilities, 88% of the facilities built in the last 10 years have closed-cycle cooling. <FN 73> Likewise, for existing plants, EPA acknowledges that:

A closed-cycle recirculating cooling system is an available technology for facilities that currently have once-through cooling water systems. <FN 74>

In the 1970s, 1980s, and 1990s, facilities of various sizes and fuel types converted from once-though cooling to closed-cycle cooling. Specifically, EPA has reported the following cooling system retrofits: The Palisades Nuclear Plant in Michigan converted to closed-cycle cooling in 1974; the Canadys (coal-fired) Steam Plant in South Carolina, converted its once-through cooling system to a closed-cycle recirculating system in two steps, first Unit 3 in 1972 and then Units 1 and 2 in 1992; in 1985, the Jeffries Coal Plant also South Carolina converted from once-through cooling to recirculating cooling towers; and finally, Unit 7 of the Pittsburg Power Plant in Contra Costa County, California, has converted to closed-cycle.

In addition, many other plants have converted from once-through cooling to closed-cycle cooling, or are planning to do so, while repowering and simultaneously improving the efficiency, air pollution rates, and total capacity of their plants. For example:

Reliant Astoria Repowering Project and the Bethlehem Energy Center in New York State are evidence that firms will seek to repower older, less efficient generating facilities and that such repowerings can include cooling towers as part of the repowered facility in place of once-through cooling. Such projects will provide significant environmental benefits in terms of reduced water usage and lowered air emissions and will offer substantial economic benefits for their owners. <FN 75>

Mkt-level impacts/Reliability/EO 13211: Energy Effects

A Retrofit Mandate Will Not Cause Energy Shortages.

A regulation requiring closed-cycle cooling for all existing facilities would not significantly affect U.S. energy supplies in the short- or long-term. Submitted with these comments is a report by Synapse Energy Economics of Boston, Massachusetts. In that its report (hereinafter, "Synapse Phase II Report"), Synapse analyzed the energy impact of an all closed-cycle cooling rule, and concludes that there would be no adverse energy reliability impact from the implementation of an all-cooling tower regulatory option. <FN 76>

Adverse energy effects of such a regulation could conceivably result from one of three causes: plants going temporarily off-line to retrofit to cooling towers; reduced energy generating efficiency (sometimes called an "energy penalty") from operating with a cooling tower; or the retirement of facilities. Synapse has carefully analyzed each of these possibilities, and none presents a significant problem.

First, Synapse calculates the percentage of national power capacity that would be off-line for retrofit at any one time. As EPA acknowledges, the new cooling towers could be built while an affected facility is operating and the attachment of the new tower to the existing cooling system would have only a one-time effect, extending a planned maintenance outage by one month. Based on EPA's estimates, Synapse notes that a national closed cycle cooling rule would cause 416 facilities, representing 33.1 percent of U.S. generating capacity, to add cooling towers. Since power plant cooling technology is dictated by 5-year NPDES permits, and since the design and construction of cooling towers can take several years, it is reasonable to assume that the facility outages required to connect these new cooling towers could and would be scheduled to occur throughout a five-year transition period. As a result, on average, only 0.5 percent of the nation's electric generating capacity would be out of service at any one time as a result of the implementation of a national closed-cycle cooling rule. <FN 77>

The same would be true on a regional basis. Only 0.75 percent of the generating capacity in the ECAR and NPCC regions, on average, would be out of service at any one time. Again, this assumes that the extra month of downtime needed to connect the new cooling towers would occur randomly throughout the year. It is far more likely, however, that the extra downtime would be preferentially scheduled to occur during the off-peak seasons when capacity reserve margins are much higher. As a result, the implementation of a national closed-cycle cooling regulation would have even less of an effect on electric system reliability than these figures would suggest. <FN 78>

Second, the energy penalties will be minor. Even assuming EPA has correctly estimated the energy penalty at 1.7 percent, this is a minor reduction considering in light of existing and predicted reserve margins, and the additional capacity expected to come on line in the near future. Moreover, EPA has significantly overstated the energy penalty, as Synapse explains in detail. <FN 79>

Third, no generating capacity will be retired as a result of the implementation of the closed-cycle cooling rule. As explained below, based on the extremely high profitability of existing nuclear and fossil fuel plants, and the relatively minor costs of retrofitting cooling towers, it is unreasonable and unrealistic to assume that any facilities will close as a result of such regulation. If anything, a cooling tower mandate might cause some retrofitting facilities to simultaneously repower from older, less efficient single-cycle generating technology to modern, more efficient combined-cycle technology. On the Hudson River, the owner of the Albany Steam Station recently received approval to repower the plant, and in so doing will reduce cooling water intake by 98-99% percent, reduce air pollution rates by a similar percentage, while nearly doubling capacity. Thus, a closed-cycle regulation may cause an increase in capacity.

Even apart from repowerings that might be caused by such a rule, there are a number of other sources of additional, new capacity which will more than compensate for any reductions in available capacity. Thus, the extremely minor capacity reduction totals discussed above overstate the effect that the implementation of a closed-cycle cooling the regulation would have on electric system reliability. A significant amount of new capacity is scheduled to come on line nationwide in the next few years. Further, there will be additional capacity available from already-scheduled repowerings of oil-, gas- and coal-fired facilities to combined-cycle plants. Synapse is aware of at least 17 coal-fired facilities have been or are planned to be repowered to use combined-cycle technology, in addition to many more repowerings from oil or gas, which EPA has reported. These repowerings could add thousands of additional megawatts of generating capacity to the national electric system and, thereby, improve system reliability while reducing water usage. Similarly, condenser upgrades improve performance in terms of fewer tube failures and lower forced outage rates. Thus, the facilities that have implemented condenser upgrades should be available for service for more of the year than they previously had been. This additional capacity can be expected to further enhance electric system reliability.

Morever, there will be additional capacity available from the implementation of power uprates at nuclear power plants. A power uprate means increasing the thermal power produced by the plant. A power uprate increases the output of the plant at a relatively low cost. The U.S. Nuclear Regulatory Commission has approved more than 60 such power uprates of between 5 and 20 percent. Requests for additional uprates are currently under review by the NRC or are planned for submission in the near future. An average increase of 10 percent in the power levels of the nation's nuclear plants would add approximately 9,000 megawatts of additional capacity to the electric system. Likewise, many nuclear power plants will be extended beyond the current 40 year terms of their Nuclear Regulatory Commission-issued operating licenses. Therefore, there may be more generating capacity available over the next 30 to 50 years than has been assumed in the EPA analyses.

Facility & firm-level costs/Econ. Practicability

The Cost of Closed-Cycle Cooling is Minimal to Industry, Would Not Cause Facilities to Close, and is Only Pennies per Month Per Household.

In the Phase II Synapse Report, Synapse analyzed and the costs of complying with regulatory options that require closed-cycle recirculating cooling systems and concluded that such costs would be extremely minor.

Based on EPA's own calculations, the compliance costs of an all cooling tower rule, would add cooling towers at 416 facilities, would increase the average price of generating electricity at the affected facilities by about one-tenth of one cent (known as a mill) per kilowatt hour. Since retail energy costs average about 8.5 cents per kilowatt hour, this represents only a 0.66 percent increase. <FN 80>

It is not clear that in deregulated markets the owners of affected facilities could pass these cost increases along to their customers. But even if they could, the overall price paid by consumers for the electricity they use would reflect a blend of both the price of generating electricity at affected facilities and the price of generating electricity at non-affected facilities. Consequently, the price of electricity actually paid by consumers would increase by less than the tenth of a cent per kilowatt hour. Indeed, as demonstrated by Synapse the average price increases to consumers caused by an all-cooling tower rule would be only one-twentieth of a cent (one-half mill) per kilowatt hour. As a result, an average consumer who uses 500 kilowatt hours per month would see his/her bill increase by only 28 cents per month if a closed-cycle regulation were adopted.

These extremely minor cost increases would also not cause any facilities to close. Based on its experience and previous work with power plants, Synapse believes that it is extremely unrealistic to expect that currently operating nuclear power plants will be retired as a result of the adoption of a flow reduction technology based regulatory options. This conclusion is based on (a) the improved performance and reduced O&M costs achieved at nuclear plants since the mid-1990s, (b) the fact that nuclear plants' low operating and fuel costs allow them to compete successfully in bid-based wholesale markets, and (c) the significant economic benefits that are available from relatively low cost investments in plant power uprates and operating life extensions.

For example, a recent Synapse analysis concluded that a $36 million investment in increasing the power level of the Vermont Yankee Nuclear Plant by 13 percent would result in a net present value benefit of $56 million (in 2001 dollars). A similar investment in extending the unit's operating life by twenty years would produce a net present value benefit of $253 million. With the opportunity for potential economic benefits of this magnitude, it is unlikely that any nuclear plant would be retired as result of the adoption of a closed-cycle retrofit mandate from the EPA.

Subject Matter Code 7.0
Best Technology Available (BTA)

EPA should promulgate a Phase II rule that mandates a closed-cycle cooling equivalent flow limit as a component of the best technology available to minimize adverse environmental impact for all existing facilities on all waters of the U.S. The only variance that can be allowed is the fundamentally different factors (FDF) variance authorized by the Supreme Court. Restoration measures cannot be used to satisfy a technology standard.

EPA Response

EPA has not selected a regulatory approach based exclusively on closed-cycle, recirculating cooling. Please refer to section VII of the preamble to the final rule for more information.

EPA agrees that it has the authority to authorize site-specific determinations of BTA for minimizing adverse environmental impacts; EPA further agrees that such determinations under § 316(b) are analogous to FDF variances under § 301.

For information about the role of restoration, please refer to sections VII and VIII of the preamble to the final rule.

Subject Matter Code 2.04.01
Require closed cycle cooling

Section 316(b) Requires Closed-Cycle Cooling as BTA because it is the Best Technology in Use.

As explained above, the Clean Water Act's technology-based limitations were designed to force the iterative development of more protective technologies, and to ratchet down discharges and other impairments to water quality until they could be eliminated. Congress and numerous federal courts have emphasized this "technology-forcing" character of the Act's categorical standards within the context of the section 301 BAT requirement. It is therefore well-settled law that BAT standards must require all existing facilities to match the environmental performance of the best performing, i.e., least polluting, least harmful, facility.

BAT must be "at a minimum, established with reference to the best performer in any industrial category." Conf. Rep. On S. 2770 (October 4, 1972), Legislative History of the Federal Water Pollution Control Act of 1972 at 170. "The BAT standard reflects the intention of Congress to use the latest scientific research and technology in setting effluent limits, pushing industries toward the goal of zero discharge as quickly as possible. In setting BAT, EPA uses not the average plant, but the optimally operating plant, the pilot plant which acts as a beacon to show what is possible." Kennecott v. EPA, 780 F.2d 445, 448 (4th Cir. 1985), citing legislative history See A Legislative History of the Water Pollution Control Act Amendments of 1972, 93d Cong., 1st Sess. (Comm. Print 1973), at 798 (hereinafter "Leg. Hist."). See A Legislative History of the Water Pollution Control Act Amendments of 1972, 93d Cong., 1st Sess. (Comm. Print 1973), at 798 (hereinafter "Leg. Hist.").;

"[I]t is clear that Congress did not intend by that phrase [i.e., BAT] to limit the technology to that which is widely in use. … 'It will be sufficient, for the purpose of setting the level of control under available technology, that there be one operating facility which demonstrates that the level can be achieved or that there is sufficient information and data from a relevant pilot plant.'" American Iron & Steel Inst. v. EPA, 526 F.2d 1027, 1058 (3d Cir. 1975), quoting legislative history. BAT must "utilize the latest technology to reach 'the greatest attainable level … which could be achieved. NRDC v. EPA, 863 F.2d 1420, 1431 (9th Cir. 1988). <FN 81>

The best-performer/optimally-operating-plant essence of BAT standards is illustrated by contrast with or "best practicable technology" or BPT standards. <FN 82> BPT was an intermediate technology standard which, under the CWA's three-step phase-in process, were completely replaced by the BAT standards in 1979. Under the obsolete BPT mandate, EPA set standards which represented the "average of the best existing performance by plants of various sizes, ages and unit processes within each industrial category or subcategory. This average is not based upon a broad range of plants within an industrial category or subcategory, but is based upon performance levels achieved by exemplary plants." Kennecott v. EPA, 780 F.2d 445, 448 (4th Circ. 1985) citing EPA v. Nat'l Crushed Stone Ass'n, 449 U.S. 64, 76 n. 15, 66 L. Ed. 2d 268, 101 S.Ct 295 (1980) (1980) quoting 39 Fed. Reg. 6580 (1974). "The distinction between 'best practicable' and 'best available' is intended to reflect the need to press toward increasingly higher levels of control. Kennecott v. EPA, 780 F.2d 445, 448 (4th Cir. 1985), citing legislative history.

Section 316(b)'s BTA mandate, which is at least as strict as BAT standards and clearly stricter that BPT, requires EPA to set extremely technology-forcing cooling water intake standards that reflect state-of-the-art controls. As with BAT, BTA requires EPA to look to the optimally-operating plant, i.e., the best performer, and to bring all facilities up to the "best of the best" level. EPA has done this for many years for most industrial dischargers, including new and existing power plants. <FN 83> The Clean Water Act requires the same for cooling water intakes at power plants.

Footnotes

81 See also Texas Oil & Gas Ass'n v. United States EPA, 161 F.3d 923, 928 (5th Cir. 1998) (BAT limitations to be based on the performance of "the single best-performing plant.") Organization Riverkeeper

Subject Matter Code 2.04.01

Require closed cycle cooling

Because closed-cycle cooling is the best technology for minimizing adverse environmental impact, is widely available for both new and existing plants, and will not cause adverse energy impacts, it is BTA for existing facilities. EPA has no discretion to determine otherwise. Indeed, for EPA to determine that a once-through plant is the "optimally operating plant, the pilot plant which acts as a beacon to show what is possible," (Kennecott v. EPA, 780 F.2d at 448) would be arbitrary and capricious and not in accordance with law.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Comment ID 316bEFR.206.030

Subject Matter Code 2.04.03

Define BTA as anything less than closed cycle

Author Name Reed Super

Organization Riverkeeper

COMPLIANCE COSTS ARE ONLY MARGINALLY RELEVANT TO THE DETERMINATION OF BTA.

The fact that closed-cycle cooling may cause facilities to incur higher compliance costs does not change the BTA determination. "Congress foresaw and accepted the economic hardship, including the closing of some plants, that [Clean Water Act] effluent limitations would cause." EPA v. National Crushed Stone, 449 U.S. 64, 79 (1980). As the Supreme Court explained, Congress devised the Act with the economic consequences in mind:

Prior to the passage of the [Clean Water] Act, Congress had before it a report jointly prepared by EPA, the Commerce Department, and the Council on Environmental Quality on the impact of the pollution control measures on industry. That report estimated that there would be 200 to 300 plant closings caused by the first set of pollution limitations. Comments in the Senate debate were explicit: 'There is no doubt that we will suffer some disruptions in our economy because of these efforts; many marginal plants may be forced to close.'

Id. at 80.

Section 316(b) does not explicitly provide that EPA may take compliance costs into consideration at all when establishing national standards requiring that cooling water intake structures reflect the best technology available. In contrast, other provisions of the Act that mandate the establishment of technology-based standards, such as Sections 304 and 306, require EPA to consider costs, and those provisions further specify how costs are to be considered. <FN 84> Significantly, the United States Court of Appeals for the D.C. Circuit has consistently held that, without specific statutory authorization for considering costs, "the EPA is not permitted to consider the cost of implementing those standards" under the Clean Air Act. American Trucking Associations v. US EPA, 175 F.3d 1027, 1040 (D.C. Cir. 1999); see also Lead Industries Assoc. v. EPA, 647 F.2d 1130, 1148 (D.C. Cir. 1980). This is especially true where the other provisions of the same statute direct EPA to consider costs, as certain sections of the Clean Water Act do. In such cases, courts conclude that Congress only intended EPA to consider costs where it has explicitly so provided. Lead Industries Assoc., 647 F.2d at 1148. Under this authority, which applies with equal force to the Clean Water Act, EPA is statutorily precluded from considering compliance costs in the setting of Phase II BTA standards.

Footnotes

84 EPA's interpretation lacks support because it is not based not on any judicial authority or a reading of the plain language of the Act. Instead, it rests on a single statement in the legislative history and on EPA's own preamble to the 1976 rule.

EPA Response

Subject Matter Code 2.04.03

Define BTA as anything less than closed cycle

Despite the lack of explicit reference to costs in section 316(b), EPA has EPA has stated that "best technology available"' should be interpreted as "best technology available commercially at an economically practicable cost." <FN 85> EPA appears to be equating role of costs under the BTA standard with the BAT standard, which is "best available technology economically achievable." If EPA's interpretation is correct, however, then EPA's consideration of costs for BTA can be no more extensive than is permitted for BAT.

Footnotes

85 EPA's interpretation lacks support because it is not based not on any judicial authority or a reading of the plain language of the Act. Instead, it rests on a single statement in the legislative history and on EPA's own preamble to the 1976 rule.

Use cost-benefit tests

Congress' goal to impose the strictest controls for existing facilities is manifested in the extent to which EPA may consider costs. In setting BAT standards, EPA may consider, among other factors, "the cost of achieving such effluent reduction," 33 U.S.C § 1314(b)(2)(B), but it cannot perform a cost-benefit analysis: "[I]f the effluent reduction is technologically feasible and economically achievable [to the industry as a whole], it must be employed." 92 Cong. Rec. S.2770 (1972)(emphasis added).

Use cost-benefit tests

Several major U.S. industries, including the steel, chemical and mining industries, have filed lawsuits against the EPA's promulgation of effluent limitation guidelines, claiming that the agency had been unreasonable by failing to consider environmental compliance costs either in establishing technology guidelines or refusing to issue variances to such standards. In each instance, the EPA's steadfast refusal to give undue consideration to pollution control compliance costs was upheld by the courts.

Courts have upheld the BAT selected by EPA for a variety of industrial categories, even though EPA predicted that the BAT would cause economic displacement, including plant closures, associated job losses and other significant impacts. For instance, the Third Circuit upheld performance standards for existing sources, which are set in accordance with the procedures for BAT standards, even though "EPA estimated that compliance with the [standards] would force 14% of all indirect discharging plants to close and cause a 1.2% reduction in total industry employment." Chemical Mfrs. Ass'n, 870 F.2d at 250. As the court explained, "Congress clearly understood that achieving the CWA's goal of eliminating all discharges would cause 'some disruption in our economy,' including plant closures and job losses." Id. at 252. The Ninth Circuit has also upheld BAT that was projected to cause plant closures, observing, "Congress contemplated the closure of some marginal plants." See Association of Pacific Fisheries v. EPA, 615 F.2d 794, 818 (9th Cir. 1980); Rybacheck, 904 F.2d at 1291.

Subject Matter Code 2.04.04
Use cost-benefit tests

The role of costs in BAT can be illustrated in contrast to the now-defunct BPT standards. To determine “best practicable technology,” a cost/benefit analysis was appropriate. For such BPT standards, the Clean Water Act allowed EPA to consider, among other factors, “the total cost of application technology in relation to the effluent reduction benefits to be achieved from such application.” 33 U.S.C. § 1314(b)(1)(B). Thus, under the BPT standard, EPA considered cost as a function of effectiveness; when the cost to reduce additional effluent became disproportionate to the amount of reduction, the additional reduction was not required. Reynolds Metals Co. v. EPA, 760 F.2d 549, 554 (4th Cir.1985). As explained above, BPT was determined by averaging the best performing plants of various sizes, ages, and processes, and applying that average as the BPT standard for each industry at that time. Organic Chemicals and Plastics and Synthetic Fibers Category Effluent Limitations Guidelines, Pretreatment Standards, and New Source Performance Standards, 52 Fed. Reg. 42522 (III)(A)(1) (to be codified at 40 C.F.R. §§ 414, 416.) This was Congress’ concession to industry to allow facilities to update and comply with approaching BAT requirements.

However, even under the less stringent BPT standard, an industrial polluter could not escape complying with the regulations based solely on inability to bear compliance costs:

Because the 1977 limitations were intended to reduce the total pollution produced by an industry, requiring compliance with BPT standards necessarily imposed additional costs on the segment of the industry with the least effective technology. If the statutory goal is to be achieved, these costs must be borne or the point source eliminated.
EPA v. National Crushed Stone, 449 U.S. 64, 78 (1980).

Thus, even under the less stringent BPT standard, costs must have a minor role and a strict cost-benefit test was not required. In Chemical Mfrs. Ass'n v. EPA, 870 F.2d 177 (5th Cir. 1989), chemical manufacturers maintained that the cost-effectiveness of Best Practicable Technology rulemaking should be measured by a "knee-of-the-curve" test to determine the point at which costs rise steeply per pound of pollutant removed. Under such a test, they argued, the BPT rules were not cost-effective. In supporting EPA’s interpretation of cost-benefit analysis and rejecting the chemical manufacturers’ argument, the Court stated,

Congress intended Section 304(b) to give the EPA broad discretion in considering the cost of pollution abatement in relation to its benefits and to preclude the EPA from giving the cost of compliance primary importance.

Chemical Mfrs. Ass'n v. EPA, 870 F.2d 177, 204 (5th Cir. 1989) (emphasis added).

Senator Muskie, the principal Senate sponsor of the Clean Water Act, described the "limited cost-benefit analysis" employed in setting BPT standards as being intended to "limit the application of technology only where the additional degree of effluent reduction is wholly out of proportion to the costs of achieving such marginal level of reduction . . . ." Remarks of Senator Muskie reprinted in Legislative History of the Water Pollution Control Act Amendments of 1972 (Committee Print compiled for the Senate Committee on Public Works by the Library of Congress) Ser. No. 93-1, p. 170 (1973) [emphasis added].

Following the phase-out of BPT, cost could be considered only if the total elimination of discharge is impossible and, even then, only with regard to establishing the appropriate level of reduction for the best within the industry – the BAT standard. Reynolds Metals Co. v. United States EPA, 760 F.2d 549, 553 (4th Cir. 1985); Texas Oil & Gas Ass'n v. EPA, 161 F.3d 923, 928 (5th Cir. 1998), quoting Chemical Mfrs. Ass'n v. EPA, 870 F.2d 177, 226 (5th Cir. 1989). Thus, for BAT (best available technology economically achievable) under Section 301, EPA must consider costs but no full cost/benefit test is permitted.

Because the standard applicable here is akin to the higher BAT standard, compliance cost is given even less weight. In American Iron & Steel Institute v. EPA, 526 F.2d 1027 (3rd Cir. 1975), members of the steel industry sought variances from BAT standards set by the EPA, claiming the cost of compliance was prohibitive. The Court, again relying on congressional intent, explained the standard for compliance cost analysis under BAT as follows:

In making the determination of 'best available' for a category or class, the Administrator is intended to apply the same principles involved in making the determination of 'best practicable' (outlined above), except as to cost-benefit analysis . . . While cost should be a factor in the Administrator's judgment, no balancing test will be required. The Administrator will be bound by a test of reasonableness. . . the reasonableness of what is 'economically achievable' should reflect an evaluation of what needs to be done to move toward the elimination of the discharge of pollutants and what is achievable through the application of available technology - without regard to cost.

Remarks of Senator Muskie reprinted in Legislative History of the Water Pollution Control Act Amendments of 1972 (Committee Print compiled for the Senate Committee on Public Works by the Library of Congress) Ser. No. 93-1, p. 170 (1973) (emphasis added). Finally, EPA must fully explain its cost analysis. See Kennecott, 780 F.2d at 456.

Subject Matter Code 2.04.03
Define BTA as anything less than closed cycle

The Clean Water Act requires EPA to determine the best technology available for minimizing the adverse environmental impact of cooling withdrawals, and set such technology as a national standard. The Phase II Proposal does neither. The performance standards fail to reflect the best technology available – in fact they recognize and permit the worst technology by far with respect to water withdrawal capacity – and the proposed site specific option obviates the national applicability of any such standards. As Woody Allen once complained about a bad restaurant: the food's lousy and the portions are too small.

Performance standards

The proposed BTA standard for in-scope facilities (i.e., those with intake flows of at least 50 mgd) is as follows:

-All facilities must reduce impingement 80 to 95 percent from the "calculation baseline"; <FN 87> and

-Facilities must also reduce entrainment 60 to 90 percent from the "calculation baseline," unless their capacity utilization rate is less than 15 percent, or their design intake flow is less than five percent of the mean annual flow from a fresh water river or stream, in which case they have no entrainment standard. <FN 88>

These standards, however, apply only to facilities that choose the compliance alternatives referred to as Track I and Track II. <FN 89> Permit applicants may instead seek a site-specific BTA determination under Track III. <FN 90> Furthermore, under any of the three tracks, applicants may meet the applicable performance standard with "restoration measures" in lieu of technologies, if the restoration will result in comparable increases in fish and shellfish in the watershed. <FN 91>

Footnotes

87 The calculation baseline is defined as a once-through cooling system with no impingement or entrainment controls. 67 Fed. Reg. 17141.

88 Id. There are slightly different standards for lakes and reservoirs, other than the Great Lakes. 40 CFR § 125.94(b)(4) [proposed].

89 Under Track I, an applicant may demonstrate that existing "design and construction technologies, operational measures, and/or restoration measures meet the performance standards." 40 CFR § 125.94(a)(1) [proposed]. Under Track II, an applicant may demonstrate that existing and proposed "design and construction technologies, operational measures, and/or restoration measures meet the performance standards." 40 CFR § 125.94(a)(2) [proposed].

90 40 CFR § 125.94(a)(3) and (c)(1) [proposed]. To get a site-specific BTA determination, applicants must show that either (1) their compliance costs would be "significantly greater" than those EPA considered in promulgating these regulations; or (2) their costs would be "significantly greater" than the benefits afforded.

91 40 CFR § 125.94(d) [proposed].

Define BTA as anything less than closed cycle

Author Name Reed Super

Organization Riverkeeper

This proposed BTA "standard" is illegal, both in the approach EPA took to select it and in the result. Furthermore, the compliance options negate any semblance of a national technology standard. EPA's Phase II Proposal violates the law and is unsound environmental regulation in at least the following respects:

-The "performance standard" is set with reference to technologies less protective than the best available, in contravention of CWA section 316(b) BTA requirement and the Clean Water Act's technology-forcing mandate.

-EPA employed a cost-benefit test (the "maximize net benefits" approach) to select BTA, thereby violating the Clean Water Act and Executive Order 12866, which require minimization of environmental impacts and prohibit cost-benefit analyses.

-Restoration measures cannot be used in lieu of technologies in a Clean Water Act technology-based requirement because they are not technologies that minimize impacts and they cannot reverse the damage caused by CWISs.

-Track III, which includes both an economic and a ecological variance, is unauthorized and illegal.

Author Name Reed Super
Organization Riverkeeper

Subject Matter Code 2.04.03
Define BTA as anything less than closed cycle

THE NATIONAL TECHNOLOGY-BASED PERFORMANCE “STANDARD” DOES NOT REFLECT BTA IN PROCESS OR PRODUCT.

1. The 60 to 90 Percent Entrainment Reduction “Standard” Is Based on Less Protective Technologies than the Best Available.

The proposal violates the Clean Water Act by basing the national BTA performance standard on technologies less effective than closed-cycle cooling, i.e. by continuing to allow once through cooling. EPA purports to require a 60 to 90 percent reduction in entrainment from the calculation baseline,” <FN 92> but the operative standard is the bottom of the range, i.e., 60 percent. This is because the proposed rule requires only technologies within or above the range, so any level of performance within the range, including 60 percent, would suffice. <FN 93>

Footnotes

92 40 CFR § 125(b)(3) [proposed]. For facilities with a capacity utilization rate of less than 15 percent, and for facilities whose design intake flow is less than five percent of the mean annual flow of a fresh water river or stream, there is no entrainment standard at all. 40 CFR § 125(b)(2) [proposed].

93 EPA set the lower end of the range (60 percent) to account for sites where the fragility of species would make them susceptible to perishing when coming in contact with the very technologies designed to protect them. The upper end of the range (90 percent) represents the maximum achieved with the technologies on which the standard is based. EPA is considering, but has not included in the Phase II Proposal, a requirement that facilities achieve the greatest reduction, within the range, that is possible at their site. 67 Fed. Reg. 17141-17142. Unless and until such requirement is included in the rule, facilities have no requirement to reduce entrainment by more than 60 percent. EPA’s anticipation that “facilities will select technologies or operational measures to achieve the greatest cost-effective reduction possible (within today’s proposed performance range),” 67 Fed. Reg at 17142, is naive. As they have for decades, generators will much more likely seek to minimize section 316(b) compliance costs as much as possible.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Author Name Reed Super
Organization Riverkeeper

Subject Matter Code 17.03.03
Benefits of reduced intake capacity

EPA acknowledges that closed-cycle cooling would reduce entrainment significantly more than the 60 percent standard:

[C]losed-cycle, recirculating cooling systems (e.g. cooling towers or ponds) can reduce mortality from impingement by up to 98 percent and entrainment by up to 98 percent when compared with conventional once-through systems. <FN 94>

Furthermore, cooling towers are not only more effective, but are also more reliable (i.e., more certain in their effectiveness), as EPA has also acknowledged:

Installed technologies may not operate at the maximum efficiency assumed by EPA in its estimates of technology effectiveness. <FN 95>

The only technology effectiveness that is certain is reductions in impingement and entrainment with cooling towers. <FN 96>

Footnotes

94 67 Fed. Reg. 17142.

95 67 Fed. Reg. 17192.

RFC: EPA rationale to not require closed-cycle

Author Name Reed Super

Organization Riverkeeper

Despite the clear superiority of cooling towers, EPA did not set the performance standard based on a closed-cycle recirculating cooling system. <FN 97> In light of the significant difference in effectiveness (98 percent <FN 98> compared to 60 percent), and the certainty afforded by cooling towers (fish kills are reduced in proportion to volume; other technologies are affected by a variety of poorly-understood factors), the 60 percent standard violates the Clean Water Act's best technology mandate.

The entrainment performance standard in the Phase II Proposal violates the Clean Water Act because EPA based it on technologies far more destructive than those in place at the best performing plants. In other words, the standard does not reflect BTA. Simply put, cooling towers are the best technology, while filter barriers, screens, and the like, are not. In fact, such barriers and screens do not address withdrawal capacity, the critical factor in entrainment, at all; instead they may be and should be a component of BTA in conjunction with closed-cycle cooling, as a great many U.S. power plants do. Instead, the Phase II proposal would continue to allow once through cooling – the worst technology with respect to capacity – at all in scope facilities.

Footnotes

97 67 Fed. Reg. 17142. EPA based the entrainment standard on aquatic filter barrier systems, fine mesh wedgewire screens, fine mesh traveling screens with fish return systems, seasonal flow restrictions, variable speed pumps and other operational measures. EPA admits that full-scale performance data are not available for entrainment reduction. Id. While a closed-cycle cooling tower would meet the performance standard (see 40 CFR § 125(b)(1) [proposed] and 67 Fed. Reg.17142), it is not required.

98 Even the lower bound of cooling tower effectiveness, 70 percent in saline waters where State regulations limit recirculation, is still significantly better than 60 percent. And as Pisces notes, the saline waters where cooling towers reduce withdrawals less also limit the effectiveness of the alternate technologies EPA relies on. Pisces Phase II Report at pp. 39-45

Use cost-benefit tests

Author Name Reed Super

Organization Riverkeeper

EPA and OIRA's Cost-Benefit Analysis Is Fundamentally-Flawed and Such Analysis May Not Legally Be Used as the Decision Criteria for BTA Determinations.

EPA Phase II Proposal relies heavily on cost-benefit analysis. After attempting to estimate the total benefits and compliance costs of the proposed alternatives, EPA chose the option predicted to have the greatest net benefit. In essence EPA replaced the Clean Water Act's BTA mandate with a cost-benefit decision-making criterion. Such use of cost-benefit analysis is not authorized by law; in fact, it is prohibited for BTA determinations. In determining BTA standards, EPA is required to give compliance costs no more than a minor role and may not use a cost-benefit analysis to mandate technologies less than the best available.

Furthermore, EPA's benefits analysis is deeply flawed in principle and in its lack of completeness. It significantly undervalues the environmental benefits of preventing fish kills. Indeed, it is impossible to represent environmental conservation in solely monetary terms.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Comment ID 316bEFR.206.046

Author Name Reed Super

Organization Riverkeeper

Subject Matter Code 10.05

RFC: Cost-benefit in proposed provision 124.95

Cost-Benefit Analyses Are Inappropriate for Environmental Harms and Benefits.

Cost-benefit analysis for environmental regulations is deeply flawed and invariably produces biased and misleading results. Unlike compliance costs, which can be readily estimated, the environmental benefits – preventing the needless diminution of aquatic and marine fauna, and all the ecosystem effects – cannot and should not be monetized. Any attempt at monetizing environmental benefits will necessarily suffer from several systemic problems. <FN 99>

First, it is not possible to realistically value the benefit of healthy marine and aquatic faunal populations. Ecosystems are immensely complex systems. There is insufficient data to fully understand these systems and identify the benefits they provide, let alone to quantify them. It is an absurd conceit to attempt to accurately estimate the value of ecological integrity given the geologic time frame for the contribution and longevity of functioning ecosystems. Instead, if something cannot be quantified, cost-benefit practitioners ignore it and therefore assume it is equal to zero, as EPA has repeatedly done in the proposed rule.

Similarly, some environmental benefits such as support for human life and civilization, as well as goals such as happiness, security and aesthetic pleasure are impossible to monetize. Failing to account for such assets leads to absurd results. Cost-benefit analyses have been used to argue that cigarette smoking should be subsidized because shorted lives would decrease national health care costs for an aging population, and that standards for preventing exposure to lead by children are too high. <FN 100>

Third, by discounting long-term benefits, cost-benefit analyses trivialize the future and make environmental restoration seem cost-ineffective. But the very nature of environmental protection is to invest now to protect resources for coming generations as well as the present. But by discounting future benefits, cost-benefit analyses make any project that does not have an immediate payoff worthless. For example, some benefits of planting a tree will not come for many years until the tree had grown enough to provide fruit, shade, habitat, aesthetic pleasure, etc. But discounting those benefits may make them so small in present dollars that it never seems cost-effective to plant a tree, when it is obvious that such is not true.

Fourth, basing regulations on cost-benefit ignores transfers of costs and therefore misallocates social resources. Comparing total costs to total benefits without regarding who pays the costs and who gets the benefits allows the power industry to continue transfer its costs on the rest of society and the environment. One result of killing fish is that fisheries become stressed, and commercial fishers are put out of work. Cost-benefit analysis does not take this into account.

Finally, the cost-benefit analysis ignores the determination, reflected in repeated Clean Water Act mandates including section 316(b), that degradation of aquatic and marine ecosystems is unnatural and unnecessary for our survival and prosperity. Instead, it presumes the massive aquatic mortality caused by power plants as the baseline, and requires a demonstration of effectiveness simply to avoid unnecessary destruction and restore a more natural ecological function. The burden should be on power plants to prove why they should be allowed to appropriate wildlife from that system for their own purposes.

Thus, cost-benefit analysis of environmental degradation is fundamentally flawed conceptually. But even assuming arguendo that such analysis could be useful, EPA's estimate for the Phase II Proposal is hopelessly incomplete and inaccurate.

Subject Matter Code 10.05

RFC: Cost-benefit in proposed provision 124.95

EPA's Cost-Benefit Analysis is Hopelessly Biased, Inaccurate and Useless.

As Dr. Ackerman explains in his comments, EPA's analysis of the benefits of reduced cooling water intake is seriously incomplete, and can be considered as no more than an extreme lower bound on the complete benefits. Cost-benefit analysis is designed to weigh the relevant costs of a proposal against the corresponding benefits. This process cannot yield a meaningful result unless the calculations of costs and benefits are both complete. In the private sector, a balance sheet that weighs all of a company's income against some of its expenditures does not provide a useful picture of the company's true financial condition. Likewise, in the public sector, a comparison of complete costs and incomplete benefits does not provide an accurate picture of net benefits to society. <FN 101>

EPA has, however, produced a comparison of complete costs and incomplete benefits in this case. The costs of reducing the impacts of cooling water intake are monetary costs for marketed goods and services, such as production and installation of screens, cooling towers, and other equipment, and as a result there are no categories of costs which are intrinsically difficult to express in monetary terms. <FN 102>

In stark comparison, the calculation of the benefits of reducing cooling water intake consists of reduced damage to aquatic ecosystems, which is difficult to measure and monetize. EPA's analysis focuses only on valuing the benefits of killing fewer fish, which is itself a complex problem. Market prices are available only for a few commercially valuable fish species, and commercial prices do not necessarily capture all the value of avoided fish mortality. Furthermore, avoided fish kills are far from the only significant benefits of reduced ecosystem damages, since many other organisms and environmental services are also affected. <FN 103>

In the preamble to the Phase II Proposal and in the supporting Economic Benefit Analysis (EBA), EPA lists the categories of benefits that have been omitted, and the reasons why the environmental impacts of cooling water intake structures the benefits of regulating them have been significantly underestimated:

-Facility-provided monitoring data, the basis for EPA's analysis, typically focus on only a subset of the species impacted by impingement and entrainment (I&E), thus underestimating total losses.

-Monitoring data often pertain to conditions existing many years ago, before the Clean Water Act had improved aquatic conditions; if the numbers and diversity of fish were depressed by degraded water quality, estimates of I&E losses would be similarly low.

-Cumulative impacts of multiple facilities on the same fish population are often important, but have been considered only to a limited extent.

-Estimated recreational and commercial values include only the proportion of I&E losses that would have been caught, typically less than 20 percent of I&E mortality of recreationally and commercially valuable species.

-Secondary economic impacts such as effects on marinas, bait sales, and property values have not been included.

-Losses of invertebrate species such as lobsters, mussels, crabs, and shrimp were not included, even though these include commercially valuable species.

-Effects on fish-eating (piscivorous) birds were not included.

-Current fishing mortality rates often reflect already-depleted fisheries, as for example in the case of winter flounder near the Brayton Point facility, one of the EBA case studies.

-Forage species, accounting for the predominant share of I&E losses, are poorly documented, and their full ecological value to the food web is not considered.

-Non-use benefits are estimated only for recreational users, not for the population as a whole.

-Thermal impact reductions are not accounted for in some options, such as replacement of once-through cooling with cooling towers. <FN 104>

In addition, another portion of the EBA, Case Study Chapter A11, re-examines the areas of incompleteness from a different perspective, focusing on the ecological services that are disrupted by I&E, but are not addressed by conventional valuation methods. As explained in the EBA, those omitted or undervalued services include:

-decreased numbers of ecological keystone, rare, or sensitive species;
-decreased numbers of popular species that are not fished, perhaps because the fishery is closed;
-decreased numbers of special status (e.g., threatened or endangered) species;
-increased numbers of exotic or disruptive species that compete well in the absence of species lost to I&E;
-disruption of ecological niches and ecological strategies used by aquatic species;
-disruption of organic carbon and nutrient transfer through the food web;
-disruption of energy transfer through the food web;
-decreased local biodiversity;
-disruption of predator-prey relationships…
-disruption of age class structures of species;
-disruption of natural selection processes;
-disruption of public uses other than fishing, such as diving, boating, and birding; and
-disruption of public satisfaction with a healthy ecosystem. <FN 105>

In addition to these admissions by EPA, the scientists at Pisces have identified other areas of undervaluation in EPA's benefits analysis. These issues are explained in the Pisces Phase II Report and in Part IV of these comments, below. The lists of omissions and underestimates presented here clearly demonstrate the incompleteness of the benefits analysis in this case. Complete costs are being compared to a limited subset of benefits, causing environmental protection to appear as though it is not cost effective, when in fact it is. As Dr. Ackerman explains, "All that can be concluded from this misleading, incomplete comparison is that true, complete benefits must be larger, and net social benefits larger as well, for each of the various options under consideration." <FN 106>

EPA Response

The Riverkeeper, Dr Ackerman, and other commenters have asserted that EPA's analysis of the benefits of reduced cooling water intake is seriously incomplete, and can be considered as no more than an extreme lower bound on the complete benefits. Commenters also asserted that the cost-benefit analysis is designed to weigh the relevant costs of a proposal against the corresponding benefits, and that this process cannot yield a meaningful result unless the calculations of costs and benefits are both complete. These commenters go on to say that EPA has produced a comparison of complete costs and incomplete benefits in this case. They assert the costs of reducing the impacts of cooling water intake are monetary costs for marketed goods and services, such as production and installation of screens, cooling towers, and other equipment, and as a result there are no categories of costs which are intrinsically difficult to express in monetary terms.

These commenters further assert that the benefits of reducing cooling water intake consists of reduced damage to aquatic ecosystems that is difficult to measure and monetize; EPA focuses on valuing the benefits of killing fewer fish, which is itself a complex problem; market prices are available only for a few commercially valuable fish species; commercial prices do not capture all the value of avoided fish mortality; avoided fish kills are not the only significant benefits of reduced ecosystem damages; and that many other organisms and environmental services are also affected. The commenter then goes on to assert EPA's list of categories of benefits omitted from the Phase II Proposal and the reasons why the environmental impacts of cooling water intake structures the benefits of regulating them have been significantly underestimated published in the preamble and supporting documents

These commenters assert that there are other areas of undervaluation in EPA's benefits analysis identified by commenters that EPA did not specifically list, and use these points to detail the incompleteness of EPA's analysis again pointing out that the benefits analysis is incomplete, especially in contrast to the completeness of the costs.

EPA agrees with the commenters that the benefit estimates are less complete than the cost estimates and that it is far more difficult to estimate benefits than it is to estimate costs because of the lack of scientific understanding of ecosystem benefits, the valuation tools available for estimating benefits, and the lack of a complete measurement of the losses. EPA provided a detailed discussion of many of the analysis shortcomings in the preamble for the proposal, the NODA, and in the documents accompanying the rule.

EPA agrees that the benefits have been omitted from the 316(b) Phase II benefits analysis, as well as from EPA's list of why the environmental impacts of cooling water intake structures and the benefits of regulating them have been significantly underestimated:

· Facility-provided monitoring data, the basis for EPA's analysis, typically focus on only a subset of the species impacted by impingement and entrainment (I&E), thus underestimating total losses.
· Monitoring data often pertain to conditions existing many years ago, before the Clean Water Act had improved aquatic conditions; if the numbers and diversity of fish were depressed by degraded water quality, estimates of I&E losses would be similarly low.
· Cumulative impacts of multiple facilities on the same fish population are often important, but have been considered only to a limited extent.
· Estimated recreational and commercial values include only the proportion of I&E losses that would have been caught, typically less than 20 percent of I&E mortality of recreationally and commercially valuable species.
· Secondary economic impacts such as effects on marinas, bait sales, and property values have not been included.
· Losses of invertebrate species such as lobsters, mussels, crabs, and shrimp were not included, even though these include commercially valuable species.
· Effects on fish-eating (piscivorous) birds were not included.
· Current fishing mortality rates often reflect already-depleted fisheries, as for example in the case of winter flounder near the Brayton Point facility, one of the EBA case studies.
· Forage species, accounting for the predominant share of I&E losses, are poorly documented, and their full ecological value to the food web is not considered.

EPA also agrees with the following taken from Chapter A9 of the EPA Case Study document which says that omitted or undervalued services include:
· decreased numbers of ecological keystone, rare, or sensitive species;
· decreased numbers of popular species that are not fished, perhaps because the fishery is closed;
· decreased numbers of special status (e.g., threatened or endangered) species;
· increased numbers of exotic or disruptive species that compete well in the absence of species lost to I&E;
· disruption of ecological niches and ecological strategies used by aquatic species;
· disruption of organic carbon and nutrient transfer through the food web;
· disruption of energy transfer through the food web;
· decreased local biodiversity;
· disruption of predator-prey relationships;
· disruption of age class structures of species;
· disruption of natural selection processes;
· disruption of public uses other than fishing, such as diving, boating, and birding; and
· disruption of public satisfaction with a healthy
· Thermal impact reductions are not accounted for in some options, such as replacement of once-through cooling with cooling towers.

Even in light of this, however, EPA disagrees that the benefit-cost analysis prepared for the 316(b) regulation is "misleading, and useless." No methods are available for estimating either costs or benefits with perfect accuracy or without uncertainty. Therefore, informed decisions must be made with the best available information and analysis. EPA's approach to benefit cost analysis of the final Section 316(b) Phase II rule is consistent with principles outlined in the EPA's Guidelines for Preparing Economic Analyses, United States EPA (EPA 240-R-00-003, DCN #6-1931). The Agency believes that despite its limitations, the benefit-cost analysis prepared for the final 316(b) rule provides useful, significant, and sufficient information for rulemaking purposes. The Agency considered all of the relevant data in the § 316(b) rulemaking process.

EPA agrees with the commenter that EPA's use of the 50% rule at proposal meant that "Non-use benefits are estimated only for recreational users, not for the population as a whole." EPA agrees that both users and nonusers may have a nonuse value for a natural resource. In view of the unavoidable uncertainties in estimating non-use benefits for this rule, the Agency presented a qualitative assessment of the non-use benefits of the environmental protections at issue in the final 316(b) benefit cost analysis.

Define BTA as anything less than closed cycle

The Use of Cost-Benefit as the Decision-Making Criterion Violates the CWA and EO 12866 Because the Law Requires Minimization of Adverse Environmental Impact, Not Maximization of Economic Benefit.

As explained above, Clean Water Act Section 316(b) requires EPA to adopt section 301 and 306 standards (i.e., mandatory limitations to be included in NPDES permits) governing cooling water intake structures. Further, these standards must reflect best technology available to minimize adverse environmental impact. This is the approach mandated by the relevant statutory authority.

In contravention of that statutory authority EPA, at the behest of OIRA, used the "maximize net benefits" approach instead of the statutorily-mandated approach. It is apparent that this was the approach used, because EPA rejected an alternative option (Federal Register Option 3 / EBA Options 1 and 2) even though it reduced impacts to a greater degree than the proposed option and was cost-effective, i.e,, benefits outweighed costs by a 3:2 margin, yielding net benefits of $255 million. <FN 107> EPA's stated rationale for rejecting this option was as follows:

EPA notes that the incremental costs of this option relative to the proposed option ($413 million) significantly outweigh the incremental benefits ($146 million). <FN 108>

Put another way, EPA chose the proposed option because it had greater net benefits (using EPA's flawed calculations) that the waterbody/capacity based closed-cycle option. This is the maximize net benefits approach.

Furthermore, it is clear that EPA adopted that approach because OIRA insisted upon it. The record clearly demonstrates that EPA had intended to propose the waterbody/capacity based closed-cycle option (Federal Register Option 3 / EBA Options 1 and 2), but was prevented from doing so by OIRA. <FN 109>

The fact the OIRA would seek to apply a "maximize net benefits" approach is perhaps not surprising since OIRA acts pursuant to Executive Order 12866, which refers to such an approach in its "Statement of Regulatory Philosophy and Principles." However, what this section of the Executive Order says is:

In choosing among alternative regulatory approaches, agencies should select those approaches that maximize net benefits (including potential economic, environmental, public health and safety, and other advantages; distributive impacts and equity), unless a statute requires another regulatory approach. <FN 110>

In this case, the statute clearly requires another regulatory approach. As explained in great detail in Part II, above, the Clean Water Act requires the imposition of a series of increasingly-stringent, technology-based controls to ratchet down water quality impairments as close to zero as possible. Costs play a minor role in EPA's best technology determinations. In promulgating BTA standards, EPA must minimize adverse environmental impacts, and costs are only relevant to the determination of whether the technology that minimizes impacts is economically achievable, or wholly disproportionate to the benefit. Since that is the regulatory approach mandated by Congress in the Clean Water Act, the statute trumps the Executive Order and the maximize net benefits principle of the EO 12866 is – by its own terms – inapplicable to Section 316(b) regulations.

As a result, EPA has, at the direction of OIRA, violated not only the Clean Water Act, but the Executive Order as well.

Option 3--Site-specific determination

THE COMPLIANCE OPTIONS ARE ILLEGAL AND UNSOUND.

Despite describing the rule as a “national minimum … technology-based performance requirements,” <FN 112> EPA has failed to set a national minimum standard for technology or performance. Instead of setting a protective, technology-based standard, the rule would adopt and codify many of the site-specific arguments which permittees typically use to avoid closed-cycle cooling requirements. Since even environmentally sympathetic regulators lack the resources needed to rebut, or in most cases fully evaluate, these arguments, the Phase II Proposal will allow applicants to continue to obstruct and delay needed technology upgrades.

The two primary components of the rule that circumvent the purported technology standard are: (1) allowing applicants to attempt to replace fish they kill through “restoration measures” instead of installing technology to reduce or eliminate (i.e., minimize) the impact; and (3) Track III, which allows applicants to obtain both a site-specific BTA determination and more lenient requirements than the national standard.

RFC: Proposed use of restoration measures

Restoration Measures are Unreliable and Cannot Be Permitted In Lieu of Technology.

EPA is proposing to allow any and all in-scope facilities to use "restoration measures" in lieu of technology, whether they choose compliance option Track I (existing operation is BTA), Track II (existing plus proposed is BTA), or Track III (site-specific BTA determination). <FN 113> More specifically, the Phase II Proposal provides:

In lieu of, or in combination with, reducing impingement mortality and entrainment by implementing design and construction technologies or operational measures to comply with the performance standards specified in paragraph (b) of this section [for Tracks I and II] or the Director's determination pursuant to paragraph (c) of this section [for Track III], you may, with the Director's approval, employ restoration measures that will result in increases in fish and shellfish in the watershed. You must demonstrate to the director that you are maintaining fish and shellfish within the water body, including community structure and function, to a level comparable to those that would result if you were to employ design and construction technologies or operational measures… <FN 114>

While such measures may beneficial in compensating for past harms to the aquatic environment, they cannot be used as a substitute for dry cooling because they do not constitute best available technology for minimizing adverse environmental impact from cooling water intake structures, which is what Section 316(b) requires. Furthermore, restoration measures do not replace or compensate for the fish killed by cooling water intake structures.

Role of Restoration

Author Name Reed Super

Organization Riverkeeper

Restoration Measures are Unreliable and Do Not Replace the Fish Killed by CWIS's.

Restoring aquatic habitat for fish, wildlife, and plant species is generally a worthwhile and environmentally beneficial activity. Throughout the country, extremely large areas of aquatic habitat have been destroyed by development, primarily by filling open water and wetlands. Restoration measures, if successful, can provide some level of mitigation for such development activities. However, restoration measures, whether successful or not, cannot replace the fish killed by impingement and entrainment at power plants.

EPA Response

EPA agrees with the commenter that restoration of aquatic ecosystems is generally a worthwhile activity. EPA also agrees that restoration does not aid precisely those individual aquatic organisms killed by impingement and entrainment in cooling water intake structures. Instead, restoration measures under today's rule are required, through the production and increase of fish and shellfish in the same waterbody or watershed as the cooling water intake structure, to minimize or to help minimize the adverse environmental impacts that derive from impingement and entrainment of individual aquatic organisms by the cooling water intake structure. For additional discussion of the role of restoration in the final rule, see the preamble to the final rule.

Subject Matter Code 11.06

RFC: Performance/effectiveness of restoration

Habitat restoration measures have been employed most prominently in an attempt to mitigate impingement and entrainment at the Salem Nuclear Generating Station in New Jersey. It is therefore critically important to acknowledge that, as the Delaware Riverkeeper Network explains in its separately-submitted comments on this rule, the mitigation experiment occurring on the Delaware at Salem is failing. PSE&G has been unable to demonstrate that its restoration effort for the fish kills at its Salem plan is providing any benefit whatsoever to the fish populations of the Delaware estuary. Thus, it cannot demonstrate that the restoration measures are in any way minimizing the impingement and entrainment of over three billion Delaware River fish. Indeed, PSE&G cannot even demonstrate that if it were successful in eradicating and/or controlling phragmites, that this success would be sustainable without continuous intervening action. In fact, the primary result of PSE&G's mitigation proposal is that the Salem facility continues to kill over three billion Delaware River fish a year while PSE&G is now also harming thousands of acres of marshland by spraying it with glyphosate only to have the targeted phragmites return. There has been no minimization of adverse impact at Salem, as required by section 316(b).

Because the PSE&G restoration project at Salem is being held up as a national model for section 316(b) compliance, it is important to understand why restoration and cannot address the concerns that section 316(b) is intended to address – i.e. impingement and entrainment of fish. PSE&G's wetlands experiment involves restoring, enhancing and/or preserving 10,000 acres of what PSE&G characterizes as degraded wetlands. The majority of those wetlands are dominated by the phragmites plant; restoration efforts include herbicide application, mowing and prescribed burning in order to remove phragmites and replace it with spartina grasses. Some freshwater diked wetland are also being converted to salt marshes. The original argument supporting this program was that enhancement of these wetlands will increase fish production in the Delaware Estuary. PSE&G is, however, unable to demonstrate that their experiment, even if successful (which is doubtful at best), actually provides benefits to the estuary ecosystem. The numerous, fundamental problems with the restoration approach at Salem include the following:

PSE&G never provided scientific data indicating that food or habitat were limiting factors for the fish populations in the Delaware Estuary – and there is in fact no data or information that would indicate that this is in fact the case. Therefore, altering wetlands to increase food and habitat availability for fish is likely not to have any effect on fish populations in the estuary. <FN 115>

PSE&G's success criteria and evaluation methodology for its wetlands enhancement efforts do not include determining whether the fish populations of the River are benefiting from the wetlands restoration efforts. Instead their success criteria focus on change in vegetation coverage, algal productivity, macrophyte productivity, etc. <FN 116>

PSE&G has failed to demonstrate that even if it is successful at replacing the existing phragmites in these areas with other species of plants, that this change in vegetation is sustainable and will not be overrun by neighboring stands of phragmites within a matter of years. <FN 117>

PSE&G has failed to conduct the baseline data on the contributions of the phragmites stands to the food chain in order to make the necessary comparisons. It is very possible that the fish used the phragmites-dominated marshes in the same way and to the same degree as they would spartina-dominated marshes and therefore nothing has been truly gained by their efforts. <FN 118>

In fact, PSE&G's own data confirms, what other scientists have found, that phragmites-dominated marshes on the Delaware Bay contribute just as much basic nutrient material into the food web as spartina-dominated marshes. "As new data are generated, the general perception that regularly flooded phragmites marshes are less functional than the spartina marshes they replace does not appear to be upheld." <FN 119>

As a result, the Salem mitigation project, rather than being an example of why mitigation should be allowed, is actually a prime example of why it should not.

117 Id.

118 Id.

119 Id., citing Judith S. Weis, Habitat and Food Value of Phragmites australis and Spartina alterniflora flor Fiddler Crabs, Grass Shrimp, and Larval Mummichogs, printed in New Jersey Flows, Water Resoruces Institute, Vol. 1, No. 1, Fall 2000. That article explained: "Efforts to restore salt marsh areas by replacing the undesired Phragmites with the desired Spartina are often justified by the assumption that the productivity of animal populations will be enhanced. However, evidence from the studies reported here as well as those of others (e.g. Fell et al., 1998; Wainright et al., 2000) does not support the general assumption that Phragmites leaf detritus is of poorer nutritional quality for estuarine consumers than that of Spartina." Phragmites is native to North America and has been found to be a component of Eastern U.S. marshes for 2000 to 4000 years at least. Multiple studies document that "Phragmites production is equivalent to the role of S. alterniflora production in the diet of key estuarine species" and that it is consumed by fish in the marsh. Phragmites has also been found beneficial in other ways with benefits beyond those provided by Spartina. For example they release less contaminants back into the environment than Spartina. "In comparison to a Spartina community, Phragmites enhances both mineral and organic decomposition, basically doubling the accretion potential of the marsh." "Phragmites function may actually exceed that of other wetland plants in ameliorating certain estuarine dilemmas like eutrophication and marsh loss." Rooth and Windham, Phragmites on Death Row: Is Biocontrol Really Warranted?, Wetland Journal, Vol, 12, No. 1, Winter 2000.

Comment ID 316bEFR.206.054

Author Name Reed Super

Organization Riverkeeper

Subject Matter Code 11.0

Role of Restoration

In the Pisces Phase II Report, the scientists at Pisces discuss habitat restoration projects at length. Pisces begins by noting that while creation of a salt-marsh may replace the destruction of a salt marsh, like-for-like restorations for impingement and entrainment are impossible on the community level. <FN 120> Further, with any restoration project, there is a considerable time-lag, between the original damage and the establishment of the new resource at its full potential. NOAA's Habitat Equivalency Analysis (HEA) states: "The principal concept underlying the method is that the public can be compensated for past losses of habitat resources through habitat replacement projects providing additional resources of the same type". (NOAA, 1995). Thus the origin of the restoration concept is to be as compensation for finite, existing, discrete and quantifiable losses, rather than justification for continuing and future loss. <FN 121>

Pisces also reviewed the data from the Salem restoration project, among others, and found as follows:

In summary, the project sought to replace lost productivity, rather than address losses at source of particular species, such as the bay anchovy. It is unclear whether the enhanced productivity in the restored saltmarsh will in fact move through the food web to increase the number of bay anchovy, and other pelagic spawning species. What is more, the increased productivity could favour other species less sensitive to impingement and entrainment than the anchovy, resulting in a change in the species balance and increased predation on the target species… [T]there is strong evidence that it does not, and was not intended to, fulfill its stated aim of equivalency with the losses at the Salem plant. <FN 122>

In addition, Pisces noted numerous other negative attributes of the Salem restoration project, including:

-Any 'new fish' that are produced by the converted saltwater wetlands will also increase the number of fish that will become impinged, entrained and killed by the power plant;

-PSE&G ignores the lost productivity of the destroyed freshwater marsh, which while as productive as a salt marsh, nevertheless provides important habitat for many species.

-The Salem Estuary Enhancement Program has had a negative impact on species, such as the horseshoe crab, which have dramatically declined since 1993. <FN 123>

In its report, Pisces also reviewed a recent power plant repermitting proceeding in Morro Bay on the California coast in which California Energy Commission rejected habitat enhancement measures in large part because it was unclear as to whether these enhancements would directly aid the species most affected by impingement and entrainment. <FN 124>

Pisces concluded that there are very serious limitations of habitat enhancement as a means of mitigation for entrainment and impingement, particularly:

-Habitat equivalency analysis is primarily aimed at offsetting past losses or damage, rather than continuing loss;

-Considerable uncertainty exists as to whether equivalence can be focused on actual species harmed;

-Potential lack of availability of sufficient habitat to adequately offset losses or damage. <FN 125>

The general availability of restoration measures renders the proposal's performance criteria ineffective because their effectiveness is typically doubtful and impossible to accurately estimate. Restoration simply cannot replace the aquatic organisms killed by power plants. By including restoration measures as a compliance option in lieu of technologies and operational measures, EPA would give a seal of approval (an EPA imprimatur), thereby misleading the state permit-writers, applicants, and the public into believing that these measures can be effective, when they are not.

EPA Response

For information on the uncertainties associated with restoration and on EPA's goals for restoration in the context of the final rule, see EPA's response to comment 316bEFR.206.055.

A Director may approve of a restoration measure if it meets the requirements in the final rule, including those in sections 125.94 and 125.95. Timing of a restoration measure's performance, availability of suitable habitat, and net ecological benefit for the purposes of restoration are factors, among others, that the permittee and the permitting authority should consider when considering a particular restoration measure (see 67 FR 17148).

Restoration measures in place of technologies

Restoration Measures Cannot Play A Role In BTA.

The uncertainty and high failure rate of restoration measures – in addition to their inability to replace fish killed by impingement and entrainment – not only makes their inclusion in this rule poor policy, it is also a violation of the Clean Water Act. BAT requirements can not be predicated on an experimental technology. [cite]. Rather, there must be at least one facility where the technology has been successfully employed. The same is true for BTA, which is substantially similar to BAT. In the case of restoration measures, EPA has no evidence of restoration measures having successfully replaced the fish killed by a power plant – certainly, there is no such evidence from Salem. As a result, restoration may not be a component of BTA

Furthermore, restoration measures cannot legally be a component of BTA because such measures, such as fish hatcheries, fish restocking programs, removal of impediments to fish migration, and the enhancement or creation of wetlands are wholly unrelated to cooling water intake structures cannot be used to fulfill the requirements of section 316(b). Section 316(b) mandates that the location, design, construction and capacity of cooling water intake structures must reflect the best technology available. Restoration measures are not related to location, design, construction or capacity of cooling water intake structures, and therefore cannot be a component of BTA. Rather these measures, when proposed in the section 316(b) context, seek to allow facilities to continue to indiscriminately kill life rather than make attempts to curb, or stop, the damage they are inflicting. As a result, they violate the mandates of section 316(b) of the Clean Water Act.

While restoration cannot play a role in meeting the requirements of section 316(b) – it may be required in addition to 316(b) technology requirements in order to remediate for the past damage inflicted by facilities' CWIS'. For many years existing facilities with CWIS' have been indiscriminately killing fish. Requiring remediation to make up for these historical impacts is justified but it does not fulfill 316(b)'s technology requirements.

EPA Response

EPA agrees with the commenter that restoration measures can entail a number of uncertainties (see discussions at 67 FR 17146-17148 and 68 FR 13541-13543). EPA also acknowledges that, historically, performance of restoration projects in general has been mixed (see, e.g., Upstream: Salmon and Society in the Pacific Northwest, National Research Council, DCN 5-4068-R1 and Compensating for Wetland Losses under the Clean Water Act, National Research Council, DCN 4-4020). The requirements for restoration projects in the final rule are intended to lessen the uncertainties of restoration projects and enhance their performance.

EPA also agrees with the commenter that restoration measures do not prevent impingement and entrainment of individual fish. However, the goal of restoration measures under today's rule is not to reduce impingement and entrainment, but rather to produce and increase fish and shellfish in the impacted waterbody or watershed and in this way minimize the adverse environmental impact caused by the cooling water intake structure.

In addition, in the final rule, restoration projects need not address the same species impacted by the cooling water intake structure, i.e. be “in-kind” restoration. Permittees may pursue “out-of-kind” restoration measures, with the approval of the permitting authority, which address organisms of species other than those impacted by the cooling water intake structure. The Director may approve out-of-kind restoration so long as the permittee can demonstrate that the ecological benefits are substantially similar to or greater than the benefits from in-kind restoration. Multi-agency watershed restoration plans, site-specific peer-reviewed studies, and/or consultation and concurrence of appropriate federal, state, and tribal natural resource agencies must be part of the basis for this demonstration.

For a discussion of EPA’s authority to include restoration measures as a compliance option in today’s rule, see the preamble to the final rule. For discussions of restoration measures as an aspect of cooling water intake structure design, see the preamble to the final rule.

The commenter’s suggestion that restoration measures be used to remediate past damage is outside the scope of today’s rule, which concerns minimizing the impacts associated with the present and future operation of cooling water intake structures.

Author Name Reed Super

Organization Riverkeeper

Subject Matter Code 2.04.03

Define BTA as anything less than closed cycle

The Track III Variances (Both Economic and Ecological) Are Unauthorized and Illegal.

The Phase II Proposal contains includes two separate variance from the performance standards. In the Track III compliance option, applicants may seek a site-specific determination of BTA requirements for a particular site. <FN 126> There are two ways to obtain a site-specific determination:

-by demonstrating that the facility's "costs of compliance with the applicable performance standards … would be significantly greater than the costs considered by the Administrator when establishing such performance standards" (the "economic variance"); or

-by demonstrating that the facility's "costs would be significantly greater than the benefits of complying with such performance standards" at the site (the "ecological variance"). <FN 127>

These two variances are unauthorized and their availability in a categorical BTA rule is illegal for several important reasons: (1) these variances unreasonably deviate from the cost test EPA has applied for 30 years of 316(b) permitting determinations; (2) the variances are unauthorized under the Clean Water Act which makes no provision for variances from BTA standards and only limited provision for variance from BAT standards; (3) the ecological variance requires the same kind of biased and inaccurate cost-benefit analysis that EPA used in determining the standard, but on a local level. If, despite its superior resources and a lengthy rule-making schedule, EPA could not come close to providing a full and accurate monetization of benefits (see Part III__, above), then state permit-writers will do an even more incomplete job with more limited resources and under the time pressure of a permitting proceeding; and (4) allowing permit standards for power plants to be determined on a site-by-site basis would allow industry to overwhelm state agencies and public intervenors with data that they will be hard-pressed to analyze, no less counter.

EPA Response

EPA disagrees. Today's rule in general, and the site-specific option in particular, will not impose a significant burden on states, tribes, local governments, environmental advocates, or the public. There is sufficient flexibility in the final rule that EPA expects facilities will use the site-specific compliance options infrequently.

Subject Matter Code 10.07.01
RFC: Appropriateness of "wholly disproportionate"

First, the variances unreasonably deviate from EPA's long-standing cost test. Even though section 316(b) contains no mention of compliance costs, EPA has always contended "that there should be some reasonable relationship between the cost of cooling water intake structure control and the environmental benefits associated with its use." <FN 128> Based on a statement by one Congressman in the 1972 legislative history, EPA has long interpreted BTA to mean "best technology available commercially at an economically practicable cost." In so doing, EPA claims to be implementing "congressional concern that the application of best technology available should not impose an impractical and unbearable burden." <FN 129> EPA has traditionally measured economic practicability by applying the "wholly disproportionate test" to compare the benefits of cooling water intake technology against marginal cost to the ratepayer, i.e., the incremental electricity cost. Under EPA's traditional wholly disproportionate cost test, a cooling water intake structure technology would not be deemed to reflect BTA if the incremental costs of requiring the use of that technology are wholly disproportionate to the environmental benefits to be gained through its use.

But in the Phase II Proposal, EPA departs from the wholly disproportionate test, and includes two far more lenient variances. Whereas the wholly disproportionate test would require a deviation from best technology available only where the compliance costs would be unconscionable or "shock the conscience," the new significantly greater than test is far more lenient. EPA has not demonstrated the requisite need rationale for this deviation. Certainly, no showing has been made that these variance are necessary to avoid an "impractical and unbearable burden" on industry. Rather, they improperly seek to minimize industry's compliance costs in contravention of the mandate to minimize environmental impacts.

Use cost-benefit tests

Author Name Reed Super

Organization Riverkeeper

Second, there is no statutory authority for variance from section 316(b) standards. Unlike BAT standards which have statutory variances in section 301(c) (economic variance to delay timetable) and section 301(n) (fundamentally different factors variance), Congress did not provide for a variance from BTA. Congress also did not provide for variance from section 306 new source performance standards. In that context, The United States Supreme Court in E.I. DuPont v. Train found unequivocally that the Clean Water Act does not allow a variance procedure for new sources:

It is clear that Congress intended these regulations to be absolute prohibitions. The use of the word "standards" implies as much. So does the description of the preferred standard as one "permitting no discharge of pollutants." It is "unlawful for any owner or operator of any new source to operate such source in violation of any standard applicable to such source." § 306(e). In striking contrast to § 301(c), there is no statutory provision for variances, and a variance provision would be inappropriate in a standard that was intended to insure national uniformity and "maximum feasible control" of new sources. <FN 130>

As with new source performance standards, no variance from BTA standards may be allowed, because EPA lacks the statutory authorization to do so.

RFC: Cost: benefit ratio for site-specific BTA?

Third, the ecological variance will require a cost-benefit analysis on the local level, which will undoubtedly be as incomplete, misleading and useless as the national cost-benefit analysis prepared for this rule, except that, as explained below, industry will likely be able to use it to its advantage.

EPA Response

Today's regulation specifies requirements for performing a benefits valuation study, which a facility seeking a site-specific determination of BTA based on cost-benefit considerations would need to provide to the Director. EPA believes that these requirements will help ensure that the site-specific benefit analyses are useful to the State Director.

Comment ID 316bEFR.206.060

Author Name Reed Super
Organization Riverkeeper

Subject Matter Code 10.07
RFC: Cost: benefit ratio for site-specific BTA?

Finally, site-specific BTA determinations will leave state agencies and interested citizens and groups at a significant disadvantage. In practice, it is at minimum a tremendous burden, and often impossible to review, comprehend, analyze and, where appropriate, refute, the enormous volume if information that applicants submit in support of their site-specific permitting demonstrations. In the absence of federal regulations, section 316(b) determinations have typically involved individualized ecological assessment and determination of best technology available for each proposed or renewed cooling water intake structure. This lack of categorical standards has resulted in uneven and conflicting regulation as well as enormous, unnecessary aquatic mortality, which runs contrary to the goals of the Clean Water Act and the direct mandate of section 316(b). The individualized assessments have typically relied on narrow and inaccurately applied population models, and have ignored other impacts on ecosystem health.

For 30 years, industry has used the threat of litigation and a variety of dubious interpretations of section 316(b) to avoid the imposition of BTA. A favorite strategy of industry is to threaten state permitting agencies with litigation in order to obtain a compromise settlement for limited mitigation or data gathering and study, rather than installing best technology. Even with extensive data collection, there has been continued disagreement among industry, permitting agencies, and environmental groups over ecological impacts.

The multiplicity of these individual determinations and the combination of ecological and mathematical/statistical expertise necessary to determine the complex population dynamics for individual species has granted industry a critical strategic advantage because of superior resources in these proceedings. This advantage is a key component in industry's strategy to avoid national technology based regulations. Industry's most common analytical tools in these individualized technical determinations are density-dependent models of fisheries populations. Cooling water users have for decades used arguments based on density-dependence to justify the destruction of large numbers of fish and crustaceans via impingement and entrainment at their CWISs. In many critical cases, mathematical models of density dependent compensation these models have been misapplied. As just one example, industry has misapplied commonly-used Ricker curves, originally developed for salmonid fisheries with intense competition for spawning space, is misapplied to the entrainment of other species which lack such intense competition. <FN 131> More fundamentally, typical compensation analysis relies on an ecologically baseless concept of "surplus production" which dismisses the ecological value of the tens of millions of fish which are a critical base of the food chain whether or not they grow to adulthood – even though their predators may be populated at far below their historic values.

Indeed, several state agencies commenting on the Phase I proposal , including New York, New Jersey and Michigan, cited the enormous burden they faced in trying to assess species and ecosystem effects caused by a particular power plant. The very purpose of categorical standards is to raise the technology determination to the federal level, and to produce national uniform technology standards that states will automatically apply, unless local water standards dictate inclusion of even stricter requirements. That is how Congress designed the Clean Water Act, and how it has functioned for 30 years. With the Phase II Proposal, EPA is attempting to rewrite the very core of the Nation's most fundamental water quality protection program. That misguided attempt will not survive judicial scrutiny.

Benefits of reduced intake capacity

Author Name Reed Super

Organization Riverkeeper

THE BENEFITS OF CLOSED-CYCLE COOLING FOR ALL IN-SCOPE FACILITIES MORE THAN JUSTIFY THE RETROFIT COSTS

As explained above in Part III, the Clean Water Act and Executive Order 12866 prohibit EPA from using cost-benefit analysis as the decision-making criterion for determining BTA standards. Nevertheless, a complete estimation of benefits would demonstrate that the monetary benefits of an all-cooling tower rule vastly exceed the costs. In his comments, Dr. Ackerman provides a more accurate, yet still conservative, estimate for just two of the dozens of areas that EPA admits it has undervalued benefits: non-use benefits and the value of fish not immediately landed by fisherman. The result of those two minor adjustments demonstrates that all of EPA's proposed options are cost-effective (i.e., benefits exceed costs), including the all cooling tower option (benefits exceed costs by $4.082 billion); the waterbody-flow-based cooling tower option (benefits exceed costs by at least $4.2 billion); and even the dry cooling option (benefits exceed costs by $7.728 billion). Notably, EPA's proposed option, which provides only 60 percent entrainment reduction, has the lowest net benefits ($3.764 billion). (See Part IV.A, below.)

Furthermore, there are a dozens of other aspects of the benefits analysis that EPA has undervalued or failed to value altogether. EPA has acknowledged many of these omissions in the preamble to the Phase II Proposal and in the EBA. In addition, as explained below and in the Pisces Phase II Report, there are myriad other significant shortcomings the benefits analysis, each resulting in an underestimation of benefits. The Pisces report demonstrates in worked examples how EPA could and should correct these omissions. Correcting for each of these undervalued aspects of the benefits analysis raises the benefits of each option, resulting in a further increase in the net benefits of the all cooling tower option. (See Part IV.B., below.)

In addition, because the costs of the cooling tower options are overstated, the net benefits of these options are actually larger, and the differential between them and the proposed option (which has no cooling towers) is even greater than adjustments to the benefits alone indicate. EPA should also make these appropriate downward adjustments to the compliance cost estimate for cooling towers. (See Part IV.C., below.)

Finally, the Habitat Replacement Cost (HRC) method of estimated benefits, which has drawn criticism from industry as overstating benefits, does in fact just the opposite. In light of the impossibility of quantifying and monetizing all the myriad, complex benefits of aquatic ecosystem protection, HRC provides a reasonable lower bound estimate of those benefits by measuring the cost to replace some, but not all of what is destroyed by power plants' cooling water intake structures. (See Part IV.D., below.)

Benefit Estimation Methodology

CORRECTING JUST TWO EVIDENT AREAS OF INCOMPLETENESS RAISES NET BENEFITS DRASTICALLY.

In his comments, Dr. Ackerman prepared an adjusted set of figures incorporating estimates of corrections to just two of EPA's many omissions and underestimates. <FN 132> Dr. Ackerman's first adjustment is for the underestimate of non-use benefits. As discussed above in Part III, EPA's estimation that non-use benefits would be only 0.5 times recreational benefits is based on extremely limited and outdated economic literature. <FN 133> Dr. Ackerman explains that a recent literature review finds that non-use benefits are on average 1.9 – 2.5 times all use values, rather than 0.5 times recreational benefits alone, as EPA assumed. Further, 1.9 – 2.5 times use value is still a conservative estimate for existence values of many natural ecosystems. <FN 134> To correct for EPA's underestimate in this area, Dr. Ackerman recalculated EPA's estimates assuming that non-use values are 2 times estimated recreational, commercial, and forage values. <FN 135>

Dr. Ackerman's second adjustment is for the unvalued fraction of the mortality of recreationally and commercially valuable species. EPA's methodology values only the fraction of those species that would have been caught in the absence of I&E mortality. That is, only the fraction of the fish that would have been caught are assigned any value; the rest are ignored, even though those same fish have the potential to be caught in subsequent years and to produce offspring which will yield increased catches in future years. The catch rate, or "landed fraction," is below 20% in every case, and below 10% in some cases. Thus, the great majority of impingement and entrainment mortality of the most valuable species is never valued.

The nonlanded fraction of these species – the ones that survive uncaught – have an obvious ecological, commercial, recreational and forage value. For one thing, most fish that are protected by CWIS technology, and that are not caught by fishermen, will still be available the next year to be caught fishermen in that year. These unlanded fish will not all disappear from the ecosystem, as EPA's models assume. Rather, many of them will be caught in future years, thus further increasing the commercial and recreational catch. <FN 136> Furthermore, these unlanded fish will reproduce, and their offspring is the source of the increased catch in future years. Since the fisheries in question are depressed (they are currently both fished and subjected to once-through cooling), the fish that are protected by CWIS technologies and not caught by fisherman will cause an increase in the population over time. Such increase will be larger than the first year increase attributable to the installation of a cooling tower, which after subtracting the nonlanded fish, is all that EPA has valued. <FN 137>

Unfortunately, EPA's available data do not presently allow for calculation of the present value of future reproduction of nonlanded fish; the calculation would be complex and would likely vary by species. Below in Part IV.B, we explain a worked example of such calculation prepared by Pisces. EPA should adopt such method for valuing the the unlanded species. But for present purposes, it is reasonable to assume that nonlanded fish have a value that is significantly greater than zero. Thus, Dr. Ackerman has conservatively assumed that nonlanded fish have a value equal to 0.25 times the value of landed fish of the same species. Dr. Ackerman's spreadsheet adjusts for the percentage reduction in losses achieved by each EBA policy option, calculating national baseline losses, and benefits of each policy option, replicating EPA's values when using EPA's assumptions.

Dr. Ackerman recalculated the spreadsheet three times: in Scenario A, keeping all EPA assumptions and input data, except assuming that non-use value is 2 times recreational, commercial and forage value; in Scenario B, restoring EPA's non-use assumption but assuming that nonlanded recreational and commercial fish are valued according to the above equation; and in Scenario C, combining my two assumptions. Dr. Ackerman's results, as shown in his Table 1, are as follows:

-Estimated benefits of each policy option are more than doubled in Scenario A, relative to the estimates in the EBA;

-Estimated benefits of each policy option are roughly doubled in Scenario B; and

-In Scenario C, combining the two adjustments, benefits of policy options are roughly 4-6 times the estimates in the EBA.

When compared to the costs of the policy options, as reported in the EBA, each of the three scenarios has significantly greater net social benefits. And, importantly, the order of policy options, ranked according to net social benefits, changes. EPA's EBA Option 5 – the dry cooling option – has the greatest net benefit in all three scenarios, as shown in Dr. Ackerman's Table 2. In Scenario C, combining the two adjustments, EPA's proposed option, i.e. EBA Option 3, is the one that fares worst. Options 1, 2, 3a, and 4 all have net benefits of $4.1 – $4.5 billion in Scenario C.

Because Dr. Ackerman's rough estimates of these two changes have such a large effect on the outcome of the analysis, EPA should explore both issues in greater detail. Specifically, as Dr. Ackerman recommends:

1. EPA should develop approaches to non-use value more consistent with the recent economic literature, to replace the outmoded "50% rule" used in the EBA; and

2. EPA should develop plausible values for the nonlanded fraction of I&E fish mortality. The one thing we know for certain is that the current estimate of zero is not the correct value. <FN 138>

The effect of such adjustments is far from trivial. They would show that all options in fact have large net benefits, and that EPA's incomplete valuation of benefits misleadingly favors the option that actually has the lowest net benefits. It is therefore critical that EPA carefully explore these corrections.

Footnotes

132 Ackerman Phase II Comments, Section 2.

133 Indeed, EPA has admitted that it understated non-use benefits. In the preamble to the Phase II Proposal it acknowledged:
-Nonuse benefits are most likely understated using the 50 percent rule because the recreational values used are likely to be understated.
-The 50 percent rule itself is conservative (e.g., only reflects any nonuse component of total value to recreational users. It does not reflect any nonuse benefits to recreational nonusers).
67 Fed. Reg. 17193.

134 Ackerman Phase II Comment at p. 6.

135 Id.

136 Of course, not all unlanded fish will return. To fully calculate this, one would have to factor in the average lifespan of the fish and average survival rates during the lifespan.

137 For a discussion of a method of calculating the worth of commercial species that are protected from impinged and entrained by cooling towers but not caught by fisherman in the first year, see Pisces Phase II Report, pp. 34-38, which is discussed below.

138 Ackerman Phase II Report at p. 8.

EPA Response

EPA agrees with the commenter that the proposed rule analysis does not include all possible benefits of CWIS, and that, therefore, the value of entrained and impinged fish to an ecosystem is likely to be underestimated. For EPA's response to comments that the Agency's benefit estimates are incomplete, please see response to comment #316bEFR.206.047.

As stated in the NODA, the rule-of-thumb approach to estimating non-use is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. Given the unavoidable uncertainties in estimating non-use benefits for this rule, the Agency presented a qualitative assessment of the benefits of the environmental protections at issue in the final 316(b) benefit cost analysis. This assessment addresses the non-landed portion of recreational and commercial fish. For a detailed response to the issue of valuing the non-landed fraction of fish please see EPA's response to comment #316bEFR.336.009.

The Agency, however, did explore several alternative non-use valuation methods to appreciate the potential magnitude of non-use values, including meta-analysis and the benefit transfer method. For detail see Chapters A12, Non-Use Meta-Analysis Methodology, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN #6-0003). EPA considered all the material together in making its final Section 316(b) policy determination.

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Benefit Estimation Methodology

MANY OTHER ADJUSTMENTS ARE REQUIRED AND WOULD FURTHER INCREASE THE TOTAL BENEFITS AND NET BENEFITS FOR ALL REGULATORY OPTIONS.

As explained in Part III, EPA's benefits analysis is drastically incomplete and undervalues the benefits of minimizing impingement and entrainment. While data limitations and other constraints make it difficult or impossible for us recalculate EPA's the entire benefits analysis (other than in the two areas addressed in Part IV.A, above), Pisces Conservation has begun that process. In their report, the scientists at Pisces have identified a number of areas – some in addition to those acknowledged by EPA – where the benefits analysis undervalues the resource. Further, they have illustrated how those errors could be corrected.

EPA Response

EPA agrees with the commenter that the proposed rule analysis does not include all possible benefits of CWIS, and that, therefore, the value of entrained and impinged fish to an ecosystem is likely to be underestimated. As stated in the NODA, EPA attempted to expand its analysis of non-use benefits categories for the final Section 316(b) Phase II rule analysis. However, given the unavoidable uncertainties in estimating non-use benefits for this rule, the Agency presented a qualitative assessment of the non-use benefits of the environmental protections at issue in the final 316(b) benefit cost analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN #6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Impacts to T&E species

Endangered Species Are Harmed and Killed By CWIS To A Far Greater Degree Than EPA Estimated.

In its benefits analysis, EPA has assumed that only two U.S. power plants (Pittsburg and Contra Costa in San Francisco Bay) out of a total of 550 in-scope facilities impinge or entrain endangered, threatened or otherwise special status species. That is, of course, patently wrong. Since power plants cooling water intake structures generally suck in a cross-section of all species present in the waterbody, any plant located near the habitat or range of a rare or special status species is likely to be impinging and/or entraining individuals of that species. As Pisces explains, "It should be assumed that all power plants situated on estuarine and coastal sites will impact to some degree threatened or endangered (T&E) species." <FN 139> Reliable data on the extent to which species are harmed and killed is not likely to be provided by the power industry for two primary reasons: first, because T&E species are, by definition, rare, they will appear in samples in much lower frequency than common species; and, second, there is a strong disincentive for plant operators to report the taking of T&E species, which may be prohibited by Federal and/or state law.

Nevertheless, it is clear that power plants do kill endangered species. As the Delaware Riverkeeper Network explains in its comments, endangered and threatened sea turtles and shortnose sturgeon are killed at Salem. Precise figures on these kills have not been provided, but they have been acknowledged and documented on the public record. A December 1998 report prepared by the National Marine Fisheries Service (NMFS) stated that Salem impacts the federally endangered shortnose sturgeon. While not a comprehensive tabulation of impacts, the report stated that 8 shortnose sturgeon were discovered in trash bars at Salem, and estimated that up to 11 shortnose sturgeon are impinged at Salem each year. Although there were no findings regarding entrainment, if adults are getting caught on trash racks it is highly likely that juveniles, and younger, are also getting killed there. Endangered and/or threatened sea turtles have also been injured and killed at Salem. The New Jersey permit record has information about the impacts to the federally threatened turtle populations injured and killed at Salem, and at one time required a turtle resuscitation program at that site. <FN 140>

There is also additional data concerning T&E species harmed and killed at other power plants. For example, the San Francisco Bay Delta estuary includes the following special status species:

1. Central Valley ESU steelhead - Oncorhynchus mykiss
2. Central Valley fall/late fall-run ESU Chinook salmon – Oncorhynchus tshwytscha
3. Central Valley spring-run ESU Chinook salmon – Oncorhynchus tshwytscha
4. Delta smelt – Hypomesus transpacificus
5. Green sturgeon – Acipenser medirostris
6. Longfin smelt – Spirinchus thaleichthys
7. Sacramento River winter-run ESU Chinook salmon – Oncorhynchus tshwytscha
8. Sacramento splittail – Pogonichthys macrolepidotus <FN 141>

These species are vulnerable to I&E at many Bay and Delta power plants in addition to the Pittsburg and Contra Costa plants.

In Morro Bay, California, an April 2002 staff report of the California Energy Commission noted that the estuary used for cooling water by Duke Energy's Morro Bay Generating Station is inhabited or potentially inhabited by the federally endangered tidewater goby (Eucycloglobius newberryi) and the steelhead trout (Oncorhyrnchus mykiss).

Lists of T&E species could be complied for almost all ocean and estuarine sites. For example, in the Hudson Estuary both shortnosed (Acipenser brevirostrum) and Atlantic sturgeon (Acipenser oxyrinchus) have been impinged on cooling water intakes. At many ocean and lower estuarine sites young turtles are potentially vulnerable to entrainment. At one power plant proposed for New York harbor, several turtle species were listed as potentially present, including:

1. Green sea turtle – Chelonia mydas
2. Loggerhead sea turtle – Caretta caretta
3. Leatherback - Dermochelys coriacea
4. Kemp's ridley turtle – Lepidochelys kempii
5. Hawksbill – Eretmochelys imbricata <FN 142>

Importantly, as Pisces notes in its report, as conservation measures for species such as sturgeons and turtles are successful, populations rise, resulting in extended ranges and the risk of higher impingement in future years. Thus, the fact that EPA is using old impingement and entrainment data reflecting the poorer water quality conditions of decades past has likely depressed the reported numbers of threatened and endangered species at power plants.

As a result, EPA's implicit assumption that T&E species are killed only at the Pittsburg and Contra Costa plants is wholly unsupportable, with the result that the benefits analysis is falsely skewed downwards. EPA should collect all available data concerning impingement and entrainment of endangered species, and collect all data of T&E ranges in the waters where in-scope facilities are located, and revise its benefits analysis to account for impacts to T&E species at the majority of the 550 in-scope facilities.

Footnotes

139 Pisces Phase II Report at p.62.

140 See August 5, 2002 comments of Delaware Riverkeeper Network.

141 Pisces Phase II Report at p 62.

142 With the exception of a few leatherbacks, most of the turtles in nearshore waters in the New York coastal region are small juveniles. The loggerhead is the most abundant, followed by the Kemp's Ridley. These two species, along with a few green turtles, move into harbours and estuarine waters, while the leatherback turtles remain along the coast and are rarely seen in embayments. Kemp's Ridley inhabits the shallower areas of Chesapeake Bay in search of blue crab, their preferred prey. Their preference for shallow waters and blue crabs makes the Kemp's Ridley the most likely sea turtle species to venture into the New York & New Jersey Harbor area. Similar lists would be produced for many east coast marine or lower estuarine power plants situated to the south of New York. Pisces Phase II Report at p. 63.

EPA Response

Please see the response to comment 316bEFR.077.008 and 316bEFR.077.053. The commenter is wrong to assert that EPA assumed that T&E species are lost to I&E only at the Pittsburg and Contra Costa facilities. Rather, EPA did a detailed analysis of T&E losses at these facilities to demonstrate the high value that is associated with such species. Unfortunately, EPA was unable to obtain impingement and entrainment data for T&E species at any of the other case study facilities, although it is known that sea turtles are lost at the Salem facility. In the case of Salem, the USFWS has not expressed concern about these losses and has issued an "incidental take" permit to the facility. Nonetheless, EPA is very concerned about impingement and entrainment of T&E species and spent considerable effort to compile information on the locations of listed marine, estuarine, and freshwater species and developed a methodology for evaluating such species. This information is presented in Chapter A13 of Part A of the Phase II Regional Study Document.

Methods to Evaluate I&E

EPA's Static Models Underestimate the Benefits of Minimizing Fish Kills.

EPA calculated the number of fish that would be protected from impingement and entrainment by the conversion to closed-cycle cooling. EPA then valued the commercial and recreational worth of those fish. For commercial fishing, it applied the traditional catch rate and valued only those fish that would be saved by a cooling tower, and then caught by a commercial fisherman. But all of the fish saved by the cooling tower have both ecological and monetary value. EPA's limited, static models do not however capture their value. As discussed above, Dr. Ackerman assigned those fish a value equal to 25 percent of the value of the landed fish. However, a more sophisticated method of valuing those fish is possible.

For step one of the analysis, assume that those fish are sterile and thus do not produce offspring. Although they escaped the fishermen in year one, the sterile, unlanded fish would still be in the waterbody in year two, year three, year four, and so on, up to the end of their lifespans, and would therefore be available to be caught by fisherman in those years. Thus, the available population would steadily increase during the lifespan of the species, at which point it would level off. EPA's static model assumes that the population increases only by the proportion of fish saved each year by the cooling tower, but it is clear that in a dynamic model, there are additional fish which will be landed, and therefore provide direct value simply because fish live much longer than one year.

For step two of the analysis, assume that the unlanded fish spawn, as they of course do. Because they are creating future generations of fish, the fish that are saved by a cooling tower and not landed by fishermen will during their lifespan, increase the population, thereby providing additional fish to be caught in subsequent years. Pisces has demonstrated with worked examples at Salem and Pilgrim a method for valuing these unlanded fish according to their reproductive value. At Salem alone, the commercial value of striped bass increased from about $56,000 per year to about $135,000 per year, which is a 141% increase. (See Pisces Phase II Report at p. 34-38.) Increases would be shown for all species at all plants, if EPA follows this method. EPA should recalculate its benefits analysis to take into account the value of fish that are not immediately landed and marketed.

EPA Response

Commenters have suggested that EPA's assessment of foregone fishery yield has neglected to account for the "reproductive value" of fish killed by I&E and has therefore underestimated net benefits. The concept of reproductive value refers to the notion that a fish killed prior to spawning represents not only a single death, but also the death of additional "potential" fish because, if the fish had not been killed, it would have spawned to produce additional fish.

This is similar to the financial concept of an interest-bearing account. That is, if a dollar is spent today, it is not simply a dollar spent, but also all of the interest that it might have accrued over time if it were saved in an interest-bearing account. According to this analogy, the spawning stock is like the principle in the bank account, and harvest is like the annual interest on the principle. However, unlike an interest-bearing account, a fish population cannot grow indefinitely because it is subject to a wide variety of biological constraints that prevent the population from growing without bound.

The commenter's example overstates the practical effect of reproductive value because it assumes that additional egg production will lead to proportional increases in the entire stock, that is, that stock size is density independent. Although EPA's analysis of foregone yield for the 316b Phase 2 rule did not include density dependent compensation or stock recruitment dynamics, EPA does not maintain that stock dynamics are, in fact, density independent.

The commenter's calculation of reproductive value also does not address the effects of the time lag between when fish are killed by I&E and when the potential additional harvest would be realized. Depending on species characteristics, the time lags involved could be many years because the expected time of realizing the reproductive value must be added to the expected time at which potential progeny would grow to harvestable age. The example cited by the commenter drastically overestimates the supposed bias because it implies that changes in the harvestable stock would be realized immediately.

For further discussion of fish population modeling in relation to the 316b rule, see EPA's response to Comment 316bEFR.005.009. Regarding compensation, please see response to Comment 316bEFR.025.015.

Cooling system costs (e.g., dry, wet, recirculating)

BECAUSE EPA HAS OVERSTATED COMPLIANCE COSTS FOR COOLING TOWERS, IT SHOULD MAKE APPROPRIATE DOWNWARD ADJUSTMENTS TO ITS ESTIMATES.

As also explained in Part III, EPA has significantly overstated the compliance costs of the closed-cycle cooling regulatory alternatives. In its comments on the proposed rule, Synapse Energy Economics describes a number of areas in which EPA must revise its cost estimates, including the following:

-EPA should annualize the capital costs of adding cooling towers over a longer period than 30 years to reflect the likely expected operating lives of those towers. <FN 143>

-Rather than using the baseline (i.e., once-through) system intake flow of affected plants to size the needed recirculating cooling towers and associated conduit systems, EPA should instead use Nuclear Regulatory Commission data indicating that "recirculating cooling systems have lower condenser flow to MW ratios than once-through systems, regardless of age or other characteristics" <FN 144> to properly size and cost the cooling system conversions. <FN 145>

-EPA should have used the cost of the more standard fiberglass reinforced plastic material for new cooling towers at existing fossil-fired facilities to calculate the capital costs of wet cooling towers, rather than redwood towers, as EPA has acknowledged that fiberglass has become "relatively standard" for new facility installations. <FN 146>

-EPA should revise its equations to more accurately reflect the actual costs of building a cooling tower in light of the fact that the equations used by EPA to quantify the capital cost of a new cooling tower produce cost estimates that "in almost all cases" exceeded the actual project costs, sometimes by as much as 25 percent of the actual costs. <FN 147> In the alternative, if the EPA decides to continue to use these equations without revision, it should not apply a 20 percent "retrofit factor" when quantifying the cost of adding a cooling tower at an existing facility because the combined use of both the existing equations and the 20 percent retrofit factor leads to unreasonably high estimates for the capital costs of adding a new cooling tower at an existing facility. <FN 148>

-EPA should adjust the costs associated with condenser upgrades (which EPA assumed affected facilities would elect to undertake as part of cooling system conversions from once-through to recirculating systems) in order to reflect reductions in O&M costs. Such O&M cost reductions can be expected from upgrading to the new materials which are less susceptible to failure and should lead to fewer tube leaks and, consequently, lower repair and repair outage-related costs. <FN 149>

-EPA should have used a range of lengths of concrete-lined steel piping for cooling water make-up water and blowdown that is more typical of existing facilities instead of using a range that might only apply to a limited number of plants. <FN 150>

-EPA should cost out all applicable compliance strategies – several of these compliance strategies are likely to be less costly than the strategies for which the EPA has developed costs – in order to develop an accurate assessment of each option's costs. <FN 151>

-EPA should reflect the repowering of coal-fired facilities to combined-cycle technology – at least 15 if which have recently occurred or are planned – because the costs of complying with any of these options would be lower for a repowered facility than for the original coal-fired plant.

-EPA should adjust its energy penalty calculations in accordance with the detailed explanations provided by Synapse. <FN 152>

Furthermore, EPA should also adjust its compliance costs to account for the fact that the costs of regulation are always overestimated in advance of their implementation. Once adopted, regulations encourage new technologies and more efficient ways of complying. Once study found that 92 percent of the time (11 out of 12 cases) costs estimated in advance of regulation were more than twice actual costs. <FN 153> Another study found that advance cost estimates were higher than actual costs 50 percent of the time, and below actual costs only 11% of the time. <FN 154> Most strikingly, before the 1990 Clean Air Act Amendments, industry anticipated that sulfur reduction measures would cost $1,500 per ton. In 2000, the actual cost was less then $150 per ton, a 90 percent decrease. <FN 155> In the present case, once cooling tower retrofits become more frequent, market factors and competition will drive the costs down. EPA's cost figures should reflect that fact.

And finally, EPA's compliance cost estimates should be adjusted to reflect the likelihood that older fossil-fired facilities will be repowered instead of retired as a result a closed-cycle retrofit mandate. Two facilities in New York State (Reliant Astoria Repowering Project and the Bethlehem Energy Center) have recently sought to significantly upgrade their plants by retrofitting closed-cycle cooling at the same time that they convert to combined-cycle natural gas technology. These plants, and others around the Country, are evidence that firms will seek to repower older, less efficient generating facilities and that such repowerings can include cooling towers as part of the repowered facility in place of once-through cooling. Such projects will provide significant environmental benefits in terms of reduced water usage and lowered air emissions and will offer substantial economic benefits for their owners. It is reasonable to assume that at least some plants will respond to a cooling tower regulation in such manner, and their costs would decrease as a result of the increased efficiency and reduced cooling water needs from combined-cycle technology.

By making these adjustments, EPA would come closer to estimating the true costs and true net benefits of the closed-cycle alternatives.

Use of Replacement Costs (HRC and hatchery-based)

THE HABITAT REPLACEMENT COST METHOD OF VALUATION PROVIDES A REASONABLE LOWER BOUND ESTIMATE OF MONETARY BENEFITS.

In several of its case studies, EPA uses calculations of habitat-based replacement cost (HRC) to value the benefits of the regulatory alternatives. Use of the HRC method is based on the following rationale: Natural ecosystems produce numerous interrelated benefits, some of which are difficult or impossible to quantify, as EPA has admitted in the preamble and EBA. Thus, given the constraints of time, resources, data and human ability to quantify complex systems, a simpler approach is to calculate – to the extent possible – the replacement cost of the ecosystem that provides the benefits. <FN 156>

As Dr. Ackerman explains in his report, restoration cost is used as a measure of damages under the Comprehensive Environmental Response Compensation and Liability Act (CERCLA) for Superfund sites; under the National Marine Sanctuaries Act; and under the oil spill provisions of the Clean Water Act. Use of restoration costs was explicitly upheld in State of Ohio vs. US Dept of Interior, in which the U.S. Court of Appeals for the District of Columbia Circuit held in the CERCLA context:

Congress established a distinct preference for restoration cost as the measure of recovery in natural resources damage cases. <FN 157>

Insurance companies frequently value damages to property at estimated replacement cost. Valuation of assets at replacement cost is also a common practice in macroeconomics, where depreciation is routinely valued at replacement cost. For example, for a marketed asset, market value (as opposed to book value) is set at the current replacement cost. Such valuation is essential in understanding investments. Likewise, any detailed analysis of capital costs focuses on “economic depreciation”, or the replacement cost of consumed capital, as distinguished from accounting measures of depreciation based on book value or tax laws. <FN 158>

HRC valuations are often more expensive than other approaches to valuation. However, this is to be expected in light of the incompleteness of valuation when each particular service or benefit must be separately estimated. A separately evaluated list benefits might, if thorough and complete, show higher benefits than HRC because nature is generally more efficient in producing “ecosystem services” than artificial replacements can be, and because restoration cannot not completely restore what was destroyed. But since EPA’s itemization of benefits is utterly incomplete and significantly undervalues the benefits of cooling towers, HRC provides a closer approximation of true benefits.

Despite its limitations, HRC is valuable contribution to the process of valuation and provides a reasonable lower bound estimate of benefits. As a result, Dr. Ackerman recommends that EPA explore HRC valuation of additional sites, to broaden the data and analysis used in the estimates of benefits in this case. Specifically he recommends that EPA revise and expand the EBA Case Studies Chapter A11, explaining and supporting HRC calculations, discussing the theoretical basis for HRC, and identifying categories of ecosystem value that are not measured by any other techniques. <FN

159>

Footnotes

156 It is not possible to fully replace the aquatic organisms and ecosystem that are destroyed by impingement and entrainment at power plants. Attempts at “replacing” fish and other aspects of the environment may provide some benefit to some species, but cannot duplicate the natural systems which were destroyed, as the Pisces Phase II Report explains at pp. 48-60. As a result, HRC will not value 100% of the loss, but only some portion of it.

EPA Response

Please see the response to comments #316EFR.005.035 and #316EFR.029.113.

As noted in the response to comment #316EFR.005.035, the Agency no longer applies the HRC method as part of its benefits analysis for the 316b rule. The Agency agrees with many comments received that, in general, "costs" should not be confused for "values." However, EPA also notes that there are many instances in which cost-based information can provide useful insights to policy makers, and that under suitable circumstances, costs can be used as a proxy for (i.e., in lieu of) more desirable but less accessible "value" information. For example, cost-based data may be viewed as an indication of “value” where the costs are borne voluntarily by the individuals involved, or in cases where public policies reflect a broad consensus based on continuous input from the general public and the broad array of interested parties (especially where an adaptive management approach enables adjustments over time in what actions are taken and what costs are incurred).

Please also see the discussion of ecosystem services and values in Chapter A9 of the Regional Studies Document prepared for the final rule (DCN #6-0003).

Option 3--Site-specific determination

THE ALTERNATIVE SITE-SPECIFIC APPROACHES TO DEFINING BTA WOULD UNFAIRLY BURDEN THE PUBLIC AND WOULD CONTRAVENE THE CLEAN WATER ACT.

In the preamble to the Phase II Proposal, EPA requested comment on several site-specific regulatory alternative approaches for determining BTA. These alternative approaches operate on an even more case-by-case and site-specific basis than the Phase II Proposal, which has one site-specific compliance option, Track III. Four site-specific approaches are described in the preamble: an EPA-developed "sample site-specific rule," complete with proposed regulatory text; a site-specific alternative based on EPA's 1977 draft guidance; a regulatory approach suggested by the Utility Water Act Group (UWAG); and a regulatory approach suggested by the Public Service Electric and Gas (PSEG). <FN 160> Each of these approaches contravenes both the letter and the spirit of the Clean Water Act and should be given no further consideration by the Agency.

Require closed cycle cooling

EPA states that the site-specific approaches “would be based on the view that the location of each power plant and the associated intake structure design, construction, and capacity are unique, and that the optimal combination of measures to reflect [BTA] for minimizing [AEI] must be determined on a case-by-case basis.” <FN 161> But this is clearly wrong. Almost without exception, impacts from cooling water intake structures are reduced by between one and two orders of magnitude by conversion from once-through to closed-cycle cooling. While other additional measures may be appropriate based on location, adverse environmental impacts cannot be minimized without closed-cycle cooling, and thus cooling towers must be required unless they are wholly disproportionate to the benefits (e.g., the highly unusual circumstance where a plant is located in a waterbody that has no fish).

Subject Matter Code 17.06

Option: Site-specific determination of BTA

Any site-specific approach would favor industry stakeholders and present an unreasonable burden on environmentalists and local officials. As EPA correctly recognized in its Phase I preamble:

The historical case-by-case approach requires significant resources on the part of the regulatory authorities that must implement section 316(b) requirement. [It] requires that each regulated facility must develop, submit, and refine studies that characterize or estimate potential adverse environmental impact. Such studies can take several years to complete and require the support of a multi-disciplinary team. In addition, given the iterative nature of the assessment process, industry as well as EPA regional and State regulatory authorities must expend significant resources assessing study plans and methods for characterizing the environmental impact occurring at each facility and evaluating those data to determine what constitutes BTA for each specific facility. <FN 162>

EPA actually understates the burden. Public commenters and intervenors have few resources to evaluate even the initial multi-disciplinary impact studies and volumes of technical supporting documents regarding CWIS characteristics and ecosystem impacts, let alone the months or years of hearings typically needed to adjudicate scientific disputes. Local officials and environmental advocates whose resources are dwarfed by those of industry should not be forced to counter industry's elaborate and self-serving technical obfuscation on generally applicable protection principles.

Footnotes

162 65 Fed. Reg. at 49079.

EPA Response

EPA disagrees that a large percentage of facilities will opt for a site-specific determination of BTA. Please refer to the response to comment 316bEFR.202.002 for more information.

Comment ID 316bEFR.206.071

Author Name Reed Super
Organization Riverkeeper

Subject Matter Code 2.04.05
Implement a site-specific alternative

Any approach that does not set specific national, uniform performance standards for the critical determination of capacity minimization would also violate the Clean Water Act. By leaving the BTA determination to the NPDES permit writer (state agencies in delegated states and EPA regional offices in non-delegated states), EPA would have abdicated its non-discretionary duty under Section 316(b) to set national BTA standards for generally applicable impact minimization parameters. Local agencies could require different technologies based on a variety of considerations outside the Clean Water Act, or could be forced to do so by the resources of industry applicants. The result of this approach would inevitably be that different facilities and states would have different BTA requirements for CWISs, thus ensuring inconsistent protection and potentially even reviving the "race to the bottom." To avoid creating a disincentive to power generators in a deregulated energy environment, or to avert fears of increased energy costs, states might be even more reluctant to establish stringent measures than they were in the pre-1972 context.

EPA Response

In today's rule, EPA explicitly provides that under section 510 of the CWA nothing in the rule precludes or denies the right of a state or political subdivision of a state or an interstate agency to adopt or enforce any requirement with respect to control or abatement of pollution that is not less stringent than those required by Federal law.

Subject Matter Code 2.04.02

Apply 316(b) before a det. of impact/AEI

Furthermore, the approaches suggested by industry would require the agency to define the phrase "adverse environmental impact" in section 316(b). The basic purpose of such a definition would be to require a determination of adverse environmental impact as a threshold before a permitting agency would even consider mandating BTA. Industry is trying to create an additional procedural hurdle to the regulation of cooling water intake structures, by requiring that a proposed CWIS attain a threshold of adverse impact before best technology can be required. That approach, however, is wholly unnecessary and inconsistent with the language of Section 316(b) and the structure of the Clean Water Act. <FN 163> The only threshold requirements for application of Section 316(b) standards are that facilities include a point source (which is a NPDES permit prerequisite), must be in an industry subject to Section 301 and 306 standards (which includes all significant users of cooling water), and must have a cooling water intake structure.

At the very least, determination of AEI as a threshold to regulation provides for months or years of delay, consuming the resources of agencies and intervenors alike, and in the case of existing facilities, unnecessarily continuing the slaughter of aquatic organisms. The New York State Department of Environmental Conservation ("DEC") has adopted the correct policy regarding adverse environmental impact as a regulatory threshold. DEC "considers the death of any fish at or through a cooling water intake to be an 'adverse impact.'" <FN 164> Like the NYS DEC, EPA should refuse to allocate public fish and wildlife resources to electric energy generators or other cooling water intakes. Congress drafted section 316(b) to minimize adverse impacts, and not merely to ensure the protection of a balanced, indigenous population as provided in section 316(a). In light of the Phase II Proposal's 50 MGD regulatory threshold (which assures that every in-scope facility will be one that causes adverse environmental impact) defining and determining the level of AEI should not create an unnecessary threshold to BTA regulation.

While it is not realistic to expect to save every fish, the killing of any aquatic life by cooling water intake structures is the adverse impact that EPA must minimize by requiring best available technology under section 316(b). Industries' proposed definition and threshold determination of AEI would complicate and delay this task.

Footnotes

163 For an in-depth discussion of why determination of AEI as a threshold to section 316(b) determination is both unnecessary and contravenes the Clean Water Act, see Minimizing adverse environmental impact: how murky the waters?, Super, R. W., and D. K. Gordon, pp 219-237 to be published in Defining and Assessing Adverse Environmental Impact, D. A. Dixon, J. Wisniewski, and J. A. Veil (Eds), 2002, (Swets & Zeitlinger and A. A. Balkema Publishers, The Netherlands).

164 New York State Department Of Environmental Conservation, Division Of Fish, Wildlife, and Marine Resources, "Clean Water Act Section 316(b), Statement provided to U.S. Environmental Protection Agency at June 29, 1998 public meeting to discuss adverse environmental impacts resulting from cooling water intake structures."

EPA Response

EPA disagrees. Today's rule in general, and the site-specific option in particular, will not impose a significant burden on states, tribes, local governments, environmental advocates, or the public. There is sufficient flexibility in the final rule that EPA expects facilities will use the site-specific compliance options infrequently.

Organization Riverkeeper

Subject Matter Code NEW
Comment on new (Phase I) facility rule

THE SEGMENTS OF THE REGULATORY COMMUNITY DEFERRED TO LATER PHASES OF THIS RULEMAKING SHOULD BE REGULATED BASED ON IMPACTS, NOT TIMING.

Pursuant to the Amended Consent Decree in Riverkeeper v. Whitman, EPA's section 316(b) rulemaking has been divided into three phases. In Phase I, EPA is required regulate all new facilities using a cooling water intake structure; Phase II must address all existing power plants above a threshold level; and Phase III captures the power plants below the Phase II threshold, as well as existing non-power plant facilities. EPA has, however, made at least two deviations from that tri-furcated scheme, by deferring regulation of certain segments of the regulated community to later phases. In both cases, EPA claimed the deferral was necessary because it lacked adequate information on the relevant industrial group during the earlier regulatory phase.

Specifically, in the Phase I NODA EPA stated that it had not considered or projected impacts on offshore and coastal oil and gas drilling facilities in its Phase I proposal. <FN 165> As a result, EPA considered not including these facilities within the scope of the Phase I rule, and instead addressing them within the scope of the Phase II or Phase III rulemaking. <FN 166> In the final Phase I Rule, EPA determined that it would "propose and take final action on regulations for new offshore and coastal oil and gas facilities, as defined at 40 CFR 435.10 and 40 CFR 435.40, in the Phase III section 316(b) rule." <FN 167>

In addition, in the Phase I rule, EPA attempted to define "new facility" more narrowly than the definition under Section 306:

Modifications to an existing cooling water intake structure that do not serve the cooling water needs of a greenfield or stand alone facility in 40 CFR 122.2 and 122.29(b)(1), (2), and (4) (i.e., a facility that meets the definition of new source or new discharger and commences construction after the effective date of the rule) do not constitute a new facility subject to this rule. Thus, the definition of new facility under this rule is narrower than the definition of new source under section 306 of the CWA. <FN 168>

EPA's intent in defining "new facility" for purposes of the Phase I scope was to exclude any facility built at a site where there is currently an existing operation devoted to the same industrial purpose, regardless of whether its industrial process are substantially independent of the existing facility at the same site. <FN 169> For example, adding a new electric-generating unit (whether peaking or not) at an existing power plant site would not be a new facility under Phase I, but would be an existing facility under Phase II, under EPA staff's interpretation. <FN 170>

As with oil and gas extraction facilities, EPA chose to delay the regulation of these new source facilities from Phase I to Phase II because it lacked information during the earlier rulemaking phase:

EPA generally deferred regulation of new sources constructed on a site at which an existing source is located (see 40 CFR 122.29(b)(3)) until the agency completes analysis of its survey data on existing facilities. <FN 171>

Thus, with both deferrals, EPA has not claimed that the relevant segment of the regulated community should be subject to the same regulations as the facilities in the later phase, only that their regulations should be promulgated at the same time as the regulations for the facilities in the later phases. But EPA has ignored this important point in the Phase II proposal.

The Phase II Proposal makes no distinction in its thresholds or standards between existing facilities and those facilities that are new sources under CWA Section 306 and were purportedly not included as new facilities under the Phase I rule. But such facilities, because they are actually new facilities and are substantially independent from industrial processes at the existing facility on the same site, have the flexibility to install the technologies required in the Phase I rule. EPA has not established why these facilities should instead be regulated like existing facilities. Now that EPA has the survey data it was waiting for, it should do one of two things in promulgating the Phase II rule: either (1) amend the definition of new facility in 40 CFR § 125.83 to make clear that such definition will be consistent with the new source definition under CWA section 306 with respect to substantially independent processes; or, (2) if these new source facilities are to be considered existing facilities for section 316(b) purposes, EPA should provide separate standards for them consistent with the new facility standards.

Similarly, in Phase III, when promulgating regulations for existing industrial and small power plant facilities, EPA should not subject new oil and gas extraction facilities to those same (likely, more lenient) regulations by default. Rather, EPA should either include new oil and gas extraction facilities in the definition of new facilities (and thereby subject them to the Phase I standards) or should provide separate appropriate standards for that industry. With respect to the environmental impacts of offshore oil rigs, it is clear that such structures act like artificial reefs and are therefore extremely effective at attracting fish, which would then be exposed to impingement and entrainment. <FN 172> Indeed, industry has claimed that their oil rigs make excellent fishing spots. Thus, stringent cooling water intake regulations are necessary to protect fish at these facilities.

Footnotes

165 66 Fed Reg. at 28856.

166 66 Fed. Reg. at 28857.

167 66 Fed. Reg. at 65311.

168 66 Fed. Reg. at 65259 (emphasis added).

169 Telephone conversation with EPA staff, January 31, 2002.

170 Id. Whether the codified text of the Phase I regulations actually accomplishes what the preamble and staff claim to have intended is far from certain. Reading the regulations alone, the definition of new facility at 40 CFR § 125.83 appears to be consistent with, not narrower than, the definition of new source under CWA Section 306 and 40 CFR 122.29 because the references and citations in the Phase I rule to "stand alone" and "greenfield" facilities (40 CFR 122.29(b)(1)(i),(ii), and (iii)) and the "substantially independent" test for stand-alone facilities have been incorporated into 40 CFR § 125.83.

171 66 Fed. Reg. at 65286.

172 See PISCES Consulting, Ltd., Comments on new data and approaches for the regulation of cooling water intake structures, prepared by Dr. P.A. Henderson, June 22, 2001 at p. 1.

EPA Response

The comments regarding the Phase I rule are outside the scope of this rulemaking and require no response.

EPA also disagrees with the commenter's characterization of the Phase I new facility definition. The definition of a "new facility" in the Phase I rule (40 CFR 125.83) includes stand-alone facilities, which are further defined as a new separate facility constructed on property where an existing facility is located and whose processes are substantially independent of the existing facility at the same site. Thus, a new unit that is substantially independent could be a new facility if it meets other applicable criteria. The example in the comment (new electric generating unit, peaking or not, would be a new facility if it was substantially independent of the existing facility or met the other criteria in the definition. EPA believes that the definition of a "new facility" in the Phase I rule is consistent with EPA regulations at 122.29, since the latter uses total replacement and substantial independence as key criteria. Given such consistency, EPA is not inclined to amend the definition of a "new facility" as part of this rule.

Organization Riverkeeper

Subject Matter Code 2.04.03

Define BTA as anything less than closed cycle

The integration of section 316(b)'s "best technology available" (BTA) requirement to minimize adverse environmental impacts with the effluent limitations under sections 301 and 306 indicates Congress's intent for national technology-based standards to control entrainment and impingement. EPA establishes industry-wide, nationally-uniform standards without regard to site-specific water parameters (such as receiving water quality) to govern the setting of individual NPDES permit limitations. Technology-based standards should bring all facilities up to state-of-the-art pollution control as quickly as possible (sometimes referred to as "technology forcing") and promote national consistency in NPDES permit limitations. <FN 27>

Congress chose the NPDES permitting program as the vehicle for minimizing adverse environmental impact by making the provisions of § 316(b) applicable to any facility containing a point source. <FN 28> Section 316(b)'s explicit cross-reference to sections 301 and 306 further clarifies that cooling water intake standards are an integral component of the NPDES technology-based regulations. Section 301 mandates the "best available technology" for existing sources while the section 306 new source performance standard must reflect the "best available demonstrated control technology." 33 U.S.C. §§ 1311(b)(2)(A), 1316(a)(1). Congress' use of substantially similar statutory language in Section 316(b) underscores its intent to incorporate that section's limitations into the categorical standards of sections 301 and 306:

[T]he regulations issued under § 316(b) are…closely related to the effluent limitations and new source performance standards of §§ 301 and 306… It bears emphasis that § 316(b)…requires § 301 and § 306 standards to deal with cooling water intake structures….[The] regulations [are] issued at least in part under the same statutory sections, some of which limit intake structures, others, effluent discharges. <FN 29>

Significantly, the Court in the VEPCO case contrasted the similarity between Section 316(b) standards and effluent limitations with the fundamentally different statutory scheme for water quality standards. <FN 30>

EPA may comply with its Section 316(b) mandate in one of two ways. One option is to implement Section 316(b) by including national performance standards for cooling water intake structures in each national, industry-specific Section 301 and 306 standard. The other option is to implement Section 316(b) with a free-standing, overarching regulation that would apply to all categories of point sources subject to Sections 301 and 306 that utilize cooling water intake structures. Either of these two options is permissible. <FN 31> EPA has chosen the latter.

But in either case, EPA's section 316(b) specifying BTA for minimizing adverse environmental impact must be national, technology-based regulations effluent limitations under sections 301 and 306. The statutory integration of these sections, along with the spare and direct "best technology available" mandate, clearly indicates Congressional intent that EPA set nationwide technology-based standards for cooling water intake structures in the same fashion as for discharges of chemical pollutants.

Footnotes

26 See 40 C.F.R Parts 402-699. In waters which violate ambient quality standards, a more restrictive set of limitations may apply. See 33 U.S.C.
§§ 1312, 1313, 40 C.F.R. Parts 130-131.

27 A primary objective of Congress in implementing nationally applicable standards was to avoid the "race to the bottom," which commonly occurred in the absence of uniform national effluent limitations prior to the adoption of the Act, where states would compete to attract and maintain industries by relaxing control requirements. See Hines, Controlling Industrial Water Pollution: Color the Problem Green, 9 B.C. Indus. and Comm. L. Rev. 553, 573 (1968); Grad, Treatise on Environmental Law, v.2, § 303[a-1].

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents. EPA has coordinated with OIRA in accordance with Executive Order 12866 and will complete any associated docketing requirements. EPA's final decisions with respect to this rule were made pursuant to, and consistent with the Clean Water Act. EPA has complied with all Administrative Procedure Act requirements regarding ex parte contacts during an informal rulemaking.

Source data used by EPA

Furthermore, the Phase II Proposal violates Section 1(b)(7) of Executive Order 12866 which states that the Agency "shall base its decisions on the best reasonably obtainable scientific, technical, economic, and other information…" because much of the biological data and economic literature (e.g., on non-use benefits) is decades out-of-date.

EPA Response

EPA disagrees that the Phase II rule violates Section 1(b)(7) of Executive Order 12866. A large number of relevant biological studies were conducted in the 1970s and 1980s as part of early 316(b) permitting. Since that time, EPA has made efforts to include more recent data where available and to assess data quality, as demonstrated by EPA's 316(b) Technology Efficacy Database. In response to the commenter's emphasis on the use of older biological studies being used to calculate non-use benefits, EPA has searched diligently to identify any relevant data, and has selected what it considers to be the best in this instance. Finally, the commenter offers no more recent data or indication that data or literature is incorrect just because it is dated. EPA believes that it is upholding the intent of Executive Order 12866, by developing a rule that will have the greatest benefit to cost ratio.

Methods to Evaluate I&E

Baseline Impingement and Entrainment Is Significantly Higher than EPA Has Estimated.

The first significant correction EPA should make is to considerably increase the baseline impingement and entrainment data. This is critical because EPA has quantified the number of fish saved by various technologies by multiplying an effectiveness factor. The resulting number of saved fish is then multiplied by the value of those fish so as to measure the monetary benefit of the fish saving technology. Putting aside for the moment the obvious problems (discussed in Part III above) of monetizing fish deaths avoided, it is clear that an accurate, current assessment of power plant fish kills is necessary as a starting point. But EPA's data significantly understates these fish kills and should be corrected in at least the following respects:

-EPA's I&E data is decades old, much of it from the 1970s and 1980s, even though fish populations, and therefore the numbers of fish impinged and entrained at power plants, has increased over and since that period of time, due largely to improving water conditions such as increased sewage treatment. EPA should increase the baseline I&E data to account for such increases, and predict future increases by extrapolating such trends into the future. (See Pisces Phase II Report at pp. 22-27.)

-EPA has failed to account for increases in flow at Salem and other similarly situated plants, even though the data clearly indicates that Salem has increased its intake flow in recent years and EPA has acknowledged that the currently larger flows are anticipated to continue. As a result, EPA should not use the average flow data or the corresponding I&E data at Salem (or at any other plant where an increase in flow is likely to continue). Rather, it should use the current and projected flow data, and the corresponding I&E totals. (See Pisces Phase II Report at pp. 2-7.)

-EPA assumed all fish impinged are age 1. In fact, fish are impinged at all ages. Older, larger fish are more valuable for two reasons. First, when landed by fisherman, they weigh more and therefore yield more revenue. Second, when not landed, they produce offspring which can increase the size of the population. An age 6 striped bass is much more fecund than an age 1 striped bass, and is therefore worth more biologically. As Pisces examples demonstrates, by assuming all fish are age 1, EPA has undervalued impingement by between one and two orders of magnitude. EPA should adjust the impingement data to take into account the actual age of fish impinged. (See Pisces Phase II Report at pp. 5-19.)

-EPA's survival rates, which are key variables used to estimate the total mortality as age 1 equivalent numbers, are most likely too low, as they are based on historical data when populations were badly suppressed by environmental damage and over-exploitation. Changing the survivorship figures used in the age 1-equivalent calculations can have a large effect on the numbers of age 1-equivalents estimated to be entrained or impinged. More reliable estimates of age-1-equivalence would be obtained by increasing survival rates by 25%. (See Pisces Phase II Report at pp. 20-21.)

EPA Response

EPA recognizes that abundances of aquatic species, and therefore the numbers of organisms vulnerable to I&E, may have increased, decreased, or stayed the same at particular sites since the time of the available I&E studies or life history data. Unfortunately, it is uncertain how old data can be adjusted to for any given facility reflect current conditions, particularly given the many variables that influence the growth of biological populations.

As is common practice for EPA's regulatory analyses, EPA is not concerned with projecting potential future conditions.

Few facility impingement and entrainment monitoring studies provide information on the age distribution of impinged fish. In EPA's original case studies, EPA assumed that all impinged fish were age 1. Based on comments on this assumption and a review of available information on the ages of impinged fish, EPA’s final analysis for the 316b Phase II rule assumed that impinged fish range in age from juvenile to age 5 and the age distribution of impinged fish is species specific and follows a fixed distribution as indicated by the set of stage-specific survival rates for each species. In all cases, this method leads to an assumed age distribution that is dominated by juvenile stages, followed by age 1-age 5 fish, each in decreasing relative abundance. Please see Chapter A5 of Part A of the Phase II Regional Study Document for additional details.

The commenter provides no biological data that would allow EPA to increase estimated I&E rates by 25%.

---National Pollutant Discharge Elimination System---
Regulations Addressing Cooling Water Intake Structures for Phase II Existing Facilities

(40 CFR Parts 9, 122, 123, 124, and 125)

Response to Comments Submitted by:

Alan E. Gaulke

On Behalf Of:

American Electric Power

Author ID Number:

316bEFR.207

Notes

EEI (316bEFR.072), EPRI (316bEFR.074), NEI (316bEFR.020), UWAG (316bEFR.041)

Comment ID 316bEFR.207.001

Author Name Alan E. Gaulke

Organization American Electric Power

Subject Matter Code SUP

General statement of support

AEP was pleased to see a number of positive features in the draft rule that should be retained in the final rule:

-EPA concluded that cooling towers are too expensive and should not be retrofitted to existing facilities,

-EPA has proposed intake technologies some of which are familiar to AEP and which AEP believes can likely be engineered to most existing cooling water intakes, if required,

-EPA considered the cost of technology and benefits to the environment, and

-EPA uses the concept that not all water bodies require the same level of protection.

EPA Response

EPA notes the comment. No response necessary.

Comment ID 316bEFR.207.002

Author Name Alan E. Gaulke

Organization American Electric Power

Subject Matter Code OPP

General Statement of Opposition

AEP believes the rule can be further improved by doing the following:

-Basing the impact assessment on a population or community-level,

-Using population modeling and fishery resource management tools to evaluate impingement and entrainment effects,

-Allowing the permit writer to conduct a more site-specific analysis to determine best technology available, and

-Correcting the numerous errors in the case studies' biological and economic analyses.

EPA Response

No response is required, as this comment summarizes the author's comments. Each issue is addressed individually in subsequent responses.

RFC: Use of previous demonstration studies

Previously approved Section 316(b) determinations should be allowed to stand

The final rule should include a provision that allows the regulatory authority to accept Section 316(b) determinations made prior to the current rule making. Permitting authorities in a number of states have already invested heavily in their own Section 316(b) implementation process. Some of those states developed their own 316 guidance manuals based on the draft EPA guidance manual (U.S. EPA, 1977) and others implemented Section 316(b) based on the site-specific guidance provided by EPA. Forcing these states to redo this work would be a waste of effort. Likewise, there would be an unnecessary duplication of effort by the owners of these facilities for which the best technology available determinations for intake structures have been made.

EPA may need to provide guidance to regulatory authorities on how to assess the existing Section 316(b) determinations. That guidance should include instructions on determining if the prior determination was scientifically sound and is still applicable to the intake structure and waterbody. For example, instructions and guidance should include advice on how to evaluate changes to the intake structure since the intake was approved best technology available, which could invalidate the earlier conclusion. Also, significant changes in the aquatic or marine community may require collection of additional biological data. Some prior Section 316(b) determinations may be valid as they are, some may need to be updated with current biological and engineering information, and others may need to be redone, in which case the state should be allowed the option of asking that the original study be redone or ask that the permit holder reapply for intake technology determination under the new rule.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule; however, existing data that is reflective of current conditions may be used to support the required studies. Please see response to comment 316bEFR.040.001 for details.

In addition, EPA plans to provide guidance on implementing the Phase II rule.

Comment ID 316bEFR.207.004

Author Name Alan E. Gaulke

Subject Matter Code 7.02

Performance standards

EPA should allow permit writers to accept intake modifications as Best Technology Available without requiring compliance monitoring

The proposed rule requires that all intakes achieve a reduction in impingement mortality and that some intakes reduce entrainment rates by amounts EPA claims are typical of reductions reported in the literature for the intake technologies listed in the proposed rule. EPA appears to have examined the literature in sufficient detail to establish a credible range of impingement mortality reductions and entrainment rate reductions achievable at many intakes.

AEP suggests that EPA allow the permit writer to accept an intake technology mutually agreeable to the permit writer and to the owner or operator of the intake structure as the condition of the permit. It would be agreed the intake modification when properly installed, operated, and maintained would achieve an acceptable level of impingement mortality or entrainment rate reduction. Compliance monitoring would be unnecessary. This would significantly reduce permit compliance costs and would reduce the permitting agency's burden. There are two reasons for AEP making this suggestion, at some intakes the owners best efforts will not achieve the range of reductions in mortality or entrainment rates and demonstrating a reduction in mortality or entrainment rates will be very difficult in many cases.

EPA Response

EPA disagrees that intake modifications should be acceptable without compliance monitoring. If the facility modifies its intake structure and reduces its flow commensurate with a close-cycle system, the facility can opt for compliance alternative 1, which does not have any comprehensive demonstration requirements. EPA has documented the relation between reduced flow and the resulting decreases in both impingement and entrainment. In other cases, the modifications made to an intake structure are not as assured of achieving the desired reductions in impingement and/or entrainment. For this reason, EPA believes compliance monitoring is warranted.

The Technology Installation and Operation Plan (TIOP) allows a facility to select a suite of design and construction technologies, operational measures, and/or restoration measures and request that the implementation of the TIOP be considered the means of determining compliance with today's rule. This option is available to the permittee with the approval of the Director.

Comment ID 316bEFR.207.005

Subject Matter Code 17.08

Option: UWAG's recommended approach

Author Name Alan E. Gaulke

Organization American Electric Power

Preferred approach to the rule

AEP recommends that EPA adopt either of the two utility approaches, which are described in Section III of the Utility Water Act Group (UWAG) comments ("Comments of the Utility Water Act Group on EPA's Proposed Section 316(b) Rule for Phase II Existing Facilities and ICR No. 2060.1"). UWAG's approach was shared with EPA directly and presented at workshops and public meetings during the Phase I and Phase II portions of the rule development. AEP prefers the UWAG approach to EPA's because the utility approach defines "adverse environmental impact" in terms of assessing impacts to the biota in the cooling source waterbody at the population or community level, and which uses principles of ecological risk assessments to determine the need for and the level of protection needed in order to have best technology available.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Comment ID 316bEFR.207.006

Author Name Alan E. Gaulke
Organization American Electric Power

Subject Matter Code 18.01

RFC: Definition of "adverse environmental impact"

AEP believes that "adverse environmental impact" must be defined in the final regulation (or at least EPA must define what adverse environmental impact is not) and that proper use of "adverse environmental impact" must be performed at the population-level.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

Comment ID 316bEFR.207.007

Author Name Alan E. Gaulke

Organization American Electric Power

Subject Matter Code SUP

General statement of support

EPA's approach has concepts and principles that make it a good starting point for a regulation that implements Section 316(b) as Congress apparently intended. It includes a strong commitment to select best technology available based on the concept that the cost of the technology bear some solid connection with the benefits to the environment. The draft rule contains a number of technical and procedural problems that need to be addressed before a workable and fair regulation can be issued in final form.

EPA Response

EPA believes today's final rule sufficiently addresses the concerns of the commenter. A more detailed discussion of the commenter's concerns can be found in the responses to comments 316bEFR.207.001-201.

Comment ID 316bEFR.207.008

Author Name Alan E. Gaulke

Organization American Electric Power

Subject Matter Code 17.03.02

RFC: EPA rationale to not require closed-cycle

EPA did not require cooling towers for intake technology

AEP agrees with EPA's conclusion that the cost of cooling towers compared with the benefits would not justify a cooling tower based standard. The estimated cost of retrofitting cooling towers to the four AEP-owned plants that were used for the Ohio River Case Study (Cardinal, Kammer, Sporn, and Tanners Creek Plants) would alone require a capital cost of $501,515,000 plus annual operation and maintenance costs (Appendix A).

EPA Response

EPA notes that the commenter's estimates of cooling tower retrofit costs at the four Ohio River facilities exceed those estimated by the Agency for the proposal and NODA. As such, these cost estimates serve to support and reinforce the Agency's decision to not base requirements of the final rule on closed-cycle cooling tower retrofits. See response to comment 316b.EFR.207.101.

Available I&E technologies

EPA has proposed effective intake technologies

AEP owns and operates facilities equipped with several of the intake technologies listed in the proposed rule, and is familiar with the literature reports of the effectiveness of those technologies not owned by AEP. These technologies can be cost effective approaches to reducing impingement and entrainment. EPA wisely opted to allow the facility owner and the permit writer to develop the intake technology that matches to site-specific conditions. There are likely to be site-specific limitations that will make one or more of the technologies too expensive or infeasible to use at some sites and feasible and cost effective to install at other sites. For example, the offshore intake at AEP's Donald C. Cook Nuclear Plant on Lake Michigan cannot be fitted with barrier nets. Barrier nets were evaluated during the original Section 316(b) evaluation of best technology available and rejected. The Tanners Creek Plant on the Ohio River could not be equipped with wedge-wire screen intakes. The volume of water used by this plant would require a large number of screen modules and this number of modules in the Ohio River could interfere with commercial and recreational navigation.

EPA Response

EPA appreciates the comment. Today's rule maintains the desired flexibility for facilities to determine the most cost-effective combination of design and construction technologies, operational measures, or restoration measures best suited to each individual facility.

Available I&E technologies

AEP encourages EPA to consider the value of behavioral barriers such as sound (which EPA mentioned once, FR 67(68): 17,142) center column), light, and physical barriers that function like behavioral barriers, angled bar racks. Behavioral barriers have advantages over physical barriers, but tend to be less well developed compared with physical barriers and may require site-specific development and fine-tuning.

EPA Response

EPA has evaluated available data on different behavioral barriers and included this discussion in Chapter 3 of the Technology Development Document (TDD). Behavioral barriers, where effective, are typically applicable to a small range of target species and must be deployed with caution.

General: cost tests

EPA correctly retains a cost benefit test in the rule

EPA correctly considers costs and benefits in the proposed rule. The draft guidance on 316(b) (U.S. EPA, 1977) had a provision that related the cost of the technology and the benefits such that the two were not wholly disproportionate. The proposed rule uses the term “significantly different.” AEP is uncertain how “wholly disproportionate” and “significantly different” compare. EPA should define “significantly different” to mean something close to a 1:1 ratio of cost to benefit to be consistent with economic principles.

EPA Response

The commenter fails to explain or document the “economic principles” it cites in order to support a 1:1 ratio of cost to benefit in the context of “significantly different."

See response to comment 316b.EFR.005.020 for the Agency's discussion of the economic principles related to maximizing net benefits.

For discussion of the definition of "significantly greater", see response to comment 316b.EFR.006.003.

Organization American Electric Power

Subject Matter Code 14.01
RFC: 5% threshold and supporting documents

Plants on rivers and entrainment reduction standards

EPA has proposed to require impingement mortality reductions at intakes on rivers where the intake flow is less than 5% of the mean annual river flow. AEP fully agrees with the concept that there is a level of effect below which there is little or no potential for adverse environmental impact. Five percent of the mean annual flow is a proportion of the river below which there is little or no potential for adverse environmental impacts except in unusual circumstances, for example, when endangered species are present and will potentially be impacted.

EPA Response

EPA notes the comment and agrees, in part, with the commenter's assertion regarding the 5% threshold for freshwater rivers and streams. EPA believes maintaining the 5% threshold for entrainment performance standards is appropriate due to the increased likelihood a facility may entrain significant numbers of non-motile organisms (primarily eggs and larvae) at these higher withdrawal levels. Impingement, while influenced by cooling water withdrawals, is less likely to be driven by higher percentage withdrawals than is entrainment. EPA believes the 5% threshold is not warranted for impingement.

Comment ID 316bEFR.207.013

Author Name Alan E. Gaulke

Organization American Electric Power

Subject Matter Code 14.02

RFC: Alt. thresholds for entrainment (E) controls

EPA should not only retain this provision in the final rule, they should seriously consider increasing the percentage to 10% or 15% of the mean annual flow OR 5% of the mean flow for the major spawning period, which would likely be from four (April through July) to six months (March through August) depending upon the river.

EPA Response

EPA believes adopting a seasonal flow based on spawning events would be difficult to incorporate into a permit as seasonal flows, as well as spawning and migration patterns, are rarely consistent year to year. Incorporating a seasonal flow (or other standard) into a permit would introduce unnecessary implementation and monitoring costs on both the permitting authority and the facility. EPA believes the design intake flow standard for riverine facilities affords a level of protection for the source water body acceptable under most, if not all, stream conditions. The 5% threshold provides a consistent metric against which permit requirements can be developed. Today's rule maintains the 5% mean annual flow threshold.

Increasing the percentage to 10% or 15%, as the commenter notes, would not minimize the entrainment impacts associated with cooling water intake structures.

Impacts of CWIS at ecosystem level (popn. vs. indiv.)

Individual vs. population-level affects

AEP urges EPA to adopt concepts of population-level effects or community-level impact assessment into the final rule. EPA presents a discussion regarding the loss of individual organisms and the potential effects those losses may have on the structure and function of the ecosystem (FR 67(68): 17,137, left-hand column). At the bottom of the left-hand column on page 17,137, EPA lists four possible ecosystem-level effects due to "[d]ecreased numbers aquatic organisms." (While "aquatic" generally means only freshwater, we presume EPA means fresh and salt-water organisms where it uses the term, aquatic.) Halfway down the middle column on page 17,137 reads as follows, "EPA believes that many cooling water intake structures have a significant negative impact on aquatic organisms at the individual level. The studies discussed below suggest that these individual-level impacts can lead to negative impacts at higher organizational levels." AEP is concerned that EPA is blurring the distinction between two fundamental ecological concepts. Individual-level effects are those that affect individual organisms and those affects are measured at the tissue and organ level within an individual organism. Examples of individual-level effects due to impingement may include descaling, abrasion, contusions, tissue damage from pressure changes, and other mechanical disruptions of tissues and organs that could occur due to an individual fish encountering a cooling water intake. These effects may or may not cause the death of that individual fish. Examining the environmental consequences of the loss of a number of individual organisms is a population-level effect, not an individual level effect.

EPA Response

Please see response to comment 316bEFR.207.015 for the discussion regarding impacts of cooling water intake structures at the individual versus population level. Please see response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define adverse environmental impact. Also, please see the response to comment 316bEFR.025.018.

EPA disagrees that the term aquatic generally means freshwater. Aquatic organisms are those growing or living in or frequenting water. In the citation provided by the author, EPA was referring to the Agency's concern regarding the loss of large numbers of organisms. The terminology confusing to this author has been removed from this section of the preamble to today's final rule.

Impacts of CWIS at ecosystem level (popn. vs. indiv.)

Determination of adverse environmental impacts at the population-level

The consequences of EPA's blurring the distinction between individual versus population-level effects is critical to the basis for EPA's justification of the approach they have taken in this rule and on the benefits EPA has estimated will result from implementing the rule as proposed.

EPA justifies rejecting the use of population-level impact assessment tools such as population modeling, stock recruitment models, and other fisheries resource management tools based partially on their assertion that impingement and entrainment affects are individual-level affects not population-level affects. EPA's interpretation of the difference between the two levels of impact analysis is best illustrated by their discussion in Chapter Al of Case Study Analysis for the Proposed Section 316(b) Phase II Existing Facilities Rule (U.S. EPA, 2002). On page A6-7 EPA states that the NPDES Permit program under Section 301(b)(1)(c) of the Clean Water Act is based on individual-level water quality criteria. EPA states that, "by evaluating the effects of pollutants on growth, reproduction and mortality of individuals, EPA uses individual impacts as surrogates and precursors of population and ecosystem impacts." The fact is that the statistical models that EPA uses to evaluate the toxicity test data used to develop the water quality criteria are models that analyze the variability of a subsample of the entire population's response to a pollutant. Lowest observable effects concentrations (LOEC) and no observable effects concentrations (NOEC), which are two examples of endpoints EPA calculates from laboratory toxicity data, are population-level endpoints and not individual-level endpoints as EPA claims. Likewise, LC5O, EC5O, and IC25 endpoints, which are endpoints commonly calculated from laboratory data used to derive water quality criteria, too are population-level affects. Thus, Section 301(b)(1)(c), the water quality control portion of the NPDES Permit program, is based on population-level effects analyses and are not just surrogates for population-level effects using individual-level effects analyses.

Section 316(b) too should be based on population-level effects just as the water quality standards implemented under Section 301(b)(1)(c) are. The water quality criteria are calculated to protect populations of species from effects that will prevent the population from thriving. Individual organisms all have a limited life span. Few if any will live for as long as a point source discharge, such as a sewage treatment plant outfall, will exist. Cooling water intakes are also likely to exist longer than the life span of most, if not all, aquatic and marine biota. Therefore, water quality criteria and NPDES Permit limits were developed based on population-level effects and population-level effects should be the organizational level used to regulate cooling water intake structures. EPA has not conducted a population-level impacts analysis for the proposed rule making. EPA can incorporate a population-level impact analysis by applying a number of well-established and accepted population modeling tools and fishery management tools to the-case studies and by incorporating the population-level analysis into the whole process of making the best technology available determination (EPRI, 1999).

EPA Response

Section 316(b) of the CWA intends to minimize adverse environmental impact of cooling water intake structures. The lifespan of cooling water intake structures in relation to aquatic and marine biota is irrelevant. Many anthropogenic activities work concurrently on the environment. It is extremely difficult to separate the effects of any one factor. Because so many factors can cause or alleviate stress on an ecosystem, the large number of organisms killed by cooling water intake structures may be causing ecosystem or population level effects even though they may not be detectable nor attributable to a particular cooling water intake structure.

EPA believes that it is reasonable to interpret the minimization of adverse environmental impact as minimizing both the loss of aquatic organisms due to impingement and entrainment and the environmental effects of such loss. The Agency has long maintained that adverse environmental impact from cooling water intake structures must be minimized to the fullest extent practicable. The objective of section 316(b) includes population effects but EPA does not view adverse environmental impact as limited to demonstrated community or population level effects. EPA has considered the consequences associated with the loss of large numbers of aquatic organisms, including impacts on the stocks of various species, loss of compensatory reserve due to the deaths of these organisms and the overall health of ecosystems. Given all of these considerations, EPA determined that there are multiple types of undesirable and unacceptable adverse environmental impacts which result from impingement and entrainment and which must be minimized. Damage on the community or population level is extremely difficult to quantify and attribute to a particular cooling water intake structure given the vast number of environmental factors and anthropogenic factors which work concurrently on fisheries at that organizational level. In addition, changes in populations may be masked by the considerable natural variation in the size of fish populations. Many cooling water intake structures have been in operation for decades. During these years, fish populations have been affected by other factors such as overfishing, habitat alteration and water quality changes. Populations of aquatic organisms in the vicinity of cooling water intake structures may appear to remain stable despite the impingement and entrainment of vast numbers; however, this stability may be due to improvements in water quality and implementation of fishery management plans, which should result in a steady increase in fish populations. At the same time, habitat degradation may be reducing populations. Because of these simultaneously-occurring factors, the determination of a change in a population that is directly attributable to the operation of a cooling water intake structure may prove to be impossible unless a facility commences or significantly changes operation and the nearby populations instantly crash in response. For these reasons, EPA has selected individuals because they are a more reliable metric than population or ecosystem level effects.

Today's rule will reduce the number of organisms killed in a waterbody by impingement and entrainment by cooling water intake structures. This reduction in fish mortality will aid fisheries by reducing one of the many types of stresses upon them. There are other sections of the Clean Water Act which seek to reduce other types of environmental stressors to improve fishing and swimming in the waters of the United States. Today's final rule serves to protect individuals which will in turn protect populations. The rule also authorizes the use of restoration measures when the Director determines that the use of design and construction technologies and/or operational measures alone is infeasible, less cost-effective, or less environmentally desirable than meeting the applicable impingement and entrainment requirements in whole or in part through the use of restoration measures.

Please see chapter A6, EPA's Approach to Modeling Effects of I&E Reductions on Fishery Yield, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule for the discussion regarding the use of population-level analyses in this rulemaking. Please see the section IV of the preamble to today's final rule and response to comment 316bEFR.025.018 for the discussion regarding environmental impacts associated with cooling water intake structures.

Impacts of CWIS at ecosystem level (popn. vs. indiv.)

Significance to AEP of EPA's using individual-level impact analyses rather than population-level analyses

EPA uses the number of fish impinged and entrained as the basis for assessing impact due to cooling water intake operation without providing a population context. The problem that this lack of a population level impact analyses creates can be illustrated with this example. An annual impingement loss of 5,000 fish from a population of 8,000 fish will likely affect the viability of the population. However, 5,000 fish lost from a population of 100,000,000 fish would very likely not affect the viability of the population and thus would not be adverse environmental impact. The proposed rule cites examples of impingement and entrainment rates for power plants on the Great Lakes, tidal rivers and ocean intakes that EPA calls extensive and appreciable. Knowing only the number of fish lost from the lake as EPA provides in their example, one has no way of knowing whether there is potential for significant harm or whether there is adverse environmental impact to be minimized.

EPA Response

Please see response to comment 316bEFR.207.015 for the discussion regarding impacts of cooling water intake structures at the individual versus population level.

The areas in which the populations are located mentioned by the author of this comment are unclear. If these two hypothetical populations occupy the same amount of space in the vicinity of the hypothetical facilities, then the difference in the numbers impinged as percentages of the populations may be a reflection of the amount of flow into the facility. In other words, for a facility to impinge only 5,000 fish in a population of 100,000,000 it would have to have a much smaller flow than a facility that impinges 5,000 fish from a population of 8,000. Or if the flows are the same at the two hypothetical facilities, then the impingement of only 5,000 fish from a population of 100,000,000 may be a reflection that this facility already has substantial impingement controls in place. Without more information, it is extremely difficult for EPA to answer this hypothetical question.

That said, if a facility is operating in a waterbody where the number of organisms killed by the intake structure represents a substantial portion of the population in the vicinity of the facility, a permit director may be justified in imposing stricter standards.

Impacts of CWIS at ecosystem level (popn. vs. indiv.)

Numbers of fish lost viewed in a population-level assessment

EPA cites one million fish were killed within a three-week period as an instance of extensive losses (FR 67(68):17,138). The event EPA refers to was reported for AEP's Donald C. Cook Nuclear Plant on Lake Michigan. Closer examination of this event and placing the one million fish lost due to impingement in a population-level context will show why AEP completely disagrees with EPA's characterization of the loss of one million fish from Lake Michigan as extensive. Nearly all of the one million fish were alewives (Alosa pseudoharengus). There is good reason to question the value of alewives even being in the Lake Michigan ecosystem, and one million alewives is a tiny portion of the alewife biomass in Lake Michigan.

Alewives were introduced to Lake Michigan in the 1940s and the initial population grew until by the late 1960s catastrophic die-offs due to lack of food, cold stress or other unknown causes were occurring at many location around Lake Michigan (Greenwood, 1970). In the late 1960s alewives died and wash up on beaches in Chicago, Milwaukee and other cities in sufficient numbers as to create windrows of dead fish several feet thick for miles along the shoreline, which caused a public health nuisance. The states bordering Lake Michigan, who had begun in the 1960s to stock trout and salmon native to the Pacific Northwest, intensified their efforts in the early 1970s to control the alewife population by stocking Lake Michigan with predators and developing a sport fishery.

Since 1970, alewives have been a significant factor, some positive and many negative, in the Lake Michigan fish community. Many factors have driven the quality and quantity of the fish community in Lake Michigan, and Madenjian, et al., (2002) documented these changes in Lake Michigan from 1970 through 2000. The authors discuss the value of alewives as a fish species in Lake Michigan and describe how alewife abundance has affected the abundance of native fish species such as deepwater sculpin (Myoxocephalus thompsoni), yellow perch (Perca fiavescens), burbot (Lota lota), and the bloater (Coregonus hoyi). They concluded the increase in abundance of the introduced alewife caused or contributed to the decline of four native species and the recovery of all five of these species was the result of the decline of the alewife populations. Madenjian, et al. (2002) attributed the decline of the alewife population entirely to predation from the stocked salmon and trout. No mention was made of cooling water intake impingement and entrainment.

Hatch, et al. (1981) estimated the biomass available to trawls taken between the depths of 9 to 110 meters was between 40,800 and 104,000 metric tons during the years 1971 through 1978. Presuming 20 alewives per kilogram, the alewife biomass expressed in numbers of fish would be between 816,000,000 and 2,080,000,000. One million alewives is 0.12% to 0.05% of the alewives in Lake Michigan between the 9 and 110-meter depth contour let alone the entire lake, hardly an extensive number of fish when compared with the entire population. Even applying the method in the proposed rule for converting forage fish biomass into sport fish biomass would result in an increase in sport fish biomass too small for anglers to perceive an increase in the quality of fishing. Fish populations that are not affected by impingement or entrainment may vary due to factors that are completely segregated from cooling water intakes. In the paper summarizing changes in fish populations of Lake

Michigan from 1970 through 2000, the authors noted increases and decreases of fish populations due to changes in predation rates, introduction of exotic species, and changes in water quality. They noted in particular the reduction in fish biomass was due to the reduction in nutrients resulting from the control of phosphorus discharges into Lake Michigan (Madenjian, et al., 2002). Unless the rule is changed to be based on impacts at the population-level or community-level impacts, cooling water owners and operators could be in the position of spending money and effort to fish populations where no measurable improvement is going to result from the effort.

EPA Response

Please see response to comment 316bEFR.207.015 for the discussion regarding impacts of cooling water intake structures at the individual versus population level. Please see response to comment 316bEFR.025.018 for the discussion regarding environmental impacts associated with cooling water intake structures.

The commenter asserts that one million fish killed by a cooling water intake structure in a 3 week period is not extensive; the commenter bases this conclusion solely on the fact that nearly all of the fish were alewives. EPA disagrees that the species of the fish makes such a huge loss (in a short period of time) somehow acceptable. In order for species to coexist in a given area and utilize the same resource, they must occupy a separate and distinct niche. EPA believes all species native to a given waterbody warrant the same level of protection. Although alewives were introduced into Lake Michigan and the author may question the value of alewives, their presence in the waterbody indicates that they do occupy a distinct niche and contribute to the food chain in the ecosystem. It should not be the role of cooling water intake structures to reduce the number of an introduced species in a waterbody because they do not distinguish between killing alewives and native fish. The facility cited, the Donald C. Cook Nuclear Plant on Lake Michigan, has experienced several emergency shutdowns due to clogging of the intake pipes by massive influxes of fish. Please see section IV of the preamble for more detail. Reducing the number of organisms impinged and entrained at this facility could aid in alleviating this problem.

Organization American Electric Power

Subject Matter Code 6.04
Impacts of CWIS at ecosystem level (popn. vs. indiv.)

Density dependent feedback is not taken into account

If EPA looks only at the number of organisms impinged and entrained and does not evaluate impacts at the population level, then EPA's assumption that all fish impinged and entrained will directly increase the population of fish in the waterbody by the number of fish impinged and entrained has no scientific support. In a waterbody where fish populations are below the carrying capacity of the waterbody, there may well be a near one-to-one increase in the population. For fish populations that are at the carrying capacity of the waterbody, there will almost certainly be no direct increase in the population. Perry et al, (2002) modeled the effects of impingement and entrainment at six of the nine power plants EPA studied in their Ohio River Case Study. The authors determined the effect on six fish populations of removing impingement and entrainment losses in five Ohio River pools. In only six out of the thirty possible combinations of species and pools was there the potential for any significant increase in population likely to occur. The other combinations of populations and pools showed there was either no likelihood for population increase (16) or the populations were of insufficient size to make a determination (8). In short, the modeling shows that a complete elimination of impingement and entrainment would likely do very little to increase those fish species populations in those pools of the river. Earlier observations on the Ohio River fish community (Van Hassel et al., 1988) showed fish populations in the river to be relatively stable (relative abundance not showing strong trends up or down) and diversity was increasing. Unless EPA uses a population-level analysis of potential impacts from impingement and entrainment, power plant owners will be modifying their cooling water intake structures at considerable expense with no discernable benefit to the ecosystem.

Unless impacts are determined using population-level assessments, a utility that opted to mitigate the impingement and entrainment losses at one of its facilities would fail to show any improvement in the fish community if the fish were at their carrying capacity in that waterbody. Fish populations at the carrying capacity of the waterbody would not increase in population with stocking, habitat improvement, or other mitigation. If fish populations do not increase due to eliminating impingement and entrainment effects, it is also possible those populations will not increase as a result of the mitigation effort.

EPA Response

EPA disagrees with this comment, reducing the number of fish killed by impingement and entrainment allows for the possibility for the population to increase. Minimizing adverse environmental impact serves to reduce one of the many stresses faced by populations of aquatic organisms. The question that should be asked in the example above, is what are the other stresses present in the waterbody that are preventing fish populations to rebound in the model? Section 316(b) is an important tool to reduce one stressor recognized by Congress: the continued killing of billions of fish yearly by cooling water intake structures. This rule will complement fishery management plans and water quality improvements that aim to reduce stress on the nation's fisheries. Please see the response to comment 316bEFR.025.015 for the discussion regarding density dependent compensation. Please see the response to comment 316bEFR.025.018 for the discussion regarding environmental impacts associated with cooling water intake structures.

Option: Site-specific determination of BTA

Site-specific factors need to be considered in determining adverse environmental impacts and best technology available

States, EPA Regional offices, and tribes implemented Section 316(b) using the draft guidance document (U.S. EPA, 1977) for all determinations of best technology available done prior to this rule making. One of the key features of the draft guidance document was the site-specific application of the decision process. Biological and engineering data and evaluations were conducted and determinations made on those data and analyses. EPA has included site-specific determinations of best technology available for those intakes where the cost of achieving the impingement and entrainment reductions significantly exceed the benefits, referred to as the cost-benefit analysis. AEP agrees the cost-benefit analysis is important in this rule and that it must be site-specific. One example of how variable entrainment and impingement rates can be at cooling water intake structures located within a few miles of each other on the same waterbody can be seen in the Ohio River Case Study (U.S. EPA, 2002). Miami Fort and Tanners Creek Plants are about five miles apart on the Ohio River. Entrainment at Miami Fort on a flow-weighted basis was nearly 30 times the rate at Tanners Creek. Impingement was twice as high at Miami Fort as it was at Tanners Creek. The reasons for the difference are unclear. One obvious feature is that the Great Miami River enters the Ohio River on the same side and between the two plants. Tanners Creek draws water from the Ohio River that is primarily Great Miami River water. Two other examples from the Ohio River Case Study illustrate the differences between plants and impingement and entrainment rates. Clifty Creek, a six-unit plant, and Kyger Creek Stations, a five-unit plant, are nearly identical in all other regards. They have identical units, nearly identical intake structures, both intake structures are set back from the shoreline of the river, and the plants have similar intake water flows. For all their similarities, Kyger Creek Station entrains about eight times more fish eggs and larval than Clifty Creek Station, and Clifty Creek impinges about twelve times more juvenile and adult fish as Kyger Creek Station.

These are not isolated examples. The entrainment and impingement rates for all the Ohio River Case Study plants were compared and there was little similarity among the plants (EA, 2002, Table 2, attached as Appendix B).

The differences among the Ohio River Case study plants alone supports the need for more site-specific application of the 316(b) rule. EPA has not examined the differences among intakes located on rivers across the country, and therefore has not justified using the Ohio River Case Study to represent the impact at river intakes across the US. They need to justify their use of one set of criteria for all river intakes. From AEP's experience, we believe EPA will conclude there is too much variability among intakes across the US to generalize from the Ohio River intakes to all river intakes across the country.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b) determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact associated with cooling water intake structures.

Definition: Waters of the U.S.

Cooling water intakes on lakes, reservoirs, and ponds

AEP has a number of cooling ponds and reservoirs that were constructed and permitted for the purpose of providing cooling water for a power plant. It is our understanding that these are part of the thermal treatment system for the plant and excluded from the waters of the U.S. definition on that basis. The discussion in the proposed rule seems to bring that understanding into question, "cooling ponds are neither categorically included nor categorically excluded from the definition of "waters of the United States." On this point AEP endorses the comment and discussion in the UWAG comments regarding cooling ponds and waters of the U.S. definitions. Intake structures on cooling ponds should not be regulated under Section 316(b).

Ecological Risk Assessment

Case Studies

EPA described their case studies as ecological risk assessments using facility data to quantitatively evaluate impingement and entrainment risks to aquatic organisms. AEP fully agrees with the intent of the case studies, but urges EPA to correct the numerous errors that occur in the case study reports. EPA cited their ecological risk assessment guidelines (U.S. EPA, 1998) as the source of the ecological risk assessment method. AEP agrees the EPA ecological risk assessment guideline is a useful and appropriate guideline for the purpose EPA intended. AEP urges EPA to use their ecological risk assessment guidelines in a much broader role in the final rule.

EPA Response

EPA agrees. Please see Chapter A1 of the Phase II Regional Study Document for a discussion of ecological risk assessment in the context of section 316b.

Ohio Watershed

Ohio River Case Study

The Ohio River Case Study was done to estimate the loss of fish from the Ohio River fish community due to impingement and entrainment at the nine power plants used in the study and to then extrapolate the impingement and entrainment losses at the nine plants to the other in-scope cooling water intakes on the river. The owners of the nine power plants in the Ohio River Case Study and several other power companies contracted an environmental consultant, EA, Engineering, Science, and Technology (EA) to review the Ohio River Case Study. EA determined that EPA improperly aggregated fish species, improperly extrapolated impingement and entrainment results from the nine plants to the other in-scope facilities, and made incorrect assumptions when using the impingement and entrainment extrapolations to estimate the benefit to the recreational fishery. EA's review is included as part of AEP's comments as Appendix B.

Dr. Ivar Strand was asked by the Electric Power Research Institute to review the economic benefit analysis of the draft Phase II rule and report his findings. Dr. Strand's report is attached to these comments as Appendix C. Some of the errors EPA made in the estimation of the number of fish and the number of pounds of production foregone that were reported in the EA review (Appendix B) inflated the impingement and entrainment losses beyond what they should be. Dr. Strand noted among other things that EPA further inflated the value of the impinged and entrained fish to a degree that the result is not believable. EPA's benefits analysis shows the impinged and entrained fish have a value of $150/pound. This is clearly an error and needs to be corrected in the final rule. Dr. Strand makes a number of suggestions as to where EPA may have made mistakes to arrive at this inflated benefit value. Dr. Strand further puts EPA's Ohio River Case Study results in perspective by citing a study of fishing success in a reach of the Ohio River that closely matches the reach of the case study (Schell, et al. 1996). In 1992 and 1993, angling in the Ohio River produced 2,500,000 fish. EPA's case study estimated 54,000 pounds of fish were lost from the Ohio River from impingement and entrainment. If the fish lost from the Ohio River due to impingement and entrainment were one pound each, the fish lost from the Ohio River would represent 2% of the angling harvest. A 2% change in angling success is probably imperceptible to anglers. The 2% changes is a maximum estimated increase. Perry et al. (2002) indicated Ohio River fish populations would generally not increase if impingement and entrainment losses were eliminated and EA (Appendix B) show that EPA's estimates of total losses were likely too high due to incorrect aggregations of larval fish and other problems with EPA's report causing the losses to be inflated.

EPA Response

The commenter expresses concern about EPA's production foregone method. For additional information on the method and adjustments made for EPA's final analysis, please see Chapter A5 of the Regional Analysis Document (DCN # 6-0003) and EPA's response to Comment 316bEFR.305.003.

Specific concerns regarding the Ohio case study analysis are addressed in EPA's response to comment 316bEFR.074.305.

Great Lakes

Great Lakes Case Study

AEP urges EPA to discard the use of the J. R. Whiting Plant as the typical Great Lakes plant. The location of this plant alone makes it unique in the entire Great Lakes. It is located at the apex of a long narrow bay formed by the Woodtick Peninsula and the western shore of Lake Erie. No other plant on the Great Lakes is located on a small shallow bay. Bays in general tend to be areas where fish congregate in larger numbers than in the open lake. Fish congregate in bays because bays tend to be more productive and there is more food there compared with the open lake. The bay formed by the Woodtick Peninsula is on the most productive end of the most productive of the five Great Lakes. Any impingement and entrainment loss extrapolations to other cooling water intakes on Lake Erie are likely to be over estimates. Lake Erie tends to be mesotrophic, a classification between oligotrophic, nutrient poor water, and eutrophic, nutrient rich water. The other four Great Lakes are more oligotrophic, and less productive than Lake Erie. Less productive lakes tend to support fewer fish in the same volume of water. Most if not all other cooling water intakes on the Great Lakes draw water from the less productive open lake. Offshore waters tend to be less productive than the shoreline. Many Great Lakes cooling water intakes are offshore, further reducing the comparability of J. R. Whiting with other Great Lakes cooling water intakes.

EPA Response

As is the case for many facility studies, JR Whiting studies were conducted over 20 years ago. EPA agrees that there may have been changes in species relative abundances since that time that would in turn influence I&E rates. However, more recent I&E data are not available.

In addition, EPA wishes to correct the commenter's misunderstanding that JR Whiting was chosen because it was likely to have higher I&E rates than other Great Lakes facilities. In fact, EPA selected the JR Whiting facility for evaluation because it was considered highly relevant for the benefits analysis, given that it is one of the few facilities that has collected I&E data before and after implementation to reduce I&E.

Finally, EPA notes that data from three facilities (JR Whiting, Monroe, and D.C. Cook) were extrapolated to other Great Lake facilities. Results were averaged across all facilities to obtain a regional estimate. See EPA's response to Comment 316bEFR.041.041 for a discussion of EPA's extrapolation approach and its objectives.

Tampa Bay Case Study

AEP urges EPA to allow great latitude in using Tampa Bay Estuary as the example of Gulf of Mexico ecosystems and potential for impact on the fish populations in the Gulf of Mexico. The contrast between Tampa Bay and Laguna Madre near Corpus Christi is stark. Tampa Bay is a mixture of freshwater from the rivers draining into the bay and the water from the Gulf. Laguna Madre is a hyper saline bay behind a barrier island. The fauna and flora of the two water bodies and the productivity of the two water bodies are very different.

EPA Response

EPA recognizes that there are site-specific details that distinguish the environment surrounding individual facilities. For the Gulf of Mexico regional analysis, EPA evaluated other facilities in addition to Tampa Bay in an attempt to capture some of the differences within the region. However, the purpose of EPA's regional analysis for the final rule was not to develop precise I&E estimates for individual facilities, but rather to develop an estimate of average I&E for the entire region. Please see Chapter A5 of the Regional Analysis Document (DCN # 6-0003) and response to Comment 316bEFR.041.041 for additional information on EPA's extrapolation approach. Details of the Gulf of Mexico regional study are provided in Part F of the Regional Analysis Document.

Cooling system costs (e.g., dry, wet, recirculating)

APPENDIX A

COST UPDATE OF COOLING TOWER RETROFIT COST ESTIMATE

JASON HETTERINGER, AEP PRO SERV

APRIL 2002

Cost Update of Cooling Tower Retrofit Cost Estimate

From: Jason Hettinger

Executive Summary:
The following American Electric Plants (AEP) were evaluated:

Plant	Costs (2002 dollars)	Capacity (MW)	Dollars per Kilowatt
Cardinal Unit 1 & Unit 2	$149,368,000	1,200	$124.47
Conesville Unit 1 - Unit 3	$34,551,000	415	$83.25
Kammer Unit 1 — Unit 3	$87,879,000	630	$139.49
Kanawha River Unit 1 & Unit 2	$43,246,000	400	$108.11
Muskingum Unit 1-Unit 4	$103,668,000	840	$123.41
Picway Unit 5	$11,004,000	100	$110.04
Sporn Unit 1 - Unit 5	$154,598,000	1,050	$147.24
Tanners Creek Unit 1 - Unit 4	$109,670,000	995	$110.22

The average dollars per kilowatt for the plants is 118.28/kW in 2002 dollars. This cost estimate was determined by using up-to-date quotes and cost factoring estimates for equipment and labor. The data, calculations, and references are located in the appendixes.

Objective:
Update the cost estimate for AEP power plants in 2002 dollars for the cooling tower retrofit estimate that was completed in 1992.

Assumptions
-All previous design assumptions are valid (B. Cashner Report)
-All locations for cooling towers are applicable per plant (B. Cashner Report)
-Delivery charges for the concrete pressure pipe are assumed for southern Ohio area and will change per plant location
-Electrical costs were very conservative and determined to be valid (including the possibility of installing new transformers or associated euipment to meet demand)
-Labor estimates were calculated based upon a determined percentage of equipment costs per

equipment type (Plant Design & Economics for Chemical Engineers; Peters & Timmerhaus; 3rd ed.; (pg 169, Table 6)

Analysis

The project completed by Bob Cashner in 1992 determined what equipment was needed to modify all once through cooling system to a closed loop cooling system for AEP plants. This project bases was evaluated and the cost analysis information was extracted for price modification from 1992 dollars to 2002 dollars. The cost analysis was based on the information developed from the 1992 cooling tower study of changing the entire large once through cooling units for the power plants to a closed loop system. The equipment size and quantity was not exhaustively examined and assumed to be valid due to the time allotted.

The first set of calculations performed used the original cost information and the time value of money equation with an average inflation factor over the past 10 years. This inflation rate was computed from the consumer price index (appendix). This information was put into a tabular format and needed to be validated. The time value of money equation used was: (199.2 Costs)*(1+.03)9 = (2002 Costs)

To validate the time value of money results, the 1992 cost estimate equations and information were recalculated. The price information was updated by contacting vendors that supplied the original quotes and cost factoring (six-tenths rule). The pricing information was gathered from the sources shown below:

Equipment (Pricing)	Source
Concrete pressure pipe	Price Brothers Budgetary quote
Motor (350 rpm, 1500-3000 hp)	Per Ideal Electric Co.
New Pumps	Cost Factored from Sand Sage Project
Impeller	Cost Factored from Sand Sage Project
Hot & Cold Sump	Per F. Brezny
Flume	Per F. Brezny
Electrical	Not changed per S. Ridenbaugh
Cooling Towers	Marley Quote (no change)

The current cost estimate includes material and labor costs and is in 2002 dollars. The labor rate was estimated on a percentage of national material costs if it was not included as a material and labor combined costs. This percentage changed due to the equipment and scope of work. Listed below are the labor estimates and percentages.

Equipment (Labor Costs)	Labor Costs as a Percent of Material
Concrete Pipe	45%
New Pump Installation	60%
Pump Impeller Replacement	50%
Pump Motor Replacement	50%

** Source: Plant Design & Economics for Chemical Engineers: Peters & Timmerhaus 3rd ed.: (pg 169, Table 6)

After the costs were determined, the difference between the time value of money calculation and cost up dating was approximately 30%. This difference was too great to justify using the time value of money as the basis to determine the dollars per kilowatt, so each AEP plant was updated using the present cost information.

Other Recommendations

The assumption of the engineering and location placements still being valid needs to be confirmed if a more precise estimate is needed (0 - + 10%). For the cost estimate of 0 -+20% this information does not need to be evaluated in detail. The following needs to be addressed to confirm the engineering analysis is still valid for a 0 - +10% cost estimate:

-Sump locations

-Cooling tower improvements

-Electrical requirements for the new equipment verses present plant structure (i.e. new transformers may need installed to meet demand)

-Improved pump efficiencies

-Cooling water flow changes

-Environmental permit costs

[see hard copy for tables in appendix]

EPA Response

EPA reviewed the appendix study and the hard copy tables. EPA notes that the costs estimated by the commenter for this Ohio River case study generally would exceed those utilizing the proposal and NODA methodology developed by the Agency. See response to comment 316b.EFR.208.002.

Ohio Watershed

INTRODUCTION

EA Engineering, Science and Technology was contracted by a consortium of Ohio River power plant operators to constructively critique the Ohio River Case Study (EPA 2002). EA was asked to review the biological assumptions and calculation methods as they were applied by EPA to the nine Ohio River Power plants utilized in the case study, the extrapolation of these data to the whole river and to comment on compensation in Ohio River fish populations.

Our comments begin with a discussion of EPA species aggregation methods, followed by sections concerning verification of EPA calculations and assumptions needed for the calculations, the extrapolation of data from the nine power plants to the whole river, discussion of EPA assumptions related to intake flow, changes in Ohio River fish populations and intake impact study methods. The comments continue with general observations concerning the RUM model and the recreational fishery, and presents a number of specific items that need clarification or correction. We conclude with three issues that should be taken into consideration, impingement number biases due to winter kill of gizzard shad, entrainment survival, and compensation.

A couple of items stand out as a result of the review of the Ohio River Case study. The way different species were lumped together by EPA produced a number of problems including the inability to accurately assess monetary values. Another is the problems and inaccuracies of extrapolating the individual number data from the nine power plants on specific reaches of the river to the entire Ohio River. These errors would be compounded if EPA attempts to extrapolate from the Ohio River system to freshwater systems nationwide. The best method for intake impact assessments continues to be a site-specific approach. Basing the extrapolations to the whole river system on observed population level impacts rather than strictly on numbers would be more acceptable..

IMPROPER AGGREGATION OF FISH SPECIES

In Chapter A5 of EPA's Ohio River Case Study ("Case Study"), it was stated that a small fraction of species identified from impingement and entrainment records were not evaluated individually, but rather were aggregated into species groups. The stated reason for this was that there was a lack of life history information for these aggregated species. This aggregation process is puzzling on several levels. In some cases, this may result at most in scientific debate. In other cases, there may be serious implications with regard to estimated impacts of entrainment and impingement, and, most importantly, related economic valuations.

First, we take exception to EPA's assertion that "a small fraction of species" was aggregated. A review of Appendix C2 of the Case Study reveals no less than 37 full species that were aggregated at one or more of the 9 CWIS facilities. When compared to Table C3-l of the Case Study, which lists 78 fish species considered to be vulnerable to Ohio River intakes, the aggregated species represent 47 percent - nearly one half—of the vulnerable species in the river (not a "small fraction").

Aside from the 37 full species that were aggregated, a number of the aggregated "species" are actually groups, e.g., "herring species," "shiner species," and "Lepomis sunfish." Many of these groupings were undoubtedly necessitated by the available state-of-the-art of larval fish taxonomy. Whereas we understand the need to deal with such groups, we believe the taxonomic choices were flawed in many cases, as discussed further below.

The aggregation rationale of "a lack of life history information" is questionable. It should be clarified here that when referencing "life history" data, EPA was referring to the few parameters listed in Appendix C l of the Case Study. These parameters are natural mortality, fishing mortality, fraction vulnerable to fishery, and weight, all by life stage. Additional life history data such as fecundity were available in the Docket. This information was used in EPA's calculation of age 1 equivalents, lost fishery yield, and production foregone. Although some of the information in Appendix C1 is based on species-specific literature data, the natural mortality rates for eggs and larvae, are, with few exceptions, not species specific. Nearly all of the egg and larval natural mortality rates in Appendix Cl are referenced to either Bartell and Campbell (2000) or PSE&G (1999). Examination of the Bartell and Campbell reference indicates that, in every case where they were referenced by EPA as the source for a species' egg and/or larval natural mortality rate, Bartell and Campbell's documentation for the numbers was "professional judgment." Thus, in no case was the natural mortality data for young life stages based on real data, or at all species specific. EPA's reference for most egg and larval natural mortality rates was PSE&G (1999). This is Appendix F of PSE&G's 1999 316(b) demonstration for the Salem Station on Delaware Bay. Based on discussions with PSE&G personnel, our understanding is that they developed generic mortality rates (as averages of mortality rates for more common estuarine species) for their non-RIS species, including some freshwater species that are rarely encountered at Salem. To the best of our understanding, EPA employed these generic (actually estuarine-species based) mortality rates for the bulk of Ohio River species. So again, just as with the Bartell and Campbell-derived numbers, the PSE&G-referenced numbers are not species specific and are not even based on freshwater species. An excellent reference which could have been used to obtain species specific information is Breder and Rosen (1966).

Aside from the questionable rationale for how the groupings or aggregations of species were derived to begin with, the implications of those groupings must be addressed. At four of the nine Ohio River CWIS evaluated, "temperate basses" were aggregated with small mouth bass. This makes no biological sense given that the white bass (the most common temperate bass in the Ohio River), is a broadcast spawner that lays over ½ million eggs (Case Study Chapter C3), whereas the small mouth bass lays many fewer eggs (3,000 to 21,100, Carlander 1977) and guards them on the nest. As a result of these important differences in life history and behavior (e.g., differences in fecundity, spawning behavior, larval survival, etc.), the loss of a given number of white bass eggs or larvae is quite different than the loss of the same number of small mouth bass eggs and larvae. Thus, lumping these species together is not valid with regard to impact, and especially valuation, because of the greater economic value assigned to the small mouth bass. For example, based on replacement value, AFS (1992) values adult white bass at $1.15 per pound, one quarter of the value assigned to adult small mouth bass ($4.48 per pound).

The primary species small mouth bass not only includes "temperate basses," as discussed above, but also includes largemouth bass and spotted bass at nearly all CWIS. While this may be a reasonable accommodation for the upper river where small mouth bass are moderately common, it constitutes a serious misrepresentation for the lower river where largemouth and spotted bass are much more common. Because of the greater value generally assigned to small mouth bass (AFS 1992), considering all Micropterus to be small mouth bass would inflate impact and valuation particularly in the lower river where small mouth is uncommon.

“Percid species” were aggregated with yellow perch at five of the CWIS evaluated. Assigning percid larvae to yellow perch is totally inappropriate. Larval taxonomy is such that when percid larvae are encountered; the taxonomist can normally assign the larvae to one of three groups; Stizostedion (walleye or sauger), yellow perch, or unidentified percids (darters). When larvae are assigned to unidentified percid, it means that the specimens in question are not Stizostedion, they are not yellow perch, but instead are one of the many darter species inhabiting the Ohio River. In rare cases, the specimens may be so damaged as to preclude assignment to any one of the three percid groups. But in the vast majority of cases, unidentified percids means they are not yellow perch, nor are they Stizostedion therefore they should not be assigned to the yellow perch category. In fact, it is very likely that even many of those specimens originally reported as yellow perch may not be that species. Yellow perch is a rare species, largely confined to the Upper Ohio. Our examination of the combined ORERP and ORSANCO database (Lohner et al 2000) reveals that only 24 adult yellow perch were collected over the 19 year period examined (1981 through 1998), an average of roughly one adult yellow perch per year despite significant effort each year over the upper and middle river. Given the miniscule adult population, the reports of rather large numbers of yellow perch larvae in the river are questionable. Some Percina larvae (logperch in particular) are quite similar to yellow perch larvae and we believe many of these early reports are based on Percina, probably logperch, rather than yellow perch. In any case, ascribing “percid species” to yellow perch would inflate impacts and valuation.

The “walleye/sauger” aggregated “species” is understandable given the state of the art of fish larval taxonomy. But it would have been much more acceptable to ascribe any reports of this “species” to the abundant sauger rather than the uncommon walleye. Again, there are implications regarding the perceived impact and valuation.

Although it may not have impact or valuation implications, the separation of emerald shiner and bluntnose minnow as primary species is biologically awkward. Any other shiner species is aggregated with emerald shiner, while “minnow species” is typically aggregated with bluntnose minnow. The bluntnose minnow is fairly common in the upper river, but rare in the lower river. Further, it is a crevice spawner with generally lower fecundity than the emerald shiner. It is likely that the “minnow species” taxon reported for a number of CWIS was most likely emerald shiner rather than bluntnose minnow. As an “r” strategist (Pianka, 1970), emerald shiner, which produces a large number of eggs, would be much more able to withstand losses than bluntnose minnow, a “k” strategist, which produces a low number of eggs.

A last example concerns gizzard shad and skipjack herring. We acknowledge that from a valuation standpoint it probably doesn’t matter which species clupeid larvae are assigned to. However, it demonstrates again that EPA did not understand the ramifications of the decisions they were making regarding aggregating of species. As best we can determine, whenever EPA saw the designation “Herring” they assigned those specimens to skipjack herring, when in fact the authors of the original reports were simply using the common name for the clupeid family, (i.e., the herrings). Unidentified herring should be assigned to gizzard shad, not to skipjack herring (or left as unidentified herring) because gizzard shad is one of the most abundant fishes in the river, whereas skipjack herring, though common, are much less abundant (EA 2001). In fact, in years of exceptional hatches, gizzard shad become a nuisance in the river and depress the catch of game species (Schell 1996).

The effect of these aggregation discrepancies on the EPA evaluation is illustrated below with examples from the actual study reports for the Ohio River CWIS facilities. These study reports are the original impingement and entrainment reports for the facilities as documented in Table C3-3, Appendix C3 of the Case Study.

-For the Cardinal facility, EPA reported 633,500 yellow perch entrained; these were recorded as "Percid (Percidae)" in the original study report. Also, 810,400 "Walleye/Sauger (Stizostedion)" reported entrained for the year in the original study report were recorded as Walleye in EPA's Table C3-10.

-For the Kammer facility, an annual entrainment estimate of 478,000 walleye in EPA Table C3-10 were recorded as "Walleye/Sauger (Stizostedion)" in the original study report. EPA reported 628,100 yellow perch entrained of which 147,000 were actually listed as "Percid (Percidae)" from the original report.

-For the Philip Sporn facility, an annual entrainment total of 19,100 small mouth bass was reported by EPA. These actually had been reported as "Temperate Bass (Morone)" in the original study report. EPA reported 1,637,500 yellow perch entrained of which 42 percent (682,400) were actually reported as "Percid (Percidae)" in the original report. Over 2 million entrained "Walleye/Sauger (Stizostedion)" reported in the original study report were recorded as walleye by the EPA.

-For the Kyger Creek facility, 95,100 small mouth bass were reported entrained by EPA; these were actually reported as the much less valuable "Temperate bass (Morone)" in the original study report. Nearly all of 15,659,000 walleye reported by EPA were actually recorded as "Walleye/Sauger (Stizostedion)" in the original study report. Similarly, nearly all of 1,199,400 yellow perch reported entrained by EPA were actually recorded as "Percid (Percidae)" in the original study report.

-For the Clifty Creek facility, EPA's entrainment Table C3-l0 contains several entries that cannot be traced back to the original study report. For example, EPA reported 319,368 sauger larvae and 58,067 walleye larvae. No such taxonomic breakdown exists in the original study report: However, the 377,592 "Walleye/Sauger (Stizostedion)" from the original study report is very close to the total of the sauger and walleye larvae reported by EPA. How EPA distinguished between species when it was not done in the original study report is unknown. Also, EPA lists 145,167 small mouth bass entrained. But there are no small mouth bass, largemouth bass, spotted bass, or even bass species reported in the original study report.

These are only a few of the aggregation discrepancies that can be identified for these and other species groups at nearly all of the Ohio River CWIS facilities. As discussed above, some may represent only biological awkwardness, but do not necessarily skew impact and valuation. Others clearly skew impact because of differences in life history parameters (e.g., Morone vs. Micropterus), and subsequent evaluation (e.g., Morone vs. Micropterus, small mouth vs. largemouth bass, percids {darters] vs. yellow perch).

What is a better approach?

(1) Do not aggregate beyond what was done by the original authors. EPA's stated reason for aggregating was found to be in fact, not true. To the extent that the life history data they employed are at all supportable, they would be equally applicable to any aggregated species.

(2) Ignore rare species. This would have virtually no effect on impact and valuation.

(3) In lieu of aggregating, apportion those unavoidable groupings, primarily from entrainment (e.g., minnow species, percid species, herring species, sunfish species) based on the known abundance of juvenile/adults in the river. Extensive monitoring programs have been carried out in the river and data exist with which to credibly apportion entrained "groups" among species.

DIFFICULTY VERIFYING EPA ASSUMPTIONS AND CALCULATIONS

It is a standard precept of science that an experiment or calculation must be able to be duplicated or verified by other parties. Given the significant environmental and economic ramifications of the proposed Phase II 316(b) rule, all necessary information should have been made available by EPA so that their calculation of impingement and entrainment impact and valuation in the Ohio River Case Study could be verified. Due to a variety of data gaps and unverifiable numbers, and in spite of considerable effort, we have been unable to do that.

We first attempted to verify model parameters, particularly life history information. Of the important egg and larvae natural mortality rates, we were able to verify one, that for natural mortality of muskellunge eggs, which was calculated from data in Carlander (1969). EPA also cited Carlander (1977) as a source of egg survival data for small mouth bass. But the egg natural mortality value in EPA Table C1-21 cannot be calculated from any survival value in Carlander (1977). A number of the natural mortality rates in EPA Appendix Cl are referenced to Bartell and Campbell (2000). In this reference, these are daily mortality rates documented as "professional judgment." We could not relate these rates to those in EPA Appendix C1. In response to our inquiry, an EPA representative informed us that the daily rates in Bartell and Campbell were multiplied by the number of days in a stage (egg or larval stage, etc.) to calculate the "Natural Mortality (per stage)" mortality rates in EPA Appendix C1. We were informed that the number of days used per stage were available in the Docket. When we accessed the spreadsheets in the docket that we had been directed to, life stage durations were not evident. Nor could we verify any of the EPA mortality rates referenced to Bartell and Campbell using any published information regarding stage duration.

We also asked an EPA representative for clarification of those egg and larval natural mortality rates for Ohio River fish that were referenced in EPA's Appendix C1 to PSE&G (1999), which is Appendix F of the 316(b) demonstration for Salem Generating Station. We were told that Salem mortality rates were only used in a "few limited cases". In fact, the majority of egg and larval natural mortality rates for Ohio River fish in Appendix C1 are referenced to PSE&G (1999). With few exceptions, we could not confirm the relationship between PSE&G values and EPA's Appendix C1 values using independent literature sources. Our question regarding which Salem rates were used for Ohio River fish has gone unanswered.

Our comments on the economic valuations are provided separately, but we note here that many of the same problems are involved; there was simply not enough information provided to verify EPA's results.

Given that EPA has extrapolated data from nine facilities to the entire Ohio River, and has indicated the possibility of extrapolating these results to other U.S. rivers, the environmental and economic implications are huge. And yet the EPA approach and results cannot be verified. We do not believe this is acceptable.

What EPA should have done, at a minimum for at least one fish species, is to make available every single input parameter and calculation, starting with the verified natural survival of an egg, and ending with the economic loss valuation for that species. in addition, all data and information used in the calculations for all species should have been provided.

PROBLEMS WITH EXTROPOLATING DATA BEYOND THE NINE CASE STUDY PLANTS

Even if we agree that the I&E estimates for the nine case study plants were developed correctly (which clearly they were not), there are problems with extrapolating these data to the remainder of the river and even more problems with extrapolating them outside the mainstem Ohio River. In Chapter C3, EPA indicates that the results from the nine case study plants were extrapolated to "other inscope and out-of-scope CWIS on the Ohio River" and that Section C3-9 represents a summary of "the total cumulative impact of all Ohio River CWIS" (p. C3-1).

On p. C3-22 they indicate that this was accomplished by assuming that I&E is strictly proportional to intake flow and that I&E at the nine Ohio River case study facilities are representative of I&E at other CWIS in the same or nearby pools. However, as documented elsewhere in this report, I&E rates are proportional to intake flow (see Section 5.3). A significant number of plants are affected by this extrapolation procedure. According to Table C3-l4, there are 10 in-scope plants that are located downstream of the McAlpine Pool (the downstream-most pool with one of nine studied plants in it):

Plant	Pool
Cane Run	Cannelton
Mill Creek	"
R. Gallager	"
Coleman	Newburgh
Elmer Smith	"
FB Culley	"
Rockport	"
Warrick	"
Joppa Steam	L&D 53
Shawnee	"

In Tables C3-15 and C3-16, EPA indicates that data from the Clifty Creek Plant (McAlpine Pool) were extrapolated to these 10 plants as well as to 8 out-of-scope facilities. However, in Table C3-l 7 and subsequent tables, data are presented separately for the Newburgh Pool, a pool which is not defined in Table C3-16.

In addition to erroneously assuming I&E is proportional to intake flow, there are serious problems with extrapolating the results from the Clifty Creek Station, a middle river plant, to these other facilities, all located in the lower river. This is because there are significant differences in community composition between the middle and lower river (Pearson and Pearson 1989). Species preferring cooler waters (e.g., walleye, small mouth bass, redhorse, yellow perch, etc.) decline rapidly in abundance as one proceeds downriver. There are even shifts in the forage community. For example, threadfin shad tends to be rare in the upper river, uncommon in the middle river, but common to abundant in the lower river (EA 1993). Several of the most valuable species listed by EPA (e.g., small mouth bass, yellow perch, and walleye) are effectively absent in the lower river. Thus, the differences between the middle and lower river are not merely exercises in biological correctness; they have clearcut valuation ramifications.

The long term fisheries studies sponsored by the Ohio River users group provides additional longitudinal trend information (EA 2001). A few taxa, notably gizzard shad and small cyprinids (primarily emerald shiner), have been abundant to very common at all study areas in all, or nearly all, years. Additional taxa have consistently been common from locations in both the upper and middle river sections, but have also demonstrated no clear longitudinal pattern. These include Lepisosteus spp. (mainly longnose gar), channel catfish, Morone spp. (mostly white bass), Stizostedion spp. (principally sauger), and drum. Conversely, several taxa have exhibited consistent longitudinal patterns with regard to abundance. Common carp, round-bodied suckers (primarily redhorses), sunfishes (mostly bluegill), certain Micropterus spp. (small mouth and spotted basses), and small percids (primarily logperch) have been most numerous at upper river study areas. In contrast, taxa that typically have been more abundant at middle river study areas include skipjack herring and flathead catfish. Carpiodes spp. (mainly river carpsucker and quiliback) and Ictiobus spp. (primarily small mouth buffalo) were more numerous in middle river study areas from 1981 through 1990, but have been as or more abundant in the upper river collections since 1991.

This leads to our final observation regarding extrapolations. Apparently EPA plans, or at least had planned, to extrapolate the Ohio River results to rivers nationwide. This should either not be done at all or done with extreme caution. As demonstrated above, even within the Ohio itself, there are significant faunal shifts as one moves throughout the river. Studies in several Ohio River tributaries, such as the Wabash River (EA 1989) and the Muskingum River (EA 1991a & b) demonstrate that even the tributaries have decidedly different fish communities. The differences will be even greater when one moves to rivers further west (e.g., the Missouri), further east (e.g., the Susquehanna), further south (e.g., the Oconee), or further north (e.g., the Wisconsin). These differences are why numerous experts, including the authors of this report, have argued that 316(b) assessments must be site-specific. In most cases, such data are available and, if they are not, then it would be the responsibility of the facility owner to collect relevant data. Such approach is far superior to extrapolating from wide geographic areas with vastly different biotas.

REVIEW OF KEY EPA ASSUMPTIONS

5.1 Impingement and entrainment studies were probably done using poor and outdated techniques.

The impingement and entrainment study techniques used in the late 1970’s at the nine Ohio River case facilities, varied to some degree due to site-specific conditions. Icthyoplankton samples were collected during a 24-hour period using submersible pumps or by tapping into the circulating water system. With two exceptions when nets with larger openings were used, the samples were filtered through nets with a mesh size of 500 or 505 um. Samples were collected on a weekly basis during spring and summer. Some programs also collected samples every two weeks in early fall and monthly during late fall and winter. The sampling period was either for one year or during the period when spawning, drift, and nursery activities would be occurring.

Impingement samples were collected for one year over 24 hour periods. For most of the studies weekly samples were collected during spring through early fall and bimonthly samples collected in late fall and winter. The exceptions were 1) W.H. Sammis where samples were collected every eight days and 2) W.C. Beckjord where samples were collected every week during April through June and every two weeks from July through March. Samples were collected from baskets or screens with a mesh size of 3/8 inch through which the screen wash was filtered.

Extrapolations of actual entrainment and impingement numbers to annual estimates were made using traditional methods. Annual extrapolations were presented by species and/or total numbers.

The methods used in the Ohio River Case Study facilities are still appropriate and are still being used. EA is conducting a number of 316(b) related studies in 2002 using the same types of gear (i.e., pumps, towed nets, and taps into the circulating water system) that were used in studies designed to investigate entrainment and impingement impacts 25 years ago. Icthyoplankton studies being conducted by EA at river locations utilize No. 0 mesh (500 um) nets and samples are collected weekly over 24 hour periods. The basic methods of obtaining samples and analyzing them have not changed. Additional freshwater larval identification keys have been published in the past 25 years. These additional keys aid in identifications from the family level to the genus and occasionally the species level for some families; however, the ability to provide accurate species level identifications for some freshwater larval fishes is still relatively rare. However in general, the taxonomy is at the level where it is often possible to appropriately aggregate genera and species to allow meaningful assessments. Cyprinidae (minnows) is an example of a family where identification keys to species or even genus level continues to be incomplete and inadequate for numerous species.

One area where new methods have been developed is in the area of entrainment survival. Historically, survival studies were not part of most 316(b) demonstrations. For most facilities, the level of intake impacts observed did not result in adverse population changes so it was not necessary to conduct follow-up survival studies.

Under the new 316(b) regulations for new facilities, USEPA is requiring verification monitoring after operation begins, which includes two years of once a month 24 hour impingement monitoring and two years of once every two weeks of entrainment sampling over a 24 hour period during peak periods of reproduction, drift and abundance. Although the studies used for the case facilities covered only one year (a number of the facilities had additional studies which were not used), these studies were much more intensive (weekly to bi-weekly impingement, and entrainment which in some cases was year round) than is now being required by the new source rule.

In conclusion, impingement and entrainment studies performed by the facilities used in the Ohio River Case Study were not conducted using poor or outdated techniques.

5.2 EPA stated that the Ohio River has improved since the impingement and entrainment studies were done and the changes have likely resulted in an underestimation of impingement and entrainment losses. Impingement and entrainment studies are now old and not representative of current conditions.

We agree that there have been improvements in the water quality of Ohio River due to a number of factors including improved wastewater treatment technologies, controls on construction stormwater runoff, tighter permit limits, improvements in urban and agricultural runoffs and improvements in wetland protection. Based on improved water quality, the EPA has made the assumption that the fish populations have shown dramatic improvement. As a result of these improvements, EPA suggests that the case studies (which ended in 1978 and 1979 not 1977 as indicated by EPA) appreciably underestimated the numbers of fish that would be entrained and impinged now.

An Ohio River users group has funded long-term fisheries monitoring at various locations in the upper and middle areas of the Ohio River beginning in the early 70's. These data, although available to EPA, appear not to have been utilized by EPA or their consultants.

Not every location is sampled every year and there have been additions and deletions to the program over time. Locations that provide long-term data and provide good spatial coverage of the river are discussed below. Annual electro fishing surveys have been conducted near the following facilities; Cardinal (river mile 76.7)(21 years), Kyger Creek (river mile 260)(16 years), Beckjord (river mile 453)(11 years), and Tanners Creek (river mile 494)(21 years). These studies have documented widely varying levels of total abundance (EA 2001, Lohner et al 2000). No clear pattern of increasing or decreasing total abundance has been evident. Numerous factors are hypothesized to influence annual variation. One of the most important of these is flow regime, which affects both spawning and recruitment success for most species, as well as sampling for all species.

Taxonomic richness has also varied considerably between years at each of the four long-term plant sites. However, the variation in richness was most associated with the presence or absence of uncommonly encountered species; no invasions or extinctions of common species were noted. High persistence, in terms of species presence, of Ohio River fish communities has been documented despite large-scale environmental perturbations (1988, 1991, and 1999 droughts; 1989 and 1990 floods).

In Chapter C3 of the Ohio River Case Study, EPA indicates that the main species at risk based on their abundance in impingement and entrainment collections are emerald shiner (Notropis atherinoides), freshwater drum (Aplodinotus grunniens), gizzard shad, (Dorosoma cepedianum), sauger (Stizostedion canadense), white bass (Morone chiysops), white crappie (Pomoxis annularis), and white sucker (Catostomus Commersoni). First of all, white sucker is an uncommon or even rare fish in the Ohio River (EA 2001) and certainly is not at particular risk.

Annual trends between 1981 and 2001 in the abundance of some of the more abundant species or groups at each of the four long-term plant sites are summarized in Table 1. Gizzard shad, common carp, several small cyprinids, sunfishes, and drum were generally common or abundant in all study years since 1981. Abundances of these species have varied widely but have not conformed to clear patterns of increasing or decreasing over time. However, several other taxa have generally increased in abundance in recent survey years, particularly since 1986. Higher catch rates of Carpiodes/Ictiobus spp., round-bodied suckers, small percids, and Stizostedion spp. have been observed since 1991, and likely reflect the change in sampling methodology to night electro fishing beginning that year rather than a real increase in their abundance. Water quality improvements are a thought to be a potential factor for the increase in abundance in recent years of skipjack herring, Hiodon spp. (notably in the upper river), channel catfish, flathead catfish, Morone spp., Micropterus spp., and drum. So although there have been some improvements, the current fish community in the Ohio River is not dramatically different than that present when the case studies were conducted. It is particularly important to recognize that the species that dominate the entrainment and/or impingement catches (i.e., gizzard shad, emerald shiner, freshwater drum, and minnows in general) have not changed in abundance. The improvements are mainly in the taxa less commonly entrained or impinged.

5.3 EPA equates higher flows with higher I&E rates.

EPA continues to assume a direct relationship between intake flow and the entrainment and impingement of organisms. The industry continues to maintain and to provide data to prove that such a direct relationship cannot be a general assumption. The relationship between a facility and entrainment and impingement is site-specific. Although flow is an important consideration for entrainment, it is not possible to predict entrainment accurately using only intake flow. Using intake flow as a direct predictor of the magnitude of intake impact on organisms that have the ability to move throughout the water column and exhibit other behavioral choices, as organisms susceptible to impingement can, is an even much greater error.

Table 2 presents the design intake flows in increasing order, for the nine facilities that are the basis of the Ohio River Case Study. Except for known errors, intake flow values were taken from the EPA case study document. For Miami Fort, since units 3 and 4 were retired in 1982, the design intake flow presented in the 316 (b) study cited by EPA rather than the present lower value EPA presented in Table C1-3 was utilized. Utility representatives indicated that the values for W.C. Beckjord and W.H. Sammis were incorrect. Therefore, the value from the 316(b) report was used for W.C. Beckjord and the value provided by the utility representative was used for W.H. Sammis. The annual entrainment and impingement numbers were obtained from the studies cited by EPA and are shown for each intake flow. There is no consistent pattern in the data.

[see hard copy for tables]

The highest entrainment occurred at a plant with a design intake flow of 1805 cfs, while the second and third highest entrainment occurred at the facilities with intake flows of 1066 and 756 cfs, respectively. The lowest entrainment occurred at a plant with a flow value of 1649 cfs, whereas the second lowest entrainment occurred at the plant with the highest intake, flow (2180 cfs). Tanners Creek and Kyger Creek have design flows that differ by <10 % yet entrainment estimates differ by 50-fold between these two plants (Table 2).

The highest impingement (2.3 million) occurred at a facility with a design intake flow of 2024 cfs, whereas the plant with the highest design flow (2180 cfs) had an estimated annual impingement rate of 379 thousand. The lowest impingement (13 thousand) occurred at a facility with an intake flow of 1086 cfs. Four facilities had impingement estimates that ranged from 162 to 186 thousand while the intake flow ranged from 756 to 1805 cfs. Impingement at two facilities ranged from 47 to 52 thousand, whereas the intake flows at these two plants ranged from 1144 to 1607 cfs, respectively.

6. GENERAL OBSERVATIONS: RUM MODEL AND RECREATIONAL FISHERY

In addition to the various detailed comments provided herein, we have several general observations regarding the report and, in particular the RUM model. We agree that the Ohio River offers excellent angling opportunities but believe EPA overstates its significance when it suggests that the river is “famed for its gamefish” (pCl-5). EPA has listed several species as recreational species (Table C3-1) that clearly are not, e.g. coho salmon, grass pickerel, paddlefish (a filter feeder that can only be caught by snagging) and stonecat.

White sucker is listed as one of the main species at risk (pC3-1), where in fact this species is quite rare in the river (EA 2001).

EPA suggests on pC3-21, pC3-38, and elsewhere that the both I & E results collected ~ 25 years ago underestimate the scope of the problem because of water quality improvements in the river. We agree that water quality has improved. However, the species that have benefited most from this improvement are non-game species and forage species (e.g., various minnows, darters, redhorse, etc.). The species vulnerable to impingement and entrainment in the 1970’s (i.e., gizzard shad, drum, emerald shiner, carpsuckers/buffaloes) are no more abundant today than they were more than 20 years ago (EA 2001). The fact that the species most susceptible to I & E continue to be abundant itself suggests the problem is not as severe as EPA suggests.

As described in greater detail elsewhere in these comments, EPA suggests that large numbers of key sport species are being lost. However, much of this “loss” is a result of the inappropriate way in which EPA aggregated species. For example, because of inappropriately grouping various species, EPA concludes that two-thirds of the dollar loss to recreational fishery comes from only two species, small mouth bass and walleye (Table C4-3).

The replacement costs for forage species (Table C4-4) are driven by a few species, some of the most prominent of which are either unaffected by the magnitude of the losses calculated by EPA or which are undesirable species. For example, population modeling efforts have shown that despite gizzard shad being the most impinged species in the river, no significant effects at the population level could be detected when the entrainment and impingement losses were added back into the system (Lohner et al. 2000). Furthermore, we are not aware of any biologists familiar with the river that believe shad populations are limited by impingement and entrainment losses. With regard to entrainment, the forage species that accounts for the most value is common carp. We do not believe there is a single fish manager on the river that believes that the loss of common carp is a bad thing. In fact, given the negative attributes of this species, we are confident these managers would like to see the number lost be increased if that were somehow possible.

In describing the RUM model, EPA notes that “A majority of anglers from Pennsylvania and West Virginia target coldwater species,” and suggests that differences in allocation of target species between Ohio’s anglers and Pennsylvania and West Virginia are unlikely to have a significant effect on welfare estimates because “a significant portion of Pennsylvania and West Virginia anglers (25 and 27 percent) target warm water species; and both coldwater (salmon) and warm water species (e.g., sauger) are affected by I&E in the Ohio River.” We are not sure about the validity of the first reason but it is absurd to suggest that coldwater species are affected by I & E in the Ohio River. On rare occasion, a trout or even a salmon has been reported from the river, but it is not biologically credible that these fish represent anything other than statistical anomalies.

EPA made numerous assumptions regarding anglers that use the Ohio River (e.g., where they came from, what species they target, the value of their trips). Apparently, most of the data EPA used came from a national survey. EPA missed an important reference. Ohio DNR (Schell 1996) conducted an extensive recreational survey of the Ohio River, which contains considerable information that EPA should have at least considered. The survey report presents data by location, pool, habitat type and the entire survey area. Information is provided for both shore and boat angling and for specific species.

On p C5-6, EPA describes bow it calculated fish abundance using data in the Ohio EPA database. The fact the values are based on catch per 300m indicates that these data came from wadeable streams, and therefore, not applicable to a large river such as the Ohio River. Furthermore, it appears that EPA ranked the sites based on total biomass. In wadeable streams most of the biomass is made up of minnows, darters, and other various non-game species (e.g. white sucker) and thus would provide little or no information for anglers to choose the streams they wished to fish. Use of wadeable stream biomass data to rank large river sites is not appropriate. Lastly, the Ohio values are relative, not absolute indicators of abundance. In a wadable stream or even a small river, the catch rate over a narrow linear band (i.e., the band covered by the electrofisher) may approximate the abundance of fish in such systems. However, in large rivers, and certainly in the Ohio River, these data would need to be expanded to account for the width of the river, as was done by Lohner et al. (2000) in their Ohio River population model. We were not able to confirm if data other than the wadeable stream information was used or if an expansion factor was applied to adjust for river width, but it appears they were not.

Even if we agreed with EPA' s assertion that the visual appearance of the site may play an important role in the anglers decision to visit a particular site (p C5-6), using total Kjeldahl nitrogen as a proxy for visual water quality at the sites is totally inappropriate.

ADDITIONAL ITEMS REQUIRING CLARIFICATION OR CORRECTION

As we reviewed the EPA document a number of individual items appeared to be incorrect or need clarification. Some of the items are presented in this section.

A. Table C3-6 on pages C3-23/24 - Annual Impingement. Clifty Creek. EPA indicated on Table C3-4 that they had used the annual impingement estimates as presented in the EIA, 1978 report. If the numbers for Clifty Creek presented in Table C3-6 are added the total number is 1,727,393; however, the actual EIA report indicates the total was 2,268,73. The numbers for individual species do not agree either.

B. Table C3-6 on pages C3-23/24 - Annual impingement. Miami Fort. EPA indicated on Table C3-4 that they multiplied the number of fish impinged by the fraction of the days sampled for the year (365/36 or 10.139) to obtain annual impingement estimates. If the species numbers for Miami Fort presented in Table C3-6 are added, the total number is 221,354. The actual report indicates 17,319 fish were actually impinged during the study. Multiplying 17,319 by 10.139 is 175,597. In addition to that inconsistency, the actual number of days sampled was 39 so the correct factor to use should have been 365/39 or 9.359, which results in an estimate of 162,089.

C. Table C3-6 on pages C3-23/24 - Annual Impingement. W.H. Sammis. This is only facility for which EPA included crayfish. If crayfish numbers are removed, the total obtained by adding the individual species numbers presented in EPA Table C3-6 is very close to the impingement estimate in the actual report.

D. Page C2-11. Kammer — The design flow presented is 1068 MGD when it is actually 1086 cfs. In terms of MGD, it would be 689. Standardization on which units to use would have prevented this type of error. The case study uses MGD, GPD, gpm, and cfs.

E. Page C2-12. Clifty Creek — The design flow presented is 2034 MGD when it is actually 2034 cfs. In terms of MGD, it would be 1312. Standardization on which units to use would have prevented this type of error.

F. Not having the definitions and source for design intake flow and average annual flow rate as presented on Table C1 -3 on page C1 -9 and operational flow as presented in Table C1l3-14 on page C3-35, made it difficult to confirm the values and utilize them in our review.

G. Table C3-2. W.C. Beckjord. EPA indicated a page (dealing with impingement methods) was missing from the document. Page 17 is the missing page from the 316(b) demonstration document for Beckjord and Miami Fort dated July 20, 1979. The page is missing from the file copy of the original report.

H. In Chapter C3 of the Ohio River Case Study, EPA indicates that the main species at risk based on their abundance in impingement and entrainment collections are emerald shiner, freshwater drum, gizzard shad, sauger, white bass, white crappie, and white sucker. It is unclear as to whether this statement refers to the numbers from the actual reports, EPA's summary of those reports (Table C3-6), or is from other summaries based on species groupings rather than individual species. Neither white crappie or white sucker appear on Table C3-6 leading one to think that this statement is based on the EPA groupings list where white crappie is included under black crappie and white sucker appears under sucker spp. At the same time for example, both skipjack herring and gizzard shad, as well as longear sunfish and sunfish spp., appear on Table C3-6 which under EPA groupings contain different species depending upon the facility. The inconsistency in how the species groupings were applied makes it difficult to confirm numbers and interpret the statements.

I. W.H. Sammis Station staff indicated that the once through intake flow indicated on page C1-1 of the case study is correct (1360 MGD, the amount submitted on the Detailed Questionnaire form was 1,361,376,000 GPD). The flow indicated on page C2-10 (1803 MGD) is incorrect. This appears to have resulted in an incorrect calculation of cfs on Table C1-3. The total for W.H. Sammis should be 2180 cfs not 2790 cfs.

J. According to Table C3-2, EPA based their extrapolations on a 1977-1978 impingement study (EIA 1978) and ignored a 1985-1986 study (EA 1987). Given the fact that EPA emphasizes that earlier studies do not reflect recent improvements in water quality, we find it curious that EPA utilized the older study and disregarded the more recent one. On page C3-16, EPA refers to the 1985-1986 study and seems to imply that they used those results. However, this interpretation is at odds with the reference they cite in Table C3-2 as the source of their data. Since both are valid studies, we recommend that both be used.

WINTER MORTALITY OF GIZZARD SHAD BIASES IMPIMGEMENT RESULTS

EPA reported, without comment, on sampling techniques at many of the CWIS that included not counting fish as impinged that were obviously dead before the impingement. We concur with this approach, as there are many occasions when a fish that died from natural, or other non-impingement causes, floats into a CWIS. Typically, following an initial cleaning run, there is a hold period of from 4 to 24 hours before screens are rotated for sampling. Experienced field technicians can easily separate live fish from those dead more than the 4-24-hour hold period, based on the physical condition of the fish.

There is another aspect of naturally dying fish that is particularly pertinent to the Ohio River that we wish to highlight. Based on the data EPA has compiled for the nine CW1S, gizzard shad is by far the most abundant impinged fish, representing approximately 85 percent of impinged fish throughout the river. It has been well-documented that the gizzard shad is vulnerable to water temperature drops and that it is "winter-killed readily" (Trautman 1981, White et al. 1986). The Ohio River drainage is near the northern extension of the species" natural range. As a result of this, it is very likely that a significant portion of the 2.3 million gizzard shad estimated to have been impinged annually at the 9 CWIS would have died naturally, probably within hours had they not been impinged. This assertion is supported by the various impingement studies on the river which show that impingement rates are highest in the winter, exactly what one would expect if winter kill is a real phenomenon. For example, at the Cardinal Plant, 93 percent of the annual estimated number of gizzard shad impinged in 1978-79 were recorded between November 23rd and January 26th. At the Miami Fort Plant, 65 percent of the total annual impingement catch of gizzard shad occurred on January 5, 1978 in association with a sudden and severe temperature drop. We believe natural winter kills of shad may have contributed to a significant overestimation of impingement impacts (and valuation) on the Ohio River.

We do not fault the sampling technologies employed in the prior impingement studies, i.e., if it was impinged and alive, it was counted. But we believe overlooking the unique and well known vulnerability of gizzard shad has resulted in biased estimates of past impingement, and would also in any future studies.

We believe that special protocols could be developed to separate true impingement mortality of gizzard shad from the concurrence of impingement and a natural winter-kill event. Lines of evidence could include:

-time of year (fall through winter)
-has the impingement event coincided with a water temperature drop?
-does the event represent a significant increase in impinged gizzard shad relative to prior days?
-is there evidence of stressed or lethargic gizzard shad in or near the intake? (Cold-stressed gizzard shad will often swim erratically on the surface.) Systematic surveys could be done, by boat if necessary, to make this determination.

Recognizing this phenomenon would remove a significant bias in the impingement estimates for the Ohio River. We further seek EPA's support in addressing this phenomenon in any future impingement studies in the gizzard shad's range, including individual site-specific assessments.

ENTRAINMENT SURVIVAL SHOULD NOT BE IGNORED

In Chapter A7 of EPA's (2002) Case Study Analysis for the Proposed Section 316(b) Phase II Existing Facilities Rule (EPA-821-R-02-002), EPA provided a discussion of current knowledge regarding entrainment survival, and proposed protocols for conducting “sound” entrainment survival studies. This discussion served in part as EPA’s rationale for assuming 100 percent mortality of entrained organisms in the Ohio River case study. The bulk of Chapter A7 consisted of EPA’s critique of 13 previous entrainment survival studies, 12 of which were reviewed and summarized by EPRJ (2000). EA doesn’t wish at this time to respond to individual points made by EPA in Chapter A7. We do, however, wish to clarify some aspects of entrainment survival. The EPRI (2000) report Review of Entrainment Survival Studies: 1970-2000 was a historical examination of entrainment survival studies. That some of the studies reviewed, particularly earlier ones, were less than scientifically rigorous should not be unexpected. EPA’s Chapter A7 fails to acknowledge the evolution of technology and techniques from earlier to later periods that permitted more scientifically credible estimates of entrainment survival. As a result, the overall tone of Chapter A7 is negative to an unwarranted extent.

The technology and experience base exists today to conduct rigorous, scientifically credible measurements of entrainment survival. The larva table technology, which was developed and refined primarily in studies of the Hudson River power plants, represents state-of-the-art technology for collection of entrained organisms with minimal sampling damage. Englert and Boreman (1988), in discussing convergent estimates of conditional entrainment mortality between government and utility scientists in the Hudson River study stated that “…the larva table demonstrated that a considerable percentage of the entrained organisms survived passage through the plant.” The acceptability of the technology by all parties was clear.

In their Chapter A7, EPA provided guidance and protocols for future entrainment survival studies. There is in fact very little that we disagree with. We submit that, with few exceptions, these protocols have already been implemented in the more comprehensive and recent entrainment survival studies that have been conducted. Nor do we disagree with EPA’s assertion that a predictive model of entrainment survival could be developed based on additional studies. This was essentially EPRI (2000)’s final conclusion with regard to entrainment survival assessment: “There is the potential, perhaps in a future project, to move from a qualitative screening tool to a quantitative predictive model.”

In summary, we believe that the tools and experience exist right now to conduct rigorous, credible assessments of entrainment survival at individual facilities, and to ultimately create a predictive model for extrapolation of entrainment survival estimates from one facility to another. We hope that this potential will not be overlooked or obviated as EPA moves toward finalization of the Phase II rule.

COMPENSATION

Compensation is fundamental to the management of all biological systems. Different compensatory mechanisms have been studied in both terrestrial and aquatic systems (Krebs 1985; Cappuccino and Price 1995; Hassel, Latto and May 1989), for most animal groups (Hassell 1978) and for plants (Harper 1977). Compensation was one of the issues the Utility Water Act Group (UWAG) addressed during the 2002 review process for the proposed 316(b) rule for new facilities. In their November 2000 comments as part of docket W-00-03, UWAG provided a review of compensation in fish. Compensation is not just a theory, the concept has been acknowledged and studied by the scientific community. Hilborn and Walters (1992) cite a number of examples of the use of compensation principles in the management of fisheries by resource agencies.

All biological populations need to have some density dependence to persist, and particularly to support exploitation (Kimmerer 1999). Density dependence refers to feedback between abundance and growth, reproduction and/or survival. It is widely acknowledged that biological populations are limited by resources such as food and space. In response to limited resources, population growth and stability is achieved by changes in birth and death rates. With decreasing population size, increased birth rates and/or decreased death rates are expected, while decreased birth rates and/or increased death rates are expected with increasing population size. Compensatory processes increase individual and population growth at low population density and decrease growth at high population density (McFadden 1977). Compensation tends to stabilize populations leading to healthier populations and communities.

Understanding the site specific role of compensation is important to accurately assessing power plant impacts on fish populations. Entrainment and impingement can remove large numbers of young fish from the population, which without compensation could result in population declines. Compensation can act to offset power plant entrainment and impingement related losses in the same way compensation operates to makeup for losses due to natural and other anthropogenic causes (Rose 1999).

The following is a summary of compensation mechanisms in fish populations based on responses at the individual level (EPRI 1987) that are expected to be operating in the Ohio River.

1. Growth compensation: As fish numbers are decreased there will be more food per individual, and therefore, on average the remaining individuals will grow faster and become larger.

2. Fecundity compensation: The fewer but larger female fish generally produce more eggs per individual and may spawn more often because there is a higher food ration per individual.

3. Mortality compensation: Due to growth compensation, the early life stages of larval and juvenile fish can grow faster and reduce the chance of becoming food. Higher food rations per individual means the individual fish is in better condition, which results in better survival.

Rose (1999) indicates that the magnitude of the compensatory response and the life stages in which they operate vary among species depending on their life history strategy and site specific conditions. The compensatory response in survival during early ages is one of the most important factors for many species (Meyers and Cadigan 1993).

Measuring the changes in growth, survival, reproduction, and movement processes that lead to compensation can be difficult in field situations. Population abundance can be measured over time to see if whether the population is stable or changing and particular life stage parameters like juvenile mortality can be measured. However, using field monitoring to track how the observed compensatory response in a population actually occurred is very difficult. But it is not necessary to understand exactly how compensation has occurred in order to quantify compensation. The fact that the long-term monitoring of the Ohio River conducted as part of the Ohio River Ecological Research Program (ORERP) has documented no major shifts in abundance provides strong albeit indirect evidence that compensation is working.

Rose (1999) indicates that methods are available that permit compensation to be represented in models that do not rely on having detailed empirical evidence for exactly how compensation is operating. If a detailed understanding of how compensation works is needed, Rose recommends an approach based on life history theory (three general strategies; opportunistic, periodic, and equilibrium) and individual based modeling.

There are a number of examples of compensation in freshwater, estuarine and marine fish species that can be found in the literature that provide evidence that compensation occurs. Species studied include striped bass (NMFS 1998, Pace 1993), blueback herring (Crecco and Gibson 1990), and yellow perch-walleye (Mills et al. 1987, Mills et al. 1987, Rose et al. 1999). Meyers et al. analyzed a number of species (1995).

EPA Response

EPA notes that the Ohio case study presented at proposal is not included in EPA's final analysis and Regional Study Document for the Phase II rule. Therefore, much of this comment no longer applies.

Nonetheless, EPA wishes to note that in all cases EPA made a good faith effort to obtain the best information available on the fish species evaluated, including information from local biologists and peer-reviewed fisheries literature. Since the time of proposal, EPA has re-evaluated much of the data used for the Ohio study to ensure the reasonableness of the data that were used and made any adjustments that were deemed necessary to improve the reliability of EPA's evaluations, including the grouping of species.

Despite EPA's extensive data collection effort, EPA recognizes that life history information is lacking or highly uncertain for many individual fish species. This is one reason EPA chose to evaluate species groups rather than individual species for its final analysis. Information on the data used for the Inland study, which replaced the Ohio study in EPA's final analysis, is available in Part H of the Regional Analysis Document (DCN #6-0003).

EPA also notes that extrapolation of I&E data was necessary because I&E studies have not been conducted at most of the over 550 facilities in scope of the rule. For an explanation of EPA's extrapolation procedure for the regional analysis for its final benefits analysis, please see Chapter A5 of the Regional Analysis Document and response to Comment 316bEFR.041.041.

EPA made a good faith effort to provide information on data sources, assumptions, and calculations used for its I&E evaluations, and regrets any difficulties the commenter may have had in locating this information. I&E methods are discussed in Chapter A5 of the Regional Analysis Document. Life history data used for the Inland analysis, along with data sources, are provided in Appendix H1 of the Inland Report presented in Part H of the Regional Analysis Document.

Regarding EPA's assumption, for the purposes of its national analysis, that I&E is proportional to flow, please see EPA's response to Comment 316bEFR.041.037.

Please see Chapter A7 of the Regional Analysis Document and response to Comment

316bEFR.306.506 for a discussion of EPA's conclusions concerning entrainment survival.

Please see response to Comment 316bEFR.025.015 for EPA's rationale for not considering potential compensation in its analyses of foregone fishery yield. Note, however, that foregone fishery yield is calculated for commercial and recreational species only, which applies to only about 2 percent of I&E losses.

Cooling system costs (e.g., dry, wet, recirculating)

Cooling System Retrofit Cost Analysis

EPRI

July 26, 2002

1. INTRODUCTION

Scope of study

The focus of this study is on the costs of the "cooling tower option" for meeting the 316 (b) regulations. Information from a variety of sources is collected and organized to provide a reliable estimate of the likely costs of retrofitting wet cooling towers onto existing plants originally constructed with once-through cooling. Costs estimated for existing plants conducted by utilities and in some cases independent studies by architect/engineering firms are identified, scaled up from the date of the study to reflect 2002 costs and correlated against postulated important plant characteristics. Studies that have attempted to use generalized costing rules to estimate the costs for all units potentially subject to the Proposed rule are examined. The results of these studies are compared with data from studies of specific plants when available. The agreement or lack thereof is used to estimate the range of costs likely to be encountered and these are compared to the EPA results.

While the primary emphasis is on the capital costs of the retrofit, it is recognized that the effects of using recirculated cooling on plants originally designed for once-through cooling can include changes in the O&M costs, an increase in the plant heat rate and a reduction in the plant output capacity particularly during the warmest and most humid days of the year. Simple estimates are provided to establish the range of these costs as well. Finally, the use of recirculated cooling, while doubtless reducing the intake of water into a plant's cooling system, may introduce other environmental impacts. These are considered briefly.

Organization of report

The remainder of the report is organized into seven sections. Sections 2 through 5 deal solely with capital costs. Section 2 reviews the EPA methodology and cost estimates. Sections 3 and 4 collect, review and correlate information from individual plant studies by utilities and A&E's (Section 3) and cost studies based on generalized costing rules (Section 4). Section 4 also presents comparisons of the studies with the individual plant information and intercomparisons of the various generalized cost estimates. Section 5 presents comparisons with EPA results.

Section 6 reviews the cost of increased O&M requirements, of increased heat rates and of hot-day capacity loss. Section 7 reviews other environmental issues that might result from the introduction of recirculated cooling on a widespread basis at once-through cooled plants. Finally, Section 8 summarizes conclusions drawn from these analyses.

2. EPA ANALYSIS

Introduction

This section provides a brief review of the cost analysis methodology used by EPA in their development of the proposed Phase II rule. In addition to the proposed rule itself, the primary sources of information are

-EPA Economic & Benefits Analysis; EPA-821-R-02-001 (2)
-Case Study Analyses; EPA-821-R-02-002 (3)
-Technical Development Document; EPA-821-R-02-003 (4)

Underlying methodology and assumptions

The EPA approach to developing the likely cost of the "all cooling towers" option is based on a few major assumptions.

1. The addition of a cooling tower at a plant will connect to the existing condenser and the circulating cooling water flow rate will be unchanged, and
2. Portions of existing condenser conduit systems can be used, although some intake modification and conduit branching may be required.
3. The EPA cost development methodology used new facility, or "greenfield", cost estimates that are then adjusted by multiplying "factors" in order to determine the cost of retrofit at a plant of the same size (circulating water flow rate).

Items 1 and 2 are illustrated for purposes of discussion in Figures 2-1 and 2-2, which show schematically the rearrangement of the circulating water piping and make-up and blowdown conduits that are needed.

[see hard copy for figure]
Figure 2-1

[see hard copy for figure]
Figure 2-2

Cooling system re-optimization:

The issue of whether the circulating water flow and condenser configuration are kept the same is an important one. Systems originally designed for and operated on once-through cooling typically have a higher condenser flow rate than do systems designed originally for recirculated cooling with cooling towers for the following reasons:

1. The circulating water loop head requirements are substantially lower for once-through systems where the major pressure drop occurs across the tube side of the condenser. In a recirculated system the head rise needed to lift the water to the spray deck at the top of the cooling tower is added to the

condenser pressure drop increasing the required pumping power by a factor of two or three if the flow rate is the same.

2. For a given heat load , the temperature rise of the cooling water as it flows through the condenser is inversely proportional to the flow rate. Therefore, for a given condensing temperature, the mean temperature difference across the condenser is greater for a lower water temperature rise (higher flow) allowing for a smaller condenser. Typically, once-through systems optimize at flow rates corresponding to a temperature rise of 10 to 15 F with a circulating water flow rate of 400 to 700 gpm/MW as shown in Figure 2-3 for the 50 plants for which cost data were obtained.

3. On the other hand, cooling towers operate more effectively at higher temperatures and lower water flow rates. The higher inlet temperatures would provide for a larger driving force for heat rejection to the atmosphere, thereby reducing the required size and fan horsepower of the tower. Therefore, compared to a once-through system, an optimized tower system normally has higher temperature rises across the condenser, lower circulating flow rates resulting in lower pumping power, a smaller and less expensive tower, but with increased condenser area.

[see hard copy for figure]
Figure 2-3

Therefore, a retrofit strategy which leaves the circulating water flow and condenser unchanged results in a tower which is more costly and pumping requirements that are higher (the tower would have to be larger to handle the higher volumes of water at the lower inlet temperature) than an optimized recirculated system but avoids the cost of retrofitting the condenser and minimizes the modifications required to the circulating water piping.

A retrofit strategy that re-optimizes the balance of the cooling system to accommodate the change to a recirculated system by cutting the circulating water flow rate by 40 to 60%, will require major condenser tube-side modifications to keep the tube side water velocities at sufficiently high levels. This typically requires a change from a one-pass to a two-pass tube side, rearrangement of the water boxes, and rerouting of the inlet and outlet piping. These modifications may require substantial time and effort to gain access to the condenser through the turbine hall walls, and to rearrange massive piping in the area below the turbine exhaust.

The approach which re-optimizes the cooling water system as part of the retrofit typically incurs higher costs for the retrofit itself but results in more efficient operation with lower heat rates and lower operating energy requirements over the remaining life of the plant. Therefore, this strategy would be preferentially applied to large, base-loaded (low heat rate plants) with long remaining life. EPA has not made this distinction in their analysis. However, as will be noted later, nearly all the case studies done at individual plants by the owners themselves or by A&E firms adopted a similar strategy so virtually no data exist to establish the difference in either capital cost or lifetime operating costs definitively.

Use of existing circulating water piping circuit

The ability to use existing circulating water piping is an important feature of minimizing the cost of retrofit. It depends on two factors: the ability of the existing piping to handle any increased pressure and the availability of a place to locate the cooling tower in reasonable proximity to the turbine hall and the existing condenser.

1. The need to pump the hot water from the condenser to the top of the tower imposes a higher pressure on the condenser tubes, the inlet and exit waterboxes and all piping from the circulating water pumps to the cooling towers. In many cases, neither the waterboxes nor the piping itself is designed to withstand this additional pressure, which might be an increase of 15 to 30 psi. In these cases, reinforcement or even replacement may be required at substantial additional cost.

2. At some sites, the only feasible place to locate a cooling tower may be quite far from the condenser and the existing inlet and discharge structures. There are also some sites that are so constrained that placement of a wet cooling tower is essentially impossible. Some studies have required the placement of the tower as much as one-half mile away, requiring the installation of 4000 to 6000 feet of new circulating water conduit.

New facility costs

The estimates for new facility costs were documented in the support documents (5, 6, 7, 8) published in conjunction with the 316(b) Phase I Rule for New Facilities. These costs were subjected to industry review at the time of that rule making but are summarized briefly here for convenience of reference.

The fundamental cost element was for the cooling tower itself. The estimates, based on “discussions with experienced industry representatives”, were as follows:

The range of costs were expressed as $ per gpm of circulating water flow for towers with water flow rates less than or greater than 10,000 gpm (corresponds to plants of about 20 MW)

BASE TOWER COSTS---NEW FACILITIES*

Circ. Water Flow Rate	Approach (Tcold – Tambient wet bulb)	Cost Factor ($/gpm)
< 10,000 gpm	10	30
“	5	50
> 10,000 gpm	10	30 - 25
	5	50 - 45

** for towers up to 204,000 gpm; larger systems assumed multiple towers

Additional scale factors included:

Material factors:
Douglas fir 1.0
Redwood 1.12
Concrete 1.4
FRP 1.1 (fiberglass reinforced plastic)

Fill factors:
Film fill 1.0
Splash fill 1.1

Non-fouling film fill   1.1

Total installed cooling tower costs were taken as 1.8 times the cooling tower capital costs.

The capital cost included

- Wet mechanical draft tower, furnished and erected (with internal tower piping, □□ risers and valves, fans, motors, electrical service and housing)
- Site preparation, clearing and grading
- Excavations for basins and piping
- Circulating water piping, valves and fittings to and from condenser
- Access roads
- Full circulating pumps and housing
- Installed concrete basins, sumps and footings
- Electrical wiring, controls and transformers
- Blowdown water treatment facility
- Acceptance testing and installation.

The x 1.8 multiplier also accounted for construction management, mobilization and demobilization, design engineering and architectural fees, contractor overhead and profit, turnkey fee and contingencies.

Therefore, for a redwood tower with splash fill designed for a 10F approach in a size range near 200,000 gpm, the cost is given by

$25/gpm x 1.12 x 1.1 x 1.8 = $55.4/gpm

Comparison with other cost estimates:

There are other recent cost estimates for new wet cooling towers to be found in publications by Maulbetsch and DiFilippo (9) and by Burns and Micheletti (10).

Costs for just the cooling tower (purchased and erected) for various local climatic conditions ranged from $20 to $25/gpm. The inclusion of the other elements included in the EPA estimate of "base capital cost" increased this value by a factor of about 1.5 resulting in a cost of $37.5/gpm to be compared to EPA's $25./gpm. However, the usual multiplier in the several studies of new and retrofit costs (including recent work by Burns & Micheletti (10), Stone & Webster (11) and others (12)) for indirect costs average to 1.35. These costs included construction management, mobilization and demobilization, design engineering and architectural fees, contractor overhead and profit, turnkey fee and contingencies. Applying this to the estimates in Maulbetsch and DiFilippo (9) gives a system installed cost of about $50/gpm, which is in essential agreement with the EPA value. An informal survey (13) of recent tower purchasers in the industry at the time of publication of the M&D report suggested that the estimates were close to the range of their recent experience.   It should be noted that significantly higher cost estimates could be found in recent literature (10, 14) although the basis for a direct comparison with EPA results is not easy to define.

Retrofit vs. new installations

Capital cost estimates for retrofit cooling towers were based on “greenfield” cost estimates described above using:

-For fossil plants: redwood, mechanical draft towers with splash fill
-For nuclear plants: concrete, mechanical draft towers with splash fill.

It was recognized that the construction and installation process was generally more difficult, time-consuming and costly when done on the site of an existing, operating facility with attendant interferences of existing structures, overhead and underground interferences and the on-going conduct of business. These additional costs were described as including such items as:

-Branching or diversion of cooling water delivery systems,
-Reinforcement of retrofitted conduit system connections,
-Partial of full demolition of conduit systems and/or structures,
-Additional excavation activities
-Temporary delays in construction schedules
-Potential small land purchases
-Hiring of additional (beyond those typical for the “greenfield” cost estimates) equipment and personnel for subsurface construction
-Potential additional cooling water (recirculating or make-up delivery needs), and
-Expedited construction schedules and administrative and construction-related safety procedures.

The factor applied to account for these costs was chosen by the Agency as 20% for “activity necessary to convert cooling systems” and 30% for “upgrading of cooling water intake structures and screens”.

In addition to this retrofit factor, two other multipliers were applied:

1. A contingency factor of 10% to account for miscellaneous unspecified uncertainties associated with a construction project, and
2. A regional cost factor to account for local differences in labor and material costs. These were applied on a state-by state basis and ranged from 0.739 (for SOuth Carolina) to 1.245 (for Alaska).

The magnitude of these adjustment factors is of paramount importance in determining the appropriateness of the estimated retrofit cost estimates. A number of comments are relevant:

1. The regional cost factor is based on well-documented information from the R. S. Means Cost Works 2001 (15). This approach to accounting for local cost differences is well established and consistent with methods in other studies.
2. The 10% contingency factor, while presented without any supporting evidence, is also consistent with similar estimating methods used by others.
3. The retrofit factor, however, is also selected without any documentation or reference to any supporting data or information based on experience with comparable projects at new vs. existing facilities. While confirming (or contradictory) evidence is difficult to find, there are reasons to believe that the 20% adjustment factor will underestimate the retrofit-related costs in many (although perhaps not all) cases. Specifically,

-Site-specific retrofit costs studies show a high degree of variability from costs based on commonly accepted scaling methods. Cooling tower cost estimating methods are often based on the use of a $/gpm rule of thumb. This is approach is used by tower vendors, A&E firms and experienced users and is based almost entirely on the field's experience with tower construction at new sites. EPA used this approach as well. It can, therefore, be reasonably assumed that the variability in careful engineering estimates of site-specific retrofit costs, which will be documented for about 50 cases in Section 3, is due to differences in the degree of difficulty associated with the retrofit aspects of each project.

-It is also reasonable to assume that the lower bound of these costs is associated with the "easiest" retrofit cases, which would correspond most closely to a new facility project free of the interferences encountered at most existing facilities. As will be seen, the lower bound of the case data corresponds reasonably well with the "greenfield" cost estimating rules proposed by EPA, while the mid-range of the data is 40 to 60% higher with many cases ranging to a factor of 2 to 4 times more expensive.

-Discussions were held with project managers at actual sites where construction projects of a similar nature to cooling system retrofits were either underway or had been estimated in detail for potential future site modifications. In all cases, the cost increments associated with constraints imposed on the project by the complexities of construction at an existing site were claimed to be significantly greater than 20%, with estimates ranging from 50% to 100%. This range is reasonably consistent with what might be inferred from the case study estimates discussed above. The reasons given for the incremental costs included many that were apparently not included (or at least not specifically identified) in EPA's discussion of their retrofit cost factor. These included

i. The need to locate new structures far from their preferred location because of pre-existing structures, switchgear, access roads, etc.
ii. The extreme difficulty of installing underground piping in the presence of pre-existing piping and cables that had to avoided or relocated. In one instance, the installation of a circulating water line for a new unit located on the back of an existing site encountered over 150 interferences and increased the cost of normal estimates on a "per ft. diameter-ft. length" basis by a factor of nearly five.
iii. The need to locate material laydown areas and crew parking areas several miles from the site with an attendant effect on productivity alone estimated at 10 to 20%.
iv. The inability, in some cases, to carry out some aspects of the project in parallel with others where the site access would be blocked by a structure that construction of them could not commence until all others were completed.

While it is not possible to generalize such experience to all sites, they establish the point that very high retrofit factors will inevitably be encountered at many facilities.

3. RETROFIT COST DATA--INDIVIDUAL PLANTS

Data Sources

Cost estimates for retrofitting once-through cooling systems to recirculated systems were solicited from many utilities including EPRI and Utility Water Act Group (UWAG) member companies. In addition, a brief literature search was conducted for published studies. Cost information was obtained for 50 plants. These were grouped by fuel type (nuclear or fossil), plant size (> or < 500MW) and source water type (fresh, brackish or saline). Table 3-1 gives the distribution of the plant data among the categories. Appendix A tabulates the plants (identified by sequential numbering as Plant “n”) with pertinent information about plant capacity, circulating water flow rate, location by region, fuel, source water type, retrofit cost data (as reported and scaled to 2002$, and the estimates for the plant from the Stone & Webster study (16).

Distribution of Plants With Data (50)

NUCLEAR (15)

	Saline	Brackish	Fresh
> 500 MW (15)	5	5	5
< 500 MW (0)	0	0	0

FOSSIL (35)

	Saline	Brackish	Fresh
> 500 MW (29)	2	8	19
< 500 MW (6)	1	1	4

Table 3-1

The source information came in varying forms and some adjustments were often required to put them on a common basis. The two most important considerations were the year in which the estimate was made and whether or not ancillary costs were included in addition to the direct costs.

Year of estimate

In all cases, the year in which the estimates were made was reported. The dates of the estimates ranged from 1973 to 2002. For estimates made in years prior to 2002, the values were scaled up to 2002 dollars using the appropriate multiplier from the Engineering News Record’s Construction Cost Index (ENR-CCI), available at http://enr.construction.com/cost/costcci.asp. These factors are displayed in Table 3-2. The increase over the past ten years is equivalent to a compound escalation rate of 2.8%.

[see hard copy for figure]

Construction Cost Index History (1908-2002)

In a few instances, the utility supplying the data provided a separate estimate of updated costs from original earlier estimates. These were generally close to, but not necessarily identical to the factor that would be derived from the ENR-CCI. In those cases, the utility estimate was used on the basis that it might better reflect local circumstances.

Level of detail

The information provided for the cost of retrofit at a particular plant varied from a “single number estimate” to fully documented engineering studies. Two important questions for the “single number estimates” were:

1. What was the extent of the retrofit?

2. What ancillary project costs were included?

Extent of retrofit

"Extent of retrofit" refers to whether or not the plant cooling system was re-optimized to account for the different operating characteristics of a recirculated system. Specifically, in what might be characterized as a "minimum modifications retrofit" the existing cooling circuit would be left largely unchanged. The circulating water flow would be kept the same; the surface condenser would be unchanged. A wet cooling tower (typically mechanical draft) would be inserted into the cooling water flow loop; the circulating water pumps would be replaced or upgraded to meet the increased head requirements imposed by the need to pump water to the top of the tower; the circulating water lines would be re-routed or reinforced as required; and make-up and blowdown pumps, lines and treatment facilities would be added. This approach is a minimum initial capital cost approach but results in a less than optimum design and operating condition for a recirculated cooling system.

Re-optimized retrofit

Compared to once-through cooling, recirculated cooling is normally designed with lower circulating water flow rates due to the higher head rise required to pump the water to the top of the tower, typically 40 to 60 feet above the condenser outlet. The lower flow results in higher temperature rise across the condenser. The tower is then optimized for a higher range (Th on – Tc off) and a lower L/G (liquid to gas ratio) than would be the case for a tower operating at the flow and temperature rise of the original once-through system. This results in a lower cost tower with a closer approach to ambient wet bulb than the unoptimized case.

However, the steam surface condenser would then need to be reconfigured to maintain its performance at the lower flow, higher range conditions. Typically, this would be accomplished by changing the tube side from a one-pass to a two-pass design in order to maintain the water velocity in the tubes at an acceptably high level. This in turn requires substantial re-arrangement of the inlet and outlet headers and piping and often considerable demolition (and subsequent rebuilding) of the turbine building walls in order to gain access to the condenser for the modifications.

Re-optimization, therefore, adds considerably to the initial capital cost of retrofit but results in a system with substantially lower operating cost (lower pump and fan power requirements) and lower performance penalties for the remaining life of the plant. Therefore, the re-optimization approach would be used only for large, typically base-load plant with a long remaining life. With only two exceptions, all of the cost information used in this analysis was for "minimum modification retrofits".

Ancillary costs

The fully documented studies presented direct cost items including purchased equipment and installation costs. Table 3-3 displays a listing of typical cost elements, taken from a published study of retrofit cost estimates for a large nuclear plant (11). In addition, ancillary cost elements are added in order to develop a realistic "total project cost". One such set of cost categories is listed in Table 3-4, taken from a study of the Millstone Plant presented to the Connecticut Department of Environmental Protection (Ref. 12). These cost are normally "factored" or estimated as a percentage of the Direct Costs. The percentages used in the Millstone study are given in Table 3-4. Based on these values, the ancillary costs add 37% to the Direct Costs of the retrofit.

[see hard copy for figure]
Table 3-3: Typical Cost Elements for Recirculated Retrofit (from Ref. 11)

Table 3-4: Typical Ancillary Costs

Cost Category	% of Direct Cost
Construction Management	7
Engineering	10
AFI*/Contingency	20

* Allowance for Indeterminates

Other studies include similar adjustments to the Direct Costs. Regardless of the exact categorization, the total adjustment ranged from 35% to 45% in the case of one utility study.

In interpreting the "single number estimates" received for individual plants, it was not clear whether the cost represented the Direct Cost or the total project cost. Telephone inquiries to all sources that could be reached indicated that in most (but not all) cases the total project cost was included but it was seldom known what percent of the total was represented by the ancillary costs. In cases where it was determined that only the direct costs had been reported, the cost was increased by 40% to put it on a consistent basis with the rest. For cases where it could not be determined which costs were reported, it was assumed that the reported cost was the total project cost.

Cost information from individual plant case studies

The cost data for each of the plants, scaled to a comparable basis in 2002$, is displayed in Figures 3-1 through 3-6.

Cost vs. Plant Size:
Figure 3-1 plots the cost against plant size in MW. This is consistent with the conventional means of normalizing cost data for power plant equipment on a $/kW basis.

[see hard copy for figure]
Figure 3-1

In this case, the correlation, while roughly proportional, is poor. The costs range from well below $100/MW to well above $250/MW. This is due in part to the fact that the cost of cooling system components is more closely related to the amount of water being circulated and cooled than to the heat load being rejected. Additionally, the circulating water flow rate per MW of plant capacity is not constant but varies considerably from plant to plant as a function of heat rate and design choice, as shown in Figure 2-3, suggesting that a correlating factor of $/gpm would be more directly related to the size and capability of the cooling system. As discussed in Section 2, this is in fact the scaling factor in common use in the cooling system industry and that which was used by EPA and others in cost analyses of both new and retrofit cooling systems.

Cost vs. Circulating Water Flow Rate

Figure 3-2 displays the same data against circulating water flow rate.

[see hard copy for figure]
Figure 3-2

While the general correlation against flow rate is improved over that against plant capacity, a considerable range still exists and numerous outliers are evident.

The following figures show the results of trying to categorize the results by plant type (fossil vs. nuclear) in Figure 3-3 and by source water type (saline vs. brackish vs. fresh) in Figure 3-4.

[see hard copy for figure]
Figure 3-3

[see hard copy for figure]
Figure 3-4

Fossil vs. nuclear plants:

The data in Figure 3-3 suggests that there is no consistent separation between the costs at nuclear vs. fossil plants. The nuclear plant cost estimates exhibit much greater variability than do the fossil plant estimates with outliers on both the high and low cost extremes. However, many of the plants fall in a range that is indistinguishable from the majority of the fossil plants over a nearly five-fold range of cooling system size as measured by circulating water flow rate.

Source water type

Figure 3-4 suggests a similar conclusion for the effect of source water type. Retrofit costs for plants using brackish water plants exhibit higher variability than do those for either fresh or saline water. While this may be indicative of greater inherent variability in water properties within the class designated as brackish, it seems unlikely that the case study results reflected that detailed an analysis. The apparent variability in costs in the brackish category may more likely be attributed to the fact that those points which might be considered outliers are also nuclear plants which exhibit greater variability for all water types.

This hypothesis is investigated further in Figures 3-5 and 3-6 that refine the analysis further by separating the data both by fuel type and source water type. Figure 3-5 shows all the fossil plants separated by water type.

[see hard copy for figure]
Figure 3-5

With one or two notable exceptions (one on the high cost side, the other on the low cost side, both of which are brackish water sites), there is reasonable correlation across all source water types within a range of +/- 35 to 50%.

On the other hand, Figure 3-6, which displays similar information for the nuclear case studies, exhibits very high variability for all source water types.

[see hard copy for figure]
Figure 3-6

The overall conclusion is that neither size nor flow rate scaling, or differences associated with fuel or service water type account adequately for the site-specific differences in retrofit costs. This is clear from a detailed look at some of the individual case study documents.

For example, in a study of nine individual plants at a single utility, the site-specific elements at each plant were factored from an in-depth study at one of the plants. The cost of retrofit was broken into 15 separate elements. The scale factors for many of the major elements varied from 1.0 to 3.3 across the other plants. In one instance, 2/3 of the cost of retrofit at one of the plants was for items that were completely absent at all the others. Clearly the retrofit costs at each of the plants was dominated by site-specific adjustments rather than by simple scale factors based on size or flow rate.

In a survey of EPRI and UWAG members, utilities were asked to assess the seriousness of eight potential site-specific issues which might make retrofit more difficult and more costly at their plants.

The specific issues raised were

1. Availability of land at the site to place a cooling tower.
2. Distance of a preferred site from the turbine/condenser
3. Likelihood of interferences to installation of new circulating water piping.
4. Unacceptable site geology or topography for tower support
5. Drift or plume problems
6. Noise problems
7. Aqueous discharge constraints on blowdown
8. Need to re-optimize condenser or reinforce condenser for increased pressure

Responses were received for a total of 56 plants. Table 3-5 indicates the number of plants at which each issue was deemed to be a problem for cooling system retrofit. Each of the issues was identified at least 1/3 of the plants with some at nearly all. The most common concerns were the difficulty of finding a site near the turbine/condenser and the difficulty of installing circulating water piping in the midst of existing underground interferences.

[see hard copy for figure]

Cooling system costs (e.g., dry, wet, recirculating)

4. INDEPENDENT RETROFIT COST STUDIES

Three independent studies have been conducted recently to estimate the cost retrofitting existing facilities from once through cooling to closed-cycle cooling. These studies were done by Stone & Webster Engineering Corporation (SWEC), the Washington Group, Incorporated (WGI) and the National Energy Technology laboratory (NETL). A brief review of the methodology used in each study and a comparison of the results to the individual plant data presented in Section 3 follows.

SWEC Study

The SWEC developed a retrofit cost estimate for each of 1041 units currently using once-through cooling. The cost for each was scaled from one of six reference plants for which detailed cost estimates of a cooling system retrofit had been conducted in the past. These reference plants, listed in Table 4-1, cover a range of plant fuel, source water type and plant size. The total retrofit cost for each reference plant was aggregated in four categories as:

-Labor
-Materials
-Equipment, and
-Indirect costs.

For each individual unit, a reference plant was chosen which was most representative of the unit being estimated. The cost was then scaled from the selected reference plant using two scale factors.

1. The labor cost component was adjusted for regional differences in wages and productivity between the individual unit and the reference plant.
2. The adjusted total cost (adjusted labor plus materials, equipment and indirect) was then scaled from the reference plant to the individual unit on the basis of circulating water flow rate.

This approach is essentially that used by EPA except that SWEC made the regional cost adjustment on the labor component while EPA applied an adjustment factor to the total cost.

The assumption was made, as it was in all of the studies and in the EPA development, that the circulating water flow rate remained the same for the retrofitted closed-cycle system as for the original once-through system.

No attempt was made to adjust each estimate for local conditions or site-specific "degree of difficulty". The cost estimates, because of the method used, will inherently reflect whatever local retrofit issues or difficulties pertained at the chosen reference plant. Figure 4-1 displays graphically the costs that would be generated by each of the reference plants for the range of circulating water flow rates. With the exception of Plant X5, they are all within a relatively narrow cost range from \$185/gpm to \$212/gpm. Plant X5 represents a situation where relatively little work had to be done to upgrade the circulating water and make-up water systems.

[see hard copy for figure]
Table 4-1

Figures 4-2 through 4-5 display comparisons to the individual plant case study data with the results of the SWEC estimates. These estimates give excellent (+/- 25%) agreement against approximately 2/3 of the individual plant data as shown in Figure 4-2 and reasonable agreement (-25%/+50%) for all but about 20% of the cases. A few points are substantial outliers exceeding the estimates by a factor of two or more.

It is noteworthy that most of the deviation is in the direction of underestimating the individual plant costs rather than overestimating. In fact, the data cluster itself has a reasonably well-defined lower bound while discontinuities and outliers characterize the high cost boundary. This is consistent with the notion of a reasonably well-defined “minimum cost retrofit” (such as might be represented by new facility construction) modified by site-specific differences, which lead to a range of high-end costs, which are not predictable on the basis of simple scaling laws.

Figures 4-3 through 4-5 break the comparison down by the categories of fuel (fossil/nuclear), source water type (fresh/brackish/saline) and SWEC reference plant.

Figure 4-3 indicates that the agreement is generally better for the fossil units than for the nuclear units, which account for all but one of the plants where the retrofit costs exceeded the estimates scaled from the nuclear reference plants by more than a factor of two. A number of the nuclear plants, however, agreed extremely well with the estimates suggesting again that sites where no significant site-specific difficulties exist are comparable and can be scaled by cooling system size or circulating water flow rate. However, sites where issues exist can incur costs significantly in excess of what would be expected.

Figure 4-4 seems to indicate greater differences from scaled estimates for brackish sites. However, as was discussed in Section 3, many of the brackish sites exhibiting large differences from the estimates are also nuclear plants making it difficult to attribute the cause of the variability to the source water or the fuel type.

Figure 4-5 shows no particular separation in the quality of the estimates associated with the choice of base reference plant. This is somewhat to be expected since the range of cost (per gpm of circulating water flow rate) is not large (+/- ~ 7% as seen from Table 4-1). Reference plant X5, the largest nuclear plant, has a significantly lower cost per gpm (by about 30% from the average of the other 5 base plants) and does under-predict three of the larger nuclear units. On the other hand, it predicts three others quite well, suggesting again that site-specific issues are often the dominant determination of the costs of retrofit.

Washington Group Study

The Washington Group completed another study to estimate the costs of cooling system retrofit (Ref. YY). The approach taken in this study was quite different. For each unit in the population of units eligible for retrofit, information was obtained from an industry database, on the power generation thermal cycle, steam conditions and unit size and grouped the units by these variables. The reject heat load to the condenser was then calculated based on heat balance equations chosen as appropriate for each grouping. A constant cooling water temperature rise across the condenser of 12° F was chosen for each unit and, from this, a cooling water flow rate could be calculated and a cooling water flow per unit plant output could be determined.

Costs for closed-cycle cooling systems were determined from vendor estimates and contractor experience for fresh and saltwater cooling systems for a range of cooling tower sizes. In addition to the cooling tower structure, costs were added for the cooling tower basin, circulating water pumps, circulating water pipe costs, make-up water treatment system, circulating water chemical treatment system, make water pump, electrical equipment and connections, and additional multipliers for engineering, construction management, interest during construction, startup, contingency and fees. All the costs were then normalized on a cost per circulating water flow rate ($/gpm) and applied to the unit groupings developed for the different thermal cycles and associated heat rates.

Retrofit issues were addressed in a limited fashion. The circulating water lines were calculated on the basis of 1000-foot length (implying a 500 foot distance between the condenser and the tower) for each case. This was felt to be longer than would normally the case in new plant construction and chosen to account for difficulty in finding a closer location for the tower at an existing site. New circulating water pumps were included to account for the increased head rise required to pump the water to the top of the tower. Beyond these two items, the cost elements were essentially identical to new facility costs.

A comparison of the results of this analysis to the individual plant costs discussed in Section 3 is presented in Figure 4-6. The WGI estimates are consistent with the lower bound of the individual plant data as might be expected for estimates which are consistent with new facility costs and which do not reflect issues related to retrofit conditions.

The range of cost per gpm costs developed in this manner range from $70 to $95 per gpm for fresh water units and from $95 to $125 per gpm for saltwater units. This compares to the SWEC scale factors based on site-specific studies of projects carried out under retrofit conditions of $140 to $212 per gpm. This comparison is further indication that a 20 to 30% adjustment to new facility costs to account for retrofit issues is insufficient.

[see hard copy for figure]
Figure 4-6

National Energy Technology Laboratory (NETL)

A brief study of retrofit costs at four sites was conducted by NETL. The sites were:

-1700 MW (2 units) nuclear plant on brackish water
-1100 MW (2 units) fossil (gas and coal) plant on brackish water
-700 MW (2 units) fossil (gas) plant on brackish water
-1850 MW (4 units) fossil (coal) plant on saline water.

The exact methodology and scope is not known but a simple comparison is made with estimates for the corresponding plants from the SWEC study in Figure 4-7. The agreement is reasonable with three of the four cases within 20% and the fourth within about 40%. While the results of such a limited sample may be fortuitous, the general agreement between two sets of estimates both of which attempted to factor in site-specific retrofit issues gives further support to the contention that a simple scaling from new facility estimates is inadequate to account for retrofit costs.

[see hard copy for figure]
Figure 4-7

5. COMPARISON OF DATA WITH EPA ESTIMATES

A comparison of EPA cost estimates with either the individual plant cost data (from Section 3) or the results of the three independent cost studies (SWEC, WGI, NETL) is difficult. EPA does not report plant-by-plant estimates. Also they include a number of cost adjustment factors and add-ons in the cost tables and example calculations which make it difficult to generalize or average across the population of plants.

As an alternative for comparison purposes, a likely upper bound of the EPA cost estimates can be established. The costs are based on new facility costs reported in Economic and Engineering Analyses of the Proposed §316(b) New Facility Rule (8). In Table A.5 of that document costs are given for a range of flows for five different materials of tower construction. For cooling water flows grater that 10,000 gpm, the highest cost per gpm is for a concrete tower with a flow rate of 11,000 gpm and equals $76/gpm. Excluding Alaska and Hawaii, the highest regional cost factor is for New Jersey and equals 1.099, bringing the adjusted cost to $83.2/gpm.

In the example calculations given in Technical Development Document for Proposed Section 316(b) Phase II Existing Facility Rule (4), the capital cost of the installed cooling system alone was increased by additional factors for

-Intake and discharge piping modification capital costs
-Cooling water intake technology retrofit capital costs, and
-Condenser upgrade capital costs.

These items added over $12.5 million to a base cooling system costs of $53,550,000 or an increase of about 25%. While these costs are apparently not applied in all cases, they suggest a potential increase in $/gpm factor of 25%, bringing the system cost to $104/gpm for new facility costs.

The authors then developed the retrofit costs by adding a 20% retrofit factor (30% for some elements of the system), a 10% "contingency factor" and a 5% factor "to account for uncertainties inherent in intake modifications at existing facilities." This would result in retrofit costs of $145 to $156/gpm, depending on whether a 20% or a 30% retrofit factor is applied.

Figure 5-1 displays the individual plant retrofit costs from Section 3 plotted as retrofit cost against circulating water flow. The correlation lines for EPA new facilities are shown, along with the adjusted EPA retrofit costs using both a 20% and a 30% retrofit factor.

As was suggested earlier, the "new facility" costs appear to give a reasonable approximation to the lower boundary of the cluster of 50 data points obtained from individual plant studies. This is consistent with the contention that the minimum cost of retrofit is close to the cost for cooling system installation at a new facility. The adjustment factors are seen to account for the additional costs associated with retrofit factors in only a fraction of the cases. The "best fit" linearization of the data points exceeds the EPA new facility costs by a factor of about x 2.3.

[see hard copy for figure]
Figure 5-1

Comparison of aggregated national costs:

SWEC, WGI and EPA each report the total national cost of retrofitting all of the units considered in their particular studies. A direct comparison of these aggregated costs is not completely straightforward, however, for two reasons:

1. The costs are not all reported on the same basis. SWEC and WGI report the sum of the capital costs for each of the units estimated. EPA reports the total as an "annualized, post-tax cost".

2. The number of units included in the estimate is not the same for all the studies.

Capital cost vs. annualized post-tax cost

The annualized, post-tax cost reported by EPA is used to put the one-time, capital cost on a comparable basis with operating costs that are incurred on a yearly basis over the life of the facility. A selected discount rate is applied over the facility life. As described on p. B1-15 of the Economic and Benefits Analysis (2), the annualized cost is defined as

Annualized cost = Capital cost x {[r x (1 + r)n]/ [(1 + r)n – 1]}

where r = discount rate
n = useful life of the equipment
In the analysis, EPA assumes

r= 7%
n = 30 years (for cooling towers)
20 years (for condensers)
10 years (for other equipment)

Rather than attempting to allocate the different cost elements among the three lifetime categories, and since the majority of the costs are for the cooling towers, this comparison uses a 30-year life for the calculated adjustment.

On this basis the annualizing factor is 0.081. (Using 25 years changes the conversion factor by only 6% from 0.081 to 0.086.)

Post-tax cost adjustment:

EPA reduces the costs by an assumed tax rate. The combined Federal and state tax liability is given by

Total tax = Federal tax + state tax – ([Federal tax] x [state tax])

The Federal tax rate is taken as 35%. The state tax rate, which may vary from 0 to 10%, was presumably applied on a state-by-state basis in EPA's estimates but was assumed to be 5% in this comparative analysis. This yields a combined tax rate of

Tax rate = 0.35 + 0.05 – (0.35 x 0.05) = 0.3825

Therefore, the annualized post-tax cost is given by

Annualized, post tax cost = Capital cost x 0.081 x (1 – 0.3825)

= Capital cost x 0.05

Number of units included:

The number of units included in the SWEC and WGI analyses is roughly equal. Both used the UDI database and excluded units currently on recirculated cooling. Both ended up with about 1200 units representing about 250 GW.

The population included in the EPA analysis is stated to be 426 "facilities" representing 353,750 MW of baseline steam capacity. A facility appears to be defined as "units with a common intake structure" and would often, but not always, corresponds to a single plant that might have several units. Therefore, 426 facilities might correspond to 1000 or more units. However, the reported capacity is substantially more than that represented by the units included in the SWEC or WGI study. Furthermore, in the text of the proposed rule (p. 91 of the Prepublication Copy", Ref. 1a) it is stated that there are 539 facilities to which the rule would apply. Of these a number of facilities are deemed to "not require any additional controls" either because they already have recirculated cooling or other forms of adequate impingement control. The remaining facilities for which some sort of additional control would be required total 349. There is no indication of how much generating capacity is represented by these units.

Therefore, the only documentable basis for scaling the reported costs to account for differences in the population of facilities for the estimated costs would be to use the 353 GW figure reported in the Benefits Analysis document. This would require either reducing the EPA estimate by a factor of 0.7 (250GW/353GW) or, alternatively increasing the SWEC and WGI estimates by a factor of 1.4. This is a substantial adjustment to be applied on the basis of such uncertain evidence, so Table 5-1 simply lists the aggregated costs as "National costs of retrofit" as reported with the annotation that they may apply to significantly different populations of facilities.

Table 5-1 Comparison of National Costs for Cooling System Retrofit

Source	National Cost ($ Billions)
EPA	13.7(1)
SWEC	25.0 to 28.0(2)
WGI	22.2(3)

Notes:
(1) Scaled from reported annualized, post-tax capital cost of $684.7 million; reported to represent 353,750 MW at 426 facilities
(2) Sum of capital costs for 1040 units representing approximately 250 GW
(3) Sum of capital costs for 1268 units representing approximately 260 GW.

6. OTHER COSTS

Introduction

The retrofitting of a plant designed for and operating on once-through cooling impose a number of continuing costs on future operations of the plant in addition to the one-time capital cost of retrofit. The most important of these are

-Additional operating power: Recirculated cooling systems will have higher power requirements as compared to once-through systems for the increased head rise required of the circulating water pumps and for the fans to draw air through the tower. The power consumed for parasitic loads cannot be sold to the grid and represents lost revenue.

-Additional maintenance costs: Recirculated systems have additional equipment that requires maintenance labor and specialty chemicals costs for water treatment systems for both the make-up and the blowdown.

-Additional fuel costs: Plant equipped with recirculated cooling systems incur efficiency losses compared with once-through cooled systems due to the higher turbine backpressures imposed on the plant by limitations of the cooling system.

-Potential for output capacity limitations: To the extent that recirculated cooling system may not be able to maintain turbine backpressure below warranty limits during the hottest and most humid hours of the year, the plant maybe forced to reduce output to protect the turbine. While this is normally not the case with an optimized, well designed recirculated cooling system as applied to a new plant, the approach to retrofit which has been used in both the EPA and other cost analyses has chosen to reduce the initial capital costs by keeping the circulating water flow and the condenser the same as for the original once-through system. This results in a system that is far from optimum and may incur capacity limitations in some locations during the summer.

The following paragraphs provide a brief assessment of the possible magnitude of these costs.

Additional operating power:

The major power costs are for the circulating water pumps and the fans. Consistent with the assumption used in the development of the capital costs, the power for pumping is based on the same circulating water flow as was used in the original once-through system. However, the head rise to be delivered by the pumps must be increased to pump the water to the top of the tower, typically 40 to 50 feet. This will increase the pumping power over the once-through system requirements by approximately 5 kW per MW. The fan power for a 170 MW steam cycle was determined in a recent study (M&D) to be approximately 7.5 kW per MW. This gives an additional operating power requirement of 12.5 kW/MW or 1.25% of plant capacity.

Estimates in the SWEC report for a single case study at a large nuclear plant indicated annual power requirements for pumps and fans of about 19,000 kW out of a gross electrical output capacity of 1,123 MW. If the original once-through system pumping power is subtracted the net increase is about 12,000kW or 1.07 kW/MW is essential agreement with the previous analysis. Both of these estimates exceed the allowance reported by EPA of 0.85% of plant capacity (0.85 kW/MW).

Additional maintenance costs:

The major parts of the additional maintenance costs are associated with the water treatment for make-up and discharge required for recirculated operation and, in some cases, the need to rebuild the tower after extended service. Both these costs are highly site and situation specific but some generalized estimates have been made.

1. An estimate of the need for upgraded materials and the costs of clarifiers and specialty chemicals was performed for the various types of make-up water and is included in this report as Appendix B.

2. A common rule of thumb (See, for example, Ref. 10) sets the annual O&M costs at 1% of system capital cost. A case study for a large nuclear plant published in 1995 (11) found O&M costs not including power at about 1.6% of estimated capital costs.

3. EPA reports O&M costs on an annualized post-tax basis at $1,117 million for a capacity of 353,000 MW inclusive of the additional operating power. Using their estimate of 0.85% of plant capacity, the power costs would account for $720 million of that amount, if valued at $0.03/kWh. The remaining annual cost of $397 million is approximately 2.9% of the estimated capital cost.

While these comparisons are necessarily superficial, it appears that the EPA cost development makes adequate allowance for O&M costs exclusive of additional power.

Energy penalty:

The turbine backpressure achievable with a once-through cooling system is nearly always lower than that achievable with a recirculated cooling tower. To supply the condenser with the same flow of cold water at the same temperature as from a once-through system, the tower would have to cool the circulating water to the same temperature as the natural source water. The ambient wet bulb temperature is the lower limit for the achievable return water temperature for the tower. A reasonable tower design will do no better than approximately an 8-10ºF approach {Approach = Tcold water - Twet bulb). In addition, the ambient wet bulb is normally higher than the temperature of water withdrawn from natural sources (rivers, lakes, oceans) for much of the year, especially during the warmer, more humid months. For those times, the condenser inlet temperature and, as a result, the condensing temperature and the turbine backpressure will be higher than would have been the case with the original once-through cooling system. This backpressure elevation is most acute during hot, humid hours, which also correspond to times of peak electricity demand. The effect of increased turbine backpressure on plant performance is shown in Figure 6-1.

[see hard copy for figure]
Figure 6-1 (excerpted from Ref. 9)

Increased heat rate results in higher fuel consumption for a given plant output. An increase in turbine backpressure of only 1 in. Hga would correspond to a fuel cost penalty of $1 million per year. This 1 in. Hga would occur with an ambient wet bulb temperature increase of only 10°F, which is well within the seasonal variability for most parts of the country. This estimate of a 1% energy penalty is in the mid-range of that estimated in a recent NETL study. (17)

If applied to the 350,000MW identified in the EPA cost development analysis and assuming a 50% capacity factor and an average fuel cost of $2.50 per million Btu gives an annual energy penalty cost of approximately $700 million as compared to the EPA estimate of $364 million. However, within the considerable uncertainties and gross approximations that must be made in lieu of a detailed case-by-case analysis, this may be considered reasonable agreement and suggests that the energy penalties have been reasonably accounted for.

Potential capacity limitations:

For older plants with conventional steam turbines, a backpressure of about 5 in. Hga may not be exceeded without risking damage to the turbine and possibly voiding any warranty that might still be in force. If the plant is "cooling system limited" it is possible that it will be unable to maintain acceptable turbine backpressure at full load during hot, humid hours. Therefore, under atmospheric conditions that would lead to higher backpressures, the plant may have to reduce steam flow and hence output to stay within allowable operating limits of the turbine. Since this capacity shortfall comes exactly at the time of peak demand and, in a competitive environment, at the time of highest energy price, the lost revenue can be substantial.

However, for a plant with a retrofitted recirculated cooling system designed to maintain 2.5 in. Hga backpressure at the annual average wet bulb temperature, such an occurrence is unlikely since it would require that the ambient wet bulb temperature rise by 25ºF above the average. An examination of the annual average vs. 1% wet bulb temperatures in climatological data listings such as the

ASHRAE Guide shows that such locations are rare. Therefore, it is reasonable to ignore potential capacity penalties in a generalized analysis although they could occur on rare occasions in a few locations.

7. ENVIRONMENTAL COMPARISONS

As summarized by EPA in the Fact Sheet on the Proposed Rule, the regulation is "designed to protect fish, shellfish and other aquatic life from being killed or injured by cooling water intake structures". The degree of the environmental harm resulting from the intake of cooling water from natural waterways has been the subject of a vast number of general analyses and site-specific studies over decades. It is not a primary topic to be addressed by this report. However, while it is unquestioned that the use of recirculated cooling at a power generation plant will substantially reduce the amount of cooling water draw into the plant, it should be recognized that recirculated cooling systems are not without environmental impacts of their own, some of which are not present with once-through cooling systems.

Brief mention will be made of seven issues to be considered in comparing the environmental effects of recirculated and once-through cooling systems. These are:

-Intake losses
-Water consumption
-Water and waste discharge and disposal
-Drift and plumes from cooling towers
-Other air emissions
-Noise
-Aesthetics.

Intake losses

As shown in Figure 2-3, the cooling water flows for once-through systems range typically from 400 to 700 gpm per MW and occasionally higher. Cooling water intake for recirculated cooling systems using mechanical draft cooing towers typically ranges from 12 to 20 gpm/MW and occasionally higher depending primarily on the cycles of concentration at which the tower is operated. While this represents a twenty- to fifty-fold reduction in the water taken into the system, it may not represent a similar reduction in the degree to which "fish, shellfish and other aquatic life are killed or injured". The survival rate of organisms entrained or impinged in once-through systems has been studied and debated extensively but is not normally assumed to be zero. It is, however, extremely unlikely that entrained organisms will survive passage through a recirculated cooling system with a cooling tower.

Water consumption

While once-through systems, as noted above, withdraw large quantities of water, they return all of the withdrawn water back to the source (or at least to nearby natural waterbodies). A recirculated cooling system, while withdrawing far less water, is designed to cool by evaporating a portion of the circulating water flow in order to cool the remainder. A typical evaporation rate for mechanical draft cooling towers is 10 gpm/MW representing 50 to 80% of the intake flow, again depending on the cycles of concentration. This loss of water to the source waterbody will exceed losses associated with increased evaporation rate from the receiving waters of a once-through cooling system. There are also cases, such as on the Potomac River, where any additional consumptive water uses can no longer be permitted.

Water and waste discharge and disposal

Recirculated cooling systems require the discharge of cooling tower blowdown, which, while regulated, may result in some water quality impact. Regulatory constraints such as pertain in California where the State Implementation Policy for implementing the receiving water standards in USEPA's California Toxics Rule allow a discharger who takes water from an impaired water body to discharge back to that water body only if the concentration of the pollutants has not been increased. This offers relief to once-through cooling, but at plants that use cooling towers blowdown treatment will be required. This will require consideration of the disposal of solid waste, such as basin sludge or water treatment system sludges from evaporation ponds, brine concentrators, side-stream softeners or other blowdown reduction processes.
Plumes and drift:

Visible plumes----On cold days, wet towers can produce a large visible plume as the warm saturated air leaving the tower mixes with the cold ambient air and water vapor condenses. In some locations, these plumes may obscure visibility, creating dangerous conditions on roadways or lead to local icing on neighboring roads or structures.

In some instances, plume abatement capability may be required on a retrofitted recirculated cooling system with the potential for increasing the cost of the tower by a factor of 2 or more.

Drift----Drift rates from modern, well designed cooling towers can be held to quite low levels. New installations have been quoted at less than 0.0005% of the circulating water flow rate. However, even that low rate will result in a total drift of nearly 2000 gallons per day from a 500 MW steam plant circulating 250,000 gpm. The environmental issues normally raised in connection with cooling tower drift are PM10 emissions, bacterial or pathogenic emissions and damage to local crops.

-PM10: The source of concern over PM10 is the fact that as the drift droplets evaporate so that the dissolved and suspended solids in the circulating water are released as air-borne particles. PM10 emissions are usually estimated (conservatively) as 100% of the TSS and TDS in the estimated drift. A recent study by Reisman and Frisbie (18) suggests that only a fraction of the solids in the drift are formed as PM10. However, this may still be a consideration in some areas.

-Infectious species: The most frequently cited public health issue in the context of cooling towers is the possibility of Legionnaire's Disease, so-called because of an outbreak at an American Legion convention in Philadelphia in 1976 attributed to pathogens (legionella pneumophilia) in the cooling tower for the HVAC system in the hotel. While the frequency of occurrence of Legionnaire's Disease is small (approximately 1400 cases reported to the Center for Disease Control annually) and the number of these attributable to cooling towers (at power plants or anywhere else) is even fewer, the question has been investigated extensively in the US and abroad. Treatments of the issue are found in the CTI and ASHRAE literature and references therein.

While the consequences of exposure can be very severe and even fatal particularly to at-risk (elderly, smokers, individuals with chronic respiratory problems or with suppressed immune systems) populations, the evidence of harm is sparse and largely anecdotal. Cooling towers are a common element of our industrial, commercial and residential scenes in high-density population areas in all climates. No compelling epidemiology has established a significant threat.

-Deleterious impacts of power plant cooling systems on surrounding agriculture have not been an issue except in a few special circumstances. One notable study was conducted in the mid-1970's at the Potomac Electric Power Company's Chalk Point Station in Maryland. In that case, the towers were run on brackish make-up water with a circulating water salinity comparable to sea water (35,000 ppm TDS); the towers were hyperbolic natural draft towers with a plume exit plane elevation of about 400 feet; and the plant was located in a tobacco-growing region with a specialty crop of leaves intended for use as the outer wrappers of cigars. High salinity droplet deposition on the leaves could create small, discolored spots making the leaf unusable without in any way affecting the health of the plant or the quality of the soil. Even under these conditions, the risk was eventually determined to be negligibly small, and the plant and towers continued to operate with no special controls and no adverse impact on the region's agricultural activity.

These issues are noted not to suggest the presence or potential of serious environmental harm from recirculated cooling systems but to note that environmental impacts are associated with such system that do not occur with once-through cooling and that should be balanced against the benefits to be derived from reducing the cooling water intake flow. It is certainly the case that these issues are the subject of concern to the public in some instances and can prolong permitting processes seeking approval for retrofit, adding to the duration and cost of the project.

Other air emissions

The primary air emissions from fossil plants are, of course, from the combustion of the fuel. As has been noted, the choice of cooling system can reduce the overall plant efficiency and capacity. Therefore, to meet a given total system load, more fuel must be burned with a corresponding increase in emissions of NOx, particulate matter, SO2 and CO2 in amounts and proportions which depend on where and in what equipment the additional fuel is used.

For recirculated cooling systems in most locations, the effect is small. On the other hand, for site-specific considerations, a case-by-case analysis of these emissions would be needed to determine what the local environmental impact of each cooling option.

Noise

Cooling tower operation is noisier than once-through cooling operation. The primary noise from cooling facilities is fan noise and "fill" noise caused by the flow of water down over the tower fill. While fan noise can be reduced through the choice of low noise fans, the water noise is less amenable to reduction and some sort of sound barrier may be required to comply with local ordinances. Here again, the issue may simply add to the difficulty of obtaining a permit, add to the cost and duration of the project and warrant consideration in the larger context of balancing the overall benefits to the environment and society of a given decision affecting the choice of cooling systems at power plants.

Aesthetics

In some cases, where plants may be sited in a scenic or urban area, cooling towers may be deemed as a significant impact on the aesthetics of the locality. This issue is also very site specific, but could result in delays or even denial of permits.

8. SUMMARY AND CONCLUSIONS

This study provides estimates and analyses of the costs of retrofitting electric power generating plants, designed for and operating on once-through cooling systems, with recirculated cooling systems using mechanical draft cooling towers. A brief discussion of the environmental impacts of recirculated cooling in comparison to those of once-through cooling is also included.

The approach to the analysis of the retrofit costs involved:

1. The gathering of data from utility sources of cost estimates made for retrofits at individual plants

2. A review and analysis of cost estimating methodologies by the Environmental Protection agency, Stone & Webster Engineering Company, the Washington Group and the National Energy Technology Laboratory, and

3. A comparison of the results of the several estimates with the individual plant data.

The conclusions of the analysis were:

1. Retrofit costs are highly variable from plant to plant. The results of this study support EPA's assertion that the costs to retrofit recirculated cooling will vary dramatically from site to site. As described in Chapter 3, the retrofit costs at each of the plants for which we have detailed data were dominated by site-specific adjustments rather than by simple scale factors based on size or flow rate.

2. This variability cannot be well accounted for by correlating factors such as $/kW or $/gpm of circulating water flow normally found to be satisfactory for new plant cost correlations

3. Differences in individual plant costs cannot be accounted for by differences in plant type (fossil vs. nuclear) or by cooling water source type (fresh, brackish, saline)

4. The variability is the result of site-specific factors associated with difficulties particularly related to the fact that retrofits present special constraints to on-site construction projects

5. Plant retrofits can be roughly assigned a "degree of difficulty classification" as "easy', "average" or "difficult" retrofits.

i. The costs for the easiest of the projects (lower bound of the individual plant data) are roughly consistent with the costs estimated for cooling system construction at new facilities and fall in the range of $125/gpm.

ii. The average difficulty projects costs cluster around $200/gpm +/- 20%

iii. The more difficult projects range from $250 to $300/gpm with a few ranging as high as $700 to $900/gpm

6. Significant costs, in addition to the initial capital costs, result from cooling system retrofits including

i. Additional requirements for operating power in the range of 1 to 1.5% of plant capacity

ii. Additional maintenance costs, primarily associated with water treatment requirements in the range of 1 to 3% of system capital costs annually.

iii. Additional fuel costs resulting from efficiency reductions imposed on the plant by the inherent limitations of recirculated cooling systems in the range of 1% on an annual average basis.

7. Recirculated cooling, while reducing water withdrawals for natural waterbodies relative to once-through cooling, has environmental impacts associated with evaporation losses, discharge of blowdown, discharge and disposal of waste water and solid waste, emissions of drift, visible plumes, additional air emissions from increased fuel consumption and noise, that are not present with once-through systems.

EPA Response

Many commenters to the proposal and the NODA assert that EPA has underestimated the costs, technical feasibility, potential energy impacts, and possible non-aquatic impacts for recirculating wet cooling tower retrofit projects. In response to the comments received, the Agency changed its methodology from proposal to NODA to include estimates of peak-summer energy penalties and to extend the net construction downtimes of nuclear plants from 1 month to 7 months. However, the Agency did not revise its estimates of the capital costs for cooling tower retrofits, which is a primary area of criticism from the adverse comments. The Agency addresses capital cost comments in the following paragraphs. In addition, commenters assert that the Agency overlooked or did not fully consider possible air emissions increases due to the energy losses associated with recirculating wet cooling. Even though the Agency conducted a national-level air emissions analysis for the proposal, commenters assert that local air emissions impacts could be a critical element of the non-aquatic environmental impacts. The Agency concedes that it did not conduct local air emission impact analyses for the engineering analysis supporting the proposal or NODA. The Agency agrees that local air emissions could be a significant concern for retrofitting very large power plants with recirculating wet cooling in urban environments and agrees with the commenters that this aspect of cooling tower retrofits should be analyzed on a site- or region-specific basis. Further, commenter assert that the Agency did not fully consider the implications of land availability (and a lack thereof) for some cooling tower retrofit scenarios. The Agency agrees that this point could be a critical element in the analysis of a site-specific cooling tower retrofit project, especially in and around metropolitan areas. The Agency agrees that a lack of available land could be a critical feasibility issue for some cooling tower projects and could greatly increase costs (due to land acquisition costs or very long piping extensions and subsequent pumping requirements).

Many of the above points are addressed in this comment, but the Agency also references comments

316b.EFR.041.021 through 316b.EFR.041.030, 316b.EFR.041.032, 316b.EFR.041.351 through 316b.EFR.041.353, 316b.EFR.041.751, 316b.EFR.072.061, 316b.EFR.074.021, 316b.EFR.075.057, and 316b.EFR.207.101. In addition, the Agency references the study from the Department of Energy titled "An Investigation Site-Specific Factors for Retrofitting Recirculating Cooling Towers at Existing Power Plants," dated January 22, 2003.

The Agency concludes after reviewing the comments referenced and the DOE study that installed cooling tower costs can exceed those considered by the Agency for the NODA and proposal analysis. The Agency notes that a wide range of estimates exist, many of which are conceptual estimates in nature with an extremely high degree of uncertainty. However, for a number of studies, the cost estimates approach and exceed the requirements of budget estimation requirements, indicating a relatively narrow range of confidence in the final estimates. The Agency concludes, as does this comment that a variety of site-specific factors can influence the costs of cooling tower retrofit installations, many of which the Agency may not have considered in its analysis of the NODA and proposal.

Generally, the Agency notes that this comment summarizes the findings of several often referred to studies of cooling tower retrofit projects and adds to the studies some new analysis and summary. The Agency observes that the commenter apparently researched at great lengths construction projects that it found "similar in nature" to cooling system retrofits and conferred with plants that have estimated costs and construction schedules for potential retrofit projects. However, it is notable that the commenter does not discuss or address the set of cases where cooling tower retrofits have actually occurred (i.e., cooling tower retrofit projects that have been physically built and paid for). The Agency compared the proposal and NODA methodology for estimating cooling tower retrofit costs versus the empirical costs for the set of actual cooling tower retrofits cases and found the two cost sets comparable. The Agency readily acknowledges that this cost comparison is not a robust empirical derivation of a cost curve that could apply to a wide range of complicated projects. However, the fact remains that the commenter has ignored the only real-life empirical examples of cooling tower retrofits in its otherwise exhaustive analysis, and yet out of hand dismisses the estimated retrofit factor utilized in the Agency's methodology.

Nonetheless, the Agency finds the general theorem of the comment to be reasonable, as stated in the following paragraphs:

"-Site-specific retrofit costs studies show a high degree of variability from costs based on commonly accepted scaling methods. Cooling tower cost estimating methods are often based on the use of a $/gpm rule of thumb. This is approach is used by tower vendors, A&E firms and experienced users and is based almost entirely on the field's experience with tower construction at new sites. EPA used this approach as well. It can, therefore, be reasonably assumed that the variability in careful engineering estimates of site-specific retrofit costs, which will be documented for about 50 cases in Section 3, is due to differences in the degree of difficulty associated with the retrofit aspects of each project.

-It is also reasonable to assume that the lower bound of these costs is associated with the "easiest" retrofit cases, which would correspond most closely to a new facility project free of the interferences encountered at most existing facilities. As will be seen, the lower bound of the case data corresponds reasonably well with the "greenfield" cost estimating rules proposed by EPA, while the mid-range of the data is 40 to 60% higher with many cases ranging to a factor of 2 to 4 times more expensive."

The Agency notes that cooling tower technology retrofits do not form the basis of the final rule, due in part to concerns outlined above (see the preamble to the final rule).

Commenters generally challenged EPA's assumptions regarding costs associated with retrofitting existing facilities to install cooling towers. While all commenters agreed with EPA that existing facilities would incur higher costs to retrofit their plants for cooling towers than new facilities would incur, most disagreed with the Agency's estimates of the degree to which costs would exceed those of new facilities. Commenters correctly pointed out that the Agency's analysis did not consider a variety of factors (such as potential for plume abatement, variable distances for recirculating piping distances, the potential for land acquisition or the unavailability of sufficient land area, and local air emissions concerns) that many facilities could reasonably expect to incur in making the transition. Based on a survey conducted by one industry commenter, EPA learned that 31 out of 56 plants surveyed said that they would need to acquire additional property to accommodate cooling towers, if required by today's rule. EPA recognizes that this could be a significant cost. EPA also recognizes that there may be impediments, irrespective of costs, to acquire land for cooling towers. Land upon which to construct cooling towers may be difficult or impossible to obtain, especially in urban areas; some facilities might even turn to displacement of wetlands as a solution. The Agency did not include these potential costs in its analysis for the NODA or proposal. In contrast to new facilities, which can take into account the Phase I requirements when choosing where to situate their structures (including cooling towers), existing facilities have far less flexibility and incur far greater costs. EPA believes that this is a special problem for existing facilities that is relevant to determining whether, as a national categorical matter, closed-cycle cooling is the best technology available for existing facilities for minimizing adverse environmental impacts associated with cooling water intake structures. EPA received retrofit cost estimates from number of commenters that indicate that such costs could be at least twice those projected by EPA.

Some commenters also assert that EPA underestimated the down time that the facility would experience as it converts to cooling towers. This, again, is not an impact that would be experienced by new facilities. EPA agrees that such down time can be significant. Indeed, one of the four retrofit case studies EPA developed indicated a down time of 10 months, and EPA believes it is reasonable to infer that many other facilities would experience the same loss.

EPA also agrees with the commenters who assert that the empirical data base of four retrofit cases to which EPA compared cooling tower retrofit costs and engineering characteristics is not representative of the broader population of facilities and could be too narrow a set from which to develop site-specific national costs. Of the four retrofits EPA studied, two were in a single state (South Carolina), none were located along a coast, and only one generated more than 500 MW of electricity. EPA also recognizes that all of these conversions were performed before 1992. While it is true that the vast majority of the new, greenfield utility and non-utility combined cycle plants built in the past 20 years have wet cooling towers, EPA believes that it is significant that so few existing facilities retrofitted to the technology during the same period. The rarity of this technology as a retrofit further indicates that it may not be economically practicable for the vast majority of existing facilities.

Another issue concerns the energy penalty. EPA examined the information it received after publication of the proposed rule and NODA, and agrees that the energy penalty associated with cooling towers, together with other factors, indicates that that technology is not the best technology available for existing facilities for minimizing adverse environmental impacts associated with cooling water intake structures. In reaching this conclusion, EPA relied on information on energy penalties provided by the U.S. Department of Energy. EPA worked closely with the U.S. Department of Energy in preparing today's rule because of their expertise in connection with power plant operation and engineering. The U.S. Department of Energy pointed out to EPA that existing fossil-fuel facilities converting from once-through cooling water systems to wet-cooling towers would produce 2.4 percent to 4.0 percent less electricity even while burning the same amount of coal. For at least one nuclear power plant, which provides 78% of the electricity consumed by the State of Vermont, the energy penalty associated with converting to cooling towers was estimated to be 5.3 percent. Expressed differently, DOE estimated that, nationally,19 additional 400-MW plants might have to be built to replace the generating capacity lost by replacing once-through cooling systems with wet cooling towers if such towers were required of all Phase II facilities.

This energy penalty leads to other negative consequences. Because this deficit is predicted to occur during the summer months (when energy demand is highest), the net effect would be more consumption of fossil fuel, which in turn increases the emission of sulfur dioxide, NOx, particulate matter, mercury and carbon dioxide. Increasing fuel consumption at existing coal power plants yields the largest increase in air emissions because existing systems are less efficient at producing power (and therefore burn more coal) and because they generally have less air pollution control equipment in place. EPA believes that it is reasonable to consider these non-water quality environmental impacts and the additional costs associated with controlling these increased emissions in making today's decision. EPA further believes that it is authorized to do so because of the links between § 316(b) and sections 301 and 306, which require EPA to consider both the energy impacts and the air pollution impacts of technologies when identifying technologies in the effluent guidelines context. See CWA section 304(b)(2)(B) (cross-referenced in § 301); CWA section 306(b)(1)(B) (new source performance standards).

Each of these factors has a cost and an economic impact that EPA believes is appropriate to consider when evaluating whether cooling towers are the best technology available for existing facilities for minimizing adverse environmental impacts associated with cooling water intake structures. The capital costs estimated by EPA at proposal are already very high; when costs reflecting reasonable changes to EPA's assumptions are added to them, the total capital cost investment and associated economic impact is simply too high at this time for EPA to be able to justify selecting cooling towers as a required technology for all existing Phase II facilities.

Authority to Submit Additional Comments

Upon examination of the materials in the rulemaking record, UWAG discovered that it was difficult or impossible to understand some of EPA's analysis, particularly its "case studies" that were used to estimate the fish, eggs, and larvae lost to cooling water intake structures at certain facilities and its economic analysis of the costs and benefits of various rulemaking alternatives. UWAG therefore asked EPA for additional explanation of the reasoning underlying the proposed rule. EPA attempted to respond to UWAG's requests for information and made its consultants available for a number of telephone conference calls during which UWAG's consultants asked questions about EPA's analyses. UWAG also submitted lists of written questions to EPA, and EPA supplied some materials in response. Some of the documents from EPA arrived too late, however, to be of use in writing comments for the August 7 deadline.

Accordingly, UWAG requested an extension of the filing deadline to address certain issues. EPA responded by saying that EPA would use its best efforts to consider additional comments submitted on or before August 21 , 2002, that addressed the following issues:

-UWAG's assessment of EPA's case studies, EPA's estimate of biological losses associated with case study facilities, and the Agency's estimate of the economic or other values associated with those losses UWAG s assessment may include existing or new data for case study facilities and/or other facilities in the same area as a case study facility.

-UWAG's assessment of the data and methods EPA used to develop estimates of baseline economic losses, and to develop estimates of the benefits of various regulatory alternatives.

-Based on the above, supplementary comments on the appropriateness of using various methods and data to estimate biological and economic losses and benefits during implementation of any Section 316(b) rules.

Letter, Geoffrey H. Grubbs, Director, EPA Office of Science and Technology, to Kristy A.N. Bulleit, UWAG counsel, July 12, 2002.

EPA Response

EPA accepted and considered all comments. EPA considered those that were submitted after the official close of the comment period to the extent it was able. Those comments were included in the public rulemaking record.

UWAG Reserves the Right to Assert that EPA's Reasoning was Inadequately Explained

Despite EPA's efforts to explain the basis for its proposed rule UWAG has found it frustrating to try to understand the sometimes cryptic documents that EPA used. Some of the questions raised in the conference calls were not answered. Several of EPA's consultants' studies, especially those on the case studies and those underlying the analysis of costs and benefits are not understandable. UWAG has done the best it could in the time available for comments, but we still believe that EPA has not entirely articulated the reasoning and basis for its proposed rule and that this falling might, depending upon the outcome of this rulemaking, rise to the level of a legal deficiency.

That said, UWAG has the following limited comments on the materials most recently received from EPA.

EPA Response

EPA has made substantial efforts to help explain the complex issues involved with 316(b), and done a great amount of public outreach, including responding to comments, creating a publicly available record and hosting conference calls. EPA notes that no specific questions were identified by the commenter. The basis for today's final rule in explained in detail in the preamble, and in the supporting records and documents.

The Tampa Bay Case Study Results are Biased High

As a part of our August 7 filing, UWAG's consultant Dr. Kyle Hartman, of West Virginia University, prepared an assessment of the biological validity of EPA's methods for producing case study estimates and extrapolating those estimates to the national level. See UWAG Phase II Comments Appendix 10. As noted in his assessment, available data suggest that there are lower levels of dissolved oxygen in upper Hillsborough Bay, where Hooker's Point and the F J Gannon Stations are located, than at Big Bend Station. Therefore, extrapolation of the Big Bend impingement and entrainment data to the other facilities is inappropriate, because Hooker's Point and F J Gannon would be expected to experience less impingement and entrainment due to their location in an area of lower dissolved oxygen. This conclusion is bolstered by a recent report by the Tampa Bay Estuary Program <FN 1> that demonstrates the extent and duration of the low dissolved oxygen problem in the area of the Hillsborough Bay plants.

Clearly, water quality in the Hillsborough Bay area has low dissolved oxygen, and thus extrapolations from areas of better water quality (i.e., the Big Bend area) to the Hillsborough Bay sites will be biased high.

Footnotes

1 Tampa Bay Estuary Program, Final Report, Examination of the Spatial and Temporal Nature of Hypoxia in Tampa Bay, Florida (Technical Report # 09-01 July 2001).

EPA Response

EPA recognizes that there are site-specific details that distinguish the environment surrounding individual facilities. However, the purpose of EPA's regional analysis for the final rule was not to develop precise I&E estimates for individual facilities, but rather to develop estimates of average I&E for entire regions. Please see Chapter A5 of the Regional Analysis Document (DCN # 6-0003) and response to Comment 316bEFR.041.041 for additional information on EPA's extrapolation approach. Instead of the case study of Tampa Bay presented at proposal, EPA expanded its analysis to the Gulf region using facilities in addition to Big Bend as a basis for extrapolation. Details of the Gulf of Mexico regional study are provided in Part F of the Regional Analysis Document.

Documents on the Cost of Biological Studies Suggest Inappropriate Year-Round Sampling

UWAG has not had time to adequately review EPA's response to UWAG's consultant Greg Seegert regarding derivation of biological study costs. However, a cursory review of that response indicates that the studies that EPA requested pertain exclusively to the collection of larval fish. Yet EPA's study plan calls for sampling every two weeks, year-round. Year-round sampling is unwarranted because the appearance of larval fish in many waters is a seasonal phenomenon. For example in freshwater systems, larval fish typically are present only during the spring and summer. Larval sampling on a year-round basis for these waterbodies would be a waste of time and money.

Withdrawal threshold of 50 MGD

125.91(a)(4)

Subpart J should apply to existing facilities that actually withdraw 50 million gallons per day (MGD) or more. It should not apply to facilities that have a design capacity of 50 MGD withdrawal capacity but in actuality withdraw much less than that due to their own water conservation efforts. We believe that the EPA's intention is to regulate facilities that withdraw a large amount of water that could impact the environment. Through this regulation, the EPA could encourage water conservation, not discourage it. A similar logic used in the proposed rule in subdivision 125.91 (d) could be applied to 125.91 (a) (4) to determine applicability based on the quantity of water actually withdrawn.

Suggested language

125.91 (a) (4): "Withdraws an average of 50 million gallons per day (MGD) or more. Whether or not 50 MGD is withdrawn must be measured on an average monthly basis. The 50 MGD threshold is met if any monthly average withdrawal is 50 MGD or more and occurs during the 12 months preceding the SPDES permit application due date."

Cooling system costs (e.g., dry, wet, recirculating)

An Investigation of Site-Specific Factors for Retrofitting Recirculating Cooling Towers at Existing Power Plants

October 8, 2002

Prepared for:
The United States Department of Energy
National Energy Technology Center
Contract No. DE-AM26-99FT40465, Task 50802

By: Parsons Infrastructure and Technology Group Inc.

1. INTRODUCTION

The protection of aquatic organisms found in the water bodies of the United States has been an important focus of environmental regulations in the United States. In 1972, Congress enacted section 316(b) of the Clean Water Act addressing the withdrawal of cooling water from surface water bodies. The congressional language mandated that:

“Any standard established pursuant to section 301 or section 306 of this Act and applicable to a point source shall require that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact.”

The U.S. Environmental Protection Agency (EPA) promulgated final section 316(b) regulations in 1976. However, in 1979, EPA formally withdrew its section 316(b) regulations as a result of a successful Federal court challenge initiated by a consortium of 58 utilities. Over the past 20 years, in the absence of Federal guidelines, many States have adopted their own regulations with respect to the implementation of section 316(b) requirements regarding cooling water intake structures. In many cases, the States had adopted a site-specific approach to determine what constitutes best technology available for minimizing adverse environmental impact.

The regulatory environment had changed by 1995 when the U.S. District Court, Southern District of New York, entered a Consent Decree between the EPA and the Hudson Riverkeeper that obligated the Agency to issue cooling water intake structure regulations within 7 years. The Consent Decree was modified on November 21, 2000 to: a) finalize new facility regulations by November 9, 2001 (Phase I); b) propose existing source large utility and non-utility power producer regulations by February 28, 2002 and issue final regulations by August 28, 2003 (Phase II); and c) propose regulations by June 15, 2003 and issue final regulations by December 15, 2004 for other existing facilities not covered in b) above (Phase III).

EPA’s Phase II proposal addressing existing facilities has been released and can be found at http://www.epa.gov/waterscience/316b/. As currently written, the proposal presents several options under consideration for the final rule. One of the options suggests that existing, once-through cooled facilities be required – based on water body type and intake flow capacity – to retrofit with recirculating wet cooling towers as a method to meet reductions in organism impingement and entrainment. EPA estimates that this option would affect 50 to 60 existing steam-condensing power generation facilities.

When considering a recirculating wet cooling tower retrofit to an existing once-through cooled facility, there are several significant site-specific issues and assumptions that must be fully analyzed a priori. Among these issues are effect on turbine performance, increased plant parasitic power losses, land space consideration, tower size and type, permitting restrictions, tower plume and noise abatement, and tower drift loss control, just to name a few. The purpose of this report is to evaluate the feasibility of a wet recirculating cooling tower retrofit at four existing steam-condensing power plants with respect to the aforementioned issues. The plants that were evaluated are the Surry Power Station (nuclear, Units 1 and 2), Hudson Generating Station (Unit 1/gas, Unit 2/coal), Barney M. Davis Power Station (natural gas, Units 1 and 2), and Big Bend Station (coal, Units 1, 2, 3, and 4). These plants were studied because of their representative fuel type and their geographic location, which underscored the very site-specific nature of the wet recirculating cooling tower retrofit option.

2. SITE DESCRIPTIONS

The four plants selected for evaluation of a potential evaporative cooling tower retrofit are briefly described below. These sites were chosen because they represent the class of power plants that could be candidates for cooling tower retrofits and encompass the range of site specific issues that may need to be addressed. They represent all fuel types and have significantly different geographic locations. An aerial photograph and map of the surrounding area for each site are included in the back of this section of the report (Figure 2-1 through Figure 2-8). The selected plants are:

-Surry Power Station (Surry County, Virginia), Units 1 and 2
-Hudson Generating Station (Jersey City, New Jersey), Units 1 and 2
-Barney M. Davis Power Station (Corpus Christi, Texas), Units 1 and 2
-Big Bend Station (Tampa Bay, Florida), Units 1, 2, 3, and 4

A sketch of a proposed cooling tower arrangement has been prepared for each site, and is superimposed on the aerial photograph for each site. The site descriptions make reference to nearby facilities such as airports, highways, tourist attractions, etc. The presence of these site-specific features must be taken into account when considering the siting of evaporative cooling towers, since these towers can cause local fogging, icing, deposition of droplets containing dissolved solids, or have other impacts such as noise, or interpose high structures in the path of an approach to an airport. It is important to recognize the inextricable tie between these cooling tower siting challenges and the potential for increased capital/operating costs to overcome them.

Surry Power Station, Units 1 and 2

Surry Unit 1 and Unit 2 are identical nuclear power plants, based on Westinghouse pressurized water reactors generating a nominal 848 MWe each. Each turbine generator has two double-flow low-pressure (LP) cylinders with 44-inch last-stage blades. Unit 1 was placed in service in December 1972 and Unit 2 in May 1973.

The site is on a point of land called Gravel Neck, which projects into the James River in Surry County, Virginia. The river is brackish. Both units share a common cooling water intake canal that is approximately 2 miles long. The cooling water is pumped from the James River into the intake canal, and a common discharge canal returns the water from the plant.

The immediate area around the plant power block is surrounded by structures or the cooling water intake and discharge canals. The most likely available vacant space for siting cooling towers that is accessible to both cooling water canals is southeast of the plant.

The Surry site is approximately 6 miles south and across the James River from the Jamestown National Historic Site. The Williamsburg Jamestown airport is 8 miles north of the site, and the Felker Army Airfield is 6 miles southeast. State parks and wetland areas surround the site. Based on this preliminary analysis, it appears as though cooling tower plume abatement design measures may not be a requirement at the Surry site.

Hudson Generating Station, Units 1 and 2

Hudson Station comprises two fossil-fuel-fired units. Hudson Unit 1 has a nominal 455 MW gas-fired supercritical steam generator with a turbine generator that has two double-flow LP cylinders with 28-inch last-stage blades. Hudson Unit 2, rated at a nominal 660 MW, has a coal-fired supercritical steam generator and a turbine with three double-flow LP cylinders with 28-inch last-stage blades. Unit 1 was placed in service in December 1964 and Unit 2 in December 1968.
The site is on the east shore of the Hackensack River on the outskirts of Jersey City, New Jersey. The river is brackish. There is an intake canal for the cooling water. The cooling water discharge appears to be on the river's edge downstream of the plant.

The immediate area around the power blocks for the two units is surrounded by the river on one side, the coal handling and storage facilities below, the substation above, and fuel oil storage facilities on the other side. The most likely large vacant area that can accommodate all the cooling towers in the same location is north of the plant across the railroad tracks.

The Hudson site is approximately ½ mile south of the New Jersey Turnpike, ¾ mile south of the Secaucus Railroad Station and ½ mile south of Amtrak tracks. Various Conrail tracks are immediately adjacent to the site on three sides. The plant is ½ mile north of Newark Avenue and the Pulaski Skyway (Route 9) and has warehouse storage sites on its immediate southern end. The Hudson plant was deemed to require plume abatement design measures, based on its proximity to roads and its general location in a heavily urban setting.

Barney M. Davis Power Station, Units 1 and 2

Barney Davis Station comprises two natural-gas-fired steam plants. Unit 1 has a nominal 353 MW gas-fired subcritical steam generator with a turbine generator that has one double-flow LP cylinder with 28-inch last-stage blades. Unit 2 has a nominal 351 MW gas-fired steam generator with a turbine that has one double-flow LP cylinder with 30-inch last-stage blades. Unit 1 was placed in service in May 1974 and Unit 2 in June 1976.

The site is approximately 1 mile inland from upper Laguna Madre, which is on the Gulf coast of Texas, just south of Corpus Christi. The seawater intake is at the end of the 1-mile-long canal to Laguna Madre. The plant discharges into the Oso Bay, which is attached to Corpus Christi Bay.

The power blocks are fairly unencumbered by surrounding facilities. The best choice for the cooling towers appears to be along the intake canal since this affords the efficient use of the existing intake canal for returning the water to the existing circulating water pumps.

The Barney Davis site is approximately 1.5 miles south of Waldron U.S. Navy Airfield, 5.5 miles south of Corpus Christi Naval Air Station, 5 miles south of State Route 358, and 15 miles south of Interstate Route 37. The area surrounding the site appears not to be heavily populated, with fish hatcheries on the northwest being one of the closest identifiable features. Based on this preliminary analysis, it appears as though cooling tower plume abatement design measures may not be a requirement at the Barney Davis site.

Big Bend Station, Units 1, 2, 3, and 4

Big Bend Station comprises four coal-fired steam plants. Units 1, 2, and 3 each have nominal 446 MW coal-fired subcritical steam generators. Units 1 and 2 each have a turbine generator with one double-flow LP cylinder with 31-inch last-stage blades. Unit 3 has a turbine with one double-flow LP cylinder with 33.5-inch last-stage blades. Unit 4 has a nominal 486 MW coal-fired steam generator with a turbine that has two double-flow LP cylinders with 26-inch last-stage blades. Unit 1 was placed in service in October 1970, Unit 2 in April 1973, Unit 3 in June 1976, and Unit 4 in February 1985.

The site is located on the lower Hillsborough Bay near Tampa Bay, Florida. The four units appear to share a common seawater intake canal north of the plants and discharge back into the bay south of the plants.

The power blocks are surrounded by the intake canal and bay on the north and south, the coal handling and storage facilities on the west, and other support facilities on the east side so that there is virtually no vacant area immediately adjacent to the power blocks. The best available vacant space appears to be on the strip of land on the north side of the intake canal. The length of this strip of land appears to be sufficient to accommodate the use of inline towers for all four units without having to place any in parallel rows.

The Big Bend site is approximately 1.5 miles north of the Apollo Beach marina, 6 miles southeast of McDill Air Force Base, 1 mile west of the Tamlani Trail highway, and 3 miles west of Interstate Route 75. Based on this preliminary analysis, it appears as though cooling tower plume abatement design measures may not be a requirement at the Big Bend site.

3. METHODOLOGY

3.1 TECHNICAL CONSIDERATIONS

Evaluation of the retrofit of evaporative cooling towers to existing power plants was based on certain assumptions. For this study, the retrofit design was configured to minimize the impact on the existing steam turbine and condenser. This minimizes capital costs and the potential for lengthy plant outages, both of which would add a significant cost penalty to the retrofit. The design approach taken maintains intact the major part of the plant circulating water system, including the circulating water pumps and intake structure, piping from the pumps to the condenser, the condenser itself, and much of the discharge piping from the condenser.

If new pumps with higher discharge pressure were employed to replace the existing circulating water pumps, the system pressure might be higher than the pressure capability of the condenser, which would necessitate expensive modifications or replacement of the condenser. The original circulating water flow and condenser range (temperature rise) were maintained to keep tube velocity at the original design value to minimize fouling. This has the added effect of minimizing the impact of the cooling tower retrofit on condensing backpressure, and thus on turbine generator output. The penalty in added auxiliary load caused by higher than optimum circulating water flow rate is minimized by the fact that modern cooling tower designs have a spray deck height that is significantly lower than previous generations of cooling tower designs. Typical once-through circulating water system designs utilize a condenser temperature rise of between 12 °F and 15 °F, whereas cooling-tower-based systems use a temperature rise of about 20 °F or higher.

The modifications to the plant involve interception of the condenser discharge piping at an appropriate location and installation of a wet pit with vertical booster pumps. These booster pumps provide the added head required to lift the water up to the cooling tower spray deck, and to compensate for added piping pressure losses and for any differential in elevation between the new pumping station and the cooling towers. Two schematic diagrams showing a typical plant configuration pre- and post-retrofit are presented as Figure 3-1 and Figure 3-2.

The retrofit design is based on the use of mechanical draft evaporative cooling towers of modern counter flow design, using film type fill. The cooling tower for each plant is comprised of a series of cells constructed of pultruded fiberglass for the linear arrays used at Hudson, Barney Davis, and Big Bend. Each cell is 66 feet square, with a deck height of 40 feet, and equipped with a 250 hp 1,800 rpm totally enclosed, fan cooled, motor driving the fan through a speed-reducing gearbox. Each cell is equipped with high-efficiency drift eliminators, to limit drift to 0.0005 percent or less. The clustered cell arrangement used at Surry utilizes a concrete structure. Cell dimensions, fan horsepower, and other details of construction are similar to those in the fiberglass cells used at the other sites.

Figure 3-3 provides an illustration (plan view) of the cooling tower cell arrays for each of the four sites evaluated. These cell arrays were chosen to efficiently use available land. The tower views are all presented at the same scale.

[see hard copy for figure]
Figure 3-2 Proposed Retrofit Cooling Tower Schematic

[see hard copy for figure]
Figure 3-3 Cooling Tower Cell Arrays (Plan View)

The need for plume abatement was evaluated for each of the four plants evaluated herein. Of the four plants, only the Hudson plant was deemed to require plume abatement design measures, based on its proximity to a road and its general location in a heavily urban setting.

The cooling tower for the Hudson plant application is equipped with a plume abatement feature, which comprises a finned tube coil mounted on top of the fan deck. The hot circulating water returning from the condenser passes through the coils first, and is cooled approximately 4 °F before exiting the coil and being routed to the spray nozzles above the fill. The fin tube coils are mounted to provide a parallel flow path with respect to the air that flows through the fill. The air streams mix in the fan exhaust; the mixed dry and humid air has a lower dewpoint, resulting in reduction in visibility of the plume and mitigation of the potential for local fogging and icing of nearby surfaces and structures. The other three plants evaluated in this study are not provided with plume abatement design features, based on the specific layout and location of each plant. If cooling tower retrofit becomes a reality for any of these plants, a more detailed study must be undertaken to thoroughly evaluate local conditions. The plume abatement feature is regulated by valves and dampers, and is only used when ambient conditions warrant. This type of plume abatement feature adds significantly to the cost of a cooling tower, potentially doubling the cost of the tower.

To accommodate the short time period available to perform the study and the lack of detailed information regarding the plant design conditions, the following simplifications or assumptions were made:

-The circulating water (CW) temperature rise across the condenser was assumed to be 15 °F. From our experience, this value is typical for many of the plants. Since the condenser temperature rise is equal to the range for the cooling tower, the cooling tower range is thus also set at 15 °F.

-Where plant data on the circulating water flow to the condenser was not available (only Surry data were), the flow was calculated using the assumed condenser rise of 15 °F, an assumed steam flow to the condenser of approximately 65 percent of the plant rated steam flow at the throttle, and a steam condensing enthalpy of 1000 Btu/lb. The percentage (65 percent) of plant rated steam flow to the condenser is based on previous experience with steam cycles using regenerative feedwater heating. The other 35 percent of the throttle steam flow is extracted from the steam turbine at various locations for feedwater heating and deaeration.

-The condenser backpressure was determined by using an assumed terminal temperature difference of 5 °F for the nuclear unit and 8 °F for the fossil units. The assumed terminal temperature differences were considered from experience to be typical values for condenser design.

-Seasonal average temperatures (cooling water and ambient wet bulb) were used to evaluate the impact of differences in condenser backpressure due to the introduction of a cooling tower into the circulating water system. Cooling water temperatures were based on available data from observation and recording stations for sites close to the plants. Likewise, the mean ambient wet bulb temperature data came from airports near the sites that record annual weather data. Monthly averages for at least the last 5 years of data were calculated and then combined into spring, summer, fall, and winter seasonal averages. Time did not permit a more detailed or exhaustive study of this type of data.

-The return cooling water temperatures from the cooling towers at various seasonal average mean wet bulb temperatures were estimated using a tower manufacturer's performance curve for the specified design duty and range. Although the sites had different design wet bulb temperatures (74, 77, 78, and 79 °F), a performance curve based on a design wet bulb temperature of 77 °F was used for all sites in determining the return water temperatures for the various seasonal temperature conditions. This approach was suggested by the tower manufacturer since the effect of the tower design wet bulb temperature is minimal. The site design wet bulb temperature was selected using standard air conditioning design values for temperatures that are exceeded no more than 2 percent of the total hours during a normal summer.

-Curves for LP turbine exhaust pressure correction to the plant output or heat rate were matched to turbines with a similar number of LP flow paths and last-stage blade length, as listed later in Table 3-2 (page 3-7). However, because of the lack of plant data for each unit, predictions of the loss of generation capability due to variations in condenser backpressure (due to the introduction of cooling towers) may not be exact, but are typical for plants with a similar type of LP turbine.

-The cooling towers were located on the best available vacant area on each site and as close as possible to the power blocks. Vacant areas were determined from USGS site aerial maps that were not necessarily current nor detailed enough to verify all obstacles to installation of towers or piping. Piping lengths were estimated using the assumed tower locations and routings that avoided existing facilities as best as could be determined from the aerial maps.

-Cooling tower blowdown is required to maintain the required quality of the recirculated water and was assumed to be at a flow that would result in a doubling of the concentration of total dissolved solids in the original feedwater. Blowdown containing twice the amount of total dissolved solids of the makeup water is considered typical for seawater cooling tower applications. Based on experience at other sites, treatment of blowdown, other than addition of chemicals to remove chlorine (if used for biological growth control), is not required. Therefore, no treatment plant or extensive equipment is expected for processing the cooling tower blowdown before discharge. Specific site conditions or local restrictions may require more extensive treatment.

A summary of cooling water temperatures (pre- and post-retrofit) is presented in Table 3-1. Although cooling water temperatures increase by 10 °F to 20 °F by adding the cooling towers, this increase does not appear to impact electricity generation to a significant extent (i.e., the annual energy penalty is less than 2 percent) at three of the four plant sites evaluated. Cooling tower retrofit impacts on steam cycle performance, such as reduced generating output, were estimated by using manufacturer's steam turbine performance characteristics for machines that have the same configuration as found in each of the cases evaluated.

Table 3-1
Seasonal Average Temperatures

	Surry	Hudson	Barney Davis	Big Bend
Seasonal Avg. Ambient Mean Wet Bulb Temp, ºF				
Spring	58	46	65	65
Summer	77	66	77	76
Fall	62	52	68	69
Winter	42	31	54	56
Seasonal Avg. River/Bay Water Temp, ºF				
Spring	60	51	74	75
Summer	83	75	86	84
Fall	67	58	74	78
Winter	41	36	56	66
Seasonal Avg. CT Return Cold Water Temp, ºF				
Spring	72	65	77	77
Summer	85	77	85	84
Fall	75	68	78	79
Winter	62	58	70	71

Based on available data, it was judged that the steam turbines installed in three of the plants evaluated (Surry, Barney Davis, and Big Bend) do not have sufficiently large last-stage blading to effectively expand the steam to backpressures consistent with condensing temperatures typically achieved with once-through cooling. In theory, reducing cooling water temperature reduces condensing backpressure and increases power output. However, in three of the specific cases evaluated here, the steam turbine generator cannot effectively utilize the reduced condensing backpressure. Only one of the four plants evaluated, Hudson Generating Station, appears to use a turbine design that can effectively utilize lower cooling water temperatures achieved with once-through cooling. A cooling tower retrofit at this plant would increase condensing backpressure (relative to once-through cooling), and thus reduce generation output. This is discussed further in Section 4.1, Discussion of Technical

Results.

Principal design parameters for each plant evaluated are summarized in Table 3-2. The condenser and cooling tower design parameters selected for each plant evaluated in this study are presented in Table 3-3.

3.2 COST ESTIMATING AND ECONOMIC CONSIDERATIONS

3.2.1 COST ESTIMATING

Separate cost estimates have been developed for each power plant unit and with total costs calculated for each site. The cost estimates are for a completed retrofit for each facility, with all-new construction and normally supplied services, including indirect costs and contingencies.

The format of each estimate has been arranged to show major cost components and their relative importance. Cost components are not arranged in any particular order of importance. Equipment costs are broken out separately and contain bulk material items. Labor costs cover site craft personnel and associated contractor markups, employee benefits, and supporting supervision, administration, and home office support. Union labor or equivalent prevailing wage rates are implied. No attempt has been made to convert or adjust labor costs for particular areas of the country.

Vendor quotes have been incorporated for major items such as cooling towers, circulating water pipes, and cooling tower pumps on a generic basis due to the lack of specific site design information. Lengths of circulating water piping were scaled from the design sketches superimposed on the aerial photos presented in Section 2. Labor costs associated with these items have been made based on experience with similar items at other sites. Allowances for costs of other items such as demolition, foundations and structures, instruments and controls, electrical, and chemical treatment were made from prior similar estimates.

Allowances for indirect costs have been included in each of the estimates based upon percentage factors. These include temporary construction services and facilities, engineering, construction management, and other professional services, owner costs, and a contingency. An allowance of 20 percent for contingencies has been included since these are existing sites and many interferences are expected. No allowances for escalation or for funds used during construction (AFDC) have been included, as there are no schedule dates considered in this study.

Costs are presented at 2002 levels in thousands of dollars for each category and also dollars per kilowatt. The overall accuracy of the estimates is expected to be ±40 percent due to the conceptual nature of the design, in accordance with the Association for the Advancement of Cost Engineering International (AACEI) guidelines. Variances beyond these ranges are possible but not likely.

3.2.2 ECONOMIC CONSIDERATIONS

Separate estimates of changes in operating and maintenance (O&M) costs caused by conversion to cooling towers at each plant have been prepared. An attempt has been made to include all major cost components for each plant.

For most of the plants it is expected that existing personnel can absorb some of the added duties that will be required to operate and maintain the new cooling system equipment. The skill level, average salaries, burdens, and overhead rates are used to estimate the cost of additional personnel that would be required (see Appendix B).

Supplies have been estimated mostly for the chemicals required for treatment of the makeup water, treatment of the cooling towers and basins, and treatment of blowdown flows prior to their discharge. The costs are similar to those needed in a new fossil plant on a per kilowatt basis.

Maintenance costs have been estimated on a percentage basis of new construction costs. The percentage chosen is an average of the various components involved. For instance, the cooling towers will have a higher percentage of maintenance than the circulating water piping. The costs will vary by year and thus an average value is shown.

The worksheets in Appendix A show the estimated power quantities and costs of the new cooling tower equipment and related systems. Allowances have been made for motor sizes, capacity factors of the existing plant, and the interchange rate for the region. These are new auxiliary loads for the existing plants.

An additional calculation has been made to account for the expected change in plant efficiency due to different cooling water temperatures during the year and their resulting impact on the condenser and turbine operations. The values shown are the average energy penalty over four different seasons of the year.

O&M costs have been grouped into two categories: fixed and variable annual costs. The way that the O&M costs were assigned to each category is described in the worksheets provided in Appendix B.

4. RESULTS

4.1 DISCUSSION OF RESULTS

The results of the study indicate that cooling tower retrofits are technically feasible at three of the four plants evaluated: Surry Nuclear Power Plant, Big Bend, and Barney Davis. The addition of cooling towers at the Hudson plant is considered feasible on a provisional basis; serious issues remain that require evaluation. These issues relate to availability of land to locate the cooling towers and route the large-diameter circulating water piping. The requirement for plume abatement at this site exacerbates the space issues, since the plume abatement requirement imposes restrictions on the cooling tower cell array configuration. Towers with plume abatement features added cannot be spaced as closely as towers without this feature.

From an economic perspective, the addition of cooling towers to the evaluated plants poses a significant added cost, both as one-time capital costs and an ongoing increase in the cost of production of electricity. The added costs range from an estimated $128/kWe for the Surry plant to $65/kWe at the Hudson plant. The cost of adding cooling towers to nuclear units is significantly higher, on a unit basis, compared to a fossil plant. This is due to the much higher heat rejection to the condenser in a nuclear unit relative to that of a fossil unit, which rejects a significant amount of waste heat to the atmosphere via the stack. Table 4-1 compares the heat rejection at Surry with a typical fossil unit. Note that the heat transfer to the condenser for each of the Surry nuclear units is more than 1½ times greater per kilowatt of electricity produced.

[see hard copy for figure]
Table 4-1 Energy Flow Comparison

The annual energy penalty caused by the installation of cooling towers at these four existing plants (see Table 4-2) is estimated to be between 1.1 and 2.1 percent of the power plant output. This loss in salable power (annual energy penalty) is due to increases in condensing backpressure and auxiliary load (cooling tower boost pumps and fans).

[see hard copy for figure]
Table 4-2 Evaluation Results – Plant Output Effects

The auxiliary power requirements for booster pumps and cooling tower fans associated with the cooling tower retrofits are significant in all four of the cases evaluated accounting for 90 to 100 percent of the estimated annual energy penalty.

In contrast, decreased plant generation output due to condenser/turbine effects of the new cooling systems is smaller than originally anticipated. Surry's capacity decrement due to the new cooling temperatures (and not new plant auxiliary loads) is only 0.002 percent or 200 kW per unit. The losses at Barney Davis and Big Bend are equally small. The Hudson plant can anticipate a loss of almost 0.7 percent, or 7,500 kWe for both units combined. However, the decrease in net plant generation output due to increased auxiliary load is much more significant, and ranges from about 1 percent for the fossil units to about 2 percent for the nuclear units (Surry).

Decreases in the performance of the steam turbines because of the change from once-through cooling to recirculated cooling water were a minor contributor to the overall energy penalty due to the factors listed below.

-First, it appears that most of the plants evaluated (except Hudson) were designed with relatively high turbine exhaust velocities. Operation on a cooling tower would shift the condensing backpressure up, and exhaust velocity down. The reduction in exhaust velocity results in lower exhaust power losses, which tends to mitigate, but not completely compensate for, any reduction in generation output caused by the higher backpressure.

-Second, the cooling tower retrofits were designed with the same condenser temperature rise (nominally 15 °F). This tends to maintain low condensing backpressures, relative to units operating with higher temperature rises.

-Third, the cooling water temperatures for the original once-through cooling water systems tend to be high; cooling water from an evaporative tower designed with a typical design basis approach (difference in temperature between cold water temperature leaving the tower and the ambient wet bulb temperature) was relatively close to the once-through cooling water temperature during the summer months. During winter, spring, and fall the differences in cold water temperatures available to the plant condensers tend to diverge (between once-through vs. cooling tower cases of each plant). However, the Surry, Barney Davis, and Big Bend plants are not significantly impacted by increased cooling water temperatures over the range of temperatures encountered in the study due to turbine characteristics referred to above.

Technical parameters describing the retrofit cooling towers and circulating water piping for each unit that was evaluated are presented in Table 4-3.

4.2 CAPITAL COST AND OPERATING COST RESULTS

From an economic perspective, the retrofit of cooling towers to the evaluated plants poses a significant added cost, both as one-time capital costs and an ongoing increase in the cost of production of electricity.

[see hard copy for figure]
Table 4-3 Evaluation Results – Technical Parameters

A summary of the results of the assessment of capital costs and other economic considerations is shown on Table 4-4.

[see hard copy for figure]
Table 4-4 Summary of Capital and Operating Costs – All Plants

Detailed capital cost estimates for each unit and plant are contained in Appendix A. The total cost per plant ranges from $23 million to $108 million or from $65 per kW to $128 per kW. As expected, the Surry Nuclear Plant has the highest cost due to its large (848 MW) size per unit and high rate of heat rejection. However, two additional factors contributed to the high cost of this plant: the use of clustered cooling towers to minimize the required land space and distance of the towers from the plant, and, secondly, the long runs of circulating water pipes to the available open areas for the towers.

The costs to retrofit cooling towers at the fossil units are relatively close to each other at $65 to $77 per kW. The installed cost of both the cooling towers and the circulating water pipe account for approximately 60 percent of the direct costs. The foundations and structures account for almost another 20 percent of direct costs.

The Hudson site cost estimate includes plume abatement technology and costs due to its location. This factor increases the cost of the towers by about 100 percent or an additional $12 million of direct costs. This had the effect of increasing the total capital cost of the installation by 22.5 percent. The Barney Davis, Surry, and Big Bend sites were not determined to need plume abatement due to their location.

The detailed calculations for annual O&M costs associated with cooling towers for each unit and plant are contained in Appendix B. Operating costs for each of the nuclear units is expected to increase about $5.8 million per year. About 60 percent of this increase is for new auxiliary power requirements to run pumps and fans. The remaining 40 percent is for additional operators and supplies. About 90 percent of the O&M costs are considered variable costs.

Operating costs for each of the fossil units is expected to increase by about $1.5 to $2.0 million per year. About 50 percent of the new costs are for new plant auxiliary loads for fans and pumping. About 90 percent of the fossil O&M costs are for variable costs.

If construction of the retrofit cooling tower system would require an extended outage, costs could increase significantly. However, it is the opinion of the Parsons engineering staff that construction and startup of new cooling tower systems at the Surry and Barney Davis sites would not result in extended outages. With proper planning and coordination with other planned outages, cutover from the older cooling systems to the new cooling towers could be accomplished without loss of generating time. This has been the experience with other plants. Therefore, the analysis shows no cost penalty for extended outages at this time.

The situation is less certain at the Hudson and Big Bend sites. The configuration of the existing site for each of these two cases makes it difficult to assess the need for extended construction outages without more detailed site information and study.

The data presented in Appendix B of this report reflect no outage. However, should it be determined upon further review and a more detailed analysis of system locations, that an extraordinary outage will be required as part of a cooling tower retrofit, the following loss of revenues can be expected per plant (i.e., all units) per month:

-Surry… $30 million per month
-Hudson… $16 million per month
-Barney Davis… $11 million per month
-Big Bend… $28 million per month

To determine these losses in revenues, a conservative assumption of $0.030/kWh was used as the value of the lost power generation each plant would suffer as a result of an extended cooling tower retrofit outage. The calculation was also based on each plant's peak net summer power output.

5. CONCLUSIONS

The conclusions reached from this study based on assumptions about, and analysis of, four "real world" power plants indicate that the retrofit of evaporative cooling towers to an electric generating plant, fossil or nuclear, imposes a significant burden in terms of capital costs ($65 to $128 per kW) and loss of net generation output (1.1 to 2.1 percent of plant electricity generation). The capital cost expenditure reflects the cost of the cooling towers, circulating water piping, and related ancillary items such as added circulating water booster and makeup pumps. The loss of salable power is due to the added auxiliary electrical load, and for certain plants, a decrement in electric generation caused by operation at higher condensing backpressures.

Operating costs are estimated to increase about $5.8 million per year for the nuclear unit studied and about $1.5 to $2.0 million per year for the fossil energy units studied. More than half of the increase in operating costs is for new auxiliary power requirements to run new pumps and cooling tower fans.

The loss of revenue due to an extended outage to accommodate a cooling tower retrofit is a potential issue. In the current study, two plants (Surry and Barney Davis) appear to be able to avoid an extension to a normal annual outage to enable the changeover to be accomplished; the other two plants (Hudson and Big Bend) have more restrictive site arrangements and may require outage extensions.

When considering a recirculating wet cooling tower retrofit to an existing once-through cooled facility, there are several significant site-specific issues and assumptions that must be fully analyzed a priori. Among these issues are effect on turbine performance, increased plant parasitic power losses, land space consideration, tower size and type, permitting restrictions, tower plume and noise abatement, and tower drift loss control.

A series of these assumptions was made to facilitate the analysis of a prospective cooling tower retrofit at the four power plant sites documented in this study. These assumptions were based on the collective experience of the Parsons engineering staff, drawing on a large number of power plant design experiences spanning the last several decades. Changes to these assumptions will affect the detailed performance and cost data presented herein, but will most likely not affect the validity of the conclusions expressed. The effect of deviations from each assumption is briefly discussed below:

Cooling Water Temperature Rise

The assumption made in this study was to maintain the original temperature rise of 15 °F. If the cooling tower retrofit were to be based on a value of 20 °F, for example (a value typically used in new power plant cooling tower installations), the capital cost of the cooling tower might decrease somewhat, but generation output might also be diminished. A more detailed study, beyond the scope of the present effort, is required to select the optimum design value.

Steam Flow to Condenser

A typical value for the fraction of throttle steam flow passed to the condenser after expansion in the steam turbine of 65 percent was assumed. Variations of plus or minus 10 percent in this flow rate are not expected to change any of the results of this study. Larger changes would require evaluation on an individual plant basis.

Seasonal Average Temperatures for Cooling Water and Ambient Wet Bulb Temperatures

The use of seasonal average temperatures instead of monthly averages is not expected to impact the results developed by this study.

Steam Turbine Exhaust Pressure Correction

The steam turbine exhaust physical design parameters coupled with condensing steam flow rates have a significant impact on steam turbine generator electric output and plant efficiency. The estimate of performance impacts due to cooling tower retrofits presented in this report is based on the assumption that the reported turbine configuration is correct for each plant. Changes in turbine configuration used in this study to alternate configurations (number of low-pressure flow paths and/or last-stage blade lengths) could have a significant impact on the predicted change in generation output.

Cooling Tower Siting

For this study, the cooling towers were sited on the closest available open land near the steam turbine generator building. If these lands were not suitable or available, and the towers were located further away, piping costs would increase.

Cooling Tower Blowdown

The report assumes that extensive and/or expensive treatment of cooling tower blowdown is not required. If specific site conditions mandate high degrees of treatment for the blowdown, the capital and operating costs of the retrofit will increase, but are not expected to increase to a level that will compromise the overall economics of the cooling tower retrofit.

Overall, any requirement to retrofit closed circuit cooling towers to plants that now utilize once-through cooling could have significant operational and financial impacts. If the motivation for this change is due to water intake concerns, other engineering solutions that modify the inlet designs should be investigated.

RFC: Proposed use of restoration measures

FR Page 17146:VI. A.5. What is the Role of Restoration Under Today's Preferred Option

In our experience, the Department has found that restoration efforts can play a limited role as part of achieving best technology available (BTA) requirements. As we have stated in our earlier correspondence, however, restoration should serve only as mitigation after all practicable efforts have been made to first avoid and then minimize aquatic resource impacts. Consistent with the hierarchy advanced by the Council on Environmental Quality, restoration should not be the first consideration in reducing adverse impacts; it should be a supplement to address truly unavoidable impacts.

Some restoration has been utilized at power plants in New York State. For example, there was a substantial effort in producing and stocking striped bass as part of the Hudson River Settlement Agreement. This agreement ended the litigation of the EPA permits issued in 1975 for the Roseton, Bowline and Indian Point Generating Stations requiring installation of closed-cycle condenser cooling at these facilities. However, the NPDES permit requirement to stock striped bass came only after exhaustive consideration of and commitment to reasonable technological and operational methods to avoid, minimize, and mitigate the impacts at these facilities.

Underlying stipulations for the striped bass hatchery restoration effort were that the brood stock be of Hudson River origin, that the fish be raised in New York, and that the fish be released into the Hudson River. The basis for these stipulations was the belief that restoration efforts by facilities impacting the Hudson River ecosystem should be as closely linked to the Hudson River as possible. In the 20-plus years since the signing of the Settlement Agreement, we believe that regulatory and resource management agencies have come to a greater appreciation of their responsibilities to manage ecosystems and that there must be a close physical and biological connection between the restoration effort and the impact. Restoration efforts outside of the watershed fail to support ecosystem management goals on the impacted system.

The striped bass hatchery operated on behalf of the Hudson River utilities underscores an important limitation on this type of restoration: a single species was produced and stocked but studies at the three plants document impacts on more than 100 species. The striped bass hatchery effort addressed a small fraction of the fish community and a small fraction of the mortality imposed on the ecosystem by these three plants. As an example, during the 1986 spawning season, the hatchery produced and stocked 530,000 striped bass into the Hudson River. This stocking contributed an estimated 1.5% to the 1+ striped bass population, as measured about 18 months later.

During the 13 years the hatchery operated (1983 through 1995), the average conditional entrainment mortality rate (the reduction in year class due to entrainment mortality) for striped bass from the Roseton, Bowline, and Indian Point Stations averaged 11% (ignoring any compensation that may have occurred). Even this very substantial hatchery effort, then, only replaced approximately 14% (1.5/11 = 14%) of the mortality imposed on striped bass by these three plants.

The Department supports the requirement in 125.94(d) that, if restoration is included as an element of achieving BTA, the permittee "... must demonstrate to the Director that you are maintaining the fish and shellfish within the waterbody, including community structure and function, to a level comparable to those that would result if you were to employ design and construction technologies or operational measures to meet that portion of the requirements of paragraphs (b) or (c) of this section that you are meeting through restoration." This standard is appropriate, but as we learned from our experience with the striped bass hatchery, complete reliance on restoration for the substantial impacts associated with the large stations in the Hudson River would be a daunting undertaking.

The bulleted list of items on Page 17147 regarding the information to be provided to the director to support consideration of restoration measures is adequately comprehensive and we do not recommend streamlining. The Department recommend a provision which would indicate that specific situations may require submission of information supplemental to that required here. It may also be helpful to require periodic comprehensive reports on the progress of the restoration efforts. These reports should include an analysis supporting any assertion that the restoration measures (and the technology plus operational measures) are maintaining the ecosystem at levels comparable to full reliance on technology and operation. EPA should also consider an explicit statement that failure of the restoration efforts to achieve their goals after a reasonable, specified time period would obligate the permittee to expand or otherwise alter their program.

A decision as to whether a permittee has achieved their goals in a restoration program and whether the restoration efforts undertaken have achieved "substantially similar performance" is viewed as a challenging element in your draft regulations. The expertise to address this issue may not be readily available in the delegated states charged with implementing these regulations, and the breadth of information one needs to make this kind of determination could lead to widely varying decisions across the nation. Perhaps EPA could provide foundational materials and relevant technical reports similar to that developed in Technical Guidance Manuals for Section 316(a) decisions to set a baseline for decision makers. EPA is in a unique position to serve as a clearinghouse for acquiring and disseminating information on restoration efforts across the nation and for the information needs and analyses of assessing their success or failure. The Department urges EPA to accept this role.

The Hudson River utilities operated the striped bass hatchery with the concurrence of and oversight from the Department. The stocking effort was conducted with the concurrence of the agency responsible for managing the State's natural resources. Any restoration of a public trust resource must have this approval.

In seeking approval to construct and operate the hatchery and stock striped bass into the Hudson River, the Utilities submitted hatchery plans so that the Department's fish production staff could review and approve the design. Aquatic biologists reviewed and approved proposed marking techniques, location and conditions of stocking, and, so that the contribution of the hatchery produced fish to the Hudson River population could be evaluated, staff also required and approved a recapture program for the marked stocked fish. Annual reports from both the production and marking effort, and from the evaluation of the contribution of the hatchery to the 1+ population were required. Staff conducted both announced and unannounced site visits to insure adherence to agreed upon protocols.

Restoration efforts must recognize that success may not be complete and so restoration should be scaled to reflect possible shortfalls. For example, the Hudson River utilities' striped bass hatchery was required to make a good faith effort to stock 600,000 three-inch fingerlings into the river each year. Intensive culture of striped bass proved to be difficult, however. Despite a very strong effort, the average number of fish stocked for the 13 years that the hatchery operated was just under 300,000 per year. This particular experience supports a 2:1 "margin of error". In the later years of operation, the average production did increase so that one could argue for, perhaps, a 1.5:1 margin. However, as noted in your supporting narrative, restoration involves much uncertainty and so a conservative multiplier is appropriate.

Accrual of ancillary or secondary benefits from restoration efforts is possible, and, on first blush, seems to warrant consideration of a reduced level of required restoration. However, the facilities that will have to implement restoration efforts are those that are using once through condenser cooling; they are discharging enormous quantities of heat into aquatic systems. EPA defines heat as a pollutant, and the excellent work EPA did in developing their Technical Guidance Manual for Section 316(a) notwithstanding, the inability to detect ecological consequences of these discharges should not be taken as proof that they do not exist. Even in the presence of some ancillary benefits of restoration programs, once-through cooling is imposing stresses on ecosystems that are not quantified nor compensated for at this time. It would be very surprising if restoration programs make an affected ecosystem "better", overall, than it would be in the absence of the facility. There may be secondary benefits; there almost certainly are secondary impacts, and therefore New York supports minimal or no credit for secondary benefits.

EPA Response

EPA agrees with the commenter that it is important for there to be a close biological and physical connection between a restoration measure and the ecological entities impacted by impingement and entrainment by a cooling water intake structure. Therefore, EPA requires in the final rule that ecological benefits from a restoration measure accrue within the same waterbody or watershed in which the impacts from a facility occur. For additional discussion of the appropriate spatial scale on which to conduct restoration measures, see the final rule.

For discussions of the consideration of design and construction technologies and operational measures before the use of restoration measures, see EPA's responses to comments 316bEFR.033.005 and 316bEFR.202.029.

Use of restoration measures alone may not be feasible for all permit applicants. The final rule allows use of restoration measures as a supplement to design and construction technologies and operational measures, as well.

The final rule allows permitting authorities the flexibility to request the information necessary for a permit applicant to demonstrate to the permitting authority's satisfaction that a restoration measure is able to meet the requirements of the final rule. EPA has included in the final rule requirements for development of an adaptive management plan and monitoring and reporting requirements. These requirements give flexibility to the permitting authority to determine what is required to ensure satisfactory performance of a particular restoration measure. For a discussion of the roles and responsibilities of the permitting authority and the permit applicant, see EPA's response to comment

316bEFR.060.026.

For a discussion of ancillary benefits associated with restoration, see EPA’s response to comment 316bEFR.032.011.

RFC: Will I&E study supply sufficient information?

FR Page 17148, VLA.6.: Impingement and Entrainment Assessment

The Department does not believe that the sampling intensity proposed here is adequate. Included in this attachment are several graphs of both entrainment and impingement data collected at the New York Power Authority's Poletti Generating Station located on the East River in New York City. Figure 1 provides an estimated number impinged for the three year program, by week. Clear seasonality is evident, and it seems obvious that during the months when impingement numbers are at their seasonal low, sampling as infrequently as monthly would probably suffice. Figure 2 provides the detailed information for the peak in impingement for the year 2000, again by week. Here it is evident that, within a month, the week selected for sampling could provide a very distorted view of what was actually happening. The Department believes that, with enough background information, one could stratify the sampling to once per month for time periods when impingement has, historically, been low. However, during periods when impingeable life stages are abundant, sampling is required at least weekly so that one can be reasonably assured of not missing important peaks. One strategy utilized by the Department in responding to requests for reduced sampling when impingement is assumed to be low is to require sampling during the first week of such a month. If estimated numbers impinged during that first sample are below a preselected threshold, further sampling during that month is not needed. If numbers are above the threshold, sampling is required during the next and succeeding weeks of that month until the estimated numbers impinged are below the threshold.

Examination of Figures 3 and 4 reveal the same situation for entrainment at this station: strong seasonality (Figure 3) and, within the seasonal peak, high variability (Figure 4). Again, stratifying the sampling program as described above for impingement, once sufficient background data is available, is a reasonable approach.

The annual variability seen in Figures 1 and 3 support a baseline period of no less than 2 years, as EPA proposes.

EPA has specified that the more intensive period of entrainment sampling occur during "the primary period of reproduction". This approach would likely underestimate the full impact. Most fish are entrainable long after the egg and larval stages, which could be interpreted as the "primary period." Instead, the Department recommends that EPA specify the period for intensified sampling as that time when entrainable life stages are abundant.

Based on our experience with installation and monitoring of mitigative technology and operational changes, the Department believes that monitoring requirements are highly specific to each situation. For example, with the modified Ristroph screens installed at Indian Point Nuclear Station, we concluded that the handling needed to get accurate estimates of impingement abundance post-installation of the upgraded screens would impose enough mortality as to significantly reduce the mitigative benefit of the installation. As a result, the Department no longer requires impingement sampling at that facility. This contrasts with the impingement mitigative barrier net that is installed each fall through spring at the nearby Bowline Generating Station. In spite of the very good job the barrier net has done over the past two decades, this technology is subject to net tearing, lifting off the bottom due to ice or floating debris, or other temporary reductions in effectiveness. As a result, weekly impingement monitoring is required to assure that the barrier net's performance is not compromised, or if it is, to provide that a crew can quickly be deployed to address the problem. One would not expect a traveling screen subject to periodic inspection and adjustment to degrade in mitigative performance overtime, while the barrier net could experience tearing or lift off the bottom, and as a consequence, quite different monitoring programs are required.

RFC: Entrainment vs. entrainment mortality

FR Page 17149, VI.A.7: How are Entrainment Mortality and Survival Considered in Determining Compliance With the Proposed Rule?

There has been considerable effort to obtain empirical estimates of post-entrainment mortality in New York, particularly at Hudson River power plants. Over the years as the sampling gear became more refined to reduce stress during the collection process on entrained and control organisms, less water was sampled and therefore fewer animals were collected: some of the data available are based on relatively low numbers of organisms. One conclusion that seems fairly well established is that the physical and thermal stresses imposed on entrained organisms do not work synergistically. What one sees is a species and life stage specific mortality rate due to mechanical stress (contact with surfaces inside the cooling system, possibly shear and hydrostatic effects, etc.) as low as 10 % for robust species such as striped bass post yolk-sac larvae and as high as 100% for species such as bay anchovy larvae. For species that do demonstrate some tolerance to mechanical stress, thermal mortality can go from none to complete as the exposure (i.e. discharge) temperature increases over a narrow range of, say, 3 to 4 degrees C above the temperature at which thermal effects are first noted. Thermal mortality also exhibits a dose-response component wherein at temperatures that cause some mortality, longer exposure to the elevated temperature results in increased mortality.

Extensive post-entrainment and thermal exposure survival studies have been conducted in New York. Excerpts from some of these studies are attached here in response to EPA's request.

There have been criticisms of post-entrainment survival studies on several issues. One is that the holding of entrained organisms in laboratory facilities that allow for latent observations is essentially putting the organisms in a protected environment where they will have respite from predation and other factors. Compared with test organisms held in convalescent facilities, entrained organisms may be less able to survive when they are returned to the natural environment. Another criticism is that, although some latent effects data are based on a 96-hour post-entrainment holding period, that period may not be sufficiently long for some stresses to be manifest. And finally, it is usually impossible to gather test organisms that have experienced the full spectrum of entrainment, especially those organisms that have been returned to the source through a high-speed diffuser. Each of these factors could increase the estimated mortality imposed on entrained organisms. Department staff account for these unknown elements of entrainment by having permit applicants calculate impacts based on both empirical estimates of entrainment mortality and on the assumption of 100% mortality. The resulting estimates likely bracket the actual impact.

EPA also requested survival studies for other technologies to possibly aid in this rulemaking. During the development of the Gunderboom Marine Life Exclusion System, Department staff conducted an assessment of the swim speed of early fish life stages in estimating the possible effects of the through-boom water velocity on early larvae. A Department memorandum entitled Gunderboom File: Impingement on Boom, a Closer Look concludes that impingement of early life stages of fish likely found in the area of the Lovett Generating Station would not be a significant concern. Still, the Hudson RiverKeeper expressed concern for the effect of impingement of eggs and early larvae on the Gunderboom and the ease with which impinged eggs could be dislodged after being impinged. In response to this concern, Department staff conducted experiments with American shad eggs and day-old larvae that are also documented in a memorandum entitled Experiments with exposure of American shad eggs and larvae to the Gunderboom Marine Life Exclusion System, also attached. Those studies concluded that: American shad eggs do not suffer any mortality after being impinged on boom fabric' for up to 4 hours; the eggs are easily dislodged after being impinged; and day-old larvae easily swam well enough to avoid impingement on Gunderboom fabric through which water was flowing at the velocity proposed for the Lovett installation.

EPA Response

Please see response to comment 316bEFR.305.001 with regard to entrainment-based performance standards. Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis. Please see the response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule.

Benefit Estimation Methodology

Author Name Peter Duncan
Organization NY State Dept of Environmental Conservation, Office of Natural Resources

Economic considerations

The Department is encouraged by the discussion and guidance of appropriate methodologies for Benefits Assessment. In general, we agree with what is presented in this section and would encourage EPA to expand this section by including more methodologies and specific guidance on appropriate economic analysis. We have the following specific comments on the discussion appearing in Section VI. 8.

EPA Response

EPA provided a detailed discussion of methodologies and specific guidance on appropriate economic analysis in the context of the Section 316(b) regulation in Part A of the final Regional Study Document for the Phase II rule. See DCN #6-0003 for detail.

EPA will work with states and regions to develop appropriate methodologies for use in permitting determinations.

General/Benefit Transfer

FR Page 17149: VI.8.(a) What Should be the Appropriate Methodology for Benefits Assessment?

The Department encourages EPA to include Benefits Transfer as an appropriate methodology provided that certain criteria are met. Survey work to gather the data needed to build a Random Utility Model can be prohibitively expensive. This is also the case for the survey work for doing Contingent Valuation. It may be possible to save money if the data already exists or the function derived from it is applicable. Given the inelastic demand for electricity, it can be assumed most costs borne by the producers will be passed on to consumers, including costs of compliance, research, and permitting applications.

In those cases where appropriate and meaningful data already exist, the option to use it should exist. Existing data and existing modeling which. has estimated a function can be used to predict a customized value for the new application. This approach is commonly referred to as a “benefit-function transfer.” We propose the EPA draw from its own publication “U.S. Environmental Protection Agency. 2000. Guidelines for Preparing Economic Analyses, EPA 240-R-00-003.” and specifically the criteria for a credible transfer given in Chapter 7, Section 5.4. This document was peer-reviewed by the U.S. EPA’s Science Advisory Board and the Board’s Environmental Economics Advisory Committee (EEAC). The EEAC comprises of some of the best economists in the world. This peer-reviewed synthesis provides a sound basis for evaluating a benefit transfer to determine if it is credible.

EPA Response

EPA agrees that benefits transfer is an appropriate methodology for estimating benefits of the final Section 316(b) Phase II rule. For the recreational fishing analysis, benefit transfer is used for the Inland region, and benefit function transfer is used for the North Atlantic region. EPA, however, has estimated RUM models for all other coastal regions (Mid-Atlantic, South Atlantic, Gulf of Mexico, and California), and for the Great Lakes region. Where benefit transfer is used, EPA has followed principles outlined in the EPA’s Guidelines for Preparing Economic Analyses, United States EPA (EPA 240-R-00-003, DCN #6-1931), and has carefully applied benefit transfer methods. Further information on the benefits transfer method EPA used to estimate recreational fishing benefits for the Inland region is provided in the final Phase II Regional Study Document (DCN #6-0003). See Chapter H4: Recreational Fishing.

Subject Matter Code 10.02.04

Valuing Forage Species (incl non-use and non-landed)

Narrative benefits assessments to supplement the listed methodologies to account for those benefits which cannot be quantified and monetized.

The Department strongly recommends that the EPA require such supplementation. As stated in the Proposed Rules, recreational fishing is the only loss where data may be available and used in a Random Utility Model. Many other categories of losses may be incurred and should be noted and discussed in order to allow for qualitative adjustments, to fully inform the public, and provide baseline data and information if conditions change in the future. Other losses or potential types of impacts may include critical, sensitive habitats, species that are not presently threatened or endangered but may become so.

The Department recommends EPA provide guidance and a description of the types of information required as content for such narrative benefits assessments. Additionally, such benefits may be identified by the public outside of standard economic and data gathering activities and as such early and significant public participation and input should be sought in order to develop an inclusive and meaningful assessment.

EPA Response

EPA agrees that total benefits include outcomes beyond recreational and commercial fishery impacts, and that these other benefit categories often are very difficult to quantify and monetize. Qualitative assessments are valuable supplements to quantitative benefits studies, and the conduct and high quality of such assessments should be encouraged.

Use of Replacement Costs (HRC and hatchery-based)

VI.8(a)(1): Baseline Impingement and Entrainment Losses

Habitat-Based Replacement Cost Analyses: (as described in Section IX. Benefit Analysis).

The Department strongly advocates the inclusion of this method as a listed and appropriate methodology for Benefits Assessment.

EPA Response

As noted in response to comment 316EFR.005.035, EPA agrees that the HRC method has value. However, the Agency no longer applies the HRC method as part of its benefits analysis for the 316b rule. The Agency agrees with many comments received that, in general, "costs" should not be confused for "values." However, EPA also notes that there are many instances in which cost-based information can provide useful insights to policy makers, and that under suitable circumstances, costs can be used as a proxy for (i.e., in lieu of) more desirable but less accessible "value" information. For example, cost-based data may be viewed as an indication of “value” where the costs are borne voluntarily by the individuals involved, or in cases where public policies reflect a broad consensus based on continuous input from the general public and the broad array of interested parties (especially where an adaptive management approach enables adjustments over time in what actions are taken and what costs are incurred).

Subject Matter Code 10.02.04

Valuing Forage Species (incl non-use and non-landed)

Inclusion of Passive or Non-use Values.

The Department strongly recommends that Passive Values be included in any and all estimation of benefits. As discussed above, many benefits cannot be quantified and the exclusion of any category, such as passive values, which can be quantified would result in serious underestimation of total benefits. Additionally, Freeman (1993) points out that passive use values are not dependent upon injuries to unique resources nor irreversible changes in the resource.

The Department agrees that application of a “ratio method” or applying a factor to the amount of use values to approximate non-use values is an efficient and practical method. We urge EPA, however, to allow upward flexibility in the actual factor applied. Site specific considerations’ must be taken into account which may be done by allowing regulators to adjust this factor to more closely approximate what they believe is more in keeping with the public interest. We believe the proposed 50% factor should be the minimum allowed as research shows many studies with much higher ratios of non-use to use benefits. For example, Brown (1993) in his meta-analysis concluded that non-use values averaged to be twice the use values which translates into an adjustment factor of 200%. As discussed in the Proposed Rule [Section 11], EPA recognizes that States assign higher priority to protect some waters over others. In cases where exceptional historic or cultural values may exist, States should be allowed to request a higher factor for the inclusion of passive values. The Department submits that it may be possible to partially address some of the issues attendant with priority watersheds by allowing flexibility in the factor applied to use values to approximate non-use values.

EPA Response

The analyses for the final Section 316(b) Phase II rule does not include estimates of passive use value.

EPA confirms that it is aware of Brown's research and conclusion that non-use values are on average double the level of use values. However, in the analyses for the NODA and for the final Section 316(b) Phase II rule, EPA did not use a rule-of-thumb approach to estimate non-use benefits. For EPA's response to comments on the use of the 50% rule-of-thumb to estimate non-use benefits, please refer to EPA's response to comment #316bEFR.005.034.

Please also refer to EPA's response to comments on the HRC methods (316bEFR.005.035) and the SRP methods (316bEFR.005.006); the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003); and to EPA’s Guidelines for Preparing Economic Analyses (EPA 240-R-00-003).

Overview of I & E effects on organisms

In a letter dated August 7, 2002, the Atlantic States Marine Fisheries Commission provided comments in response to the proposed Environmental Protection Agency Section 316(b) regulations under the Clean Water Act. In this letter, the Commission expressed concerns regarding the potential impacts of power plant impingement and entrainment that may be misconstrued to imply that the Commission has developed a policy on the magnitude of these impacts. As you may be aware, the Commission is currently conducting a study to evaluate the coastwide cumulative impacts of power plant impingement and entrainment on Atlantic menhaden stocks This study will link impingement and entrainment mortality directly to the Virtual Population Analysis (WA) stock assessment in order to evaluate population level impacts to Atlantic menhaden. We are also conducting a study on multispecies interactions between Atlantic menhaden, striped bass, weakfish, and bluefish which will allow us to evaluate mortality caused by predator/prey effects. In combination, these two studies will provide the Commission and our member states the ability to concurrently evaluate the relative impacts of predator/prey mortality, mortality caused by power plant impingement and entrainment, and fishing mortality.

The Commission continues to be concerned with the potential impacts caused by power plant impingement and entrainment. However, we are very interested in developing a sound scientific basis for any policies the Commission formulates concerning impingement and entrainment mortality. We are hopeful that this study, in conjunction with other studies conducted by state and federal marine fisheries agencies, as well as the power plant industry, will provide the science necessary to more fully understand the potential impacts of impingement and entrainment. The Commission does not currently have any policies concerning the potential destruction caused by impingement and entrainment, and will develop these policies only upon completion of this scientific study

EPA Response

EPA thanks the commenter for this clarification. The study mentioned by the commenter has not been completed to date and could not be used as part of this section 316(b) Phase II rulemaking. Please see the response to comment 316bEFR.025.018 for the discussion regarding the environmental impacts associated with cooling water intake structures.

Cooling system costs (e.g., dry, wet, recirculating)

An Investigation Site-Specific Factors for Retrofitting Recirculating Cooling Towers at Existing Power Plants

January 22, 2003

Prepared by

The United States Department of Energy
National Energy Technology Laboratory

Background

This addendum updates a report prepared by Parsons Corporation (Parsons) for the Department of Energy/Office of Fossil Energy's National Energy Technology Laboratory (DOE/NETL). The purpose of the addendum is to provide further information on the critical role that site-specific factors can have on the cost and feasibility of retrofitting cooling towers on thermoelectric power plants that currently employ once-through cooling.

The Parsons report was commissioned during the relatively brief interagency review period for the Environmental Protection Agency's §316(b) Phase II proposed rule for existing power plants. One of the Agency's regulatory options under consideration at that time was to require that over fifty (50) existing thermoelectric power plants retrofit from once-through cooling systems to wet recirculating towers. The Parsons analysis focused on the feasibility of implementing such a requirement on four existing steam-condensing power plants taking into consideration site-specific factors. DOE/NETL used the results of the analysis to provide input to EPA during the proposal's public comment period on the impacts that site-specific factors could have on retrofitting once-through plants with recirculating cooling towers.

The Parsons report was intended to provide a preliminary assessment -- a "30,000-foot view"-- of how site-specific factors might affect the cost of installation of cooling towers and ancillary equipment and any resultant economic and energy impacts on plant operations. Parsons was tasked with completing the study in four weeks and was instructed not to contact the utilities that owned the four plants since the interagency review process was ongoing. Therefore, Parsons was not able to obtain the requisite plant data from the plant operators that would typically be used to generate a detailed site-specific analysis. Nevertheless, while using only publicly available information and aerial photographs, the Parsons study concluded that the retrofit of closed-loop cooling systems at the four existing power plants would impose significant capital cost burdens and loss of net generation output.

Subsequent to the issuance of the Parsons report, DOE/NETL had discussions with each of the four utilities that own the power plants evaluated in the study. These discussions focused on actual site-specific concerns expressed by these utilities. We also sought comment about design parameters selected in the study and input on other issues that would affect the installation and operation of cooling towers at these and similar plants that DOE/NETL was unable to obtain during the interagency review. The subject addendum summarizes the supplementary information that was provided by the four utilities and presents a discussion of the impact of this new information on the cOst and feasibility of retrofitting wet cooling towers on the four power plants.

The overall conclusion based on DOE/NETL analysis of the supplemental site-specific information is that cooling towers can be more difficult, and more costly, to retrofit than one would assume based solely on publicly available information. Based on this additional information, we believe that it is critical that EPA recognizes in its rulemaking process that the cost and operational impacts of retrofitting once-through cooling systems must be evaluated on a case-by-case basis. The additional site-specific information also makes it clear that adverse environmental impacts (AEI) beyond those associated with impingement and entrainment and beyond water quality in general, would be caused by a requirement to retrofit to wet cooling towers. The other AEI include endangered species issues, visibility issues, noise pollution, salt corrosion, increased air emissions, and increased waste, and would impact cooling tower retrofit options.

General Issues

Siting

Parsons utilized publicly available aerial photographs to recommend locations for the installation of cooling towers at each of the plants. Additional site-specific information provided by the utilities has shown that most of the locations suggested in the report would not be feasible due to factors unknown at the time of the Parson's study. These factors include the presence of existing landfills, desalinization plants, railroad tracks, and other facilities, as well as commitments to use the targeted location for other purposes. The result of the actual site-specific information is that three of the four sites would require a more remote placement of the towers that would result in higher costs and possibly longer outage times.

Plume Abatement

One of the four plants investigated by the Parsons report was deemed to require plume abatement. Additional information provided by the utilities indicates that at least three of the four plants would likely require plume abatement due to local factors that were not known at the time of the Parsons study. Plume abatement measures would double the capital cost of the resulting cooling tower and result in other AEI.

Salt Drift

Even with optimum drift control there will be particulate emissions of salt from cooling towers employing salt water. These will have corrosive impacts within the power plant and may have adverse environmental impacts outside the plant boundaries. The consequences of adequately addressing salt emissions from the cooling towers include adding additional cost for salt drift reduction at three of the four plants and recognition of other AEI. At one of the plants it is likely that the State and Federal air quality standards for particulate emissions would be exceeded and a variance for the wet tower would be extremely unlikely.

Due to the need to re-site several of the wet towers based on new actual plant-specific information, the new locations close to urban areas would require some amount of noise abatement technologies. These would both increase the original Parsons' cost estimates and create additional AEI.

Local Uses Related to Cooling Water Intake and Discharge

At the nuclear facility that was evaluated the intake canal and pumps are also used for emergency cooling. In addition, at one of the fossil-fuel-fired plants, the discharge canal is used to dilute brine discharge from a desalination plant as well as to provide a warm water sanctuary for manatees, an endangered species. While these site-specific considerations were not included in the initial Parsons study they clearly would limit the practicality of reducing cooling water flow rates at these plants that would result from the installation of a closed-loop system.

Outage Times

The Parsons study assumed conservatively that all of the construction required for retrofitting the cooling tower systems could be performed while the plant is on line, thereby minimizing cost and energy impacts due to plant outages. Based on the input provided by the site operators, it appears that an extended outage would be required by two of the four plants resulting in losses in revenue. The impact of the loss of generating capacity - aside from the loss of revenue attributable to the plant - from these units during retrofit would need to be evaluated based on the historical records and projections of future dispatch for each plant.

Energy Penalty

The Parsons study used nearby wet bulb temperatures that were lower than temperatures actually experienced at some plant sites. This would result in an increase in actual energy penalty. Furthermore, the Parsons study is based on a 2 percentile of maximum wet-bulb incidence rather than the 1 percentile normally used to calculate the impacts on electricity generation during the times of peak summer demand. The 1 percentile of maximum wet-bulb temperature is typically a few degrees higher than the 2 percentile. For a given cooling tower design, an increase in wet-bulb temperature translates directly to increases in condenser temperature, with corresponding increases in turbine back pressure and the resultant energy penalty.

Revenue Loss

In terms of lost revenues, Parsons assumed a conservative replacement cost of electricity based on the average annual price of electricity of $0.03/kWh. However, the greatest loss in energy output from plants with cooling towers would be on the hottest, most humid days of the year when market prices for electricity are far greater than $0.03/kWh. The value of lost revenue could be calculated more accurately by looking at historical records of each plant and the specific price of power in each region, a level of detail that was neither feasible, nor in the scope of the Parsons study. Nevertheless, this lost revenue could be significant in some cases.

General Conclusions

The Parsons report highlighted the critical importance of site-specific factors such as those discussed above in the final determination of the costs and impacts of retrofitting to recirculating cooling towers in existing power plants. At the plants considered in this study, the incorporation of additional actual and more detailed site-specific information had the impact of increasing cooling tower capital cost estimates by as much as 100 percent. More importantly, other uses or beneficial impacts of the existing cooling water systems suggest that some cooling tower projects that seem workable as a general proposition are impractical at any cost when these site-specific uses are considered.

The opportunity to consult with the utility companies has demonstrated that the issue of retrofitting cooling towers is even more complex than shown in the report. Therefore, DOE/NETL reiterates its strong preference for a site-specific approach to implementation of §316b regulations. In addition, the finding that non-water related adverse environmental impacts will almost certainly result from installation of cooling towers at some, if not most, sites leads us to conclude that all AEI should be considered in a regulation that contemplates measures such as retrofitting cooling towers.

Plant Specific Issues and Responses

Subsequent to the issuance of the Parsons report, DOE/NETL obtained site-specific information from the electric-utility companies that operated the four plants included in the Parsons report that was not available at the time the report was prepared. Input was provided from America Electric Power (AEP) Company Inc., owner of the Barney M. Davis plant, Tampa Electric Company (TECO) Inc., owner of the Big Bend Station, PSEG Fossil LLC, owners of the Hudson Generating Station, and Dominion Virginia Power Inc., owner of the Surry Power Station.

The following presents a discussion of the comments received and DOE/NETL's assessment of those comments that would significantly impact the general conclusions reached in the Parsons report.

Big Bend Station

Siting Issues

The Parsons report sited the "conceptual" cooling tower on land that is unavailable. Part of the "conceptual" cooling tower is located on land that is occupied by a 25 million gallon per day seawater desalination plant that is under construction at the Big Bend power station.

An alternative possibility would be to construct a cooling tower south of the plant at a site currently used for byproduct management operations (beneficial use of waste to produce gypsum). The land is adjacent to the Apollo Beach residential community and proximate to an undeveloped coastal area covered with sensitive vegetation. Major modifications to the design of the cooling tower system, if sited at this location, would likely be required to minimize adverse environmental impacts and accommodate local permitting requirements. These modifications would require significantly higher costs. Furthermore, the existing byproduct management activities would have to be relocated and changed, thus requiring a detailed alternative analysis to minimize the impact on byproduct handling.

Plume Abatement Issues

The Parsons report does not include plume abatement technology in the cost estimate for the closed-loop, wet cooling tower retrofit at the Big Bend Station site. However, the Big Bend site is located adjacent to the Apollo Beach residential community. Although the need for plume abatement technology at the Big Bend Station site would not be determined until the actual permitting process was completed, the inclusion of such technology would likely be needed and would double the cooling towers' capital costs and significantly increase their annual operating and maintenance costs.

Adverse Environmental Impact Issues

The Parsons report does not include several potential adverse environmental impact issues associated with installation of a cooling tower system as defined in their conceptual study. The adverse environmental impacts that would need to be considered, and potential remedies sought include: (1) impact on endangered species such as the manatee that live in warmer waters created from the Big Bend discharge during the winter months; (2) increased air pollution emissions from power production due to loss in power plant efficiency; (3) visibility concerns from cooling tower plume; and (4) increased particulate emissions from cooling tower exhaust.

The Big Bend Station cooling water discharge provides a warm water refuge for manatees in the winter season and the discharge canal has been designated by the State of Florida as a Manatee Sanctuary. This benefit would be lost if the Big Bend Station were to retrofit their once-through cooling system with a recirculating cooling tower system.

The best available location for siting a cooling tower requires relocation of gypsum handling and raises the potential for salt contamination. A careful analysis and design would be required to determine if saleable gypsum can still be produced or if alternative disposition would be required.

Remedies to mitigate or avoid these potential adverse environmental impacts are site-specific and would require a detailed assessment of alternative measures.

Big Bend Station currently has a salable byproduct, gypsum, with annual revenue of $2 million. If the chloride level of the gypsum were raised above acceptable limits from exposure to salt drift, these revenues would be lost. Alternative utilization paths for the gypsum would have to be explored. Soil stabilization and trail construction are two potential uses. If alternative beneficial uses cannot be found, gypsum disposal costs would likely be an order of magnitude higher than current gypsum sales resulting in a total annual net revenue loss of about $20 million.

Outage Time

It is likely that tie-in of a cooling tower system would be scheduled concurrent with a major outage for the power plant. Since the cooling tower tie-in would need to accommodate connections with the condenser and the desalination plant, it is likely that the cooling tower tie-in outage would significantly exceed a scheduled outage. Given the substantial congestion amongst above and underground facilities and the complexities associated with new lines and sumps for the desalination plant at the Big Bend Station, DOE/NETL believes that the cooling tower tie-in outage time would require a detailed engineering analysis estimate.

Energy Penalty

The energy penalty estimated in the study for the cooling tower retrofit probably underestimated the actual energy penalty for the following reasons: (1) the temperature rise across the condensers is designed for a 17 degree rise rather than the 15 degree rise assumed in the Parsons report; (2) Big Bend Station rejects 70 percent of the rated steam flow rather than the 65 percent rejection rate assumed in the Parsons report; (3) turbine configurations for 2 of the 4 units at Big Bend Power Station were different than assumed in the Parsons report; and (4) the wet bulb temperature and summer average water temperature at the Big Bend Station are higher than estimated in the Parsons report.

The steam turbine exhaust physical design parameters coupled with condensing steam flow rates have a significant impact on steam turbine generator electric output and plant efficiency. Changes in turbine configuration from those used in the Parsons study could have a significant impact on the predicted change in generation output. Seasonal average values for cooling water and ambient wet bulb temperature do not reflect the extreme hot summer weather, which is coincident with highest demand for power and the highest cost for replacement power. The combination of factors listed above will increase the energy penalty estimated in the Parsons report. A more detailed study, beyond the scope of the “conceptual” estimate, is required to provide a more accurate estimate of energy penalty.

Economic Issues

The desalination plant begins operation this year and was not pictured on the aerial photo used by Parsons. Neglecting the existence of the desalination plant significantly reduces plant cost associated with installation of a cooling tower at the Big Bend Station. The desalination plant is currently configured to dilute brine discharge with water discharged from the once through cooling system. The reduced water discharge associated with a cooling tower would require an alternative strategy to be developed for the disposal of brine concentrate. Tampa Electric Company considered one other option that entailed discharging the brine concentrate via pipeline into the center of Tampa Bay. That study indicated that the plant would not be economically feasible if a mid-bay discharge were included. Since the current rulemaking could result in installation of such a discharge system 5 or more years after the desalination system is in operation and when it’s capacity will be more than four times the initial capacity, DOE/NETL is unable to determine the magnitude of the potential cost impact on this project.

In addition to cost increases related to providing dilution for the desalination brine, siting issues associated with the cooling tower in a less convenient location than assumed in the Parsons report would significantly increase capital and operating. costs at the power plant. There is also a potential annual loss in revenue of $20 million if gypsum byproduct sales are lost due to higher chloride content of the gypsum from salt drift deposition and more difficult management of gypsum because of encroachment of the cooling tower at the gypsum treatment area.

Revenues lost from extended outage time to tie-in the cooling tower system are expected to be significant. It is not possible to quantify lost revenues without a detailed engineering study.

The capital cost of the cooling tower situated on available land is estimated to be twice the capital cost estimated in the Parsons conceptual estimate. The major reason for this cost increase is the likely need to install plume abatement technology. If a cooling tower system were to be installed at Big Bend Station there would also likely be a need to have an extensive review of adverse environmental impacts that would increase the normal time needed to secure local, State, and Federal permits.

Hudson Generating Station

Siting Issues

Due to local sensitivity to a fatal Conrail train accident that occurred several years ago, it would be politically unacceptable to locate the cooling towers in proximity to the railroad tracks as they are shown in the Parsons design. That is, even a plume abated cooling tower under some conditions of weather could produce a low hanging plume that would obscure the visibility of any trains and its drift could ice the tracks.

In addition, planned modifications to the New Jersey Turnpike will physically interfere with the cooling tower location as proposed in the Parsons report. The SCRs and scrubbers that PSEG is obligated to regulatory agencies to install in 2006 and 2007 would prevent location closer to the powerhouse.

A more suitable location, further away from the power house, would entail considerably higher construction costs and pumping power requirements. This location, toward the North, would be on the other side of the Conrail railroad tracks and in the case of Unit 2, also across Penhorn Creek.

In that location, a full evaluation of the capital costs would require adding expensive bridging and tunneling of large diameter pipes to and from the towers to traverse these barriers. The stream crossings would also be subject to large permitting costs because of the environmental issues involved. This difference is reflected in the site-specific cost estimate PSEG prepared in 1997 (see below), which budgets $35,067,804 for pumps and piping systems, versus the total cost of $11,918,000 estimated for the same items in the Parsons report.

Noise Issues

Because the design is very open, noise abatement features on a wet-dry tower are generally a necessity, particularly if the tower is to be located near an urban environment, as would be the case at Hudson. The capital costs of noise abatement attenuation on cooling towers are usually very significant. The resulting operating costs can also be much greater. This aspect of the application of a wet-dry cooling tower design is neglected in total and thus these costs are not reflected in the Parsons report.

Energy Penalty Issues

PSEG identified several assumptions in the Parsons report that would tend to underestimate the energy penalty associated with the installation of wet-dry cooling towers at the Hudson site.

-The study is based on a circulating cooling water flow that is 20,000 gallons per minute lower than the actual value. This means that the tower size and pumping power needed may have been underestimated by approximately 9 percent in the report.

-The study is based on a 2 percentile of maximum wet bulb incidence rather than the 1 normally used.

This means that the lower corresponding wet-bulb temperature (74°F) selected in the study instead of the higher 1 percentile wet bulb of 76°F. This change would mean a 2 degrees F increase in condenser temperature, with corresponding increases in turbine back pressure and associated energy penalty.

-The adverse impacts of using brackish water in a cooling tower, as regards lower evaporation potential, lower thermodynamic properties, and extra pumping power requirements due to greater density were not included in the Parsons report.

Salt Drift Issues

Compliance with State and Federal air quality regulations would likely not be possible for particulate emissions (PM) from mechanical draft cooling towers at Hudson Generation Station. Predicted PM emissions due to salt drift from the mechanical draft tower on Unit No. 2 exceed the maximum allowable rate of 30 pounds per hour and thus a variance from these regulations would be required. Due to the urban setting of the site, PSEG believes that obtaining this variance would be difficult or impossible.

Cooling Tower Blowdown Issues

Water quality regulations are strict in New Jersey and require treating the cooling tower blowdown water. Both the temperature and pollutant levels of any returning water must achieve regulatory permit compliance.

PSEG's detailed site-specific study, made in 1997 (see below), estimates that treating the cooling tower blowdown water at Hudson to meet these regulatory requirements would require a $5,508,000 treatment facility. This treatment facility was not included in the Parsons estimate.

Outage Issues

The Parsons report assumes that retrofit work would fit into the normal spring or fall outage timeframe. However, a more likely scenario is that an extended scheduled outage would be required for the final tie-ins, intake modifications, existing CW piping modifications, services, start-up and testing. This outage construction period was estimated by the PSEG engineering study to be from 2 to 3 months for Hudson Station.

Permitting Issues

PSEG has recently obtained licenses and permits for the installation of a new, combined cycle unit with recirculating cooling towers at its Linden Generating Station. Based on this experience, PSEG estimates that it would take at least one year to acquire the four Federal, eight State, one county, and four municipal permits required for the retrofit of Hudson station with closed cycle cooling. This significant permitting effort was not included in the Parsons estimate for the proposed conversion.

Differences in Construction Cost Estimates

In 1997 PSEG obtained turnkey budget pricing from three respected cooling tower manufacturers based on a specification derived from a detailed site-specific engineering study defining the requirements for the potential conversion of Hudson Station to closed-cycle cooling.

-Based on the lowest of those vendor quotes, that turnkey tower cost of $48,580,000 (in 1997 dollars) was approximately twice the corresponding $24,800,000 (in 2002

-The total estimated project cost for the conversion of Hudson units 1 and 2 to wet-dry towers was $168,250,250 (in 1997 dollars), and was more than double the corresponding $73,524,000 (in 2002 dollars) total project cost estimated by Parsons.

-The significant difference in costs between the vendor quotes and PSEG's estimated project cost and the costs estimated by Parsons further highlights the need for site-specific information in determining the economic feasibility of retrofitting once-through power plants with closed-loop systems.

Surry Power Station

Plume Abatement Issues

The Parsons report did not include plume abatement technology in the cost estimate for the closed-loop wet cooling tower retrofit at the Surry Power Station site. However, based on the relatively close proximity of Colonial Williamsburg (8 miles) and Busch Gardens (7.5 miles) to the Surry Power Station, plume abatement technology could be required. Although the need for plume abatement technology at the Surry Power Station site would not be determined until the actual permitting process was completed, the inclusion of such technology would double the cooling towers' capital costs and significantly increase their annual operating and maintenance costs.

Emergency Services Issues

Dominion expressed concern with respect to maintaining the integrity of operation of the Surry Power Station's Emergency Service Water pumps under the proposed wet cooling tower retrofit design. Preserving the integrity and operation of the Surry Power Station's Emergency Service Water pumps is a significant safety issue. Dominion's concern is valid and serves to underscore how the understanding of truly site-specific issues is critically important to the retrofit design process.

Lost Revenue Issues

The Parsons report assumed that lost power could be replaced at an average annual electricity cost of $0.03/kWh. The greatest loss in energy output from plants with cooling towers would be on the hottest, most humid days of the year when market prices are far greater than $0.03/kWh. The value of lost revenue could be calculated more accurately by looking at historical records of each plant and the specific price of power in each region, a level of detail that was neither feasible, nor in the scope of the Parsons study. Nevertheless, this lost revenue could be significant in some cases and also serves to underscore the site-specific nature of retrofitting with cooling towers.

Dominion Virginia Power presents data in support of their position that the Parsons study may underestimate the energy penalty that is attributable to the warmer cooling water temperatures associated with the installation of cooling towers at the Surry Power Station site. The issue of lost revenue, from the preceding paragraph, becomes more significant as the actual energy penalty becomes larger.

Barney M. Davis

Salt Drift

There are several research facilities that lease space on the Barney M. Davis property. These facilities are located between 500 to 1000 feet downwind from the site of the proposed cooling towers. Based on this information and considering the corrosivity of the drift, some type of drift abatement might be required. Salt drift control is a site-specific issue and if it should be required at the Barney M. Davis site, it would increase the proposed cooling towers' capital and annual operating and maintenance costs over that which was reported in the Parsons study and cause other AEI.

Capital Cost Issues

AEP Inc. secured a cooling tower budget estimate, using actual Barney M. Davis plant operating conditions, from the Marley Cooling Technologies Company. AEP's cooling tower material and labor costs, using a wet-bulb temperature of 77°F, an 8 °F approach temperature, an 180,000 gallon per minute flow rate, and a 20°F condenser range, was between $5.2 and $5.5 million per tower. The Parsons material and labor estimate using the same wet-bulb and approach temperatures, but with a 215,000 gallon per minute flow rate and a 15 °F condenser range, was $4.8 million. In this manner, the Parsons report may have underestimated the material and labor costs for a wet cooling tower retrofit at the Barney M. Davis plant by between 8 and 15 percent. Cooling water flow rate and the coolant temperature range through the condenser are two site-specific operating parameters that directly affect the proposed cooling towers' costs and the potential energy penalties associated with their retrofit to once-through cooled facilities.

The city of Corpus Christi, Texas commissioned a desalinization plant feasibility study, sited at the Barney M. Davis plant, which concluded that the total dissolved solids (TDS) in the desalinization plant's brine discharge would necessitate the construction of a 10 mile long pipeline across the sea grass beds of the Laguna Madre, across Padre Island, and extend out 30 feet of water into the Gulf of Mexico. Regardless of the eventual outcome of the desalinization plant, the TDS in the blowdown of the proposed cooling towers would require that it be disposed in an identical manner. Engineers at AEP Inc. were able to use the desalinization plant feasibility study to extrapolate a capital cost of presented in the Parsons report. There would also be increased costs to perform an environmental assessment and mitigation of the sea grass beds.

To place this letter in context, I should first note that on July 19, 2002, I submitted comments on the proposed regulations. <FN 2> My comments focused on the economic analysis that EPA prepared to support the above proposed rule under Section 316(b)of the Clean Water Act, which directs EPA to identify “cooling water intake structures” (“CWIS”) that “reflect the best technology available for minimizing adverse environmental impact,” including impingement and entrainment ("I&E”) of aquatic organisms at plants’ water intake structures.

In those comments, I stated that I found EPA’s economic analysis offered in support of the rule to be severely flawed, biased, and misleading. I noted that some of the methodologies employed were neither recommended nor endorsed by EPA’s own Guidelines for Preparing Economic Analyses or by the U.S. Office of Management and Budget’s guidelines under Executive Order 12866. <FN 3>

My comments were especially critical of the methods used by EPA to estimate the economic benefits of the proposed regulations. In particular, I found that a number of the methods used by EPA to estimate benefits, including its Habitat Replacement Cost (“HRC”) and Societal Revealed Preference (“SRP”) methods, were inconsistent with the most basic principles of economics. Consequently, the benefit estimates derived from them could neither be considered reliable nor defensible. In addition to critiquing those methods, I noted specific alternative approaches that EPA could employ to provide valid estimates of the benefits it seeks to measure.

On August 1, 2002, Dr. Ackerman submitted comments on the proposed regulations on behalf of Riverkeeper. <FN 4> To a significant degree, the Ackerman comments attempt to rebut my July 19th comments.

The arguments presented in the Ackerman comments do not withstand scrutiny. <FN 5> My previous comments focused on issues related to the objective implementation of benefit-cost analysis, based on established economic theory and empirical research. Unfortunately, the Ackerman comments intermix and thereby confuse those issues with personal value judgments about the benefits of environmental resources and the usefulness of benefit-cost analysis in environmental decision making. In Section I of these comments, I discuss this problem. In Section II, I assess the Ackerman comments’ contention that EPA has underestimated total benefits due to omissions of various types of benefits. I find these claims unconvincing and lacking in any rigorous proof. Moreover, the Ackerman comments fail to take note of the numerous other flaws in EPA’s existing estimates that others and I have identified in previous comments. Considering the fact that these flaws introduce significant upward bias to EPA’s estimates, the argument in the Ackerman comments that EPA underestimates actual benefits is even less convincing.

In Section III, I examine the specific adjustments that the Ackerman comments propose to make to EPA’s benefit estimates. These adjustments are best characterized as essentially arbitrary. The adjustment that the Ackerman comments would make to EPA’s non-use value estimates based on the unfounded claim that significant non-use values must be associated with the proposed regulations because previous research has found non-use values for other, unrelated environmental improvements, including improvements in air quality and visibility at the Grand Canyon and prevention of regional extinction of the bald eagle. The Ackerman comments provide no evidence of why, given the specific environmental improvements associated with the proposed regulations, non-use value should be of any specific magnitude. A second adjustment that the Ackerman comments propose relates to the value of increases in the population of recreationally and commercially valuable fish that are not caught. This proposed adjustment may introduce double-counting, and it highlights an important flaw in EPA's analysis that may have caused its estimates to overstate, rather than understate, benefits.

In Section IV examine the case that the Ackerman comments make for the HRC and SRP methods. Here and elsewhere, the Ackerman comments mischaracterize the state of modern economics. The Ackerman comments incorrectly suggest that there is no consensus among economists on the basic economic principles that make the HRC and SRP methods fundamentally flawed.

The Ackerman comments fail to address my fundamental critique of the HRC method: benefits and costs bear no systematic relationship to each other; and the cost of a good or service cannot be used as a proxy for its respective benefits except in those situations where individuals (or groups) have been observed to voluntarily purchase the good or service. Hence, the cost of habitat replacement provides no information about the benefit of that replacement or of any other means to achieve the same outcome, such as the technological requirements considered in the proposed regulations. The HRC method is based upon a simple yet profound confusion of benefits with costs.

In defense of the similarly flawed SRP method, the Ackerman comments confound objective questions about the implementation of benefit-cost analysis with normative questions about its use in decision-making; and the Ackerman comments inaccurately characterize the state of knowledge regarding the economics of public goods and environmental protection. Overall, the Ackerman comments fail to offer any rigorous or meaningful response to the critique I offered in my previous comments of the SRP method, namely that this approach, like the HRC method, is premised upon a confusion of benefits with costs.

The Ackerman comments conclude with what is described as an assessment of the merits of the "All Cooling Tower" option that EPA has considered in its proposed regulations. As I explain in Section V, below, the Ackerman comments present a one-sided description of the tradeoff between benefits and costs, including a dramatically incomplete accounting of costs, as estimated by EPA. The attempted assessment is therefore misleading.

The Ackerman comments suggest throughout that I am hostile to methodological innovations in environmental economics, particularly with regard to methods of estimating the economic benefits of environmental policies. To the contrary, I believe it is clear from my criticisms of EPA's analysis that my motive (which, in any event, is irrelevant) is to improve the rigor of EPA's economic analysis in order to ensure that it can withstand close scrutiny. For close to two decades, through my research, teaching, and outreach activities, I have worked relentlessly to develop innovative environmental policies, and new and improved methods of estimating the benefits and the costs of such public policies. The driving force behind my previous comments on EPA's economic analysis was the same concern that led me to devote considerable time to serving as a Member and Chairman of the Environmental Economics Advisory Committee of EPA's Science Advisory Board. By providing comments, I hope to help EPA employ an improved economic analysis in its rulemaking that will provide an accurate, objective, and hence ultimately useful assessment of the proposed regulations' benefits and costs.

Benefit Estimation Methodology

Confusion of Positive and Normative Economic Issues

Clearly, the Ackerman comments reflect strong philosophical views regarding the use of benefit-cost analysis in environmental policymaking. Philosophically or ethically based opposition to the use of benefit-cost analysis surely ought not to disqualify someone from commenting on a proposed rule. In this case, however, the Ackerman Comments intermix and thereby confuse questions regarding the appropriate role of benefit-cost analysis in policymaking with questions regarding the correct implementation of such analytical methods.<FN 6>For example, in an effort to provide support for arguments on behalf of EPA's SRP method, the Ackerman comments invoke Kenneth Arrow's impossibility theorem. <FN 7>While Professor Arrow's significant contribution to economic thought has enriched debate about how benefit-cost analysis can or ought to be used in public policymaking, it does not inform questions about the correct measurement of benefits and costs. For that matter, Professor Arrow has written elsewhere of the significant value that properly executed benefit-cost analysis can bring to public decision making.<FN 8>

In contributing to public policy debates, the economics profession has long since established clear distinctions between "positive" and "nonnative" economics. 'While the former deals with questions for which objective and rigorously proven answers can be provided, the latter deals with questions that inevitably involve opinions informed by individual values. The proper implementation of benefit-cost analysis falls squarely within the arena of positive economics. Rigorously established methods that are firmly rooted in widely-accepted economic theory can provide objective information on whether a regulation is economically efficient, that is, whether the amount that all those benefiting from a regulation would be willing to pay for those benefits exceeds the total amount that would need to be paid to individuals burdened by the regulation to ensure that no one is made worse off. In contrast, questions about the appropriate use of the efficiency criterion and the role of benefit-cost analysis in policymaking are distinctly in the realm of normative economics.

The Ackerman comments confuse these two distinct questions, letting philosophical views about the use of benefit-cost analysis in decision making lead to statements on objective issues of benefit valuation that contradict the basic principles of economics. In contrast, in the comments I offered, I focused on objectively assessing the valuation methods used by EPA, using as a guide the foundations of economic thought that have been developed over centuries and which enjoy broad acceptance.

Footnotes

6 EPA invited comments on normative as well as positive issues in its proposed 31G(b) rule, and in my previous comments, I addressed both dimensions. In section 1of my July 19,2002 comments, I examined alternative decision criteria being considered by EPA; in sections 2, I examined the concept and measure of economic practicability; in sections 3 and 4, I commented on EPA's methodology of benefit analysis and its application; and in section 5, I commented on EPA's proposed trading program. The critical issue is that normative and positive dimensions should not be intermixed and confused.

7 See: Arrow, K. J. Social choice and individual values. New York Wiley, 1951.

8 In the one article of which I am aware in which Professor Arrow has directly considered practical questions regarding the

potential use of benefit-cost analysis in environmental policymaking, he -along with me and his other co-authors -had this to say: “Benefit-cost analysis can play an important role in legislative and regulatory policy debates onprotecting and improving health, safety, and the natural environment.” He and his co-authors concluded, “If properly done, benefit-cost analysis can be of great help to agencies participating in the development of environmental, health, and safety regulations, and it can likewise be useful in evaluating agency decision-making and in shaping statutes.” Arrow, K. J., M. L. Cropper, G. C. Eads, R. W. Hahn, L. B. Lave, R. G. Noll, P. R. Portney, M. Russell, R. Schmalensee, V. K. Smith, and R. N. Stavins. “Is There a Role for Benefit-Cost Analysis in Environmental, Health, and Safety Regulation?” Science, April 12, 1996,Volume 272, pp. 221-222.

EPA Response

The comments presented here regarding normative vs. positive economics are philosophical in nature. While the issues raised are certainly valid, they are more properly argued in the political arena, at the level where the procedures for regulatory analysis are determined. However, EPA points out that benefit-related considerations are not the only issues EPA must consider in making regulatory decisions, and that other factors should also be weighed. No methods are available for estimating either costs or benefits with perfect accuracy or without uncertainty. Therefore, informed decisions must be made with the best available information and analysis. EPA’s approach to benefit cost analysis of the final Section 316(b) Phase II rule is consistent with principles outlined in the EPA’s Guidelines for Preparing Economic Analyses, United States EPA (EPA 240-R-00-003).

Benefit Estimation Methodology

The Implications of Additional Benefit Categories

The first section of the Ackerman comments focuses on the “incomplete” nature of EPA’s benefit estimates as evidence that EPA has substantially underestimated the benefits of the proposed regulations. The Ackerman comments devote so much attention to enumerating the types of benefits that are supposedly omitted that they fail to establish the second argument that is essential for their criticism: that, in the context of the benefits and costs that are measured, the magnitude of the supposedly omitted benefits is sufficiently large to affect conclusions comparing benefits and costs.

The analogy offered by the Ackerman comments of recent corporate governance issues illustrates the shortcoming of the comments’ focus on the number (rather than the magnitude) of omitted benefits. Investors were not harmed by revelations about the financial condition of firms simply because those firms’ balance sheets had omitted particular items. Rather, investors were harmed because those items, if included, would have significantly altered perceptions of the firms’ financial condition. Yet, in arguing that EPA has substantially underestimated benefits of the proposed regulations, the Ackerman comments rely on the number of omitted benefit categories, rather than their magnitude.

It should be noted that any omitted benefits must overcome two hurdles in terms of magnitude for their inclusion to increase EPA’s existing benefit estimate. Not only must the omitted benefits be large enough to lead to non-trivial changes in annual benefits (which EPA’s estimates suggest are on the order of hundreds of millions of dollars). More importantly, as others and I have pointed out in previous comments, many of those benefits that are already quantified in EPA’s analysis are themselves substantially overstated, due to numerous significant flaws in EPA’s estimation methods.<FN 9> These flaws extend well beyond the use of the HRC and SRP methods, which the Ackerman comments support and I address in Section IV, below.<FN 10> Therefore, to bring about a valid increase in estimated benefits, the omitted benefits must be of sufficient magnitude to more than offset the substantial reduction in benefits that would result from correcting the flaws in EPA’s previous analysis.

In a few areas, such as those I consider below in Section III, the Ackerman comments do offer quantitative estimates. For example, drawing from an EPA analysis of a different proposed rulemaking, the Ackerman comments suggest that EPA’s omission of particular types of recreational benefits may have caused recreational benefits to be understated by a factor of four or more.<FN 11> To justify this assertion, the comments point out that the analysis for the other rulemaking, which established effluent guidelines for metal product and machinery facilities (“the MP&M rule”), estimated benefits from types of recreational activities omitted from EPA’s economic analysis of the proposed regulations: non-fishing-related recreational boating, near-water activities, and wildlife viewing. But the Ackerman comments do not address whether the nature and magnitude of environmental improvements expected from the MP&M rule are sufficiently similar to those anticipated from the proposed regulations to lend credibility to the comments’ assessment of recreational benefits. In fact, they are not similar at all.

In the preamble to the notice of proposed rulemaking for the proposed regulations, EPA states that "the majority of environmental impacts associated with intake structures are caused by water withdrawals that ultimately result in aquatic organism losses."<FN 12> EPA goes on to state that these population losses may lead to general ecosystem effects (such as those cited by the Ackerman comments). In stark contrast, EPA expects the MP&M rule to reduce pollution loading in the nation's surface waters by millions of pounds. EPA found that "10,443 stream reaches exceed chronic or acute aquatic life ambient water quality criteria ("AWQC") and/or human health AWQC values at the baseline discharge levels. The proposed rule is expected to eliminate exceedences on 1,185 of these discharge reaches ... 1,837 reaches will experience partial water quality improvements from reduced occurrence of some pollutant concentrations in excess of AWQC "limits." <FN 13> Such environmental improvements go well beyond affecting only the population of aquatic organisms in the affected streams. EPA also expects that this rule will improve the health of fish, general water quality, and presumably the willingness of people to use affected streams. There may be good reasons why non-fishing recreational benefits were worthwhile to consider in the MP&M rule, but were sensibly omitted in the economic analysis of the proposed 316(b) regulations. At best, the calculations in the Ackerman comments represent a crude and inappropriate "benefit transfer."

Three general conclusions can be reached in regard to the contention in the Ackerman comments that the omitted benefits are significant in magnitude because of the number of benefit categories that have been omitted. First, it is reasonable to assume that EPA would focus on analyzing those benefit categories that it anticipated would have the greatest impact on its total benefit estimates. Second, some of the "omitted benefits" cited in the Ackerman comments are trivial or non-existent. For example, the Ackerman comments suggest that benefits are underestimated because secondary economic impacts on property values have not been considered.<FN 14> While economic research has found that property values can be adversely affected by some undesirable environmental conditions, such as those resulting from proximity to landfills, there is no evidence that the value of property is appreciably affected by the population, or even species composition, of fish in water adjacent to it.<FN 15> Indeed, it is far more likely that property values may be negatively affected by conditions associated with some of the technologies that EPA has considered for reducing I&E impacts, such as noise and vapor plumes that are typically associated with cooling towers.

Third, some of the arguments in the Ackerman comments that benefits were undercounted actually highlight reasons why benefits may have been overstated. For example, the Ackerman comments cite EPA's caveat that "monitoring data often pertain to conditions existing many years ago, before the Clean Water Act had improved aquatic conditions; if the numbers and diversity fish were depressed by degraded water quality, estimates of I&E losses would be similarly low."<FN 16> But, the opposite would be true in places where fish populations have decreased during the intervening years, due to overfishing. In such places, the use of historic data will overestimate the population of fish potentially susceptible to I&E, because fishing has depleted the stock of affected fish in the intervening years.

Footnotes

9 Along with my previous comments, those by Triangle Economic Research, National Economic Research Associates, and Professor Ivar Strand all addressed these flaws.

10 To name just a few, the flaws include: failure to take into account the timing with which benefits will be realized; the assumption that the fishing industry will enjoy economic profits well above those enjoyed by other competitive industries; and the assumption that unrealistically high economic profits will also be enjoyed by industries down the production chain

from the fishing industry.

11 Ackerman (2002), p. 6.

12 67 Fed. Reg. 17,136 (April 9,2002).

13 66 Fed. Reg. 504 (January 3,2001).

14 Ackerman (2002), p. 4.

15 Furthermore, it would be gross double-counting to estimate economic damages to commercial and recreational fish populations and then add property-value impacts. Onlyif there are other impacts not reflected in the impacts on the fish populations (such as rendering the water more swimmable) would capitalization of impacts into property-value changes reflect anything other than what was already estimated. Note that property-value capitalizes use values, not non-use values.

16 Ackerman(2002), p. 4.

EPA Response

The comment implies that EPA has omitted no significant benefits, and states that EPA's benefit analysis overstates benefits that are included. EPA disagrees. EPA believes that the proposed rule analysis does not include all possible benefits of CWIS, and that, therefore, the value of entrained and impinged fish to an ecosystem is likely to be underestimated. This is supported by the fact that, for the 316(b) Phase II regulation, the Agency was not able monetize benefits for 98.2% of the age 1 equivalent losses of all commercial, recreational, and forage species. (The percentages by region are as follows: California 95.2%, North Atlantic 99.0%, Mid Atlantic 98.4%, South Atlantic 98.1%, Gulf of Mexico 95.8%, Great Lakes 99.8%, and Inland 99.9%.) This means that the benefit analysis represents the benefits associated with less than 2% of the total age 1 equivalents lost due to impingement and entrainment by cooling water intake structures (CWISs).

As stated in the NODA, EPA attempted to include non-use benefits categories for the final Section 316(b) Phase II rule analysis. However, given the unavoidable uncertainties in estimating non-use benefits at the national level, the Agency presented a qualitative assessment of the non-use benefits of the environmental protections at issue in the final 316(b) benefit cost analysis. The Agency has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment

#316bEFR.306.106.

This comment states, in response to a comment submitted by Dr. Ackerman, that Dr. Ackerman failed to consider the magnitude of possible omitted benefits, and therefore Dr. Ackerman's comments are unfounded. These comments based on responding to another comment are not based on EPA's actual analysis. EPA has not applied analysis from the MP&M rule to the 316b benefits analysis, so comments regarding this topic are not relevant.

EPA interpreted Dr. Ackerman's comments to mean that the Agency should have estimated non-fishing related recreational boating and near water activities for the 316(b) regulation. EPA agrees that a complete assessment of benefits for the regulation would include these benefit categories, but data limitations prevented it.

The comment suggests that, in places where overfishing has occurred, benefits may be overstated, as smaller stocks of fish are available to be harmed by I&E. However, it is not clear whether reductions in stocks over time are a result of overfishing, or of cumulative I&E and thermal affects from facilities included in the 316b regulation. Without empirical evidence to support this comment, this point is not relevant.

Benefit Estimation Methodology

Proposed Adjustments to EPA's Benefit Estimates

Two adjustments to EPA's benefit estimates are presented in the Ackerman comments, and these are central to the argument that EPA has undercounted benefits. First, the Ackerman comments make an adjustment to EPA's estimate of non-use benefits. But, in so doing, they fail to consider those factors that affect the magnitude of non-use benefits, the most important of which is the nature and magnitude of the environmental improvement of concern. In my previous comments, I presented a number of criticisms of EPA's use of the "50% rule" in estimating non-use benefits. First, no economic basis exists for believing that the ratio of non-use to use benefits from previous research could be applied to the environmental improvement being considered by EPA without any consideration for how that improvement differed from those examined in the research on which EPA relied. This is a particularly significant flaw, given that the literature review on which the 50% rule is based did not include any studies that addressed non-use values associated with reducing I&E impacts. More generally, some of the water quality improvements examined in the literature review are of afar greater magnitude and a different nature than those expected from the proposed regulations.<FN 17>

Focusing only on the dated nature (approximately twenty years old) of the literature review used by EPA to justify the 50% rule, the Ackerman comments present adjustments to the ratio of non-use to use values. These adjustments, however, are no less flawed than EPA's original estimates, because they fail to take into account the nature and magnitude of the respective environmental improvements. The Ackerman comments suggest a new "200% rule"! This suggestion is based on a literature review performed by Thomas Brown ten years ago that considered 31 contingent valuation studies. The proposed "200% rule" comes from the median non-use to use value ratio found in Brown's literature review.

Economic research has clearly identified factors that bring about very different ratios of use to non-use values among environmental improvements, including: the magnitude and nature of the improvements; the uniqueness of the resources affected; the degree of public familiarity with the resources; and the extent to which there are opportunities for use of the resources.<FN 18>The Ackerman comments fail to note that the ratios of non-use to use values in the studies examined by Brown range from 0.1 to nearly 11.0, and include studies of the value of preventing deterioration in air quality at the Grand Canyon and preventing extinction of the bald eagle in New England, both of which are clearly inappropriate to consider in estimating the non-use value arising from the proposed regulations. <FN 19>Moreover, Brown himself recognizes that there is reason to believe that the ratio would vary across environmental improvements.<FN 20>

The implausibility of the Ackerman comments' estimates of non-use value is revealed by the arguments in the comments themselves. The comments' estimated benefits for EPA's option 5-which would entail reductions in I&E at all affected facilities commensurate with the use of dry cooling-imply that the non-use value associated with such an option would exceed $6.2 billion annually.<FN

21> Note, however, that the Ackerman comments also highlight one of the studies reviewed by Brown, which “found a nationwide non-user willingness to pay ... for improving water quality in all U.S. rivers and lakes to a fishable level -implying a nationwide total value of more than $11 billion in 1981 dollars, or closer to $ 20 billion in today’s dollars."< FN 22>Thus, the adjustments proposed by the Ackerman comments imply that the non-use value that society places on eliminating I&E impacts on aquatic populations located in the immediate vicinity of just 550 facilities is filly one-third of the non-use value society places on substantially reducing pollutants and thereby improving water quality in 3.7 million miles of rivers and streams and 40.6 million acres of lakes nationwide. <FN 23>

To support their own estimates and to call into question my earlier criticisms of EPA’s nonuse value estimates, the Ackerman comments conclude:

Dr. Stavins’ casual and undocumented suggestion that non-use values might be close to zero for this case appears to be quite at odds with the evidence of substantial nonuser willingness to pay for improved water quality. Other studies routinely find vast existence values for endangered species, for clean air in national parks, and other environmental resources and amenities. The surprising value, the figure that is out of line with the recent literature, is the very low estimate of non-use value found in (EPA’s analysis). <FN 24>

My suggestion in my previous comments that-in this specific context-non-use value could be very small (if measurable at all) was neither casual nor undocumented. In contrast with the estimate of non-use value in the Ackerman comments, which is based on non-use values from different and vastly more significant environmental improvements, my earlier conclusion was based on consideration of the specific environmental improvement anticipated from the proposed regulations. Significant non-use benefits may be derived from the existence of endangered species, and clean air in national treasures such as the Grand Canyon. But the proposed regulations are expected to bring about largely incremental changes in the populations of various aquatic species. No case has been made that the regulation will affect the very existence of unique resources with high public awareness levels. Hence, the Ackerman comments have no basis for asserting that EPA’s existing estimate of non-use value is significantly below (“out of line with”) the recent literature. In fact, as I have explained in detail in my original comments, it is biased upward, indeed dramatically upward.

The second adjustment that the Ackerman comments seek to make to EPA’s benefit estimate is linked with the value of the share of the increased fish population that is commercially or recreationally valuable, but not caught. For such an increment to represent a valid economic benefit, this portion of the fish population must yield either use or non-use benefits (or both) not already counted by EPA. Clearly, EPA has incorporated an estimate of non-use benefits from reduced I&E in its analysis. Even if Dr. Ackerman disagrees with that estimate, there is no basis for arguing that EPA’s estimate fails to include the non-use benefits of the entire increase in fish populations, including those that are not caught. Therefore, for the Ackerman comments to avoid double-counting in making this adjustment, the benefit of these commercially and recreationally valuable fish that are not caught must arise from use value. Indeed, the Ackerman comments support the adjustment on the basis of use value associated with these fish. Yet, in so doing, the comments highlight another aspect of EPA’s analysis that may have contributed to overestimated benefits.

The argument made by the Ackerman comments is that even if certain commercially and recreationally valuable fish are not caught, their offspring may be, and therefore use value should be assigned to those fish that are not caught to account for the use value of their offspring.<FN 25> This argument highlights a flaw in EPA's benefits assessment, but contrary to the contention in the Ackerman comments, we cannot assume that this flaw will cause the benefits of the rule to be underestimated. Rather than estimating changes in the total population of commercially and recreationally valuable fish (and hence fish catch) due to reduced I&E, EPA estimates the number of fish that have historically been impinged or entrained each year, and estimates the share of those fish that would have been caught if they were not subjected to impingement or entrainment. While the former approach would account for increased catch of the offspring of fish that would have been impinged or entrained in the absence of the proposed regulations, the latter approach does not. However, the Ackerman comments fail to note that the approach chosen by EPA also ignores the mitigation of the impact of existing I&E on fish populations and catch levels resulting from compensatory effects.

Mitigation of population impacts by compensatory effects is perfectly consistent with commonly accepted density-dependent population models that EPA discusses but chooses not to employ in its analysis. While the failure to consider increases in catch attributable to offspring of those fish that avoid I&E would tend to bias downward EPA's estimate of the increased fish catch, EPA's decision not to account for compensatory effects would lead to an upward bias in that estimate. Taking into account these opposing effects, ecological expertise is required to come to the judgment made in the Ackerman comments that the net effect on benefit estimates would be negative. In summary, economic theory and empirical research do not support either of the adjustments proposed by the Ackerman comments.

Footnotes

I7 For example, one of the studies examined in the literature review estimated the non-use value associated with reductions in pollution that would bring surface waters nationwide from being so polluted as to be unusable for any recreation, to being boatable and even swimmable.

18 See: Freeman, A. Myrick. The Measurement of Environmental and Resource Values: Theory and Methods. Second Edition. Washington, D.C.: Resources for the Future, 2003.

19 The prevention of air quality deterioration in the Grand Canyon and of the extinction of the bald eagle in New England differ significantly from reductions in I&E in several respects that would make their ratio of non-use value to use value inapplicable to that for reductions in I&E. These include the uniqueness and familiarity of the affected resource as well as the nature and extent of the environmental improvements in question. For example, one would expect the non-use value of preventing a species' extinction to be vastly greaterthan that for preventing marginal changes in its population.

20 It is also worth noting that the Ackerman comments apply the 200% rule to EPA's estimates of commercial, recreational, and forage fish use benefits, despite the fact that the literature review on which this adjustment is based solely considers the ratio between recreational use and non-use benefits. In addition, as it is unlikely that researchers would examine non-use values for environmental improvements that are not expected to have significant values, the lower bound of 0.1 in the range of ratios likely overstates the actual lower bound across all environmental improvements.

21 This non-use value in excess of $6.2 billion can be derived from a comparison of the Ackerman comments' estimated benefits for option 5 under scenario B and C presented in Table 1 of Ackerman (2002). In scenario B, the Ackerman comments adjust EPA's existing estimate to create a value for the increase in fish populations that are not caught by fishermen. In scenario C, the Ackerman comments add the adjustment for non-use value to the existing adjustment for those fish that are not caught. The differencein the two estimates, $6.2 billion, is therefore solely attributable to non-use value.

EPA Response

This comment largely is a reply to a comment by another individual, made regarding EPA's proposed rule. Therefore, many of the points made are no longer relevant or are not relevant to EPA's analysis.

As stated in the NODA, the rule-of-thumb approach to estimating non-use is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. Given the unavoidable uncertainties in estimating non-use benefits, the Agency presented a qualitative assessment of the benefits of the environmental protections at issue in the final 316(b) benefit cost analysis. The Agency has provided several measures that indicate the potential magnitude of non-use values for this rule, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services.

With respect to complaints concerning EPA's use of mean ratios from the studies referenced in the Akerman comments, EPA has the following responses. Calculating an arithmetic mean is a simple, accepted method of considering a number of different results in combination. Using an arithmetic mean of non-use to use value ratios from the 8 studies that were consulted can be viewed as a simple version of a "meta-analysis" of surface water improvement valuation studies. Use of an arithmetic mean in this context can be reasonable.

That being said, EPA agrees with the commenter that the calculation of mean ratios does not account for differences in resource characteristics and the magnitude of environmental improvements between the study areas and the sites considered in the original studies. In other words, an arithmetic mean is not capable of teasing out the possible effect of various specific factors in the studies (e.g., geographic scale of environmental improvements) that might influence non-use values. While this does not render the approach "completely inappropriate" or unreasonable, it is a shortcoming. EPA believes, however, that this shortcoming can be overcome by a meta-analysis approach. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis.
For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

The comment implies that non-use values are unlikely to exist except for unique resources whose existence is threatened. The comment provides no evidence that the fish affected by I&E are both easily replaceable and non-unique. For EPA's response to comments regarding evidence of non-use values for temporary losses to common species please see the response to comment #316bEFR.306.302.

Use of Replacement Costs (HRC and hatchery-based)

EPA's Flawed Benefit Estimation Methods

One of the most troubling aspects of EPA's economic analysis, which I addressed in detail in my July 2002 comments, is its use of two fundamentally flawed methods to estimate benefits, the Habitat Replacement Cost method and the Societal Revealed Preference method. The Ackerman comments seek to promote these methods and attempt to rebut my criticism of them. In so doing, however, the comments: mischaracterize my criticism; incorrectly suggest that there is disagreement among economists regarding the basic economic principles that are relevant for judging the validity of these methods; offer a flawed and misleading description of economic principles; and employ inconsistent logic. In the end, the Ackerman comments offer no insights or valid arguments that in any way diminish my original conclusion that these two methods are fundamentally flawed and provide highly biased "benefit estimates.''

The Ackerman comments suggest that my concern regarding EPA's methods of analysis is predominantly that they are not recommended in EPA's Guidelines for Preparing Economic Analyses. This is incorrect. My fundamental point is that the HRC and SRP methods are completely inconsistent with economic theory and empirical practice; both are measures of costs, not of benefits. It is because of this reality that neither is endorsed by EPA's Guidelines. By focusing on the Guidelines, the Ackerman comments ignore my most important criticism of EPA's HRC and SRP methods: they have no foundation whatsoever in economic theory or practice, as they confuse the most basic economic concepts of benefits and costs.<FN 26>

Furthermore, contrary to what is suggested in the Ackerman comments, the fact that EPA's Guidelines are to be updated periodically to reflect any important methodological developments (as I recommended in my letter of transmittal to the EPA Administrator, which the Ackerman comments cite) does not somehow validate the two invalid methods, which are inconsistent with centuries-old economic principles that are found in introductory economic textbooks. While these two methods are certainly not innovative, they also are not new. Both the methods themselves and the flaws that make them invalid for measuring benefits have been considered before.

One of the most misleading parts of the Ackerman comments seeks to establish support for the HRC and SRP methods by misrepresenting what is, in reality, tremendous consensus among economists regarding fundamental theories of economics. Describing the HRC and SRP methods as unorthodox but "innovative," the Ackerman comments attempt to place them in the company of "alternative perspectives that question the textbook wisdom." <FN 27> Incredibly, the Ackerman comments suggest that the economics profession as a whole is exhibiting increased interest in unconventional theories, and by implication HRC and SRP, because recent Nobel laureates-including Joseph Stiglitz, George Akerlof, and Michael Spence-are "famous for their unorthodox views.''<FN 28> This line of reasoning is illogical and fallacious. The ideas and work that won these three individuals the Nobel Prize are broadly accepted in the economics profession. Rather than questioning the textbook wisdom, their ideas are found in virtually all of even the most elementary economics textbooks. Moreover, while many unresolved questions are still actively debated in economics, no economist would question the fundamental difference between benefits and costs, which makes both HRC and SRP completely invalid as benefit estimation methods.

Footnotes

26 I address the flaws associated with these methods in more depth below.

27 Ackerman (2002), p. 11.

28 Ackerman (2002), p. 11.

EPA Response

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule. Please see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method. Please also see EPA’s response to comment #316bEFR.005.035.

EPA does not use the Societal Revealed Preference (SRP) method in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA’s response to comments on the SRP, please see the response to comment #316bEFR.005.006

Please also see Dr. Ackerman's comments: #316bEFR.014.001 through #316bEFR.014.012.

Use of Replacement Costs (HRC and hatchery-based)

Habitat Replacement Cost Method

EPA's HRC method, which the Agency claims in its economic analysis is an alternative method for valuing benefits, is actually nothing of the kind. The Habitat Replacement Cost method is-pure and simple-a measure of costs, not benefits. The habitat replacement costs are the design, implementation, administration, maintenance, and monitoring costs of various identified means of restoring aquatic habitats in the hopes of producing the same in situ services and service flows that are associated with the various technological alternatives under consideration. In other words, these are the costs of another alternative-and one that can be very costly-for achieving the same functions as targeted by the proposed regulation. While mitigation, restocking, and/or habitat restoration may be acceptable approaches as alternatives to the installation of specific technologies in order to offset I&E losses, the cost of such alternatives is in no sense whatsoever a reasonable proxy for the value (that is, the benefit) of reducing I&E.

The specific arguments offered by the Ackerman comments in support of EPA's HRC method actually make clear why the method cannot be used to develop reasonable estimates of real benefits. For example, the Ackerman comments state that "restoration cost is used as a measure of damages under CERCLA for Superfund sites, under the National Marine Sanctuaries Act, and under the oil spill provisions of the Clean Water Act." <FN 29> or not restoration cost measures have been employed in retrospective (ex post) natural resource damage assessments is irrelevant for prospective (ex ante) assessments of the benefits and costs of the proposed regulatory changes under the Clean Water Act. Even if restoration costs have been employed in other policy contexts to guide decisions about compensation for environmental damages, this certainly does not indicate that restoration costs are a valid measure of the benefits from avoiding environmental damages or, for that matter, the benefits of the associated restorative action. <FN 30>

To further justify their endorsement of the HRC method, the Ackerman comments contend that it is common practice in economics to value assets at their replacement cost. The very contention made in the Ackerman comments confirms my previous critique of HRC by making clear the specific and limited circumstances in which replacement costs can serve as a valid measure of value: "market value is current replacement cost, for a marketed asset" (emphasis added).<FN 31> It is well known that the replacement cost of an asset can be assumed to be less than or equal to its market value (its benefit) only if that replacement is undertaken voluntarily.<FN 32> This clearly does not apply to habitat restoration activities considered by EPA in its HRC method. As EPA has not indicated that there is evidence of such restoration being undertaken voluntarily by individuals, there is no basis whatsoever for simply asserting that its benefits, and thus the benefits of reducing I&E to achieve the same outcome, are greater than its costs.

The Ackerman comments' characterization of environmental resources as natural capital or natural assets does not change the reality that their real benefits are determined by the value that society places on their contribution to the various ecosystem or other services they provide (whether in terms of use or non-use value), not by their replacement cost. Indeed, this conclusion is reached in the very book that the Ackerman comments themselves cite.<FN 33> There is no basis for asserting that replacement costs are necessarily less than benefits; hence there is surely no basis for using replacement costs as a proxy for real benefits.

As I made clear in my previous comments, the fundamental distinction of whether or not a good or service is marketed differentiates the invalid HRC method from legitimate applications of “defensive expenditure” and “averting behavior” methods to estimate benefits. Those methods are based upon observed actions, that is, individual behavior. In particular, a necessary condition for using defensive expenditures or averting behavior for purposes of benefit estimation is that the researcher observes people revealing their preferences by actually (and voluntarily) incurring costs to avert (or tolerate) the environmental disruption in question.<FN 34> By observing individuals take actions that involve incurring particular costs, one can infer that the individual is taking that action because its benefits to that individual outweigh its costs. Yet, one can only infer this if the individual is voluntarily taking an action, that is, making a choice that is based on his or her own preferences rather than being compelled by an external mandate. This is obviously not the case with the hypothetical habitat replacement activities that EPA uses to develop its cost estimates. Indeed, EPA makes no claims that such activities have actually and voluntarily been carried out by individuals.

It is important to recognize that the HRC method is not merely a flawed approach to estimating benefits; it is not a benefit-estimation method at all. Such “avoided-cost methods benefit estimation” have long been recognized as invalid.<FN 35> Applying these methods will mean that any proposed project (whether the project is good or bad for the environment) can be made to appear desirable. By taking the next most costly approach of achieving an objective and calling that the project’s benefits, one will always find that “benefits”-so measured-exceed costs. This completely faulty reasoning will come back to haunt EPA when others use it to push for actions that are unreasonably expensive or even environmentally harmful.

Footnotes

29 Ackerman (2002), p. 13.

30 While sometimes using restoration costs to assess natural resource damages under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), the Natural Resource Damage Assessment Models employed for this purpose explicitly differentiate the cost of restoration from the actual benefits associated with that restoration. In determining whether to include active restoration of an impaired natural resource -and the associated cost -in the damage calculation, as opposed to assuming natural restoration, a submodel of the Natural Resource Damage Assessment Models “analyzes the costs and benefits of any possible habitat restoration and restocking actions to determine whether these forms of active restoration or natural recovery shouldbe assumed for purposes of the models’ damage calculations. ... If the costs exceed ten times the measured benefits, then the submodel assumes, for purposes of generating a damage figure, that natural recovery, rather than active restoration, will be used to reestablish baseline conditions.” Natural Resource Damage Assessments -Type A Procedures. 61 Fed. Reg. 20,559-20,614 (May 7,1996) at 20,56520,566.

32 See: Freeman (2003).

33 The text to which the Ackerman comments refer states, “Treating natural and environmental resources as assets will be an important element in revisions to the methods for resource evaluation. At a conceptual level this strategy implies that the evaluation of proposed i.e.,public investments) ...allocation decisions that involve services of an environmental resource should be based on their effects on the value of that resource as an asset in relation to their costs.” In other words, habitat restoration (a public investment) should be evaluated by comparing its benefits (effects on the value of that resource as an asset) to the restoration costs. This text clearly does not suggest that restoration costs must be less than the resulting benefits,

or that they are in any way a valid measure of benefits. V. Kerry Smith, Estimating Economic Valuesfor Nature: Methods for Non-Market Valuation. Brookfield, US: Edward Elgar, 1996: p. 8.

35 Stavins (2002).

EPA Response

EPA agrees with Dr. Stavins' initial statement: "EPA’s HRC method, which the Agency claims in its economic analysis is an alternative method for valuing benefits, is actually nothing of the kind. The Habitat Replacement Cost method is-pure and simple-a measure of costs, not benefits. The habitat replacement costs are the design, implementation, administration, maintenance, and monitoring costs of various identified means of restoring aquatic habitats in the hopes of producing the same in situ services and service flows that are associated with the various technological alternatives under consideration. In other words, these are the costs of another alternative-and one that can be very costly-for achieving the same functions as targeted by the proposed regulation."

EPA also believes that it may be very costly to achieve the same functions as targeted by the regulation as reductions in I&E are likely to be less costly than actions taken to restore the losses after they have occurred.

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule. However, as noted in EPA’s response to comment #316bEFR.005.035, EPA does feel the method has value.

Please see EPA's response to comment #316bEFR.005.035. Please also see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method.

On a similar note, please refer to EPA's comments on the societal revealed preference (SRP) methods in the response to comment #316bEFR.005.006.

Revealed preference

Societal Revealed Preference Method

Related to but distinct from EPA's proposed Habitat Replacement Cost method is a proposed approach for valuing threatened and endangered species. EPA characterizes this approach as "societal revealed preference." The proposed method is not a revealed-preference method, has no foundation in economic theory, and is not accepted by economists as a legitimate empirical method of valuation. Like the HRC method, it is no more or less than a method of cost analysis mistakenly applied to the benefit-side of the ledger. The Ackerman comments applaud this approach, labeling it as innovative!

This "innovative alternative," like the HRC approach, is a totally invalid, non-economic approach for "benefit" estimation. It takes the historical cost to restore particular species under various government mandates (which were themselves adopted without any systematic benefit cost analysis) as an indication of valuation of these species, thus using program costs as a measure of benefits. This is, of course, a complete corruption of the notion of a revealed-preference method, an essential characteristic of which is that the benefit-the willingness to pay-is revealed by those individuals (or groups) who are doing the paying, not by the judgment of others (in this case, legislatures, executive departments and agencies, and/or courts). There is no sound logic behind taking the costs that are incurred in achieving various government programs and policies as being indicative of the true benefits of those programs and policies.

The very purpose of a benefit-cost analysis is to assess projects, programs, and policies by comparing their benefits and their costs. The SRP methodology completely reverses this, and takes the fact that a project, program, or policy exists as evidence that its benefits exceed its costs (and therefore that its benefits can be proxied by its costs, at a minimum). Use of this approach would imply that any project, program, or policy that is approved by a legislature, executive agency, or court has true benefits at least equal to its costs, and-presumably-that failure of the government to carry out any project, program, or policy indicates that its social benefits are less than its costs. This makes a complete sham of the very process in which the proposed 316(b) rule is being considered. It also would render meaningless requirements for benefit/cost analysis, such as those imposed under Executive Order 12866.

In their discussion of EPA's SRP method, the Ackerman comments: (1) confuse questions of positive and normative economics; (2) incorrectly characterize my critique of the SRP method; and (3) reveal a fundamental misconception of the economics of public goods and environmental improvements. The blurring of the difference between positive and normative questions regarding benefit-cost analysis, which I addressed in Section I, is most prevalent in this part of the Ackerman comments. <FN 36>

Moreover, the Ackerman comments misrepresent my critique of EPA's SRP method. They suggest that my critique is focused on nothing more than who makes a choice-an individual, a group, or society at large. The Ackerman comments thereby fail to address the fundamental point that I emphasized in my comments, which renders invalid EPA's attempted extension of revealed preference methods to prior government policies. The central argument in my critique is that in order for revealed preference methods to produce a valid measure of benefits, the individual or group deciding to take an action to achieve some benefits must have demonstrated willingness-to-pay with regard to that action. Only then can we reasonably assume that the (unobserved) benefits of that action are at least as great as the observed costs.

In any context in which the individuals (or groups) making a decision do not bear the full costs of that decision, one cannot assume that the benefits are greater than the costs associated with that decision (which include costs born by those who did not make the decision). This does not refer only to government decisions, but rather to any decisions where costs are not fully born by decision makers.<FN 37> By contesting this conclusion, the Ackerman comments are ignoring decades of research in economics and in political economy regarding the incentives facing -and decisions made by -regulators, and they are likewise ignoring a similarly extensive body of research on corporate governance.

It is because political choices, such as environmental policies, are made by decision-makers who do not bear the full burden of the cost associated with those choices that EPA's SRP method is an invalid attempt to extend the notion of revealed preference methods. Therefore, the Ackerman comments are completely incorrect when they suggest that "the revealed preference procedure employed by EPA would be entirely orthodox and familiar, even qualifying for endorsement by Dr. Stavins and the Guidelines for Preparing Economic Analyses, if it referred to individual rather than social choice." <FN 38> In order to be a valid revealed-preference measure of benefits, a measure must not only be based on individual (or group) choice, it must be based on individual or group choice where the individual or individuals clearly bear the cost associated with the choice.

Although Dr. Ackerman is surely aware of this distinction, the Ackerman comments fail to acknowledge its centrality to my critique of EPA's SRP method, and remarkably, the Ackerman comments claim that it is evidence that I have drifted "out of economic theory and into political debate."<FN 39> To the contrary, rather than making a judgment as to the "arbitrariness and unrepresentativeness of all government actions," as the Ackerman comments contend, my comments simply identify the limited contexts in which individual and collective choices can provide rigorous evidence of social (economic) valuation.

Thus, there is no basis in economics for the assertion in the Ackerman comments that the existence of an environmental policy implies that its benefits exceed its costs. The Ackerman comments use rhetorical questions, rather than economic principles, to support this claim:

Do people feel that the decisions about environmental protection, made on their behalf by their elected representatives, are hopelessly inefficient and expensive? Is there a groundswell of popular demand to save money by eliminating the Clean Air Act, the Clean Water Act, protection for endangered species, and all the rest?<FN 40>

The answers to both questions, of course, are irrelevant to the question of whether the cost of any specific environmental policy or regulation provides a reliable measure of its benefits. The fact that environmental policies in the aggregate may or may not be viewed as hopelessly inefficient and expensive provides no support for the contention that specific policies used by EPA in its SRP method have benefits greater than costs. Indeed, a significant amount of economic research has found strong evidence that specific policies impose costs that are greater than their benefits.<FN 41> Moreover, the question at hand has nothing to do with whether the Clean Air Act should be repealed, an utterly irrelevant straw man set forth in the Ackerman comments. Rather, the relevant question is whether EPA has any basis for asserting-with no supporting evidence-that particular past species preservation efforts yielded benefits greater than costs, simply because those policies exist.

The arguments that the Ackerman comments advance in support of EPA's SRP method also ignore existing economic knowledge regarding public goods.<FN 42> First, the comments state that "as textbooks often point out, there is no such thing as an individual demand curve for national defense."<FN 43> This statement is incontrovertibly incorrect, as can be seen by referring to any introductory economics textbook.<FN44> Indeed, society's willingness to pay for a public good has long been thought of as the sum of the value that each individual places on that good, and can thereby be represented as the vertical sum of each individual's demand for the public good.

The Ackerman comments also confound two distinct concepts, the difference between which is essential for understanding the economics of public goods: the amount that an individual would voluntarily contribute to the provision of a public good; and the value that the same individual places on the provision of that good. The confusion is made evident by the discussion in the Ackerman comments of the free-rider problem and my colleague Amartya Sen's commentary on individuals' willingness to pay for preventing environmental damages. Both the well-known free-rider problem and Sen's commentary deal with the fact that individuals' actual voluntary payments for public goods depart from the values they may place on those public goods, because of nonexcludability. That is, unlike the case of private goods, individuals who do not contribute to the provision of public goods cannot be kept from enjoying the benefits of those goods.

For example, while it is possible to keep an individual out of a concert if she or he does not pay for it, there is no way to prevent any one resident of a county from enjoying the benefits of national defense. As a result, individuals will tend to free-ride, or not contribute voluntarily to the financing of a public good even though they may value it, if they believe that it will be provided even without their contribution. Consequently, the amount that an individual will contribute for the provision of a public good does not provide a reliable indication of the value that the individual places on that good. For the same reason, as Amartya Sen points out, the amount that an individual would contribute to the provision of a public good would certainly depend on what others would contribute. This is not a commentary on peoples' valuation of public goods (indirectly estimated by valid willingness-to-pay or willingness-to-accept measures), but a commentary on actual voluntary payments for the use of public goods. The Ackerman comments have thoroughly confused this literature.

So, both the free-rider problem and Sen's comments provide insight into why public goods are often provided at levels below what is socially desirable. But quite contrary to the impression given by the Ackerman comments, implications for establishing valid measures of the benefits of public goods have been thoroughly considered and addressed by economists. For example, the freerider problem, and its implications for how individuals' preferences are reflected in their choices, is one of the reasons why stated-preference methods of benefit valuation offer the only valid means of measuring the benefits of some public goods. Moreover, the very issue raised by Amartya Sen is one of the many reasons why so much effort has been devoted to establishing appropriate techniques for conducting stated-preference surveys, so that they can yield reliable estimates of the value that individuals, and thus society, place on public goods.<FN 45>

Footnotes

36 In particular, the Ackerman comments confuse legitimate questions of how issues of social choice should influence the policy making process with questions of whether choices made by government can be used objectively, in the same manner as individual choices, to establish valid measures of benefits.

37 It is worth noting that the logic behind this conclusion is the same as that behind the idea of economic externalities, which justify many environmental policies: if an individual does not bear the full cost of her or his actions, she or he may engage in those actions even though the social benefit of them may not exceed their social cost.

38 Ackerman (2002), p. 15.

39 Ackerman (2002), p. 16.

40 Ackerman (2002), p. 16.

41 Numerous regulations enacted to reduce human health risk have been found to impose costs much greater than the estimated benefits of their associated risk-reductions. See, for example, Table 1 of Viscusi, W. K. "Regulating the Regulators." University of Chicago Law Review. 63, 1996: pp. 1423-1461. Reprinted in Stavins, R. (ed.) Economics of the Environment. New York W.W. Norton & Company, 2000: pp. 325-354. Contrary to the claim ofthe Ackerman comments (Ackerman (2002), p. 17), many of the inefficient regulations highlighted in Table 1 of Viscusi (2000) are finalized, implemented rules.

42 Economists consider a good (or service) to be a "public good" if it is impossible to exclude individuals from enjoying the benefits of the good once it is provided (nonexcludability), and the enjoyment of that good by one individual does not diminish the amount of the good available to others (indivisibility). Aside from numerous environmental resourcessuch as clean air, national defense is another example of such a good.

43 Ackerman (2002), p. 16.

44 These textbooks, which are widely used in college economics courses, explicitly state that individuals do have demand curves for public goods such as national defense, and the social demand curve for such a good is simply the vertical sum of each individual's demand curve for that good. That is, because of the nonexcludability of public goods, the social value of a particular amount of such a good can be thought of as the sum of each individuals' willingness to pay for that amount. See: Stiglitz, J. The Economics of the Public Sector. New York W.W. Norton & Company, 2000: Figure 6.7 and the associated text on pp. 142 -146; or Tietenberg, T. Environmental and Natural Resource Economics: Sixth Edition. Boston: Addison Wesley, 2003, Figure 4.6 and text on pp. 72-75.

45 Towards this end, in 1993, a panel of economists and other social scientists appointed by the National Oceanic and Atmospheric Administration, that included Nobel Laureates Kenneth Arrow and Robert Solow, issued guidelines on the appropriate implementation of contingent valuation studies to address concerns about the reliability of estimates derived from such studies. See Arrow, K., R. Solow, P. Portney, E. Learner, R. Radner, and H. Schuman. "Report of the NOM Panel on Contingent Valuation."In 58 Fed. Reg. 10 (January 15, 1993).

EPA Response

The SRP method is not used to estimate benefits for the final Section 316(b) Phase II rule. For EPA's response to comments on the SRP method, please see comment #316bEFR.005.006. Most of Dr. Stavins' comments are directed at another commenter, and thus require no further response from EPA.

Valuing Forage Species (incl non-use and non-landed)

Evaluating the Benefits and Costs of the "AI1 Cooling Tower" Option

Having failed to make a convincing case that EPA has underestimated actual benefits, the Ackerman comments conclude by posing a question about the merits of the "All Cooling Tower" option that EPA has considered for its proposed regulations. In this question, the Ackerman comments introduce an emotional and misleading characterization of the important decision problem faced by the US. Environmental Protection Agency: "If the public was asked, 'Are you willing to pay 28 cents more per month on your electric bill to avoid massive fish mortality and other underwater environmental damages caused by power plants?', I feel confident the answer would be 'Yes.,''<FN 46>

Portraying costs on the basis of cost per household per month has the effect, of course, of making EPA's estimate of billions of dollars in annual cost appear much smaller. More important, the Ackerman comments' qualitative and emotional description of benefits ("massive fish mortality and other underwater environmental damages caused by power plants") exaggerates reality in a completely unqualified and unquantified manner. Why did the comments not offer a more dispassionate and meaningful description of benefits that would be consistent with their description of costs? For example, they could have described the percentage increase in fish populations that could be expected from EPA's "All Cooling Tower" option. More important still, the Ackerman comments' question understates by an order of magnitude the actual cost of the stated option. Multiplying 28 cents by 12 months and approximately 110 million households, one arrives at an annual cost of $370 million, hardly 10 percent of EPA's annual social cost estimate of $3.5 billion, which are presented in Table 2 of the Ackerman comments.

In addition to increased electricity bills, households will face increases in the cost of consumer goods and services as commercial and industrial electricity users pass on higher production costs to their customers. Moreover, because the proposed regulation will reduce the profits of both electricity producers and firms that use electricity, federal and state governments will face reduced tax revenues, which will lead either to cuts in spending or to the need to increase tax rates. In its analysis, EPA estimated the lost tax-revenue associated with the "All Cooling Tower" option at approximately $1.2 billion annually.<FN 47> The Ackerman comments thus conclude by offering a highly biased and incomplete picture of the tradeoffs that must be considered in evaluating the proposed regulations.

Footnotes

46 Ackerman (2002), p. 18.

47 For all but one option, EPA estimated both the associated social cost and the post-tax compliance cost for electricity producers. Lost tax revenue, which is considered in the social cost estimate, explains nearly all of the difference between these two cost estimates. Hence, for its "All Cooling Towers" option, EPA's estimates for the annual social cost, $3.5 billion, and annual private post-tax compliance cost, $2.3 billion, imply $1.2 billion in lost tax revenue annually.

EPA Response

EPA appreciates the insights provided by the continuing discourse amongst commenters with differing points of view. The issue of whether it is more useful to portray impacts on a per household basis or on a national aggregate basis is complex, but both perspectives provide useful insights to the public, stakeholders, and decision-makers.

With respect to benefits, the suitable perspective is whether individuals (or households) have a willingness to pay that exceeds the costs that they would have to bear under the rule. Therefore, the use of per household costs as a benchmark in this instance thus seems wholly appropriate.

In the analysis for the final rule, EPA estimates the overall cost per household to be $1.21. For more detail please see Chapter B2 of the EBA (DCN #6-0002), section B2-2 on costs per household.

Please see EPA's response to comments on the break even analysis in the response to comment #316bEFR.306.106; and on the feasibility of performing original stated preference research in the response to comment #316bEFR.306.105.

Benefit Estimation Methodology

Conclusions

I conclude that the Ackerman comments on the economic analysis for the proposed regulations add no new insight into appropriate methods for estimating the economic benefits of those regulations. The Ackerman comments do not make substantive contributions to EPA's efforts to measure these benefits objectively. Of greater concern, the comments mix objective questions regarding techniques for measuring benefits with normative questions regarding the role of benefit-cost analysis in environmental policymaking, and incorrectly represent my previous criticisms, the state of consensus among economists on the most basic economic principles, and the nature and meaning of those principles themselves.

Contrary to their claims, the Ackerman comments have provided no compelling evidence whatsoever that "EPA's analysis of the benefits of reducing cooling water intake ... underestimates true, complete benefits by an unknown but large amount." <FN 48> The comments do not even offer evidence that the magnitude of omitted or undercounted benefits is sufficiently large to offset the severe upward bias in EPA's existing estimate, resulting from numerous flaws that other people and I have previously identified. The Ackerman comments' adjustments to EPA's existing benefit estimates are flawed, biased, and fundamentally arbitrary. The arguments in support of EPA's Habitat Replacement Cost and Societal Revealed Preference methods rest on mischaracterizations of prior criticisms, flawed understanding of economic principles, and personal opinions not based on professional expertise.

In closing, I wish to note that I recognize that it was very challenging for EPA to carry out such a large-scale and detailed analysis of the proposed rule. As I indicated in my previous comments, I was disappointed by EPA's initial analysis, but I am hopeful that its revised analysis will be significantly improved, and will be consistent with economic theory and best practice as supported by EPA's Guidelines for Preparing Economic Analyses, OMB's Guidelines, and other sound guides to benefit-cost analysis and environmental economics more broadly.

The comments offered by outside experts can be helpful in this regard. However, I find that the assessment of EPA's economic analysis in the Ackerman comments is not helpful, because it is itself highly biased and misleading. The characterization of economic theory and empirical methods is severely flawed, and the numerical estimates in the Ackerman comments are biased toward greatly exaggerating the proposed rule's implementation benefits relative to its costs. Nevertheless, I remain hopeful that EPA will benefit from other outside comments it has received, and will move forward to produce a sound economic analysis of the proposed regulation and an environmentally and economically sensible rule for implementation of Section 316(b) of the Clean Water Act.

Streamlined Technology Option

The "Streamlined Technology Option for Certain Locations" can offer opportunities as I suggested in the NODA to develop a streamlined Comprehensive Demonstration Study (CDS) and could offer opportunities beyond the current scope of the NODA if allowed by the EPA on a case by case approach. The CDS in the water quality permitting process has proven to be the primary source of information and very comprehensive as in the Bonnet Carre Power, LLC water quality permitting effort. If the selection of certain technologies can meet the performance standards (which some can in combination with other components) and reduce the need for a comprehensive CDS, this would offer a wider range of options for industry.

The CDS as defined in 125.95(b) is comprehensive in regards to extensive data collection. Water quality permitting is no longer just effluent characterization and discharge limits, but also aquatic collection, and identification and numeration. It is possible to streamline the CDS process beyond the "Streamlined Technology Option for Certain Locations" by substituting species profiling within the habitats of the surface water in place of a large aquatic sampling regime. This would reduce a burden on permit applicants. The purpose of this approach is to reduce the need for a population study for the aquatic species. This consideration could simplify the CDS efforts. A representation of this approach is as follows:

- The initial step of the CDS is to determine the fish species associated with the surface water. This would be accomplished through a review of current and historical reference material and actual studies collected within 5-years. For example, it has been determined for the Lower Mississippi River that there are 133 fish species for consideration.

- In order to determine the geographical reach of these fish species in the surface water, specifically in the location of the CWIS, preferred habitats would be identified for each fish species. For example, there are 13 aquatic habitats for the Lower Mississippi River (Baker et. a!. 1991).

- The preferred habitats associated with the CWIS are defined by the habitat zones (cross-section of the surface water at the CWIS location) and the distribution ranges (water column depths for each habitat zone including the CWIS location). The fish species would be mapped in egg, larval, and adult stages within each habitat zone and distribution range to assist in the evaluation of impacts for the CWIS. This is accomplished through life cycle and behavior pattern information/data. For example, one would ascertain that only a portion of the 133 fish species on the Lower Mississippi River would be associated with the habitat of the CWIS. Additionally, the design features of the CWIS and the sweeping velocity and/or other characteristics of the surface water can later be taken under considerations.

- The CWIS locations would be identified for the Baseline, Track I, and current design of the CWIS as specified within the limitations of the 316(b) Rule and correlated to the fish species (including egg and larval) based on preferred habitats. This also includes determining the zone of influence for the CWIS.

- Technology options would then be applied to enhance protection of egg, larval, and fish species for I&E (i.e. wedge-wire screens or other) to reach the desired performance standards.

- The "Adaptive Management" approach combined with the regulatory monitoring for I&E would allow a facility to make adjustments to the CWIS if needed.

This approach to a streamlined CDS is to focus on the diversity of aquatic species within the surface water; the life cycles, behavior patterns, preferred habitat, and characteristics of the surface water combined with technology rather than a population study of aquatic species. The premise of this approach is if the species are protected from potential impacts the population and the relative abundance of those species are protected for that geographical reach. Additionally, the streamlined CDS could be defined for specific surface waters such as the Lower Mississippi, Ohio and Missouri Rivers were flows larger and many intakes are well below the 5% annual mean.

EPA Response

As part of the Impingement Mortality and Entrainment Characterization Study (§125.95(b)3)), EPA states that it will accept historical studies review as long as the data is still representative of current conditions at the facility. EPA also will accept well-documented general information, such as preferred habitat, as part of the submittal of existing data. The critical factor for EPA is that any information submitted must be representative of the current conditions at the site. It is the burden of the applicants to prove that studies submitted to EPA represent current biological conditions at their facilities. EPA disagrees, however, that it should substitute the species categorization component of the Comprehensive Demonstration Study with generalized study of the ambient conditions of an entire waterbody or segment of a waterbody, primarily because such generalized data may not be representative of the conditions at the site. For example, the intake may be located near a unique microhabitat and have species assemblages that a waterbody-scale general study would not capture. EPA believes that it has greatly streamlined the Comprehensive Demonstration Study requirements and thereby reduced burden for permit applicants. For details on EPA's streamlining efforts please refer to EPA's response to comment 316bEFR.034.005.

Cooling system costs (e.g., dry, wet, recirculating)

During the first comment period, EPA's estimates of the cost of retrofitting existing facilities with cooling towers received significant criticism. Reliable cost estimates for this technology are essential for a reasonable evaluation of the WBC option, which is the only alternative to the preferred option for which cost estimates are presented in the NODA. in the NODA. EPA discusses two studies performed by the U.S. Department of Energy (DOE) that estimate the capital costs of installing cooling towers at four existing facilities. As EPA notes, DOE's initial study, which involved a limited, site-specific investigation of these facilities, led to capital cost estimates that are higher than those that would be produced by EPA's 316(b) Phase II costing methodology. In fact, my analysis indicates that DOE's estimates are 65 to 104 percent greater than those that would be produced by EPA's methodology. A follow-up study by DOE, involving discussions with the plants' operators and more detailed investigations of site-specific conditions, suggested that more reliable cost estimates might be 230 to nearly 310 percent greater than those produced by EPA's methodology. Moreover, site-specific capital cost estimates that I used in my economic analysis of retrofitting Brayton Point Station with cooling towers raise additional concerns about EPA's methodology. In that case, a site-specific analysis led to capital cost estimates that were 150 percent higher than would result from EPA's methodology.

DOE's study and the analysis at Brayton Point Station suggest that EPA's methodology may systematically underestimate costs, and also makes clear that site-specific factors can cause costs to deviate dramatically from those estimated by EPA's method. In addition, EPA's analysis indicates that the requirement for certain facilities to install cooling towers is the primary factor differentiating the WBC option from EPA's current preferred regulatory option. As a result, revisions to the cost estimates for retrofitting facilities with cooling towers in line with the information presented above could perhaps more than double the added cost associated with the WBC option, which is currently estimated to be in excess of $850 million.

EPA Response

The Agency has reviewed the study (An Investigation Site-Specific Factors for Retrofitting Recirculating Cooling Towers at Existing Power Plants, January 22, 2003)prepared on behalf of the Department of Energy and finds the principles and concepts behind the analysis to be sound.

Cooling system costs (e.g., dry, wet, recirculating)

Another significant contributor to the cost of retrofitting a facility with cooling towers is the opportunity cost of generation outages during the installation period. The NODA raises new questions about the length of such outages. While the NODA indicates that adjustments have been made to outage assumptions for nuclear facilities, comments are requested on the duration of outages at non-nuclear facilities. The DOE study cited by EPA in the NODA offers important insights. The ultimate conclusion of that study is that necessary outages can last well beyond the duration of routine scheduled outages, but that a site-specific engineering assessment is necessary to estimate accurately the length of such outages. Here again, detailed analysis of the cost of retrofitting Brayton Point Station with cooling towers confirms DOE's conclusions. In that case, because of particular aspects of the facility's design, each unit would have to undergo an eight month outage to install cooling towers, seven months longer than a typical scheduled outage. Given that site-specific factors are clearly a critical determinant of outage duration, EPA should carefully consider the evidence provided to it in evaluating the reasonableness of its existing assumption for the average outage duration. This assumption is an essential element of EPA's analysis because, for some facilities, the opportunity cost of a month-long outage could be on the order of $10 million per 1,000 megawatts of capacity.

EPA Response

The final rule is not based on cooling tower technologies, in part, due to the uncertainty inherent in construction downtimes. Therefore, the commenters concerns have been met.

Use of Replacement Costs (HRC and hatchery-based)

The NODA indicates that EPA has substantially revised its benefit estimates. Unfortunately, on net, the revisions have left EPA's estimates no less flawed than those produced by the original analysis. Nonetheless, prior to addressing the most problematic aspect of these revisions, it is worthwhile addressing the improvements that EPA has also made. Primary among them is that EPA appears to have recognized flaws in its original analysis of non-use values. To estimate non-use values, EPA had relied on three methods that are variations on fundamentally flawed "avoided cost measures of benefits." The habitat replacement cost method and forage fish replacement cost method both involved labeling as a "benefit" the cost of a hypothetical alternative to reductions in I&E that would purportedly achieve the same regulatory objective (at greater cost). The societal revealed preference approach entailed labeling as a "benefit" the historical cost to comply with previous regulations or other government initiatives that have achieved objectives that were similar to those of the proposed rule. A review of the NODA leaves the impression that EPA now judges those methods to be unreliable and invalid means of benefit estimation. Yet, given that some of the methods are currently being employed by EPA's regional offices in analyses supporting on-going regulatory proceedings, EPA should make clear its conclusion that these methods are invalid.

EPA Response

EPA agrees that the Habitat-based Replacement Cost (HRC) method provides estimates of costs rather than benefits, but disagrees with the comment that it is an invalid method. HRC is closely related to approaches such as Habitat Equivalency Analysis used by federal and state agencies to monetize damages in cases where physical impacts are otherwise difficult to value. EPA believes that the analysis of replacement costs is a valuable tool for regulators to use in evaluating I&E losses.

However, EPA does not use the HRC method in the cost benefit analysis for the final Section 316(b) Phase II rule. Please see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-0003) for additional discussion of the HRC method. Please also see EPA's response to comment #316bEFR.005.035.

Benefit Estimation Methodology

In addition to removing the flawed "avoided cost measures of benefits," EPA also made important revisions to its existing analysis of recreational and commercial fishing benefits. Among these are: its introduction of discounting in estimating future recreational and commercial fishing benefits; replacement of flawed benefit transfer methods for estimating recreational fishing benefits in favor of a greater use of random utility models; and the elimination of a previous assumption that total economic surplus resulting from increased commercial fish catch is 4.5 times that enjoyed by fishermen alone. Together, these revisions would make EPA's benefit estimates more reliable, but they are overshadowed by the introduction of a new, severely flawed and invalid measure of non-use values.

EPA Response

The commenter notes EPA's revisions to benefits assessment methodologies presented in the NODA. The commenter states that these revisions "would make EPA's benefit estimates more reliable." The commenter, however, questions the validity of EPA's approach to measuring non-use benefits presented in the NODA.

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to uncertainty in monetizing national benefits associated with non-use values for the final rule. The Agency, however, has explored several approaches that indicate the potential significance of non-use values. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

While EPA should be commended for ceasing to rely on "avoided cost measures of benefits,' it has replaced those methods with another fundamentally flawed method for estimating non-use value. Indeed, the new analysis cannot be considered any less flawed or any more reliable than those previously employed by EPA. It seeks to estimate the non-use value of reductions in I&E by using a benefit transfer method, but the analysis attempts to transfer estimates from a stated preference study of the total value that individuals place on restoration and preservation of wetlands and eelgrass. EPA's analysis fails to meet both the soundness and similarity criteria essential to benefit transfer, thereby leading to results that are invalid and misleading.

Given the selection of individuals surveyed in the original study on which EPA relies, and the fact that they were given no information about the magnitude of ecological impacts associated with the restoration they were valuing, the original study provides no basis for EPA to estimate non-use values estimated, let alone to determine non-use values attributable to particular ecological services, such as fish production. Even if one were to set aside these concerns about the soundness of the original study for the analysis that EPA employs, the differences between the resource valued in the study and those that EPA seeks to value are insurmountable. And in the process of attempting the transfer, EPA ignores basic economic theory regarding non-use values and makes adjustments to the original values that are unsupported by the studies on which it relies. This valuation method is invalid and unreliable, and should not be incorporated in EPA's final analysis of the proposed regulation.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values in the benefits analysis due to unavoidable uncertainty in monetizing non-use values. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Cooling system costs (e.g., dry, wet, recirculating)

Author Name Robert Stavins

Organization Environmental Economics Program, John F. Kennedy School of Government, Harvard University

In summary, the Notice of Data Availability includes significant changes to and information regarding EPA's economic analysis for the proposed 316(b) Phase II rule. Important new information is presented regarding both the capital costs of retrofitting existing facilities with cooling towers and outages that will be required while those retrofits are conducted. When combined with evidence from an analysis of the cost of installing cooling towers at Brayton Point Station, it is clear that more reliable estimates of capital costs may be more than 100 percent greater than those estimated by EPA. This information lends further support to existing criticisms of EPA's capital cost estimates. It also makes clear that the added costs that would be imposed by the waterbody/capacity-based option, relative to EPA's preferred option, are likely to be much greater than EPA has acknowledged.

EPA Response

The Agency has not included cooling towers as a basis for the final rule.

Valuing Forage Species (incl non-use and non-landed)

EPA has also made revisions to its benefit analysis, addressing some of the flaws that I identified in my previous comments. But due to its pursuit of a new non-use value analysis that is conceptually flawed and impossible to implement reliably, the overall analysis and the estimates it produces are no more reliable or valid than the “avoided cost measures of benefits” that this new analysis has replaced. As I stated in my prior comments, if EPA believes there are legitimate and significant non-use values, they should be estimated with original applications of the best stated preference methods. The possible existence of excluded use values or unassessed non-use values does not justify the employment of conceptually flawed approaches.

EPA Response

EPA does not agree that the only acceptable method of estimating non-use benefits would be to conduct an original stated preference study. Many resource economists support the idea that benefits transfer analyses, properly conducted, can be used as an alternative to a primary research survey in order to estimate non-use benefits. While it might be preferable to conduct such research in an ideal world, EPA did not deem it feasible as a matter of cost or timing to conduct such a primary study here. EPA also notes that failing to assess non-use values would only tend to make the qualitative assessment of ecological benefits all the more important.

For EPA’s response to the issue of conducting an original stated preference survey, please see response to comment number #316bEFR.306.106.

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency’s non-use valuation methods in responses to a number of comments. For EPA’s benefit transfer approach, please see EPA’s response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. Cooling system costs (e.g., dry, wet, recirculating)

The Cost of Retrofitting Existing Facilities with Cooling Towers

The NODA's discussion of EPA's cost estimates for retrofitting existing facilities with cooling towers contains new evidence that supports existing concerns about the validity of those estimates. Of course, these estimates, which EPA has not yet revised, have a critical impact on the cost of the WBC option. There are two important elements of the cost of retrofitting facilities with cooling towers that are discussed in the NODA: the capital cost of installing and connecting cooling towers, and the duration of outages required to facilitate that installation.

A. Capital Cost Estimates for Retrofitting Facilities with Cooling Towers

For its analysis of the cost of the WBC option, EPA modified the costing methodology that it developed for its 316(b) Phase I rule for new facilities.<FN 7> It should be noted that this modified methodology was heavily criticized for producing unreasonably low estimates.<FN 8> The method assumes that the cost of a mechanical draft wet cooling tower is affected only by cooling water flow, the type of material used to build the tower, the type of fill media used in the tower, and the potential need for noise reduction. To modify a cost estimate to apply it to an existing facility, EPA multiplies the estimate by a "retrofit factor" to account for the increased cost associated with retrofitting a facility, compared to incorporating cooling towers into the facility's original design and construction. In an attempt to adjust for regional differences in construction costs, EPA also applies a "State-Specific Capital Cost Factor" to the capital cost estimate.<FN 9>

In the NODA, EPA presents new information that further supports previous criticism of the methodology. EPA describes a study performed by the U.S. Department of Energy (DOE) that examines the cost of retrofitting four facilities with cooling towers, which "found costs at these facilities would be higher than EPA estimated for similar facilities in its proposed record."<FN 10> For the four facilities studied by DOE, a comparison of DOE's capital cost estimates with those derived from the EPA methodology reveals that DOE's site-specific study led to increases in cost estimates, relative to EPA's method, ranging from 65 percent to 104 percent (see Exhibits 1-5). Moreover, after producing these initial estimates, DOE conducted a more detailed analysis of the facilities, which included conversations with the facilities' operators. This further analysis led DOE to the conclusion that its initial estimates, which were based on limited site-specific information, had to be increased by "as much as 100 percent."<FN 11> This implies that actual costs may be 230 to nearly 310 percent greater than those produced by the EPA methodology.

Cooling system costs (e.g., dry, wet, recirculating)

The on-going permitting of Brayton Point Station offers another comparison of estimates derived from the EPA methodology with those developed by a site-specific investigation. While EPA makes clear in the NODA that it anticipates costs at specific sites may differ significantly from those estimated using its costing methodology,<FN 12> EPA - Region 1 adopted that methodology to estimate the cost of retrofitting Brayton Point Station with cooling towers. While Region 1 made limited modifications to EPA's costing methodology, a site-specific analysis led to cost estimates that were 150 percent greater than those produced by the strict application of EPA's methodology (see Exhibit 6). In summary, the total capital cost estimate for retrofitting all five facilities that results from site-specific analyses is 96 percent greater than EPA's estimate.<FN 13> This difference is far greater than the 25 percent error margins that EPA implied may be associated with its costing methodology in the analysis of the proposed rule.<FN 14> Indeed, absent any other evidence to the contrary, detailed estimates from these five facilities suggest that EPA's methodology for estimating capital cost may lead to severely downward biased estimates.

Given the magnitude of the differences in estimates described above, and the number of facilities examined in those estimates, EPA should reevaluate its estimates of the cost of retrofitting facilities with cooling towers. This is particularly important, as it appears that errors in EPA's methodology for estimating the cost of retrofitting facilities with cooling towers will translate into errors of nearly equal size in its estimate of the incremental cost of the WBC option relative to its current preferred option. Table A1-1 of EPA's 316(b) Phase II Economic and Benefits Analysis suggests that the primary, if not the only, difference between the WBC option and the preferred option is that certain facilities that would have only installed impingement and entrainment controls under the latter option would be required to install cooling towers under the former option.<FN 15> As a result, the added cost of the WBC option, which EPA currently estimates to be in excess of $850 million, would be determined largely by the cost of installing cooling towers.<FN 16> The incorporation of cost estimates consistent with those reported by DOE could perhaps more than double this estimate of the WBC option's added cost. The potential for such a significant increase in the added cost of the waterbody/capacity-based option underscores the need for EPA to reconsider its cost analysis in light of the DOE studies.

Footnotes

12 In discussing its revisions to cost estimates for other technologies, EPA states that "compliance costs for a particular facility [may] significantly exceed those estimated in the analysis for the ... rule." 68 Fed. Reg. 13,525.

13 It should be noted that this comparison relies on estimates from DOE's original study, estimates that DOE later suggested may need to be increased by as much as 100 percent.

14 U.S. EPA, 2002, p. 2.23.

15 U.S. EPA. Economic and Benefits Analysis for the Proposed Section 316(b) Phase II Existing Facilities Rule. February 28, 2002. p. A1-9. (Hereafter U.S. EPA, 2002b)

16 See Exhibit 7, 68 Fed. Reg. 13,535.

EPA Response

The Agency has not included cooling towers as a basis for the final rule.

The Agency notes that for the final permit analysis that EPA Region I utilized a different methodology than that described by the commenter for estimating the potential costs of implementing cooling tower retrofits for the Brayton Point plant.

Assumptions Regarding the Duration of Generation Outages

In addition to introducing information that calls into question the reliability of its methodology for estimating the capital cost of retrofitting existing facilities with cooling towers, the NODA also introduces new information regarding the duration of outages associated with cooling tower installations. In the NODA, EPA reveals that it is revising its assumption regarding the duration of outages at nuclear plants associated with installing cooling towers from four weeks to seven months.<FN 17> In addition, EPA is requesting additional comment on whether site-specific factors may cause outages at non-nuclear power plants to exceed EPA's existing assumption of four weeks, and whether it should revise that assumption in its analysis. Such a request for comments is especially warranted given information presented in the DOE studies described above. In the addendum to its initial study, DOE found that conditions at two of the four plants would result in "extended outage[s]" during the installation of the cooling towers that would "significantly exceed a scheduled outage."<FN 18> In particular, DOE emphasized that a reliable estimate of outage durations "would require a detailed engineering analysis estimate."<FN 19>

Here again, the on-going permitting process at Brayton Point Station provides additional insight on this matter. In the context of that process, Stone and Webster, Inc., a firm with decades of experience planning and executing power plant improvements and intimate knowledge of Brayton Point Station, found that generation outages would be required for seven months beyond the length of scheduled outages. While site-specific factors are clearly a critical determinant of outage duration, EPA should carefully consider the evidence provided to it in evaluating the reasonableness of its existing assumption for the average, nationwide outage duration at non-nuclear facilities. This is particularly important, give the magnitude of costs associated with these outages. Many of the facilities that would be required to install cooling towers offer baseload generation that is often significantly less costly than electricity generation by the marginal generating units. It is not unreasonable to assume that, in some cases, the cost to society of a month-long outage could be on the order of $10 million per 1,000 megawatts of capacity.

Conclusions Regarding Cost Analysis

In summary, the NODA presents significant new information regarding both the capital costs of retrofitting existing facilities with cooling towers and the outages that will be required while those retrofits are conducted. Both assumptions have substantial effects on estimates of the absolute and incremental cost of the WBC option. As a result, EPA's current cost analysis, which fails to address the implications of this new information in any meaningful way, may underestimate the total and incremental cost associated with this option by a significant margin.

Benefit Estimation Methodology

II. Changes to EPA's Original Benefits Analysis

In my previous comments on the proposed rule, I reached the following conclusions, among others, regarding EPA's original benefits analysis: (1) EPA's estimates of commercial fishery impacts were severely flawed, due in part to a lack of reliance on standard and accepted bioeconomic models, and adoption of approaches which lack foundation in the scientific literature; (2) EPA's analysis of recreational fishery benefits was likewise flawed, because of reliance on problematic applications of benefit transfer methods; (3) the habitat replacement cost method used by EPA commits one of the gravest of errors in economics, actually confusing benefits and costs, and -as such- this method is a completely invalid approach to identifying benefits; and (4) the "societal revealed preference" approach employed by EPA has no foundation in economic theory, is not accepted by economists as a legitimate empirical method of valuation, and -like the HRC method- is no more than a method of cost analysis mistakenly applied to the benefit-side of the ledger.<FN 20>

The NODA presents significant revisions to EPA's original benefits analysis. Some of these revisions have corrected the serious flaws that I described above. Yet, one of the most significant changes is a new method that EPA has introduced for estimating non-use value. This method involves flaws that are different from those of the "avoided cost measures of benefits" previously employed by EPA, but are no less severe. Indeed, when one considers all of the revisions that EPA has made, the net result is an analysis whose benefit estimates are no more reliable or valid than those that EPA presented with the proposed rulemaking. After commenting briefly on those revisions that have improved EPA's analysis in this section, I turn to EPA's new non-use value analysis.

Footnotes

20 See Stavins, 2002, pp. 14-15

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to uncertainty in monetizing national benefits associated with non-use values for the final rule. The Agency, however, has explored several approaches that indicate the potential significance of non-use values. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers;

and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Use of Replacement Costs (HRC and hatchery-based)

Removal of “Avoided Cost Measures of Benefits”

Primary among the improvements that EPA has made to its benefit estimates is its apparent decision to no longer rely on “avoided cost measures” for estimating certain components of benefits. To estimate non-use values, EPA had relied on three methods that are variations on the fundamentally flawed avoided cost measures.<FN 21> The habitat replacement cost method and forage fish replacement cost method both involved labeling as a “benefit” the cost of a hypothetical alternative to reductions in I&E that would purportedly achieve the same regulatory objective as the proposed rule (at greater cost). The societal revealed preference approach entailed labeling as a “benefit” the historical cost to comply with previous regulations or initiatives that have achieved similar objectives to those of the proposed rule.

Numerous individuals, including myself, submitted comments addressing the severe problems associated with these methods. Most prominent among these problems is the fact that they are not merely flawed approaches to estimating benefits; rather they are not benefit-estimation methods at all.<FN 22> By employing these methods, EPA committed a fundamental error by confusing benefits and costs.

Footnotes

21 It is very important that the approach taken by EPA with its completely invalid HRC method not be confused with legitimate applications of “defensive expenditure” or “averting behavior” methods of estimating benefits. Those methods are based upon observed actions, that is, individual behavior. In particular, a necessary condition for using defensive expenditures or averting behavior for purposes of benefit estimation is that the researcher observes people revealing their preferences by actually (and voluntarily) incurring costs to avert (or tolerate) the environmental disruption in question. See Freeman, A. Myrick. The Measurement of Environmental and Resource Values: Theory and Methods. Washington, D.C.: Resources for the Future, Second Edition, 2003; and Abdalla, C., B. Roacham, and D. Epp. “Valuing Environmental Quality Changes Using Averting Expenditures: An Application to Groundwater Contamination.” Land Economics 68(1992): 163-169.

22 Stavins, 2002, 24-28

EPA Response

EPA agrees with the comment that Region 1 used a revised version of the HRC methods in its permitting materials. The description of the methods used by Region 1 makes clear that EPA understands that the costs estimated are costs and not benefits.

EPA disagrees with the commenter that the HRC is an invalid measure - and only agrees that HRC results are a measure of benefits. EPA believes that analysis of replacement costs are a valuable tool for regulators to use in evaluating I&E entrainment losses.

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule. Please see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-0003) for additional discussion of the HRC method. Please also see EPA's response to comment #316bEFR.005.035.

EPA does not use the Societal Revealed Preference (SRP) method in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the SRP, please see the response to comment #316bEFR.005.006

In the analyses for the NODA and the final rule, EPA no longer uses hatchery costs to estimate impacts on forage species. Instead EPA translates foregone production among forage species into foregone production among harvested species that are impinged and entrained using an assumed trophic transfer ratio, and then translates foregone production among these harvested species to foregone yield. Further information on the methods EPA used to estimate forage losses is provided in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003). See Chapter A5: Methods Used to Evaluate I&E.

Use of Replacement Costs (HRC and hatchery-based)

Author Name Robert Stavins

Organization Environmental Economics Program, John F. Kennedy School of Government, Harvard University

In light of EPA's decision to introduce a new non-use value analysis, and the lack of any mention of these avoided cost methods in the NODA, despite the severe criticism that they received during the previous comment period, it appears that EPA has recognized that these methods are fundamentally flawed and produce invalid and unreliable benefit estimates. But the methods continue to be used by EPA's regional offices to support on-going permitting decisions. For
example, Region 1 issued its draft permit for Brayton Point Station near the end of the comment period on EPA's proposed rule. Perhaps aware of the criticisms that had already been made of the habitat replacement cost method that it used in its analysis of the draft permit, Region 1 included in its determination documents a revised version of the chapter on the habitat replacement cost method that originally appeared in Part A of EPA's Case Study Analysis.<FN 23> Given the potential for this method to continue to be applied inappropriately in the future, EPA should state clearly that "avoided cost measures of benefits" are not valid measures of true benefits.

23 See U.S. EPA. Chapter A11: Habitat-Based Replacement Cost Method. Updated "with Agency assistance." May 23, 2002. in U.S. EPA - New England. Selected Reports Prepared for or by U.S. EPA as part of the Administrative Record for the National Pollutant Discharge Elimination System (NPDES) Draft Permit for Brayton Point Station Somerset, MA. July 22, 2002.

EPA Response

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule. Please see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method. Please also see EPA's response to comment #316bEFR.005.035.

EPA does not use the Societal Revealed Preference (SRP) method in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the SRP, please see the response to comment #316bEFR.005.006

In the analyses for the NODA and the final rule, EPA no longer uses hatchery costs to estimate impacts on forage species. Instead EPA translates foregone production among forage species into foregone production among harvested species that are impinged and entrained using an assumed trophic transfer ratio, and then translates foregone production among these harvested species to foregone yield. Further information on the methods EPA used to estimate forage losses is provided in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003). See Chapter A5: Methods Used to Evaluate I&E.

Benefit Estimation Methodology

Improvements to Recreational and Commercial Fishing Benefit Estimates

A number of additional flaws that others and I highlighted in previous comments on the proposed rule were corrected by EPA in the NODA. Among those flaws, some of the most significant were: the failure to consider the timing with which benefits from increased fish catch are realized and to discount those benefits accordingly; the failure to conduct appropriate benefit transfer in estimating recreational fishing benefits; and the assumption that total economic surplus resulting from increased commercial fish catch is 4.5 times that enjoyed by fishermen alone. I address each of these below.

Discounting

Once construction commences for any of the technologies considered in EPA's analysis, a period of time will pass before that construction is completed, the technology begins to operate, and I&E reductions can commence. Furthermore, once I&E reductions begin, there is a significant delay- potentially on the order of two decades or more- before a new equilibrium fish stock is achieved and benefits (such as increased fish catch) reach their full annual levels. In a valid economic analysis, such delays are extremely important, and have profound effects on benefit estimates in the presence of appropriate discounting. Yet, in its original benefits analysis, EPA completely failed to consider the timing of benefits, and thereby imparted a very significant upward bias to its benefit estimates. EPA recognizes this shortcoming in the NODA, and revises its method to take into account the timing with which benefits are realized, discounting those benefits accordingly.<FN 24>

Footnotes

24 In the NODA, EPA appears to discount to account for the lag between when a fish avoids I&E due to the implementation of new cooling water intake technologies and when it is eventually caught. Another important lag, particularly for the WBC option, is that between when costs are first incurred to begin building the proposed technologies, and when I&E reductions first occur. For the installation of cooling towers, this period could last as long as four years. See 68 Fed. Reg. 13,548.

EPA Response

The commenter states that EPA corrected a number of methodological flaws highlighted in the public comments on the proposed rule in the NODA. The commenter notes that the Agency "revised its method to take into account the timing with which benefits are realized, discounting those benefits accordingly." For the final Section 316(b) Phase II rule, the Agency followed the methodology outlined in the NODA. See the final Phase II Regional Studies Document (DCN #6-0003) for detail.

Improvements to Recreational and Commercial Fishing Benefit Estimates

A number of additional flaws that others and I highlighted in previous comments on the proposed rule were corrected by EPA in the NODA. Among those flaws, some of the most significant were: the failure to consider the timing with which benefits from increased fish catch are realized and to discount those benefits accordingly; the failure to conduct appropriate benefit transfer in estimating recreational fishing benefits; and the assumption that total economic surplus resulting from increased commercial fish catch is 4.5 times that enjoyed by fishermen alone. I address each of these below.

Inappropriate Benefit Transfer in Estimating Recreational Fishing Benefits

To value impacts on recreational fishing in some of its case study analyses, EPA relied upon the benefit transfer method. This method takes estimates of anticipated increases in recreational fishing catch (due to reductions in I&E) and values this catch. Values per fish are drawn from results of previous studies of recreational benefits from other fisheries in other locations. This method of benefit estimation is described in EPA's Guidelines, which sets out simple and clear conditions that must be met in order to obtain reliable results using such techniques. The two key conditions for a reliable benefit transfer are "soundness" (of the original study) and "similarity" (between the conditions and benefits in the original study and those in the "transfer study" for which benefit estimates are sought). As I describe in my July 19, 2002 comments, at least in the Case Study Analysis of Brayton Point Station, EPA's benefit transfer failed in meeting both conditions.<FN 25>

Possibly in response to my own and others' criticisms of the methods EPA employed in estimating recreational fishing benefits, the NODA indicates that EPA has revised its analysis of recreational fishing benefits by conducting "region-specific models of recreational anglers' behavior."<FN 26> If correctly implemented, the use of these random utility models will lead to more reliable recreational fishing benefit estimates.

Commercial Fishing Benefits

Improvements to Recreational and Commercial Fishing Benefit Estimates

A number of additional flaws that others and I highlighted in previous comments on the proposed rule were corrected by EPA in the NODA. Among those flaws, some of the most significant were: the failure to consider the timing with which benefits from increased fish catch are realized and to discount those benefits accordingly; the failure to conduct appropriate benefit transfer in estimating recreational fishing benefits; and the assumption that total economic surplus resulting from increased commercial fish catch is 4.5 times that enjoyed by fishermen alone. I address each of these below.

Assumptions About Total Economic Surplus from Commercial Fishing Catch

In its original analysis of commercial fishing benefits, having established an estimate of producer surplus from increased fish catch that was itself subject to criticism and subsequently revised, EPA proceeded to assume that "total economic surplus arising from the increase in commercial fish catch is 4.5 times greater than the producer surplus alone."<FN 27> In making this assumption, EPA contended that benefits of additional catch may accrue not only to the commercial fishing sector, but also to processors and retailers. As I made clear in my previous comments, EPA arrives at this assumption by inappropriately applying findings from other studies to an analysis of the long-run benefits from increased fish catch.<FN 28> EPA's revisions appropriately addressed this criticism. In the NODA, EPA found that the application of this total surplus multiplier was inappropriate because "the magnitude of the changes in commercial catch modeled in the Holt and Bishop paper [from which it drew this multiplier] is, in most cases, larger than the magnitude of the expected changes as a result of the Phase II regulations. Since the magnitude of the change assumed in the Holt and Bishop (2002) paper is much larger, the benefits may be quite different."<FN 29> Together with the changes to its recreational fishing benefit estimates and the introduction of discounting, this revision makes this particular aspect of EPA's benefit analysis more consistent with economic theory and empirical practice.

Peconic-based approach

EPA's New Non-Use Value Analysis

The new method proposed by EPA to assess non-use value associated with I&E reductions is severely and fundamentally flawed, and should not be included in the regulatory analysis. Building upon the withdrawn habitat replacement cost method, EPA now proposes to use estimates of benefits (willingness-to-pay) for specific aquatic habitats -wetlands and eelgrass- as proxies for the non-use value of fishery impacts due to impingement and entrainment (I&E).<FN 30> As I explain at length below, this claimed "benefit transfer" violates the most fundamental requirements of such transfers set out in EPA's own Guidelines, in OMB's guidance documents, and in standard scholarly references, and introduces a series of arbitrary judgments that further render the analysis invalid and the results unreliable. It is also worth noting that two of the authors of the original study on which EPA relied for this benefit transfer have submitted comments to the record making clear that their study cannot be used as a basis for a valid or reliable benefit transfer intended to develop estimates of the non-use value of I&E reductions.<FN 31>

EPA's new method is no less flawed than the previously employed "avoided cost measures of benefits." Moreover, the NODA makes the implications of this flawed and biased analysis of non-use value transparent and striking. While EPA does not present revised nationwide benefit estimates, it does produce estimates for the North Atlantic Region. Those estimates indicate that non-use value now makes up 97 percent of EPA's total benefits estimate!<FN 32> Thus, EPA's estimate of total benefits is nearly completely dependent on this new, fundamentally flawed approach. In essence, this new method seeks to salvage the habitat replacement cost analysis by using the results of that analysis regarding the amount of habitat restoration that would be required to offset I&E. But rather than estimating the cost of that restoration, EPA presents estimates of what it claims to be the portion of non-use value of that restoration that is attributable to resulting fish production. In terms of the underlying biological analysis, this method is no less flawed than the habitat replacement cost method in deriving estimates of the habitat restoration required to offset I&E losses. Indeed, EPA appears to have done nothing to address significant criticisms of its biological analysis that were made in comments submitted during the first comment period on the proposed regulations.<FN 33>

EPA attempts to value the fish production associated with this restoration using a benefit transfer approach. In so doing, EPA has failed to such a degree in meeting the soundness and similarity criteria of benefit transfer that its resulting "benefit" estimates provide no useful information as to true non-use benefits of reductions in I&E. Indeed, the only improvement that it has made relative to the habitat replacement cost method is that EPA is at least attempting to measure benefits rather than costs.

While the original study on which EPA relies for its benefit transfer may be sound, given the objectives that it sought to achieve, the design of the original study makes it unsound as a basis for meeting the objectives of EPA's benefit transfer. In addition, even if the original study could be considered a sound basis for EPA's benefit transfer, the differences between the resource being valued in that study and the resource that EPA attempts to value are so great that it is impossible to accomplish a valid and reliable benefit transfer. Finally, putting aside the impossibility of the task that EPA has attempted, fundamental flaws are evident in the few steps that it takes to account for these differences. Before addressing the failure of EPA's benefit transfer to meet the soundness and similarity criteria and the specific flaws associated with each step in that transfer, I briefly describe the analysis that EPA has performed.

Footnotes

30 While the method is briefly described in the Federal Register publication of the NODA, a more detailed description can be found in: Memorandum to the Section 316(b) Record from Lynne Tudor, Elena Besedin, Marisa Mazzotta, Robert Johnston, and Elizabeth Strange, March 12, 2003, titled "Estimating Total and Non-Use Values for Fish, Based on Habitat Values for Coastal Wetlands and Eelgrass (SAV)." (Hereafter Tudor et al., 2003)

31 In their comments, James Opaluch, Ph.D., and Thomas Grigalunas, Ph.D., found that: Overall, we believe that the results [of EPA's new non-use value analysis] cannot be used to assess the potential economic benefits for assessing alternative cooling water control technologies, for three principle reasons[.]First, the PES study results were intended to develop priorities for resource preservation and restoration programs, not absolute dollar values. Second, the information provided to respondents to the PES resource survey was inadequate to support a valuation of quantitative changes in fish and shellfish due to changes in eelgrass or wetland resources. Third, even if the dollar results of eelgrass and wetlands from the PES resource study could be relied upon, the transfer of these results from the PES sample studied to other populations, such as those in the North Atlantic Region, would likely overstate values because of the substantial difference in socioeconomic and demographic characteristics which exist between the two areas.

Opaluch, James J., and Thomas A. Grigalunas. Letter to the Proposed Rule Comment Clerk — OW-2002-0049, Re: Comments on Notice of Data Availability, Proposed Regulations to Establish Requirements for Cooling Water Intake Structures at Phase II Existing Facilities. June 2, 2003.

32 See Table X-44, 68 Fed. Reg. 13,577.

33 These comments found that EPA's habitat replacement cost analysis failed to identify correctly and evaluate appropriately restoration techniques that would increase the production of species affected by I&E. See French McCay, Deborah. Letter to Proposed Rule Comment Clerk — W-00-32, Re: Comments on Proposed Rule, RIN 2040-AD62 Clean Water Act Section 316(b) — National Pollutant Discharge Elimination System — Proposed Regulations for Cooling Water Intake Structures at Phase II Existing Facilities, EPA ICR no. 2060.01. August 5, 2002.

EPA Response

The commenter's specific objection to the biological analysis is unclear, and therefore EPA cannot respond to the general comment that "this method is no less flawed than the habitat replacement cost method in deriving estimates of the habitat restoration required to offset I&E losses."

For EPA's response to comments on similarity between the study and policy resources, please see the response to comment #316bEFR.307.061.

For EPA's response to comments regarding the allocation of values for various wetland services using the Johnston, et al. study, please see the response to comment #316bEFR.303.021.

Finally, the Agency notes that although two of the authors of the original studies on which EPA relied for this benefits transfer submitted comments on behalf of the regulated industry, two other investigators of the original studies (Dr. Marisa Mazzotta and Dr. Robert Johnston) served as EPA's consultants for the cost benefit analysis of the final Section 316(b) Phase II regulation.

Regardless of the substance of any of the commenter's arguments, the habitat-based approach is not used in the cost-benefit analysis for the final section 316(b) rule. Instead, the Agency used this approach to provide useful information for policymakers to consider in determining the final 316(b) Phase II rule.

Subject Matter Code 10.02.04.01

Peconic-based approach

EPA begins its new non-use value analysis by estimating the quantity of eelgrass and wetland restoration that would be required to offset losses of particular species affected by I&E. To do this, EPA divides the estimated I&E losses of each species (whose production EPA believes can be benefited by the habitat in question) by the measured abundance of the species in that habitat. As EPA believes fish abundance can be used as a proxy for fish production, it uses this exercise to produce an estimate of the number of acres of habitat restoration that would be necessary to offset I&E losses. In the habitat replacement cost analysis, EPA multiplied that number of acres by the per acre cost of restoration to arrive at its estimates of "benefits." In its new analysis, EPA seeks to derive an estimate of the amount that society would be willing to pay for the portion of the habitat restoration's non-use value that is attributable to the resulting fish production.

To develop an estimate of this non-use value, EPA relies on a study that estimates individuals' per-acre willingness-to-pay for the preservation and restoration of eelgrass and wetlands in the Peconic Estuary System in eastern Long Island, New York.<FN 34> Because the values estimated in this study are total values, including use and non-use value, EPA attempts to isolate non-use value by examining the values expressed by individuals that do not fish or shellfish. By assuming that the only users of wetlands and eelgrass are those who fish or shellfish, and thus any households that do not fish or shellfish can only hold non-use values for wetlands and eelgrass, EPA uses the total value expressed by households that do not fish or shellfish as a measure of the per-household non-use value of the habitats.

EPA then seeks to determine what share of this non-use value is attributable to the habitats' impact on fish and shellfish production. In the case of eelgrass, EPA assumes that a household's non-use value for eelgrass is entirely due to its impact on fish and shellfish production, and is unaffected by any other attributes of eelgrass. In the case of wetlands, EPA relies on a study that examines individuals' relative preferences for four different kinds of habitat services that wetlands provide.<FN 35> Based on this study by Johnston et al. (2002), which examines the marginal benefit derived from changes in the impact of wetland restoration on four habitat services, EPA assumes that approximately one-quarter of the non-use value of wetlands is attributable to wetlands' impacts on fish production. EPA thus arrives at estimates of the per-household, non-use value per-acre of wetlands and eelgrass restoration that is attributable to fish production services provided by those habitats. EPA multiplies this by the total number of acres of restoration required, leading to its estimate of non-use value per household for fish production resulting from the habitat restoration that EPA assumes would offset I&E.

The final step in EPA's analysis involves multiplying this per-household value by various populations that EPA assumes would hold these values. The two populations that EPA chooses for its alternative estimates are: all households in counties abutting the water bodies that may be affected by I&E; and all households within 32.4 miles of facilities where I&E may be occurring. For its estimates using the latter population, EPA produces two alternative estimates based on alternative assumptions about the effect of distance from the affected water body on non-use value.

Peconic-based approach

The first criterion that must be met in order to ensure the reliability of estimates resulting from a benefit transfer is the soundness of the method employed in the original study from which estimates are transferred. While a study may be sound for meeting its own objectives, it may be unsound for meeting the objectives desired by those conducting a benefit transfer. This is clearly the case in EPA's analysis, a point that is not only expanded on below, but was also made by the original study's authors in comments on the NODA that they have submitted to EPA.<FN 36> The original study that EPA uses sought to evaluate the relative values that residents of the towns surrounding the Peconic Estuary System placed on various resources, including wetlands and eelgrass. While the study developed estimates of the values that residents placed on the various resources, the study's authors strongly cautioned that: "we believe that the resource priorities or relative values of resources are more reliable than are the dollar estimates of values and recommend that relative values, rather than dollar values, be used ...."<FN 37> EPA ignored this warning and transferred the dollar values for wetlands and eelgrass from this study.

EPA also fails to account for two other factors that significantly affect the soundness of the original study for meeting the objectives sought by EPA. Seeking to compensate for significant differences between the type of value being estimated in the original study and that which EPA seeks to estimate, and between the resources being valued, EPA makes two adjustments in transferring estimates from the original study. First, EPA attempts to develop a non-use value estimate from the original study's estimate of the total value that respondents placed on the resources. Second, EPA attempts to determine what share of the value that individuals hold for wetlands and eelgrass is attributable to those habitats' impacts on fish production. While there are significant conceptual flaws with these steps, which I address below, it is also clear that such adjustments cannot be reliable, given the information contained in the original study.

The original study examined only the total value that residents placed on various resources, including wetlands and eelgrass. There is clear evidence in the study that the vast majority of individuals surveyed were users of the resources, at least in the case of wetlands. The study found that 81 percent of respondents engaged in recreational activities in the Peconic Estuary System that would likely benefit from wetlands and, in some cases, eelgrass.<FN 38> For example, 40 percent fished, 54 percent walked and hiked, and 45 percent boated. Moreover, an even greater percentage of the respondents likely drove by the wetlands, enjoying the use value of scenic views that such resources afford. While the original study did not provide information on this, according to its authors, the average distance of survey respondents' homes to the Peconic Bay was likely eight miles, suggesting that many would often have occasion to see the wetlands.<FN 39> EPA identifies what it considers to be a group of non-users and assumes that their total value is a reliable indication of non-use value. But, as I describe below, it is highly probable that those individuals EPA considered to be non-users were in fact users of the resource. In fact, it is also highly probable that the original study surveyed too few true non-users to provide reliable non-use estimates even if EPA had properly isolated those non-users.

The validity of EPA's analysis also depends on the assumption that the non-use values that individuals place on a habitat such as wetlands are not values for the holistic resource or for intrinsic characteristics of the resource, but rather the sum of separable non-use values for the habitat's various ecological services. In particular, EPA assumes that it can estimate what share of the original study's survey respondents' non-use value for wetlands and eelgrass is attributable to a particular, quantifiable level of fish production associated with increased habitat. In order for EPA to develop an estimate of the share of survey respondents' non-use value that is attributable the habitats' fish production services, two conditions must hold. First, the extent to which those habitats contribute to the various ecological services, including a quantifiable level of fish production, must either have been common knowledge to the survey respondents or it must have been made known to them during the survey. Second, EPA must be able to determine the share of individuals' non-use value that can be attributed to the various ecological services. While the latter is a conceptual issue I address below, the former underscores that the original study cannot be considered a sound basis for the analysis EPA undertakes.

In the NODA, EPA outlines the "best practices" that should be met in designing a reliable stated preference survey, the method employed by the original study on which EPA relies. In so doing, EPA recognizes and summarizes the guidelines set forth in 1992 by a National Oceanic and Atmospheric Administration (NOAA) panel on contingent valuation.<FN 40> In introducing those guidelines, the NOAA panel stated that "any [contingent valuation] study should adhere [to the guidelines] if the study is to produce information useful in [benefit estimation]."<FN 41> One critical guideline that EPA also specifically mentions in the NODA is that "[a]dequate information must be provided to respondents about the environmental program [improvement] that is offered. It must be defined in a way that is relevant to [benefit estimation]."<FN 42> In conducting its new non-use value analysis, EPA completely ignores this guidance. EPA's estimates of the non-use value that individuals place on fish production from wetlands and eelgrass restoration are based on total values for wetlands and eelgrass restoration expressed by survey respondents who were told nothing to help them understand the level of impact that either wetlands or eelgrass habitat might have on fish production.

Much of the other research from which EPA draws in conducting its non-use value analysis makes clear that the validity of EPA's analysis is undermined by the fact that the original study did not provide survey respondents with information about the impact of habitat restoration on ecological services. The central finding of the Johnston et al. (2002) study, which is a critical component of EPA's analysis, is that different types of wetlands restoration can lead to dramatically different impacts on fish production and that the economic benefits from restoration depend on the extent to which restoration affects fish production and other ecological services. Therefore, given that no information on the impact of wetlands on various ecological services was provided to survey respondents in the original study, the variation in survey respondents' willingness-to-pay for wetland restoration may have been largely due to different perceptions about the impact of that restoration on ecological services. EPA's own analysis of the number of acres of restoration required to offset I&E indicates that the level of fish production associated with wetlands and eelgrass habitat could not be common knowledge among survey respondents: "Unfortunately, available quantitative data is not sufficient to estimate reliably the increase in fish production ... from the habitat restoration actions .... There is also limited data available on the production of these species in natural habitats that could be used to estimate production in restored habitats."<FN 43>

Even if the original study had estimated total non-use values for habitat restoration held by survey respondents who had been given clear, quantitative information regarding the impact of restoration on various ecological services, EPA would face an impossible task in seeking to determine the share of that value that is attributable to specific ecological services. The original study on which EPA relied for its benefit transfer simply cannot be considered a sound basis for the transfer that EPA attempts. This alone is sufficient to judge that the method employed by EPA is unsuitable for inclusion in the economic analysis of the proposed rule. Yet, numerous additional flaws in the new analysis lend further support to this conclusion.

EPA Response

For EPA's response to the first issue addressed in the comment regarding the soundness of estimates for benefit transfer please see comment #316bEFR.307.061.

Second issue – EPA attempts to develop a non-use value estimate from the original study's estimate of total value; 81% of the population engage in recreational activities; even more probably drive by the wetlands and enjoy scenic views; EPA identifies "what it considers to be … non-users" and assumes their total value = nonuse value:

EPA is unaware of any direct uses for eelgrass other than fish and shellfish and possibly bird watching related uses for eelgrass. Eelgrass beds can be a detriment to recreational boating, as the grasses foul boats' rudders and propellers. They are not visible above the water, so they don't provide aesthetic values. While wetlands might provide other use values, such as aesthetic values, EPA was interested in the non-use values for fish production services of wetlands.

The Johnston et al. (2002) survey and results, upon which the value proportions are estimated, indicates that individuals do recognize and value the various services of wetlands (DCN 6-3151).

In the Peconic survey, eelgrass was explicitly described as "fish and shellfish habitat." Thus, it is appropriate to assume that respondents believed that restoring eelgrass would increase fish and shellfish populations in the Estuary. Although services of wetlands were not described in detail in the survey, participants in focus groups were aware that wetlands provide fish habitat. In focus groups for the Rhode Island wetlands survey, which was also used in the analysis, respondents also were aware of fish habitat services of wetlands. It seems reasonable to assume that residents of coastal states in general are aware of fish habitat as one of the services provided by coastal wetlands.

Whether one measures total WTP only (as in the Peconic study) or estimates component values for wetland services (as in Johnston et al.), the fact remains that wetlands in the Peconic and those in Narragansett Bay are quite similar. Narragansett Bay and Peconic salt-water wetlands actually represent a relatively close match for the purposes of benefits transfer. Indeed, real world benefit transfers rarely include study and target sites that are as closely related as Narragansett Bay and Peconic saltwater wetlands.

For EPA's response to comments regarding the connection between values for habitat and values for fish and shellfish, please see the response to comment #316bEFR307.061.

EPA notes that the habitat-based approach is not used in the cost-benefit analysis for the final section 316(b) rule. Instead, the Agency used this approach to provide useful information for policymakers to consider in determining the final 316(b) Phase II rule.

Peconic-based approach

The second criterion that must be met in any benefit transfer to ensure the validity of the resulting estimates is similarity between the original study and the analysis to which benefits are transferred. This includes similarity of the environmental improvement being valued in both cases, as well as similarity in the population that is presumed to value that improvement. Common concerns regarding a lack of similarity between the two cases include differences in: the magnitude of the environmental improvements, the demographics of the populations valuing the improvements, and the availability of substitutes for the resources being improved.<FN 44>

Such concerns pale in comparison, however, with the problems regarding similarity in EPA's analysis. EPA seeks to develop non-use values for reductions in the mortality rate of various aquatic organisms by transferring estimates of the total value placed on preserving or restoring habitats (eelgrass and wetlands). EPA's own Guidelines make clear that such differences in the resource being valued between the original study and the transfer study imply that a benefit transfer cannot be accomplished: "Assessing studies for applicability involves determining whether available studies are comparable to the policy case. Specifically: the basic commodities [environmental improvements being valued] must be essentially equivalent; the baseline and extent of the change should be similar; and the affected populations should be similar" [emphasis added].<FN 45> EPA's analysis fails to meet the first condition, described above, that must be met.

It may be the case, in theory, that the non-use value that society enjoys from the restoration of wetlands and eelgrass may be partly comprised of the non-use value of species that are benefited by that habitat. But in practice, given existing economic knowledge, it is impossible for EPA to develop a reliable estimate for the share of society's non-use value for wetlands and eelgrass restoration that is due to any resulting increase in fish production. Moreover, in the few steps that EPA took in attempting to accomplish this task, it failed to consider the most fundamental economic knowledge about non-use values and information presented in the studies on which it relied.

In its analysis, EPA seeks to compensate for the fact that not only are the resources being valued in the policy case and the original study dramatically dissimilar, but the type of value that EPA is trying to estimate, non-use value, is also different from that estimated in the original study, total value. One means of deriving non-use values from total values in the context of a stated preference method is examining the total values held by the subset of respondents that are not users of the resource being valued, and can therefore only hold non-use values. While this is the approach that EPA attempts, its application is fundamentally flawed. EPA "re-estimated the Peconic model with separate coefficients for users and non-users of fishery resources. The Agency defined users as those who stated that they either fish or shellfish, thus deriving indirect use values from the fish habitat services of eelgrass and wetlands. EPA estimated non-use values for those who do not fish or shellfish."<FN 46> This ignores clear evidence in the documentation of the original study that while 40 percent of the survey respondents may fish and 27 percent may shellfish, 81 percent engage in some recreational use of the Peconic Bay, and it is likely that even more engage in other activities, such as driving along the shore, that would lead to use values from increased wetlands.<FN 47> Consequently, the “non-use” values that EPA derives from its adjustment will not only include non-use values, but also non-fishing use values, which are likely to be substantial.

Having developed its flawed estimates of non-use value for wetland and eelgrass restoration, EPA seeks to determine what share of that value is attributable solely to the impact of that habitat on fish production, as opposed to other services and attributes. Some of the most significant conceptual flaws in EPA’s analysis are made apparent in this step. EPA’s assumption that society’s non-use values for eelgrass and wetlands are entirely due to the physical ecological services that those habitats provide is the most important assumption in EPA’s new method and its most problematic.

Economic research has shown that non-use values are often most significantly influenced by the unique and intrinsic characteristics of specific resources. For example, the non-use value of the bald eagle has little to do with how much or what type of ecosystem services it provides, but rather mostly arises from the fact that it is our country’s national symbol. In like manner, the authors of the original study on which EPA bases its analysis explained that one of the primary motivations for that study was to estimate “the value residents ... hold for the ... ‘sense of place’ [that the wetlands, eelgrass and other resources] provide.”<FN 48> Moreover, the contribution of those habitats to the “sense of place” in some communities may be significantly greater than in others. In other words, not only are there aspects of a resource beyond its ecological services that affect non-use value, but the importance of those intrinsic and unique characteristics of a resource may vary substantially among populations.

Ignoring this fundamental aspect of non-use value, EPA assumes that the non-use value that it has estimated for wetlands is entirely and equally attributable to four ecological services, including fish production. This would suggest that EPA believes that individuals hold no non-use value for the numerous other ecological services that wetlands provide, such as improving water quality by reducing the flow of nutrients and pollutants into nearby bodies of water.<FN 49> But this conclusion is not supported by the Johnston et al. (2002) study, on which EPA relies for its division of wetlands non-use value. That study examines the marginal increase in total benefits (i.e., use and non-use values) from increases in the ecological services of wetlands.<FN 50> It provides no insights into marginal increases in non-use value associated with improvements in particular ecological services, and it makes no attempt to estimate the share of total non-use value those ecological services together comprise, relative to other characteristics of the wetlands that would influence non-use value.

Footnotes

44 These considerations are set forth in both EPA’s Guidelines and in the U.S. Office of Management and Budget’s recently published “Draft Guidelines for the Conduct of Regulatory Analysis and the Format of Accounting Statements.” See EPA, 2000, pp. 85 - 87; and 68 Fed. Reg. 5,492 - 5,527.

45 EPA, 2000, pp. 86 - 87.

46 Tudor et al., 2003, p. 8.

47 In a footnote, EPA recognizes that there may be other users of the wetlands aside from those who fish and shellfish. But EPA claims that it adequately adjusts for this in a following step where EPA makes assumptions about the share of the non-use value of wetlands that is attributable to fish production, as opposed to other ecological services. This is wrong. The step to which EPA refers simply makes assumptions about what share of a fixed non-use value for wetlands should be attributed to various ecological services. It is incapable of correcting for errors in the definition of non-users, which would cause the estimate of total non-use value to be overstated, because that estimate includes individuals’ use values. See footnote 11 in Tudor et al., 2003, p. 8.

48 Opaluch et al., 1998, p. 5.

49 EPA also assumes that the entire non-use value of eelgrass is attributable to fish and eelgrass production, ignoring both the intrinsic value of that habitat and other ecological services, such as water quality benefits.

50 EPA explicitly recognizes this by stating, “Given the four habitat services considered in the [Johnston et al.] survey ... each service provides roughly 1/4 ... of the total marginal utility associated with the combination of habitat improvements and mosquito control [which together make up the four habitat services described above].” Tudor et al., 2003, p. 16.

EPA Response

The comment focuses on the similarity issues in EPA’s benefit transfer of non-use values.

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values at the national level for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document.

For EPA’s benefit transfer approach, please see EPA’s response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region.

See EPA’s comment #316bEFR303.020 regarding the definition of users vs. nonusers.
The Agency also points out that the fact that 81 % of survey respondents engage in some type of recreational use of the Peconic Bay underscores EPA’s point that by monetizing only recreational and commercial fishing benefits for the Section 316(b) regulation, the benefit analysis significantly underestimates the total benefit of the regulation. EPA was not able to monetize other benefit categories such as watching wildlife while scuba diving or walking on the beach. It is also important to note that this 81% of the household would likely to have relatively high non-use values due to familiarity with the resource.

As shown by empirical studies, the non-use values for users tend to be significantly higher compared to the non-use values held by non-users of these resources. (Whitehead and Blomquist, 1991; (DCN #4-2193)).

Regarding the allocation of wetlands values to different services, this comment is based on arbitrary assumptions unsupported by the focus groups that supported the Johnston et al. (2002) survey and results, upon which the value proportions are estimated (DCN #6-3151). The survey applied by Johnston et al. (2002) to assess values for wetland restoration was designed based on over 16 months of focus groups and interviews with wetland policymakers and over 100 Rhode Island residents. The purpose of this careful preparation was to ensure that the survey captured the full range of values relevant to wetland restoration in Rhode Island. Within the scale of wetland restoration options available, and also the scale of 316b policies, values related to issues such as “sense of place” and water quality impacts were either unimportant to focus group participants, or were judged as trivial impacts by wetlands scientists who were also interviewed. In sum, the Johnston et al. (2002) survey was designed to capture the full range of relevant values, based on a combination of interviews with wetlands scientists and experts, and focus groups with Rhode Island residents.

The final step in EPA's new analysis entails making a judgment regarding the population that may hold the per-household non-use value that EPA has attempted to estimate. Given that EPA has not conducted an original study to examine how non-use value for reductions in I&E may be affected by distance from the affected resource, it has no basis on which to make this judgment. Hence, the judgments are arbitrary, and yet they dramatically affect EPA's ultimate estimate of nonuse value.

EPA Response

The comment states that EPA has no basis to make a judgment of the affected population for its non-use benefit transfer. EPA disagrees. EPA believes that it has conservatively estimated the extent of the affected population in the study area based on households in counties abutting the affected water body, and households within 32.4 miles of the affected water body. The 32.4 mile figure was chosen based on results from the Rhode Island wetlands study. This study showed that Rhode Island residents who live in the most western parts of Rhode Island and as far as 32.4 miles from Narragansett Bay value wetland restoration in the Bay (see Chapter C6 the final Phase II Regional Studies Document, DCN #6-0003).

In the Peconic study, the survey was conducted only in the towns surrounding the Estuary, so it is impossible to determine from the survey results whether Long Island residents living at a distance from the Estuary would also value habitat improvements in the Estuary. However, evidence suggests that this is likely to be true. The Peconic study included a second survey of recreational users of the Estuary, which found that people traveled great distances to visit the Estuary and recreate there, indicating that these people would likely value the Estuary's habitats. They simply were not asked these questions, so the extent of the market for restoration and protection of the Peconic Estuary's services has not been conclusively determined.

In summary, EPA's new non-use value analysis offers estimates that are no more valid or reliable than those produced by the "avoided cost measures of benefits" that it replaced. It fails to meet both the soundness and similarity criteria that are essential for assessing the validity of benefit transfer methods and applications. Not only are there insurmountable differences between the resource valued in the original study on which EPA relied and the resource that it seeks to value, but in the process of attempting the transfer, EPA has ignored basic economic theory regarding non-use value, and has made adjustments to the original values that are unsupported by the studies on which it relies. Simply put, this new method cannot be considered a valid or reliable basis on which to evaluate the economic benefits from the alternative regulatory options.

EPA Response

The comment states that EPA's non-use valuation estimates are not valid or reliable. EPA disagrees. For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values in this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document.

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. Cooling system costs (e.g., dry, wet, recirculating)

Conclusions

The Notice of Data Availability for EPA's proposed 316(b) Phase II rule includes significant changes to, and information regarding, the economic analysis that it employed in supporting that proposed rule. The NODA presents new information regarding both the capital costs of retrofitting existing facilities with cooling towers and the outages that will be required while those retrofits are conducted. When combined with evidence from an analysis of the cost of installing cooling towers at Brayton Point Station, it suggests that more reliable estimates of capital costs may be more than 100 percent greater than those estimated by EPA. This information lends further support to criticisms of EPA's capital cost estimates and suggests that EPA has underestimated the total and incremental costs associated with the waterbody/capacity-based option by a substantial margin.

EPA has made revisions to its benefit analysis, addressing many of the flaws that I identified in my previous comments. But, due to its pursuit of a new non-use value analysis that is conceptually flawed and impossible to implement reliably, the overall analysis and the estimates it produces are no more reliable or valid than the “avoided cost measures of benefits” that the analysis replaced. As I stated in my prior comments, if EPA believes there are legitimate and significant non-use values, they should be estimated with original applications of the best stated-preference methods. The possible existence of excluded use values or non-use values does not justify the employment of conceptually flawed and empirically invalid approaches.

EPA Response

The comment states that EPA’s non-use value analysis is conceptually flawed and unreliable. EPA disagrees. For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values in connection with this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN #6-0002).

EPA has responded to concerns regarding the Agency’s non-use valuation methods in responses to a number of comments. For EPA’s benefit transfer approach, please see EPA’s response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA’s meta-analysis please see EPA’s responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA’s meta-analysis. For EPA’s response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

The comment also states that EPA should conduct a stated preference study of non-use values. EPA does not believe this is necessary. For a discussion of limits to EPA doing original stated preference work in support of the 316(b) regulation, please see comment #316bEFR.303.007.

Dr. Opaluch was the Principle Investigator for the Peconic Estuary System (PES) study relied upon by EPA, and both Dr. Opaluch and Dr. Grigalunas were major contributors to the PES study.

Overall, we believe that the results given in the Tudor et al. memorandum cannot be used to assess the potential economic benefits of alternative cooling water control technologies, for three principle reasons:

- First, the PES study results were intended to develop priorities for resource preservation and restoration programs, not absolute dollar values.

- Second, the information provided to respondents to the PES resource survey was inadequate to support a valuation of quantitative changes in fish and shellfish due to changes in eelgrass or wetland resources.

- Third, even if the dollar results of eelgrass and wetlands from the PES resource study could be relied upon, the transfer of these results from the PES sample studied to other populations, such as those in the North Atlantic Region, would likely overstate values because of the substantial difference in socioeconomic and demographic characteristics which exist between the two areas.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. Peconic-based approach

The PES Study was Intended to Develop Relative Priorities, Not Absolute Dollar Values

The Peconic Estuary System (PES) resource valuation study (Mazzotta, 1996; Opaluch et. al., 1999) primarily was an attempt to develop and apply a method -Contingent Choice -- to elicit relative resource preference priorities in order to contribute to setting natural resource preservation and restoration priorities in the PES. It was pursued as an alternative to the Contingent Valuation Method (CVM), which provides dollar estimates only, specifically because the authors were skeptical of dollar measures of value for natural amenities estimated using CVM, which have been the subject of much debate and controversy in the environmental economics profession (e.g. Hausman, 1993; Opaluch and Grigalunas, 1993; Grigalunas and Opaluch, 1993).

In our view, the PES resource value study results for eelgrass and tidal wetlands should be interpreted as providing relative resource preference rankings rather than absolute dollar values for the resources studied. A major reason for this conclusion is that the results reflect symbolic components, for example, with people wanting to "take action" to protect the environment in general, rather than selecting a particular resource program. Significantly, we found that the results are robust with respect to relative ranking, but not with respect to dollar values.

In fact, the information gathered in connection with the study indicated that the dollar values might not only be unreliable, but generally biased upwards. Important sources of symbolic values in dollar estimates were identified in another analysis of the PES data (Mazzotta et al, 1998). This further analysis found that people appeared to place value on the symbolic notion of "taking actions that protect the environment" beyond values associated with the specific level of resource protection that is provided by those actions. Although it may be feasible to correct for this particular source of symbolic effects, the dollar values likely suffer from other types of symbolic effects that cannot be measured with the available data. For example, during focus groups and debriefings for the PES study, some respondents indicated that they considered dollar payments only when they could not otherwise make a decision. Still others indicated that they selected the more expensive option, not because they preferred it but because it indicated a higher value for the environment. For these reasons, and others, we have expressed confidence in use of relative values of resources, not monetary values.

EPA Response

The comment states that the values estimated in the Peconic study used for EPA's benefit transfer of non-use values are not precise enough for EPA's benefit transfer. EPA disagrees. At issue here is what level of precision of value estimates is required for this particular policy analysis. The results of the Peconic survey have been used by the Peconic Estuary Program to evaluate options and plan for preservation and restoration actions in the Estuary, under the National Estuary Program, programs that require expenditure of scarce public funds and thus have significant opportunity costs for the public.

The Peconic model was designed to both measure dollar values and develop priorities; the dollar values estimated through the PES study have been published in the peer-reviewed literature. As clearly stated by Johnston et al. (Johnston, R.J., J.J. Opaluch, T.A. Grigalunas, and M.J. Mazzotta. 2001. Estimating Amenity Benefits of Coastal Farmland. Growth and Change 32(summer): 305-325. DCN #5-1276) on page 313: "Contingent choice questions were designed to measure respondents' values for changes in the natural resources of the Peconic Estuary system…." Nearly identical text is found in Johnston et al. (Johnston, R.J., T.A. Grigalunas, J.J. Opaluch, J. Diamantedes, and M. Mazzotta. 2002. Valuing Estuarine Resource Services Using Economic and Ecological Models: The Peconic Estuary System Study. Coastal Management 30(1): 47-66; DCN #5-1275).

The original Peconic study concludes that

the minimum conditions for economic rationality are met, with mixed results for the more rigorous tests. The estimated coefficients for all models have the correct sign and are statistically significant. Relative values and priorities are consistent across model specifications, and estimates of dollar values are not highly sensitive to specification. ….

Overall, there is no strong evidence that people are unable to make tradeoffs that express their priorities for resources. Open-ended comments and other qualitative evidence suggest that respondents were concerned about the issues, accepted the scenarios, and made an effort to provide thoughtful answers …

…[R]esponses provide robust estimates of people's priorities and relative values for the natural resources…. Although the dollar values may not be precise, they may be appropriately used to indicate the general magnitude of benefits of different programs as part of a decision-making process that considers a variety of factors, including economic benefits. (Mazzotta, 1996; DCN #5-1284)

The model used for benefit transfer is the model that was intended to correct for possible symbolic values (as described by Johnston et al., 2002), and hence provides the most conservative value estimates for an additional acre of wetlands and eelgrass. This model separates values for simply "taking action" from values for specific resources.

EPA recognizes that the Peconic study does not provide perfect estimates of dollar values. There is no study in existence that provides perfectly reliable dollar values for non-marketed goods. Every non-market valuation study contains some level of bias or uncertainty. However, the Agency believes that the values provided are useful for indicating the magnitude of benefits that would be provided by restoring fish habitat.

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including the benefit transfer referred to by this comment. EPA believes that the values provided, while not perfectly ideal, are adequately reliable for the context, and that they could be used in evaluating regulatory options.

EPA notes that the habitat-based approach is not used in the cost-benefit analysis for the final section 316(b) Phase II rule. Instead, the Agency used this approach to provide useful information for policymaking officials to consider in otherwise reviewing a final conclusion over the final 316(b) Phase II rule.

Peconic-based approach

The Information Available to Respondents in the PES Study was Insufficient to Support Valuation of Changes in Fish Production Due to Changes in Eelgrass or Tidal Wetland Resources

Serious problems arise from the use of the PES results for the estimated value of eelgrass and wetlands to "get at" the value of fisheries, which is what the EPA memorandum (Tudor, 2003) attempts to do. The questionnaire used in the PES study (Mazzotta, 1996; Opaluch et al., 1999) indicated only in very general terms that eelgrass is a habitat for finfish and shellfish. However, no quantitative information whatsoever was provided regarding the significance of eelgrass or wetlands as a habitat for fish and shellfish. Furthermore, no quantitative information was provided about how changes in eelgrass or tidal wetlands would affect the stock of fish. As a result, the survey respondents in the PES study relied upon by EPA would have had no way of knowing the quantitative link between eelgrass and wetlands and fish and shellfish.

In stated preference studies, a minimum condition is that the commodity must be well defined by the survey instrument. This means that the respondents must have available to them information about the commodity and its attributes that is sufficient to allow them to assign it a value. The "fish and shellfish" presumed to be "produced" by eelgrass and tidal wetlands were not quantified in the materials provided to respondents in the PES study. Nor would people generally be expected to have any significant independent knowledge of the effect of changes in eelgrass and wetlands acreage on fish production. In the absence of this information, it is not reasonable to treat the values given to the eelgrass and wetland resources themselves as reflective of the values that would be placed on the production of fish and shellfish.

EPA Response

The comment refers to EPA's benefit transfer of non-use values. For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values in connection with this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including the benefit transfer referred to here.

The comment states that it is not appropriate to use values for habitat to value fish and shellfish. Please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish.

Peconic-based approach

The Significant Differences Between the Population Surveyed in the Peconic Bay Area and Other Areas in the North Atlantic Region Further Undermine the Use of this Benefit Transfer

A third serious problem arises when EPA transfers the values estimated for Peconic Bay to other geographical locations in the North Atlantic Region, such as Mount Hope Bay, in Rhode Island. The use of Benefit Transfer (B-T) is common in economics, and is acceptable -- provided that certain conditions are met. Above, we pointed out that the use of wetlands and eelgrass to value additional fish and shellfish is not appropriate in this case since the PES survey respondents had no basis for determining how many fish and shellfish would be "produced" by adding a unit of habitat. Hence, B-T is not valid in this case. Even so, we comment here on another issue concerning the use of B-T in EPA's analysis.

An important consideration in B-T is that the areas involved – the study area and the area to which the estimates are transferred -- must be similar. However, it is clear that the respondents to the PES questionnaire would likely have quite different socioeconomic and demographic characteristics than those in other parts of the North Atlantic Region for which EPA calculates non-use values. (Tudor, et al., 2003) This can be seen by comparing the population in the Peconic Bay study with the populations around the Brayton Point facility in Mount Hope Bay, one of the areas within the Northeast Region (Tudor, et. al, 2003).

As illustrated in Table 1, the Peconic Bay and Mount Hope Bay may not be distant geographically, but the economic and demographic characteristics of the populations of interest are quite different. The PES survey was administered as an intercept survey to residents and second homeowners at various sites throughout the PES. The survey was administered during the peak summer season in August, 1995 and included residents and seasonal homeowners, and the latter tend to be quite wealthy and highly educated. In contrast, the general population around Brayton Point tends to have a lower household income and fewer residents have four-year college or advanced degrees. The PES survey respondents are much wealthier and much better educated than the population around the Brayton Point facility (Table 1). Income and education were found to be very important variables explaining respondent's preferences and willingness to pay for PES resource programs (Mazzotta, 1996; Opaluch, et al., 1999). Hence, even if the PES estimates of eelgrass were valid estimates for additional fish and shellfish, they could not be applied to the area around Brayton Point without a likely substantial downward adjustment.

The population around Brayton Point considered by EPA also has far more residents who do not speak English well than is true for the PES study respondents (Table 1). Indeed, non-English speaking individuals were not included in any focus groups for the PES study. Hence, there is no way of knowing the preferences and attitudes of non-English speaking residents of the PES. For this reason, Carson et al. (1994), for example, in their study of contamination in the southern California Bight dropped from the affected population all households that were not fluent in English on the basis that it would be inappropriate to include such individuals when no focus groups were done with non-

English speaking populations. EPA's failure to take into account this important difference further undermines the results of its B-T analysis.

Table 1. Comparison of Economic and Demographic Characteristics of PES Survey Respondents (Mazzotta, 1996) in PES Towns (Census Data) and in Counties in the Vicinity of Brayton Point Station (Census Data) Examined in the EPA Memo (Tudor, et. Al., 2003)

(See Table 1. On page 5)

Conclusion

For the foregoing reasons, we believe that EPA's use of the PES study is not a valid application of B-T, and that the values calculated in the Tudor et al. memorandum can not be considered to accurately identify the benefits associated with EPA's proposed cooling water intake technologies.

EPA Response

The comment refers to EPA's benefit transfer of non-use values. For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including the benefit transfer referred to here.

The comment states that the demographics of residents of the Peconic Estuary region are quite different from those of residents of the Mount Hope Bay region. EPA does not agree. In fact, residents of the Peconic region do not have quite different demographics from residents of the region around Mount Hope Bay. EPA has addressed the issue of demographics in its analysis, as follows: Corrections were made to WTP values to account for differences in demographics between survey respondents and the general population of the East End of Long Island. These adjustments were made by weighting the model coefficients, using weights that correct for the proportion of the population in each income and education group, according to the U.S. Census, versus the proportion of survey respondents in each group. Values for seasonal residents were similarly adjusted downwards, based on these weights and the proportion of the sample who are seasonal residents. Demographics of the affected population in the Brayton Point case study region (Bristol County, MA; Newport County, RI; and Bristol County, RI) are quite similar to those of the general population of the East End of Long Island.   The Brayton Point region has slightly lower education levels, and slightly higher income levels, on average, than the Peconic region. While values presented in the analysis were adjusted to the Peconic levels, they could be easily re-adjusted to reflect New England levels. However, based on the small differences in demographics between the regions, the effect is likely to be negligible. For information on demographics of the affected population in the original study region and the Brayton Point study region see DCN #6-2501.

The comment also suggests that non-English speaking residents be excluded from calculations of total non-use value. EPA does not agree that certain groups of people should be assigned zero value. EPA agrees that the PES study does not provide information on the preferences and attitudes of non-English speaking residents of the PES, because these individuals were not included in any focus groups. However, there is no empirical evidence to suggest that non-English-speaking people do not value fishery resources. Therefore, the Agency believes that completely excluding non-English speaking households from the analysis is inappropriate.

EPA notes that the benefit transfer method (habitat-based approach) is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. See also EPA's response to comments # 316bEFR.307.061 regarding using habitat values to estimate values for fish, and #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer.

Assumptions about I&E survival

Author Name Thomas Englert

Organization Lawler, Matusky & Skelly Engineers on behalf of PG&E National Energy Group

Environment Survival

EPA requested comment on whether it is appropriate to allow consideration of entrainment mortality and survival in benefit estimates. While I agree that it is correct to assume no survival of entrained organisms for the "baseline" condition, for the reasons discussed below, I believe that EPA should allow consideration of entrainment survival in a utility's demonstration of compliance with the entrainment performance standard.

The peer-reviewed report published by EPRI (2000) <FN 2> summarizes 36 studies from 21 power plants. The studies report that hardy species showed entrainment survivals greater than 50%, and that even some fragile species showed survivals of about 25%.

As early as 1979, when they presented their testimony in the Hudson River power plant case, consultants to EPA recognized the reality of through-plant survival and accounted for it in their calculations of plant impacts. This recognition was based on their extensive review of plant sampling programs and data and their personal observation of sampling while it was being conducted at the plants. For EPA to take the position that entrainment survival should now be ignored in power plant loss calculations is both unsupported and a step backward.

Footnotes

2 EPRI (Electric Power Research Institute) 2000. Review of entrainment survival studies; 1970-2000. Report No. 1000757. Palo Alto, California

EPA Response

In today's final rule, EPA has set requirements for reducing entrainment rather than reducing entrainment mortality. EPA chose this approach because EPA does not have sufficient data to establish performance standards based on entrainment survival for the technologies used as the basis for today's rule. If entrainment survival were to be incorporated into any determination of compliance with the performance standards, then the actual performance standard would need to be higher. Please see the response to comment 002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analyses. Please see the chapter, Entrainment Survival, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule.

Performance standards

Perhaps most important, ignoring the fact that many species and life stages survive entrainment can lead to incorrect evaluations of the effectiveness of cooling-water and intake technologies. For example, the impact of flow reductions achieved through closed-cycle cooling can be overestimated. This is because, under reduced flow conditions, including use of closed-cycle cooling, more entrained organisms are likely to die because they experience greater levels of thermal stress than would occur under once-through cooling. As a result, the potential benefits of flow reduction may be partially or even totally offset for some species by the increase in through-plant mortality. Similarly, retrofitting intakes with fine mesh screens, which causes many organisms that would otherwise be entrained to become impinged, could result in greater losses if survival on the fine mesh screens is less than would occur with through-plant passage.

For all of the preceding reasons, EPA needs to:

- Recognize that through-plant survival occurs

- Account for through-plant survival in its evaluation of technologies and determination of which cooling-water and intake systems are in fact the most effective in reducing organism losses at power plants.

EPA Response

EPA disagrees. Today's final rule sets performance standards for reducing entrainment rather than reducing entrainment mortality. EPA chose this approach because EPA does not have sufficient data to establish performance standards based on entrainment survival for the technologies used as the basis for today's rule. If entrainment survival were to be incorporated into any determination of compliance with the performance standards, then the actual performance standard that would need to be met would be higher.

Based on its review of all entrainment survival studies available to the Agency, EPA believes that its assumption of zero percent survival in the benefits assessment is justified. The studies reviewed are characterized by significant uncertainty and variability which complicates efforts to synthesize the various results in a manner that would provide useful generalizations of the results or application to other particular facilities for the benefits assessment. The primary issue with regard to these studies is whether the results can support a defensible estimate of survival substantially different from the value zero percent survival assumed by EPA. The review of the studies has shown that while some individual organisms may be alive in some of the discharge samples, the proportion of the organisms that are alive in the samples is highly variable and unpredictable. In addition, the studies contain various sources of potential bias which cause the estimated survival rates to be higher than the actual survival rates. For these reasons, EPA believes the current state of knowledge does not support reliable predictions of entrainment survival that would provide a defensible estimate for entrainment survival above zero.

EPA methods: age 1 equiv, yield, prod foregone

Production Foregone

In my letter of August 6, 2002 to EPA (containing initial comments to the Phase II Rulemaking for Existing Facilities), I summarized my review of EPA's application of the Production Foregone Model in the Brayton Point Station case study contained in the proposed Section 316 (b) Regulation for Existing Facilities. In that review I identified two major problems with EPA's production foregone calculation:

- Instead of using life-stage initial and final weights to compute initial biomass values and life stage growth rates, respectively (Rago, 1984 <FN 3> and Ricker, 1975 <FN 4>), EPA used mean weights of individuals at the midpoint of the life stage. (EPA used mean midpoint weights to compute initial life-stage biomass, and used the difference between mean midpoint weights of one life stage and the next stage to calculate growth rate of the earlier life stage.)

-For many species, EPA's mean midpoint weights of early life stages were much too heavy, sometimes thousands of times too heavy.

The combined effect of these two errors was that, for a number of key species, EPA grossly overestimated production foregone due to entrainment and impingement at Brayton Point Station. These same errors were then perpetuated in the EPA, Region I Determinations Document for Brayton Point Station's Draft Permit dated July 22, 2002.

Review of NODA Table X-7 and Appendix 1: Life History Parameter Values Used to Evaluate I&E in the North Atlantic Region reveals that, with the exception of some minor adjustments in egg weights, EPA has perpetuated the errors in its prior production foregone analyses and again produced gross overestimates of the actual losses. As in its calculations prior to issuing the NODA, EPA shows very high production foregone for bay anchovy, tautog, winter flounder, and weakfish. LMS analyses presented in my August 6, 2002 letter showed that EPA's errors caused overestimates of production foregone for these species by factors ranging from 53 to 1200. Even the EPA adjustments in egg weights seen in the NODA show glaring inconsistencies, reflecting the types of errors EPA has made in the estimation of weights for other early life stages. For example, in Table 1-51, the weight of an egg with a diameter of 1.0 mm is reported as 0.00000115 lb, <FN 5> whereas in Table 1-24 the weight of an egg identical size is listed as 0.0539 lb, a difference of more than three orders of magnitude. Although these weights are for different species, the similarity of the eggs' physical dimensions and densities means that their weights should be approximately the same.

EPA errors in larval weights are equally obvious and actually of more importance in the calculation of production forgone. In Table 1-51, weights listed for winter flounder larval stages at Brayton Point and Millstone are 10,000 times heavier than those listed for larval stages at the Pilgrim Power Plant (Table 1-52), in spite of the fact that egg weights listed for winter flounder for all three plants are the same. Additionally, the larval weights in Table 1-51 are 1,000 times greater than the egg values, even though on page 9 of its response to UWAG Questions Re; Phase II Proposal Record (Revised December 2, 2002), EPA indicates that larval weights should be only slightly larger than egg weights. These types of inconsistencies, coupled with the errors in formulation of production foregone, identify and explain EPA's gross overestimation of winter flounder and other species production forgone losses at Brayton Point Station.

It is disturbing indeed to see that EPA has apparently ignored most of the comments I and others have made on its production foregone calculations and perpetuated in the NODA the same errors previously identified in the Brayton Point case study and draft permit.

4 Ricker, W.E. 1975. Computation and Interpretation of Biological Statistics of Fish Populations. Bull. Fish. Res. Board can., 191. 382 pp.

5 The value in Table 1-51 is consistent with the weight of a sphere of 1.0 mm diameter and the same density as water; therefore, it is a good approximation of weight of an egg of that diameter.

EPA Response

Several commenters have raised questions about the EPA calculations of production foregone, primarily with regard to the values of stage-specific fish weights. These commenters have claimed that in some cases the weight parameters used by EPA may lead to overestimation of production foregone. Some commenters have also questioned inconsistencies between values used for the same species occurring in different regions, and apparent discontinuities in weights between early life stages. EPA's responses to these inter-related issues are addressed in the following sections.

Unrealistic Weight Parameters
EPA relied upon numerous published records, local experts, and other resources to develop weight estimates. Through the course of reviewing public comments on the initial case studies and later comments on the NODA, EPA has reviewed and revised many of the weight parameters to correct clerical errors and to improve upon certain biological interpretations. Following suggestions of commenters, EPA also revised some of its approximation methods, including the use of volumetric methods to improve estimates of egg weights.

Use of Mean Weights per Stage
Some commenter indicated that the mathematical definition used to calculate estimates of foregone production require weights that represent the beginning and the end of each life stage. EPA acknowledges that this is ideal. However, such data are seldom available. With few exceptions, facility impingement and entrainment records did not provide a comprehensive set of the relevant fish weights, so it was necessary for EPA to conduct an extensive literature search to obtain weights. The weights used by EPA in its analyses include a variety of types of values, some of which are unknown because in some cases the reference documents are not explicit about whether the values represent weights for the beginning, the end, or midpoints of particular stages. This issue is also complicated by the fact that some weights are determined indirectly through length-weight regression relationships. Length-at-age values found in different literature sources may also represent different parts of a lifestage.

Although such uncertainty is unfortunate, EPA believes that the practical effect on the benefits estimation is negligible. EPA disagrees with the characterizations put forth by some commenter that accuracy of these estimates are of vital importance to the benefits estimates. EPA notes that the benefits assessment does not put any direct valuation on the production foregone, per se. Production foregone estimates are used only in the context of the trophic transfer model, which is used only to generate estimates of incremental foregone yield attributable to losses of forage species. The portion of the total benefits associated with the trophic transfer pathway is quite small, usually less than five percent of the total within any particular region. Thus, even if inflated estimates of production foregone caused the trophic transfer model to overestimate foregone yield, the practical effect on the total benefits estimate would be very small.

EPA methods: age 1 equiv, yield, prod foregone

Trophic Transfer Efficiency

In the case studies to support the proposed regulation, EPA used a net trophic transfer efficiency of 2.5% to estimate the yield of harvested species lost as a result of entrainment and impingement losses forage species. In the NODA, EPA says that, based on "additional review of the scientific literature," it has modified the model so that the net trophic transfer efficiency is 20%.

This is clearly a dramatic change because it means that 8 times as much of the production foregone for forage species will now be translated into lost yield. The basis for this change is not well documented. EPA provides only one reference dealing with the trophic transfer issue, and that reference is based on studies prior to 1988. Thus it does not include recent work done with bioenergetics models that support a value of 10% (PSE&G, 1999) <FN 6> the value we used in converting forage losses into production foregone of harvestable species.

Furthermore, the approach in the NODA assumes that all the lost forage production would have been consumed by harvestable species. (EPA does not make clear how the lost production would be allocated among the harvestable species.) In contrast, in the February 2002 case study, EPA assumed correctly that a large portion of the production foregone is likely consumed by intermediate predators and then by harvestable species. The latest assumption by EPA in the NODA- that all forage biomass is consumed directly by harvestable species-clearly leads to an overestimate of losses of harvestable species.

The combined effect of the elimination of the intermediate predator pathway and the use of an inflated value for trophic transfer efficiency results in a considerable overestimate of the amount of fishery yield lost due to losses of forage species at power plants. This could lead to incorrect conclusions regarding the value of various intake technologies in reducing entrainment and impingement losses.

Footnotes

EPA Response

Several commenters have questioned the simple trophic transfer model that EPA used to estimate the foregone yield that could result from losses of forage species. The trophic transfer model used by EPA is highly generalized. However, EPA believes that the effort necessary to perform more detailed analyses of the wide variety of food webs affected by I&E is unwarranted because the effort required to do so would be very substantial, with added value disproportionate to the added costs of the assessment. For its final analysis, EPA has used a 10% net efficiency based on information in Pauly and Christensen (1995) (DCN# 6-1004). EPA notes that the practical value of developing further refinements of the trophic transfer model are unwarranted due to (a) the likelihood that any single model will be inadequate for all situations and (b) the relatively minor contribution to total benefits that this pathway adds.

Subject Matter Code 7.04

Streamlined Technology Option

The first streamlined technology option (i.e., cylindrical wedge wire screens in freshwater rivers and streams) may work, with some modifications, to meet the entrainment reduction standard, most importantly that the slot size is selected in accordance with the size of eggs and larvae to be protected at the site. In general, while existing research indicates that slot size of 0.5 to 1.0 mm may be protective in all cases; in some situations, it may be over-protective. In many cases, slot sizes of 1.5 mm and higher will afford the same level of protection as the narrower slot sizes. Given the direct relation between slot size and intake flow, wider slots will minimize unnecessary retrofit costs. We do note that screens configured as noted in EPA’s wording (including a slot width of 1.75 mm as assumed from EPA cost analyses) should virtually eliminate impingement of juvenile and adult fish. The uncertainty regards entrainment reduction may be reduced with additional research.

EPA Response

EPA agrees that the slot size of the wedgewire screen must be sufficiently protective to assure proper application of the preapproved technology. This is reflected in § 125.99(a)(1)(D), which states that “The slot size is appropriate for the size of eggs, larvae, and juveniles of all fish and shellfish to be protected at the site” is one of the conditions that constitute approved design and construction technologies for purposes of §125.94(a)(iv). As such, EPA had not specified a universal slot size, but rather left it to the discretion of the Director to select an appropriate slot size based upon the unique assemblage requiring protection from entrainment at a facility. Please refer to EPA’s responses to comments 316bEFR.017.003 and EPA's 316bEFR.063.005 for additional details of how the Director will determine compliance.

Comment ID 316bEFR.306.004

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Subject Matter Code 7.04

Streamlined Technology Option

The second streamlined option would establish the criteria and process for approving cooling water intake structure (CWIS) control technologies for complying with Phase II section 316(b) requirements. This option would allow the development of information demonstrating the effectiveness of other technologies to meet the impingement mortality and entrainment performance standards when operated under defined conditions. The second option differs from the first in that it calls for the systematic development of criteria for the approval of technologies to meet the §316(b) fish protection goals. If EPA adopts scientifically sound criteria for approving technologies and sufficient input is solicited from resource agencies, industry, and stakeholders, this approach could lead to the development of a functioning streamlined approach to implementing §316(b). Via this approach, EPA and industry could effectively collaborate to identify and improve on existing fish protection technologies. EPRI would also be pleased to participate in such a collaborative process.

EPA Response

EPA appreciates EPRI's support.

Use of Replacement Costs (HRC and hatchery-based)

EPA's apparent elimination of the Habitat Replacement Cost (HRC) approach for estimating the national economic benefits from the proposed rule is correct. As we noted in our comments on the proposed rule, costs are not a measure of benefits. The new regional benefits estimation approach used by EPA is also an improvement toward more accurately estimating national benefits of the proposed rule. As subsequently discussed, we continue to identify, however, conceptual errors in both the estimation of regional losses and in economically valuing those losses that result in significantly overestimating the benefits of the proposed rule.

EPA Response

This comment acknowledges that EPA does not use the HRC method in the cost benefit analysis for the NODA or the final Section 316(b) Phase II rule.

It also refers very generally to other perceived errors. The specific comments to these errors are included elsewhere in the author's comments and responses are provided for those comments.

Regional Benefits Approach

While EPA's revised biological, engineering, and economic analyses that support the proposed rule have been improved since proposal, they continue to have numerous conceptual flaws that result in grossly overestimating fish losses at CWIS and the potential economic benefits that may accrue from their protection. Drs. Lawrence Barnthouse (Appendix A) and Webb Van Winkle (Appendix D) both note the conceptual and parameter errors in estimating fish losses in the two case studies presented in the NODA. Most notably, the new EPA assumption concerning impingement age distributions is incorrect based on extensive monitoring data, and greatly overstates the benefits of reducing impingement. As both also note, EPA's failure to consider entrainment survival (see subsequent summary comments) and density-dependent processes also contributes to the inflation of the national benefits of the rule.

EPA Response

Regarding the age of impinged fish, please see EPA's response to Comment 316bEFR.029.105.

For EPA's conclusions about entrainment survival see Chapter A7 of the Phase II Case Study Document (DCN #6-0003) and response to Comment 316bEFR.306.506.

For a discussion of EPA's assumptions concerning density dependence see the response to Comment 316bEFR.025.015.

Comment ID 316bEFR.306.007

Subject Matter Code 10.02.04.01

Peconic-based approach

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Dr. Ivar Strand (Professor Emeritus, Fisheries Economics, University of Maryland – Appendix B), notes how EPA's revised economic analyses, most importantly the nonuse valuation approach, while notable for apparently abandoning the HRC approach remains technically flawed and greatly over-estimates likely benefits that could be attained. In particular, Dr Strand notes that EPA's estimates of non-use value in the North Atlantic region raise substantial concerns, the most prominent among them are:

- There is no research that addresses the non-use value inherent to fish and shellfish stocks affected by the proposed regulations. Does the non-use value change with decreases in numbers of fish and shellfish impinged and entrained? Or is it more akin to existence value, with a threshold effect? No one knows but EPA assumes that non-use value changes with decreases in numbers of fish and shellfish impinged and entrained;

- To obtain non-use values of changes in North Atlantic fish and shellfish stocks, EPA uses a willingness to pay per wetland or eelgrass acre contained in a study of eastern Long Island. In that study, the authors specifically state "we believe that the resource priorities or relative values of resources are more reliable than are the dollar estimates of values and recommend that relative values, rather than dollar values, be used in the process of selecting management actions" (p 5,Opaluch et al. 1998);

- In responding to the valuation questions about wetlands and eelgrass acreage changes in this study, the respondents had no information regarding the effect of wetlands and eelgrass acreage on fish and shellfish populations;

- The population on which the values are derived is quite affluent and resides nearby the resource in question. This is not representative of the North Atlantic population to whom the non-use values were extrapolated. This creates an upward bias in the aggregate of non-use values;

- In transforming the questionable value per acre of wetlands and eelgrass in the North Atlantic into a value per change in fish population, EPA goes through a process that relies on numerous assumptions and judgments. These result in a fundamentally arbitrary and excessively large non-use value.

EPA Response

The comment states that no research addresses the non-use value intrinsic to affected fish and shellfish stocks; and that non-use value may change with changes in fish populations, or may have a threshold effect. For the final 316b rule analysis, EPA, recognizing the uncertainties associated with the measurement of non-use values for this rule, has not included quantitative measures of nonuse values. However, the Agency has considered several measures that indicate the potential magnitude of non-use values, including a peer-reviewed meta-analysis of non-use values, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II

Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002). The agency would like to point out that the HRC method is a useful tool in the regulatory decision making process. The Agency, while not abandoning it, is no longer using it in the national cost-benefit analysis.

The rest of the comment deals with specifics of EPA's benefit transfer approach to estimating non-use values. For EPA's responses on these topics, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services.

RFC: Proposed use of restoration measures

EPA's provision for restoration as a mitigation approach is reflective of the state-of science that is increasingly demonstrating that aquatic community health and fish productivity is related to habitat quality and that aquatic habitat loss and alteration is one of the major factors responsible for fish population declines. More importantly, ecosystem research is finding that habitat loss and alteration may ultimately prove to be more deleterious to stock restoration efforts than over exploitation of adults. Increasingly, resource management agencies are adopting management strategies designed to protect and restore critical aquatic habitat. Peru's research on habitat restoration and other environmental enhancements supports EPA's proposal to allow habitat restoration as an approach to mitigate for impingement and entrainment (I&E) losses. EPRI recently completed a report that provides an assessment of the state-of science on restoration and habitat enhancement strategies for mitigating the impacts of I&E. This report is included in this comment package. The report concludes that restoration science is rapidly evolving, restoration projects are increasingly demonstrating success, and, most importantly, while projects can mitigate for I&E losses, they also provide long-term ancillary environmental benefits. Unlike with CWIS fish protection hardware where population benefits are highly uncertain, fish population and other environmental benefits will result from effectively designed environmental enhancement and restoration projects. EPRI has relatively minor comments relative to EPA's refinement of the requisite information to support restoration proposal.

EPA Response

For a discussion of restoration measures, see EPA's response to comment 316bEFR.074.007.

Cooling system costs (e.g., dry, wet, recirculating)

At the request of EPRI, Dr. John Maulbetsch reviewed the document prepared by Synapse Energy Economics, Inc. entitled "Comments on EPA's Proposed Clean Water Act Section 316(b) regulations for Cooling Water Intake Structures at Phase II Existing Facilities" dated August 7, 2002 (EPA Docket No. W-00-32). This document was prepared by Synapse for the Riverkeeper, Inc. and submitted in response to the EPA proposed Phase II rule. Details of Dr. Maulbetsch's review can found in Appendix C; however, his findings can be summarized in the following points:

-The costs of major cooling tower retrofit projects at existing, operating power generating facilities are fundamentally site specific in nature. In the absence of detailed studies at individual sites, it is impossible to make generalized statements about the costs of retrofit with any degree of precision. EPRI studies (EPRI 2002d – Cooling System Retrofit Cost Analysis Report) have demonstrated the high degree of variability in the costs resulting from site-specific factors.

-The outage times required for units to install recirculated cooling are not trivial, and certainly could have impact on grid reliability in the case of the All Cooling Tower Option.

-In typical retrofit circumstances, the cooling tower would have to be sized for the higher flow rates associated with once-through cooling. Redesign and conversion of the cooling system to accommodate the lower flows and smaller towers of a typical recirculating system would entail extensive revisions to the plant cooling system, more extensive outages, and an overall increase in capital cost over the unoptimized system.

-EPA estimates of retrofit costs are lower than the estimates prepared by engineering firms for nearly every one of 50 site-specific studies EPRI obtained, sometimes by a factor of more than 2x.

-Locating a cooling tower in an existing site is not always easy, possible, or cheap, and can include the need for long circulating water lines, additional land purchases, etc.

-EPA was prudent in its determination that wet cooling is not a reasonable alternative for retrofit to existing facilities. In addition, I would add that the retrofit of dry cooling to existing plants would be even more problematic, increases technical complexity, costs, and efficiency penalties, and most assuredly would require extended outages.

EPA Response

The Agency responded to the referenced document (as summarized by the Riverkeeper's comments) at response to comment 316b.EFR.404.058.

The Agency responds to the individual points made the commenter in this summary comment in responses 316b.EFR.306.401 through 316b.EFR.306.406.

Ecological Evaluation Methodology

EPA is inconsistent in the methods and rigor they use for scientific analysis and in dealing with uncertainties associated with those analyses. For entrainment survival, EPA set a standard of rigor that is unique from all the analyses it conducted for all other parts of the rule development. In this analysis, EPA sets a condition of certainty so high that it is virtually impossible to reach credible scientific conclusions concerning entrainment survival. EPA similarly completely ignores density dependent processes that we know with scientific certainty must exist (otherwise all populations would rapidly spiral out of control or become extinct). Both entrainment survival and density dependent responses significantly mitigate losses due to impingement and entrainment. Failure to consider them greatly inflates regional and national fish losses and the economic benefits associated with attainment of the proposed performance standards. While ignoring entrainment survival and density dependence, EPA uses a questionably appropriate single study on willingness to pay for habitat and makes a benefit transfer analysis based on that one study to estimate economic benefits for the protection of nonuse values for the entire North Atlantic Region. Inconsistent scientific standards for acceptance and rejection of scientific data are found throughout the rule documentation. As we have previously commented and as noted by Drs. Barnthouse, Van Winkle and Strand whose comments are appended, the inconsistencies are biased toward data that overly inflate fish losses, performance of technologies, and economic benefits. We recommend that EPA use a consistent set of scientific rigor with quantitative uncertainty analysis for all analyses conducted to support the proposed rule. The appendices offer some suggested improvements that could be made to more effectively deal with and
represent uncertainties.

EPA Response

The commenter argues that EPA has used "inconsistent scientific standards for acceptance and rejection of scientific data," but does not provide any examples. EPA disagrees with this characterization of its analyses. While it is true that EPA sometimes used different life history parameter values for the same species located in different regions, this was done at the recommendation of local fisheries experts to reflect regional differences and thereby improve region-specific estimates. See Chapter A7 of the Phase II Regional Report for a discussion of EPA's assumptions about entrainment survival and its response to Comment 316bEFR.025.015 for a discussion of density dependence. Please also see Chapter A6 of the Regional Analysis Document (DCN #6-0003) and EPA's response to Comment 316bEFR.041.843 regarding uncertainty in the context of its 316b analyses. Responses to Comment 316bEFR.338.046, 316bEFR.338.047, 316bEFR.206.047,and 316bEFR.307.061 discuss nonuse benefits.

Entrainment survival chapter

Author Name Doug Dixon & Kent Zammit

Organization EPRI

EPA's continued determination that CWIS entrainment survival is 0% (based on its additional analyses) is scientifically untenable. With 100% certainty, scientific study has documented that entrainment survival occurs and that for many species, survival can exceed 50%. Entrainment survival monitoring methods have significantly advanced since the early 1970s and results collected since the late 1970s are valid. In lieu of accepting or using fixed entrainment survival values in its analyses, EPA could employ uncertainty or sensitivity analyses that illustrate the range of reasonable regional and national fish losses and associated economic benefits based on entrainment survival ranges observed in the scientific literature.

EPA Response

Please see response to comment 316bEFR.305.001 with regard to entrainment-based performance standards. Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis. Please see the response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule.

In addition to the conceptual flaws noted above and discussed herein, it has been almost impossible to verify or check the implementation of the methodology EPA employed. We found it nearly impossible in the amount of time available to track or find supporting documents in the docket, and verify calculations of impingement and entrainment losses at the plant level by species, to waterbody type and regional impingement and entrainment losses. Basically, we could not reproduce the numbers presented by EPA, as for example, in tables X-6 through X-10.

EPA Response

EPA has made every effort to provide assistance to the public to access and understand data used to support today's final rule.

Benefit Estimation Methodology

Author Name Doug Dixon & Kent Zammit
Organization EPRI

EPRI requested a review by Drs. Lawrence Barnthouse and Webb Van Winkle of the comments submitted by Pisces, Inc. (August 2002) on behalf of the Riverkeeper, Inc. in response to the EPA proposed Phase II rule. They both found numerous conceptual errors in the analyses performed and comments made that would result, if employed by EPA, in further inflating fish losses and the economic benefits of their protection. Details from Drs. Barnthouse and Van Winkle review of the Pisces Report can be found in Appendices A and D, respectively.

EPA Response

This comment does not focus on EPA's analysis, but rather on public comments submitted on EPA's analysis. No response is required.

Performance standards

While we agree that high levels of fish protection can be attained for some species and life stages with many of the technologies reviewed by EPA, we continue to believe that EPA has not accurately expressed the impingement mortality and entrainment performance standards in terms that are comparable to the metrics by which performance has been historically assessed. The database of information from which EPA derives the proposed "standards" is a research database and not a database resulting from long-term compliance assessments. Field research was generally conducted under short-term optimal operational and environmental conditions. The data, therefore, does not represent long-term performance following routine operation & maintenance and exposure of the technology to the extremes of environmental conditions. Other site-specific issues, as subsequently noted, may also impair performance during certain time periods. We, therefore, recommend caution in adoption of "performance standard ranges" based on the research database. Unlike "end of pipe" technologies that are not subject to performance confounding environmental elements, "front of pipe" technologies are heavily influence by them. EPA may wish to alternatively consider performance "targets" as a fish protection objective, allowing the state resource agencies the flexibility of determining if those targets have been achieved.

Subject Matter Code 7.02

Performance standards

EPA's recognition that the proposed performance standards cannot apply to "all species and all life stages" is also notable. EPA requests comments on more practical measures including the "all species" and "representative indicator species (RIS)" approaches as well as whether they should apply to numbers or biomass of organisms. All of these approaches can be fundamentally correct depending upon site-specific issues and the technology or restoration approach pursued to mitigate fish losses. The RIS approach has a long established history of use in scientific investigations relative to 316(b) and other water quality issues. We do note that EPA should consider providing flexibility in identifying the number of inclusive species that are either of concern to the resource agencies and tribes and/or comprise the majority of species impact by CWIS operations. This is an alternative to an arbitrary selection of 10 to 15 species considered by EPA. The "all species" approach may be relevant when impingement and entrainment is overwhelmingly dominated by one or a few species. Numbers of organisms will generally be the metric for measurement; however, biomass could be the relevant metric when restoration is the compliance option that is pursued. Measuring biomass may also be efficient for assessing entrainment reduction, particularly when entrainment is dominated by only a few species. Measuring biomass avoids labor intensive microscopic taxonomy and counting. We do note that EPA may wish to consider providing the option to use equivalent adult analyses, particularly for evaluating entrainment reduction performance. Essentially, it may be more cost-effective to protect late stage but entrainable juveniles that are equivalent in number to eggs or early stage larvae. Overall, because of species, technology, operational, and resource management-specific issues, allowing for maximum flexibility in selection of species and metrics for analysis may be the most defensible scientific approach.

EPA Response

Performance standards

EPA's recognition that technologies cannot perform as a result of major episodic events that result in natural mortality of fish and their subsequent "collection" by CWIS is noted. Inclusion of language that reflects fish that are moribund and dead on-arrival and their exclusion when measuring technology performance is technically and practically the preferred approach. EPRI recommends that EPA also consider accommodating for seasonal and episodic debris events in the impingement and entrainment "targets" that may preclude a technology's ability to provide fish protection. Such events include corn shuck loading in the central U.S., leaf and woody debris loading, heavy suspended sediment loads including extreme bed-load transport, seaweed and jellyfish loading following ocean and estuarine storm events (and non-storm events), and other site- and water body-specific seasonal and episodic biological and physical phenomena. EPA may also wish to consider precluding the application of the standards to exotic (invasive) and other nuisance species whose ecosystem removal is a preferred aquatic resource management approach.

EPA Response

EPA believes today's final rule maintains sufficient flexibility to accommodate the situations presented by the commenter. In recognition of the difficulty in establishing a uniform means of measuring compliance with these standards, today's final rule defers to the Director to determine the most appropriate means by which compliance with the rule's requirements is to be measured.

RFC: Appropriateness of "significantly greater"

EPA's incorporation of the cost-benefit test as an alternative form of the site-specific assessment process (as EPRI has noted in previous comments) is supported by the scientific database of information. Nearly 30 years of national and international research on CWIS impacts and fish protection technologies has demonstrated that impacts and technology effectiveness to address impacts where they exist (as subsequently summarized) are a site-specific issue. EPA's draft 1976 guidance reflects this knowledge. The importance of site-specificity was further articulated during presentations at the recent EPA-sponsored symposium on cooling water intake structure technologies (May 6-7, 2003 in Arlington, VA). A structured site-specific approach, using, for example, EPA's own Ecological Risk Assessment process would allow for efficient determination of impacts and installation of effective fish protection technologies where application of technologies will result in net environmental benefits.

EPA Response

Supports the rule. No response necessary.

Overview of I & E effects on organisms

Finally, though we briefed EPA in our previous comments, we have completed our own analysis and have located other supporting information on water withdrawal impacts. We believe that the public record should clearly reflect this information because it relates to the environmental benefits that may (or may not) be derived from implementation of the proposed rule. Nearly 30 years of historical data and analyses by many public and private research organizations indicate that ‘adverse environmental impact’ (AEI), as defined at the population level and attributable to CWIS is extremely limited or nonexistent. EPRI’s recently completed analyses (preliminary results were submitted to EPA in August 2002) indicate that water withdrawal impacts are insignificant relative to other environmental factors and that there is virtually no direct relationship between water withdrawal and fish population and ecosystem health. As we have previously reported, biannual EPA reports to the U.S. Congress on the state of the nation’s water quality conditions, based on information provided by the States, have never identified CWIS impacts as a water quality or resource impairment of concern. The State of Maryland has the most comprehensive power plant research program in the U.S. and they have concluded relative to CWIS impacts "…that while operations of individual power plants impact various ecosystem elements in various ways, those impacts, taken together, have had no identifiable substantive cumulative impact on Maryland's aquatic resources to date" (M-PPRP 1999 and Richkus and McLean 2000 in Dixon et al. 2000). Long-term analyses of fish populations in the Hudson River and Delaware Bay have similarly failed to detect an impact associated with long-term operation of CWIS. More recently, the Texas Commission on Environmental Quality has reported (TCEQ 2003) that examination of 30 years of CWIS data in the Houston Ship Channel found either an upward trend or no statistically significant change in total abundance, species richness, and diversity for over 100 taxonomic fish groups examined. Only one species of fish demonstrated a downward trend. Finally, the Hudson Riverkeeper organization frequently states “…CWIS have contributed to the decline of recreational and commercial fisheries” – no refereed scientific documentation is provided to support such a conclusion and EPRI is not aware of any such evidence. This extensive data base suggests that aquatic community and population health is not measurably affected by CWIS operations and that implementation of fish protection technologies, except for restoration approaches, to achieve the EPA required performance standards may not have measurable benefits that will accrue at multiple ecological scales including population, community, or ecosystem levels.

EPA Response

Please see response to comment 316bEFR.025.018 for the discussion on the environmental impacts associated with cooling water intake structures. The reports identified by the commenter, which are submitted by States under section 305(b) of the Clean Water Act, tend to focus on water quality problems associated with the presence of pollutants. Indeed, this is to be expected in view of the reference in section 305(b)(1)(A) to the water quality criteria guidance published by EPA under section 304 of the Clean Water Act concerning the presence of pollutants and the reference to pollutants throughout section 305(b). Moreover, section 305(b) does not require States to identify the source or cause of the water quality concern. Therefore, the fact that cooling water intake structures are not identified in these section 305(b) reports is not a basis for declining to regulate them.

Overview of I & E effects on organisms

Water Withdrawal Impact Information

EPRI funded the Oak Ridge National Laboratory to investigate the relationship between water withdrawal (e.g., cooling, irrigation, public supply, hydropower), including cumulative impacts, and the health of fish populations and communities in the water body from which it is withdrawn. Preliminary results were presented in our comments on the EPA proposed draft rule (August 2002). This effort is now complete and the final report (EPRI 2003a) is included in this comment package. Results of the analyses support the non-flow reduction alternative and further demonstrate the site-specificity of impacts.

The study tested the hypothesis of a dose-response model relating volume of water withdrawn (as the “dose”) to the status of fish populations (the “response”). A corollary question is whether there is some lower threshold of water intake volume in relation to water body volume below which the numbers of fish involved are inconsequential for survival of fish populations (consistent with a threshold dose-response model). We analyzed many types of withdrawals from water storage reservoirs as well as CWIS in order to have a wider range of withdrawal volumes for identifying a possible dose response pattern (note: the aquatic environment does not discern between withdrawal use patterns).

The ORNL project team approached the analyses in six parts: (1) provision of background information on CWIS and discussions of a dose-response model approach, a hierarchical framework to view potential biological impacts, and the definition of adverse environmental impacts; (2) characterization of the withdrawal of surface waters throughout the United States from perspectives of geographic distribution and use type; (3) original data analyses to determine if there is a relationship between the amount of water withdrawn from reservoir systems (via normal reservoir discharge and/or CWIS withdrawal) and various measures of a fish population or community health; (4) analysis of the potential impacts of low-volume water withdrawal; (5) summarization of previous studies that provide insight into the relationship between intake volume and population level effects; and (6) summarization of the importance of other factors that contribute to the risk of environmental impact of CWIS, such as location of intake, temporal effects, species characteristics, water body type, and cumulative effects of other sources of mortality.

The analyses and reviews did not find a dose-response relationship between volume of water withdrawn and status of fish populations. Evidence from multiple sources does not support that the dose-response model is anything other than a horizontal line, with a slope of zero (no response), and high variability. Additional findings include the following:

- Except for some specific regions (power plants on the Great Lakes and Northeast U.S.), no national relationship was found between the numbers of organisms entrained and the volume of water withdrawn. Even when a relationship was found, correlations were very weak. High variability was common in all analyses
performed.

- A summary of Russian reservoir research indicated that the ecological zone from which water is withdrawn was the major factor in determining species and numbers of fish entrained.

- Analysis of Texas and Tennessee Valley Authority reservoirs showed no consistent relationship between intake rate and fish population response at reservoir withdrawal rates of 1 to 5,200 MGD.

- The proportion of the source water that is withdrawn in a given length of time appears to affect fish populations more directly than the absolute volume withdrawn.

- Where long time series of data on the factors affecting fish productivity, along with data on fish population dynamics, are available, e.g., the 20-year National Reservoir Research Program, volumetric flow relationships have not ranked high for determining fish productivity. Other factors are more influential in determining effects on fish communities and populations, such as total dissolved solids, reservoir morphology, weather anomalies, the ecological zone from which water is withdrawn, seasonal reservoir drawdown, seasonal timing of water withdrawals, and life strategies of affected species.

- Cooling ponds and reservoirs with high water turnover rates often have highly productive fish populations.

Site-specific analyses, undertaken with knowledge of the potential effects of water withdrawal, remain essential for predicting or monitoring fish population effects of water intakes. Site-specific details of the environment and specific fish populations appear to predominate over a simple dose-response model in determining whether populations are affected by specific water withdrawal rates.

Overview of I & E effects on organisms

In addition to the information contained in the EPRI study, the Texas Commission on Environmental Quality (TCEQ) recently completed and reported on the results of a 30- year (1972-2001) study that evaluated the nekton collected from the cooling water intake traveling screens at two facilities located on the Houston Ship Channel (HSC) (TCEQ 2003). The objectives of this report were to (1) evaluate nekton community structure in the HSC, and identify the most common and abundant species; (2) evaluate potential long-term trends with the nekton community and with individual species; (3) evaluate the relationship between the nekton and abiotic factors; and (4) determine the degree of impact cooling water intake systems have on nekton populations. The two facilities examined included Houston Lighting and Power Deepwater Plant (HL&P) and the downstream Oxyvinyls-Houston Operations (Oxyvinyls). Key findings included the following:

- Species richness, diversity, and CPUE for most species were higher at Oxyvinyls compared to HL&P indicating better overall conditions for nekton closer to the open bay.

- At HL&P, statistical analysis revealed an upward trend in total abundance (CPUE), species richness, and diversity over the 30 years. This upward trend in abundance included brown shrimp, white shrimp, and blue crabs (some of the most frequently impinged species at the plant). No species at HL&P demonstrated a statistically significant decline over the 30 years.

- At Oxyvinyls, an upward trend was observed with diversity, while species richness and total abundance (CPUE) showed no statistically significant changes over the 30 years. Abundance of bay anchovy, brown shrimp and blue crab (also some of the most frequently impinged species at this plant) demonstrated an upward trend, while black drum demonstrated a downward trend.

- Biomass collection estimates for the two facilities for white shrimp, brown shrimp, blue crab, and four commercial fish species were estimated to be less than one percent of the average commercial/recreational landings in the Galveston Bay system. The annual biomass estimate for Atlantic croaker collected at Oxyvinyls, however, caused concern. The degree of impact to the total bay population, however, is difficult to assess due to unknown standing crops.

- The upward trends in abundance of aquatic organisms at both stations are presumably due to major improvements in dissolved oxygen levels in the HSC.

Results of these analyses are consistent with the long-term findings of estuarine CWIS impact assessment in the Chesapeake Bay (Richkus and McLean 2000; McLean et al. 2003), Hudson River (Barnthouse 2000), Connecticut River (EPRI 2001 Connecticut River Ecological Study Re-Visited) and Delaware Bay (Barnthouse et al. 2003). Furthermore, much as occurred in the Hudson River where a ten-fold increase in striped bass stocks occurred following a fishing moratorium, the increase in abundance of most species in the HSC indicates that CWIS operation does not retard aquatic community recovery when other major stresses are reduced or eliminated, and, therefore, the CWIS operations alone do not cause significant impacts.

EPA Response

Please see the response to comment 316bEFR.025.018 for the discussion regarding the environmental impacts associated with cooling water intake structures. EPA agrees with this commenter that many environmental and anthropogenic factors work concurrently on the environment. It is difficult to separate out the effects of any one factor in particular on fish populations.

RFC: Proposed use of restoration measures

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Restoration/Enhancement as a I&E Mitigation Approach

Research is increasingly demonstrating that aquatic community health and fish productivity is related to habitat quality and that aquatic habitat loss and alteration is one of the major factors responsible for fish population declines. As Langton et al. (1996) note, habitat loss and alteration may ultimately prove to be more deleterious to stock restoration efforts than over exploitation of adults. Increasingly, resource management agencies are adopting management strategies designed to protect and restore critical aquatic habitat (Langton et al. 1996; Minns 1997; Fluharty 2000; Saunders et al. 2002). Based on our reviews, EPRI believes that the existing and rapidly growing body of scientific evidence strongly supports EPA’s proposal to allow restoration as an approach to mitigate for I&E losses.

RFC: Proposed use of restoration measures

EPRI has initiated research on the state-of-science and feasibility of using restoration or environmental enhancement as an approach for mitigating CWIS impacts. Research is being performed for EPRI by Argonne National Laboratory. We have now completed our final report Enhancement Strategies for Mitigating Potential Operational Impacts of Cooling Water Intake Structures (EPRI 2003b) and copies have been electronically filed to the Public Docket. This report describes environmental enhancement or restoration approaches that may be applicable for mitigating impingement and entrainment impacts associated with CWISs. These approaches are described with respect to their underlying objectives, implementation and operational requirements, costs, current use by government and the private sector, and advantages and limitations for potentially mitigating CWIS operational impacts.

Environmental enhancement and trading strategies were evaluated against a variety of technical, ecological, regulatory, and operational parameters, including technological status, potential relationship to CWIS impacts, and the current level-of-use and state-of the- science. A variety of sources were used to collect information for evaluation in this report, including scientific journals; technical publications; conference and workshop proceedings; government, non-governmental organizations (NGO), and private sector publications and websites; and personal communications with technical and regulatory experts. The project team did not comparatively evaluate the various enhancement and trading approaches, but rather addressed each on its own merits.

Enhancement approaches fell into two general categories: 1) those that directly address fish numbers; and 2) those that address habitat. Stocking addresses fish numbers, and may mitigate CWIS impacts by replacing fish directly affected by impingement or entrainment. Habitat enhancement approaches may mitigate impacts by providing more or better quality habitat to support fish reproduction, growth and survival. These approaches include restoration of fish passage, creation or restoration of wetlands and submerged aquatic vegetation beds, creation of artificial habitats such as reefs, and improving water quality parameters that limit community and ecosystem productivity. These enhancement approaches are widely used by a variety of government agencies and NGOs to successfully manage, restore, and/or protect fisheries resources in marine and freshwater environments. Trading approaches could include: 1) fish-for-fish trading that allows a cooling water user that provides greater CWIS impact reductions than required by its permit to trade those excess reductions to a second cooling water user; and 2) pollutants-for-fish trading that allows a cooling water user to have relaxed CWIS impact limits in its permit in exchange for reducing the load of key pollutants. Each enhancement and trading approach has its own set of design, implementation, operation, and cost requirements and constraints, as well as unique regulatory implications. These factors are discussed in detail in the EPRI report.

Overview of I & E effects on organisms

Comments on Riverkeeper's Presentations at the EPA CWIS Technology Conference: May 6-7, 2003, Arlington, VA

EPRI submits the following comments on the presentation by Reed Super, Riverkeeper, Inc. at EPA Cooling Water Intake Symposium, May 6-7, 2003, entitled "An Overview of Flow Reduction Technologies" and 'Retrofit of Closed-Cycle Cooling Towers"

While these presentations do highlight the fact that entrainment, and to a much lesser extent, impingement can often be reduced by flow reduction, several of the points made in the presentations (and likely in the papers to be submitted) were over-simplification or overstatement of the potential for reduced impacts and in some cases miss-represented scientific information. Specific comments are:

- Drastic reductions in I&E (~95%) – This statement makes the assumption that impingement and entrainment mortality are directly proportional to flow, which is incorrect. EPRI has submitted to EPA a report that examined the potential correlation of impingement to velocity. The extensive analysis of all available data sets showed a very poor correlation. It would therefore be incorrect to assume that a 95% reduction in flow would result in a 95% reduction in impingement. A second EPRI study (EPRI 2003a) found that, except for some specific regions (power plants on the Great Lakes and Northeast U.S.), no national relationship was found between the numbers of organisms entrained and the volume of water withdrawn. Even where relationships were identified, those relationships were generally weak (low R2) and often driven by a few outliers which that when deleted negated any relationships found. High variability was common in all analyses performed. In addition, this statement does not take into account the entrainment and impingement survival that has been documented at many stations and by EPRI. Flow reductions can also impact entrainment mortality. Mortality can be increased with reduced flows if the peak temperature rises. In addition, flow reduction through the use of recirculated cooling would result in 100% mortality of the entrained organisms (although the number entrained would be significantly lower). Rough estimates show that if you have an entrainment survival of 50-70% (common for many species) and salinity that requires 1-3 cycles of concentration, total entrainment mortality between once-through and recirculated cooling would be essentially equal.

EPA Response

Please see response to Comment 316bEFR.041.037 regarding the assumption made for EPA's analysis that I&E is proportional to flow.

Please see Chapter A7 of the Regional Analysis Document (DNC #)and response to Comment 316bEFR.306.506 for a discussion of EPA's conclusions regarding entrainment survival.

Overview of I & E effects on organisms

Comments on Riverkeeper's Presentations at the EPA CWIS Technology Conference: May 6-7, 2003, Arlington, VA

EPRI submits the following comments on the presentation by Reed Super, Riverkeeper, Inc. at EPA Cooling Water Intake Symposium, May 6-7, 2003, entitled "An Overview of Flow Reduction Technologies" and 'Retrofit of Closed-Cycle Cooling Towers"

While these presentations do highlight the fact that entrainment, and to a much lesser extent, impingement can often be reduced by flow reduction, several of the points made in the presentations (and likely in the papers to be submitted) were over-simplification or overstatement of the potential for reduced impacts and in some cases miss-represented scientific information. Specific comments are:

- Reduction of flow would allow the source to be switched to municipal water supply or effluent – EPRI assumes that this statement would apply in cases where a once-through system is retrofitted with a recirculated wet system. In such a case, it may be technically possible to switch to municipal water, but it may not be feasible, practical or environmentally beneficial. For example, the municipality that would serve the plant may not have capacity in their distribution system to meet this increased demand. Such a demand may further tax a subsurface aquifer at a time when population growth, water quality degradation and drought are over-taxing such sources. And finally, if that municipality withdraws water from the same surface source, the reduction in withdrawal is negated, and any impacts would be simply shifted to a different intake. Of course, if they switch to reclaimed water, the withdrawal impact would be zero.

EPA Response

This comment does not address the Phase II rule, but rather a presentation by an organization other than EPA. Nevertheless, the comment does generally acknowledge that entrainment and impingement can be reduced through flow reduction, a concept that is incorporated into parts of the final rule. Although EPA does not necessarily agree with all of the commenter's points addressing the potential use of effluent or public water system water for cooling, in developing the rule EPA has considered these possibilities (see, 67 FR 17129; April 9, 2002) and the final rule includes certain provisions that clarify such use. (See, 40 CFR 125.91(c) and (d)).

Comments on Riverkeeper's Presentations at the EPA CWIS Technology Conference: May 6-7, 2003, Arlington, VA

EPRI submits the following comments on the presentation by Reed Super, Riverkeeper, Inc. at EPA Cooling Water Intake Symposium, May 6-7, 2003, entitled "An Overview of Flow Reduction Technologies" and 'Retrofit of Closed-Cycle Cooling Towers"

While these presentations do highlight the fact that entrainment, and to a much lesser extent, impingement can often be reduced by flow reduction, several of the points made in the presentations (and likely in the papers to be submitted) were over-simplification or overstatement of the potential for reduced impacts and in some cases miss-represented scientific information. Specific comments are:

- Repowering (add combustion turbine) (33%) – While EPRI does not believe that repowering can be considered a CWIS technology, we do believe that repowering can provide benefits in fish protection. Most repowering projects derive about 2/3 of the capacity from the combustion turbines and approximately 1/3 from the heat recovery steam generator/steam cycle. The latter cycle would still require cooling water, and in the case of using once-through cooling, could theoretically offer a 66% savings in cooling water use under the same operating conditions. However, the station could also be repowered to deliver approximately three times the original capacity if the original water flows are retained. All of the environmental benefits and impacts have to be considered in such a decision. For example, a station could be repowered with no net increase in capacity. In such a case, the station could potentially reduce cooling water flow by 66%. But data may show that overall aquatic impacts would be lower by maintaining a higher flow rate (could still be lower than original design) that enhances entrainment survival and minimizes impacts of the thermal plume by reducing the discharge temperatures.

EPA Response

This comment does not address the Phase II rule, but rather a presentation by an organization other than EPA. Nevertheless, the comment does generally acknowledge that entrainment and impingement can be reduced through flow reduction, a concept that is incorporated into parts of the final rule. Although EPA does not necessarily agree with all of the commenter's point addressing repowering, EPA recognizes that repowering using combined-cycle processes may offer the opportunity for some facilities to either lower their cooling water needs or increase their power output while maintaining their existing cooling water flow. However, existing facilities that repower can just as easily use such technology to increase both their output and cooling water flow.

Overview of I & E effects on organisms

Comments on Riverkeeper's Presentations at the EPA CWIS Technology Conference: May 6-7, 2003, Arlington, VA

EPRI submits the following comments on the presentation by Reed Super, Riverkeeper, Inc. at EPA Cooling Water Intake Symposium, May 6-7, 2003, entitled "An Overview of Flow Reduction Technologies" and 'Retrofit of Closed-Cycle Cooling Towers"

While these presentations do highlight the fact that entrainment, and to a much lesser extent, impingement can often be reduced by flow reduction, several of the points made in the presentations (and likely in the papers to be submitted) were over-simplification or overstatement of the potential for reduced impacts and in some cases miss-represented scientific information. Specific comments are:

- Flow/Impingement Relationships – It is possible to plot a curve through any available dataset (including randomly generated numbers) and derive a mathematical expression, but the equation for that curve cannot be used to predict further data points without some indication of the accuracy of the curve-fit. There is no indication of the R2 value for any of the equations presented, and until that is demonstrated, and the developer can show the data set was large enough to provide an accurate prediction, and can demonstrate the sensitivity of the predictions to factors such as water type, species entrained or impinged, size relationships, etc., these formulas cannot be considered as accurate predictive tools. Extensive EPRI work on this subject has failed to identify a close correlation between E/I and any other factor recorded in the performance of available studies. These formulas would also imply that E/I is uniform throughout the flow withdrawal, with no correlation to events commonly documented (increased entrainment counts during spawning seasons, impingement events related to natural causes, etc.) EPRI has also demonstrated that the flow of water out of a system does not correlate to an impact to that system and it's populations, even in the case of quantified entrainment and impingement losses (EPRI 2001, 2003a).

EPA Response

Please see response to comment 316bEFR.041.037 regarding the assumption used for EPA's analysis that impingement and entrainment are proportional to flow. Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define adverse environmental impact in today's final rule.

Comments on Riverkeeper's Presentations at the EPA CWIS Technology Conference: May 6-7, 2003, Arlington, VA

EPRI submits the following comments on the presentation by Reed Super, Riverkeeper, Inc. at EPA Cooling Water Intake Symposium, May 6-7, 2003, entitled "An Overview of Flow Reduction Technologies" and 'Retrofit of Closed-Cycle Cooling Towers"

While these presentations do highlight the fact that entrainment, and to a much lesser extent, impingement can often be reduced by flow reduction, several of the points made in the presentations (and likely in the papers to be submitted) were over-simplification or overstatement of the potential for reduced impacts and in some cases miss-represented scientific information. Specific comments are:

- Cooling Systems, Flow and E+I – This chart oversimplifies the impact reduction achievable by ignoring entrainment and impingement survival and assuming impingement and entrainment reductions are directly correlated to flow. This graph does demonstrate that if wet towers are considered for a particular site, the huge cost of going further to dry or wet/dry cooling does not result in significant additional reduction in impingement or entrainment.

EPA Response

Please see EPA's response to Comment 316bEFR.041.037 regarding the assumption used for EPA's analysis that I&E are proportional to flow.

EPA notes that cooling towers are not required by today's final rule.

Cooling system costs (e.g., dry, wet, recirculating)

Comments on Riverkeeper's Presentations at the EPA CWIS Technology Conference: May 6-7, 2003, Arlington, VA

EPRI submits the following comments on the presentation by Reed Super, Riverkeeper, Inc. at EPA Cooling Water Intake Symposium, May 6-7, 2003, entitled "An Overview of Flow Reduction Technologies" and 'Retrofit of Closed-Cycle Cooling Towers"

While these presentations do highlight the fact that entrainment, and to a much lesser extent, impingement can often be reduced by flow reduction, several of the points made in the presentations (and likely in the papers to be submitted) were over-simplification or overstatement of the potential for reduced impacts and in some cases miss-represented scientific information. Specific comments are:

- Flow Reduction at Replacement Plant (Morro Bay) – While Riverkeeper's characterization of these data would lead one to believe that the incremental cost for adopting dry cooling is low, the fact remains that the estimates for Morro Bay show a $52M differential in capital cost and a 1.5% energy penalty. The slide also gives the impression that this is somehow the cost differential for a 1000MW gas-fired plant with a 1954 vintage heat rate. It was, of course, for a 1,200MW combined cycle plant, of which only 400 MW was generated with steam with cooling water requirements. In today's competitive power pool, the addition of $52M in capital costs is significant enough to potentially eliminate the profitability of many of these projects. As an example, many of the recent CA power projects have been delayed or cancelled due to the current power market conditions, with many of those facilities not having the additional expense of dry cooling mandates. Duke Energy stated publicly on more than one occasion that a requirement to install ACCs at Morro Bay would cause them to have to abandon the project. The quoted energy penalty of 1.5% also appears to be low, and may refer only to the increased backpressure on the steam turbine or the parasitic load of pumps and fans, but does not appear to include both. Morro Bay is also located in a very moderate climate, where temperatures are normally low due to the effects of the Pacific Ocean and meteorological conditions. These moderate temperatures greatly reduce the expected heat rate penalties from dry cooling, and cannot be translated to the typical conditions expected throughout most of the country, where penalties could be much greater during seasons when temperatures are higher.

EPA Response

The Agency agrees with the commenter's counter arguments regarding Riverkeeper's technology conference discussion of the Morro Bay replacement plant. The Agency reiterates the point made by the commenter about the energy penalty estimates of dry cooling being potentially much higher than 1.5 percent, as stated by Riverkeeper. The Agency refers to the energy penalty study it conducted for the New Facility 316(b) rule (as outlined in the EPA-821-R-01-036), which found that energy penalties for new facility dry cooling plants can significantly exceed 1.5 percent. The Agency also references the independent energy penalty study conducted by the Department of Energy on cooling tower retrofit projects, as presented in comments 316b.EFR.010.101 through 316b.EFR.010.103. The

Agency responds to the comments from the Riverkeeper relating to the 316(b) proposal, NODA, and technology conference in other comment responses.

Impacts of CWIS at ecosystem level (popn. vs. indiv.)

Comments on Riverkeeper's Presentations at the EPA CWIS Technology Conference: May 6-7, 2003, Arlington, VA

EPRI submits the following comments on the presentation by Reed Super, Riverkeeper, Inc. at EPA Cooling Water Intake Symposium, May 6-7, 2003, entitled "An Overview of Flow Reduction Technologies" and 'Retrofit of Closed-Cycle Cooling Towers"

While these presentations do highlight the fact that entrainment, and to a much lesser extent, impingement can often be reduced by flow reduction, several of the points made in the presentations (and likely in the papers to be submitted) were over-simplification or overstatement of the potential for reduced impacts and in some cases miss-represented scientific information. Specific comments are:

- Decline in winter flounder associated with operation of Brayton Point – A graph was presented that implied an association between start-up operation of the Brayton Point Power Station and a tremendous decline in abundance of winter flounder in Mount Hope Bay from which cooling water is derived. Mount Hope Bay has experienced an 87% decline during the mid to late 1980's in winter flounder. However, this same decline also occurred in nearby Narragansett Bay, which is not affected by Station operations. In fact, the winter flounder decline is a coast wide phenomenon generally believed to be due to over exploitation that began about the same time Brayton Point operations were initiated. Changes in North Atlantic climatic factors are also believed to have contributed to the coast wide decline.

EPA Response

EPA agrees that many factors can effect populations concurrently. It is difficult to separate the affects of any one factor. The data that EPA have received indicate that while both Mount Hope Bay and Narragansett Bay have shown a downward trend of finfish abundance, significantly greater declines have occurred in Mount Hope Bay where the Brayton Point Station operates and correspond in time with a 45 percent increase in cooling water withdrawal from the bay due to the modification of Unit 4 from a closed-cycle recirculating system to a once-through cooling water system and a similar increase in the facility's thermal discharge (please see section IV of the preamble for more detail).

Methods to Evaluate I&E

Comments on the Pisces Report Submitted on Behalf of the Riverkeeper, Inc. in Response to the Proposed EPA Phase II Rule <FN 1>

EPRI requested a review of this report by Drs. Lawrence Barnthouse and Webb Van Winkle. Their detailed comments can be found in Appendices A and D, respectively. In reviewing Pisces' comments, they both identified several significant errors and misinterpretations, and they found that most of Pisces' major conclusions are incorrect. The following are summary points from their review:

- In its analysis of entrainment and impingement loss rates, Pisces used an inapplicable data set and misinterpreted cooling water withdrawal data for the Salem Generating Station. There is no evidence that EPA had underestimated these losses as commented by Pisces.

Footnotes

EPA methods: age 1 equiv, yield, prod foregone

Comments on the Pisces Report Submitted on Behalf of the Riverkeeper, Inc. in Response to the Proposed EPA Phase II Rule 1

EPRI requested a review of this report by Drs. Lawrence Barnthouse and Webb Van Winkle. Their detailed comments can be found in Appendices A and D, respectively. In reviewing Pisces' comments, they both identified several significant errors and misinterpretations, and they found that most of Pisces' major conclusions are incorrect. The following are summary points from their review:

- Pisces' assertion concerning the impact of impinging fish older than one year-of-age is partially correct. However, the conclusion that impingement loss rates, when expressed as age-1 equivalent losses, are nearly as large as entrainment loss rates is based on invalid reasoning and is incorrect. Essentially, Pisces used incorrect natural mortality rates and incorrectly assumed that scaling older fish backwards to age 1 is equivalent to scaling younger fish forward to age 1. This latter assumption is incorrect because no foregone yield or reproduction would accrue due to the deaths of these older fish.

EPA Response

EPA agrees with the commenter.

Comments on the Pisces Report Submitted on Behalf of the Riverkeeper, Inc. in Response to the Proposed EPA Phase II Rule 1

EPRI requested a review of this report by Drs. Lawrence Barnthouse and Webb Van Winkle. Their detailed comments can be found in Appendices A and D, respectively. In reviewing Pisces' comments, they both identified several significant errors and misinterpretations, and they found that most of Pisces' major conclusions are incorrect. The following are summary points from their review:

- Pisces' analysis of variability and bias in estimates of natural survival rates for early life stages of fish is invalid and the conclusion that survival rates for all species should be increased by 25% is incorrect. Analysis of EPA survival data indicates that they are consistent with literature values and, unlike Pisces assertions, EPA survivorship data does not include the effects of power stations and, therefore, they (survivorship) are not biased high. Further Pisces assertion that conditional mortality rates are typically in the 10% -25% range is not true. These rates have only been observed at a few sites (Hudson River and Delaware Bay) and for only the most susceptible species at those sites. Values this high are definitely not representative of all sites or species nationwide.

EPA Response

EPA agrees with the commenters that there is no justification for increasing EPA's loss estimates by 25%. However, EPA disagrees with the commenters' assertions about conditional mortality rates. It is correct that conditional mortality rates are between 10-25% at facilities were such calculations have been made. However, because few facilities have calculated conditional mortality rates, it is not known what such rates are nationwide.

Cooling system costs (e.g., dry, wet, recirculating)

IV. Engineering Cost Analysis – Technology Cost Modules and Facility-Level Costing Options

The following comments are submitted by EPRI as supported expert consultants from Alden Research Laboratory, Inc (Alden).

General Comments on Costs

- In general, the costs associated with fish protection technologies, as presented in the NODA, are more accurate than those presented at proposal. In addition, the revised NODA costs reflect EPA's increased appreciation for the cost variation associated with site-specific conditions. A comparison of the revised EPA costs and those from site-specific data developed by Alden indicate that the ranges in costs often overlap. However, site-specific costs generally have a substantially higher upper limit (Table 1). EPA costs are driven entirely by flow rate. Therefore, for any given technology, the lowest flow facility will always have the lowest EPA estimated cost. Likewise, for any given technology the highest flow facility will always have the highest cost. In addition, since EPA costs are algorithmic, a hypothetical cost can be generated for any flow rate. Historic costs, by contrast, are influenced by flow, but are also driven by site-specific factors that are not flow related (e.g., available space, species to be protected, degree of fouling, etc.) Therefore, the historic low and high costs may or may not be associated with the lowest and highest flow rates. Since historic data is derived from existing designs and installations, costs can not be generated for any flow rate. To make a meaningful comparison between the ranges of EPA costs and ranges of historic costs for each technology, Alden took the lowest and highest cost installations in the historic database, determined the flow rate for those facilities, and 22 used those flow rates to compute an equivalent EPA cost (using the algorithms provided in the NODA). These comparisons are presented in Table 1.

Table 1.- A comparison of site-specific costs developed from historical data and costs developed by EPA in the NODA.

[Please see hardcopy page 22 for table]

EPA Response

EPA notes that the following statements by the commenter in characterizing the costs developed by the Agency are incorrect: "EPA costs are driven entirely by flow rate. Therefore, for any given technology, the lowest flow facility will always have the lowest EPA estimated cost. Likewise, for any given technology the highest flow facility will always have the highest cost." The fact is that although the capital costs developed by EPA are driven primarily by the flow rate, a variety of site-specific or technology related costs drive the capital, operation and maintenance, permitting, pilot study, monitoring, and connection outage costs. Similarly, the commenter is incorrect in concluding that site-specific factors do not play a significant part in EPA's cost estimates. The Agency's development of technology costs incorporated available space as a factor in the determination of which technologies would be candidates at certain facilities. The Agency incorporated potential for bio-fouling in specific technology module costs. In addition, the Agency addressed the type of water (saline vs. fresh), the navigability of the waterway, the degree of debris loading at the intake, the distance of a potential relocation of an intake, the velocity of the existing intake and potential need for building a larger structure to reduce velocity to account for sensitive species survival, the distance needed for proper fish return systems, the type of plant (i.e., nuclear vs. non-nuclear) and other site-specific factors. The end result is that EPA's costs as applied through its site-tailored application methodology vary between facilities based on a variety of factors, including flow. The commenter's elementary summary of EPA's cost methodology is incorrect and misrepresents the national costs of the final rule.

One very significant item the Agency includes in its cost estimates is largely unrelated to flow: facility downtimes due to construction. These downtime costs can be a sizeable driver of the overall annualized costs of retrofitting some of the technologies forming the basis of the final rule and are relatively unrelated to the flow rate of an intake. This is an important point to consider in the context of the commenter's review of and comparison to the Agency's costs: the commenter failed to account for the total costs EPA considered in its analysis by ignoring the downtime (and other substantial) costs and therefore, the conclusions of the commenter relating to the costs developed by the Agency for the NODA preferred option and, hence, the final rule are not based on definitive comparisons of the sum total of the EPA costs considered. In addition, the commenter also did not incorporate into its determination of what it deemed "EPA costs" those costs for pilot studies, demonstration studies, recurring monitoring and reporting, and initial permitting costs for which the Agency provided information in the NODA. Because the commenter did not provide itemized costs for its data set of costs against which it compared EPA's, it is not possible to ascertain whether or not these pilot, demonstration, and permitting costs were aggregated in the commenter's data set and this further brings into question the comparisons made by the commenter and the conclusions reached.

Subject Matter Code 9.07

Cost Modules

The logic underlying the application of the cost modules also shows EPA's increased awareness of site-specific issues that influence the practicability of retrofitting certain fish protection technologies. However, EPA largely ignored species and life stage considerations relative to the efficacy of technologies and their associated costs. For example, costs associated with a wedge wire screen will be greater if particularly small slot sizes (e.g., 0.5 versus 1.0 mm or larger) are necessary to protect the species and life stages at a given site. In addition, the presence of fragile species in large numbers at a given site may preclude the use of technologies that physically handle fish (e.g., modified screens). By contrast, the composition of species and life stages in the vicinity of a CWIS may warrant the use of less protective technologies (e.g., wedge wire screens with larger slot sizes) than those selected by EPA.

EPA Response

The Agency notes the comment and has incorporated the suggestion of utilizing small and large slot sizes for fine-mesh wedgewire screens (see response to comment 316b.EFR.306.046). The Agency concedes that it did not have sufficient information to make extremely rigorous site-specific determinations for the vast number of facilities in-scope of the final rule as to the specific species and life stages that are present at all these facilities. The Agency also contends that acquisition of this information is not practical or feasible for a project the size of this final rule. As such, the Agency approached the costing effort and application of cost modules in a manner that would be applicable for a wide variety of typical cases. The general approach of the Agency was to approach the application of technology modules conservatively so as to apply the best performing technologies in cases where uncertainty about life stages and species exist. Therefore, in the example case given by the commenter of wedgewire with larger slot sizes than those selected by EPA the net effect would be for the Agency to have conservatively estimated costs for this particular example case. For the case that the presence of fragile species in large numbers at a given site may preclude the use of technologies that physically handle fish, such as modified screens, the Agency notes that its analysis would not be able to identify all of these situations due to the fact that no national data set exists upon which to base the determinations. Therefore, in order to account for these cases the Agency applied a variety of modules that do not physically handle fish to a variety of cases, thereby incorporating into the national cost estimates the expected variation between sites experiencing this phenomenon. The Agency refers to the Technical Development Document for further analysis of the variety and methodology for selecting and assigning technology modules for the final rule cost analysis.

Comment ID 316bEFR.306.040

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Subject Matter Code 9.07

Cost Modules

EPA guidance on the use of the cost modules is required. Use of the spreadsheets provided in the NODA is not clear. The cost modules could be used to compare site-specific costs to EPA's costs during a cost-cost test. The cost modules should not be used to determine the appropriate technology alternative for a given facility. Selection of an appropriate alternative or a suite of alternatives is a site-specific process as discussed in detail in EPRI's 2000 guidance document (Procedural Guideline for Evaluating Alternative Fish Protection Technologies to meet § 316(b) Requirements of the Clean Water Act) (EPRI 2000a) which has been previously submitted to EPA.

EPA Response

The Agency agrees that a site-specific process is necessary to determine the appropriate compliance method for a plant. Hence, the Agency has included in the final rule costs for conducting comprehensive demonstration studies and pilot studies for complying facilities.

The Agency notes that it provided specific guidance to the commenter (i.e., employees of Alden Labs) as follow-up on the use of the documentation in the NODA for the technology cost modules. For the final rule, the Agency has provided a more "user-friendly" tool for executing the technology costing modules. As such, the requests of the commenter have been met.

Intake structure technology costs (e.g., screens, etc)

A 6-month compliance schedule is not a realistic time frame for the design and installation of even the simplest impingement reduction technology. Retrofitting traveling screens with fish removal features or fish return systems would require more than 6 months. Efforts would include detailed design, preparation of construction and fabrication drawings and specifications, procurement and fabrication of components, and complete installation. At least one year would be required to complete even simple modifications.

EPA Response

See the preamble to the final rule for a discussion of the time frames for submitting the studies required by the rule and of the ways that compliance with the rule can be demonstrated.

Cost Modules

Specific Comments on Cost Modules

EPA uses the 1.0 ft/s velocity as a criterion for the application of modules. Expanded intakes (module 3), wedge wire screens (on shore or offshore; module 4 and module 7, respectively) and dual flow screens (module 11) were generally applied when intake velocities were above “roughly” 1 ft/s. The costs included in modules for these technologies include the cost associated with lowering intake velocity (i.e., increasing the number of screens). Adding fish handling systems (coarse or fine mesh; module 1 and module 2, respectively), were applied when intake velocity was “roughly” 1 ft/s or below. The off shore options (modules 8 and 9) and barrier nets (module 5) had no velocity criterion. We assume that this is a through-screen velocity. In our opinion, there is no evidence to suggest that many of technologies cannot be operated effectively at velocities above 1.0 ft/s (in fact, the EPRI-Alden developed Modular Inclined Screen (MIS) works effectively up to approach velocities of 3.0 ft/s and higher) (EPRI 1996). Using the velocity criterion in the application of the modules will lead to the application of more costly velocity reducing technologies in cases where less expensive and equally effective technologies may be available. Using a conservative velocity criterion of 1 ft/s will overestimate the number of facilities installing velocity-reducing technologies and underestimate the costs of implementing the Rule on a national level.

EPA Response

The commenter is incorrect in the following statement: ” Using a conservative velocity criterion of 1 ft/s will overestimate the number of facilities installing velocity-reducing technologies and underestimate the costs of implementing the Rule on a national level.”

In fact, this statement contradicts the commenter's previous sentence in which it states, “Using the velocity criterion in the application of the modules will lead to the application of more costly velocity reducing technologies in cases where less expensive and equally effective technologies may be available.”

By using a criterion of 1 ft/sec, above which generally more expensive technologies would be implemented, the costs of the national rule would be greater than in a case, such as that suggested by the commenter, that a higher velocity criterion would be used. The commenter's assertion in the final sentence of the comment – that national costs may be underestimated due to the Agency’s velocity criterion – is not at all supported by the body of the rest of the comment.

As to the matter of whether or not technologies may operate well and protect organisms at velocities above roughly 1 ft / sec, the Agency agrees with the commenters assertion that this can be the case. This is potentially the case for velocity cap technologies, which the Agency applies to a few moderate velocity cases in its module cost applications. The Agency utilizes the concept of velocity criterion in the analysis of technology applications as a screening component of the analysis, and not as the primary basis for decisions. The Agency notes that the final rule has no requirements based on velocity. As to the matter of the basis of the velocity criterion, the Agency utilized the reported, design through screen intake velocities that it obtained through the 316(b) survey.

Cost Modules

The open area for traveling screen mesh varies according to the selected mesh opening and material. EPA's assumed open area of 68% may overestimate through mesh- opening velocities in larger mesh sizes and underestimate through-mesh velocities in finer mesh sizes. The approach velocity immediately upstream of the screen mesh would be a more appropriate and consistent method for defining impingement velocities. In angled screens, the component of approach velocity that is normal to the screen face should be the defined impingement velocity.

EPA Response

The Agency's assumption for the open area of a traveling screen is the median, typical opening of those intakes within the scope of the rule. The Agency acknowledges that it may overstate or understate mesh-opening velocities in some cases, but that is the nature of a median, and for the purposes of the national rule estimates is appropriate. As such the Agency continues to view its assumption regarding open area, which is endorsed by the expertise of the leading manufacturers and vendors of screening technologies, as reasonable for the final rule analysis. Because the Agency relied upon the 316(b) survey data applicable to those facilities within the scope of the rule, it utilized the through-screen velocities reported by the facilities. Hence, although approach velocity would be a reasonable metric for sizing impingement velocities, the Agency referred to the available data for its reasonable analysis.

Information from vendors and the questionnaires indicates that the majority of existing traveling screens use coarse mesh screens and the most prevalent size is 3/8 in mesh. The vendors stated that typical wire is #14 gauge (0.08 in. diameter). Percent open area for square mesh can be calculated as:

Percent Open Area (%) = 100 * (opening side) 2 / (opening side + wire diameter) 2

A traveling screen vendor explained that while finer mesh will tend to result in lower percent open areas, the difference is not that great if finer wire is also used (Brackett Green 2002). Finer wire can be used as long as there is sufficient support for the mesh. EPA notes that all of the traveling screen technologies used as the basis of compliance involve fine mesh overlays. In such systems the coarser mesh screens provide structural support for fine mesh screens. The commenter notes that approach velocity would be a more appropriate and consistent method of defining impingement velocities. EPA notes that the use of a consistent value for percent open area effectively results in an approach velocity to through screen velocity ratio that is constant. In other words, the 1.0 fps through screen velocity is equivalent to an approach velocity of 0.68 fps. Vendors have noted that the slight increase in through screen velocity has not been an issue with respect to screen performance. Rather, finer mesh sometimes resulted in operational problems associated with an increase in the amount of debris collected. EPA addressed this potential problem by including costs for physically removing the fine mesh overlays during annual periods of heavy debris loading.

EPA reviewed the use of percent open area as it was applied to various technologies. For the new larger intake structure EPA concluded that use of the percent open area of 68% and a target through-screen velocity of 1.0 fps may produce a less than ideal design. While existing intakes with through flow screens do not have the luxury of being able to increase the screen area available for through flow screens, newly installed screen structures can be designed to produce any target through-screen velocity as long as space is available. EPA has concluded that in estimating the new intake structure screen width, a 50% percent open area (rather than 68%) is more consistent with the finer screen mesh. Vendor data indicate that typical Fine Mesh Screens have open space ranging of 50% (Industrial Screen Products) to 58.5% (Screen Services - #69 Johnson Vee-Wire screen) or lower for very fine screens. As such. EPA has decided to reduce the percent open space value used in calculating the size of the new larger intake from 68% to 50%.

Cost Modules

Module 2 – Add Fine Mesh Traveling Screens with Fish Handling and Return

-Fine mesh overlays will not work. Fine mesh screens need to be constructed of components that are designed to withstand the rigors of continuous rotation.

-In addition, acceptable hydraulic conditions within the fish buckets and a smooth transition between the buckets and screen mesh would not be achieved with overlays.

-The effectiveness of the low-pressure, internal spray wash system in gently removing organisms would be diminished due to the obstruction resulting from the presence of the coarse mesh.

-EPA uses fine mesh of 1-2 mm for the traveling screen option. A finer mesh may be required to protect certain species and life stages.

EPA Response

The commenter states that fine mesh overlays won't work because they won't withstand rigors of continuous rotation, will not achieve acceptable hydraulic conditions within the fish buckets smooth transition between buckets and screen, and the effectiveness of the low pressure spray wash system would be diminished. EPA contacted the vendor who has extensive experience installing fine mesh overlays and his responses to issues posed by the commenter disagree with the assertions of the comment (see DCN 6-3587).

EPA also notes that fine mesh overlays are only added where the existing screens already have fish handling and return technology. It is assumed that existing systems use fish handling technology that employs properly designed baskets and fish buckets with hydraulic conditions that minimize impingement. EPRI's comment is correct where the Past attempts to add fish baskets without employing redesigned baskets resulted in poor hydraulic conditions.

Cost Modules

Module 3 – Add New Larger Intake Structure with Fine Mesh, Handling and Return

-EPA applied this module to facilities that are required to meet only the impingement standard and where EPA determined that intake velocities were “extremely high.” EPA should define “extremely high.” Application of this module to impingement-only sites is likely to drive the national costs higher.

EPA Response

For the case of impingement only facilities to which the Agency applied enlarged intakes the velocity definition of “extremely high” was those cases above 3 ft / sec. The cases of application of impingement only sites with the new larger intake module was rare for the final rule. The Agency utilized it to represent cases when the shoreline traveling screen systems would not provide adequate impingement survival protection at extreme velocities. The alternative technologies to enlarging an intake would be to install a barrier net system or relocate the intake to offshore. The barrier net system is not practical for cases of navigable waterways and the relocation of the intake would correspond approximately to the costs of building a larger intake. EPA notes that reducing the approach velocity is the obvious non-flow-reduction solution for facilities which are experiencing impingement problems. Such a modification cannot be performed without substantial modification of the intake structure. As such, there are cases, in the Agency’s opinion that would reasonable correspond to the necessity of enlarging the intake structure for controlling impingement. Because the Agency applies the technology module to only a select set of cases in which other less costly technologies would not be practical, the Agency views the effect on national costs to be reasonable and not an overestimate, as the commenter asserts.

Cost Modules

Module 4 – Add Passive Fine Mesh Screens at Shoreline

-Wedge wire screen costs are based on 1.75 mm openings. This opening size will not be effective in eliminating entrainment of many species and life stages. The use of 0.5 or 1.0 mm slot sizes will greatly increase the costs of affected facilities.

-EPA stated that currents "are utilized for controlling impingement." In reality, impingement is correlated to the ratio of slot velocity to sweeping velocity.

EPA Response

EPA selected 1.75 mm openings based on the "typical" fine mesh size reported by vendors. In comment 316b.EFR.306.045 the commenter has noted that depending on site-specific data such as species and life stage requiring protection, some facilities may require smaller mesh sizes (e.g., 0.5 to 1.0 mm) and some larger mesh sizes with corresponding higher and lower costs than the cost of the "typical" fine mesh design. EPA has concluded that design values selected for the modules will tend to produce a balance of higher and lower than actual costs such that the overall total represents a reasonable estimate of the national total. EPA realizes that the costs for smaller mesh screens increases significantly as the mesh size becomes smaller due to the decrease in percent open area of the finer mesh screens and increased O&M due to capture of additional debris. Vendors were questioned about installation of fine mesh screens and stated that anything less than 1.0 was rare. EPA expects that the use of very fine mesh (i.e., <1.0 mm slot size) will be limited to a small subset of facilities. In order to determine the relative cost for these facilities, EPA reviewed the technical data from the vendors and selected a slot size of 0.03 inches (0.76 mm) as representative of the smaller "very fine" mesh. Capital and O&M cost estimates were then developed for passive screens with this slot size. Therefore, to be conservative (i.e., erring towards higher national costs) the Agency has applied the fine-mesh wedgewire system in roughly 25 % of cases (those in estuarine and ocean environments).

EPA agrees that the degree of impingement is correlated to the ratio of slot velocity to sweeping velocity. However, EPA notes that even in situations where this ratio is high (i.e., installations with low sweeping velocity), that the system performance with respect to impingement and entrainment will be much improved over the system it replaces if designed properly.

Module 5 – Add Fish Barrier Net

-In some cases, EPA applied this module in combination with entrainment reduction technologies. Using technologies in combination is an innovative approach that is generally lacking elsewhere in the NODA, but should be considered.

EPA Response

The commenter notes that combining technologies like was done with fish barrier nets is innovative and encourages EPA to consider applying other technologies in combinations. Adding fish barrier nets to intake systems in conjunction with existing or improved shore-based technologies generally requires little or no major modification to the existing intake structure. Since the nets are generally targeted to sensitive species that do not require fine mesh, the use and function of the shore-based screening system is often still required for the entire system to function properly. Also where nets are only required on a seasonal basis or would be damaged during winter months, a shore-based screening system is still required during the period of non-deployment. In other words these technologies are more easily combined without having to consider the effect each has on the other. Aquatic filter barriers (AFB) could also be applied in combination with other technologies, but EPA notes that if the AFB functions properly a shore-based screening system would be rendered redundant. Such redundancy may serve as a backup or insurance that the entire system will continue to function should the AFB fail, but a screen system would not be required to operated except to maintain it in working order. If after a reasonable time the AFB has demonstrated itself to be reliable, shore-based screens may be abandoned altogether. Another module technology that may be used in combination with other technologies is adding a velocity cap at a submerged intake in combination with improvements to a shore-based screening system. The application of such a system would require knowledge of site-specific conditions that is not available to EPA for the model facilities.

Module 7 – Relocate Intake to Submerged Offshore with Passive Screens

-This module was applied to reduce velocity at facilities where there was insufficient space in the vicinity of the CWIS to expand the intake. To determine the distance of piping, EPA used the median distance of other offshore passive screens in the same water body type. EPA should have used bathymetry in the vicinity of the CWIS to determine the location of the technology.

-It appears that this was the "default" module: "…the Agency relied on this module to represent situations where there was not one module that stood out as the clear choice alternative." Because Module 7 is relatively expensive, default application of this module will likely increase the national cost estimate.

-Although not explicitly stated, this option should provide "location" benefits similar to those for Module 9.

EPA Response

EPA did not use bathymetry data to determine the distance to the new submerged offshore intake because no such data is readily available for all facilities in-scope of the rule. Lacking this data, EPA chose to use the median distance offshore of existing submerged intakes for facilities in the database that reported such data. Recognizing that there are general differences in the bathymetry of different waterbody types, EPA divided the facility data into waterbody types and then used the median value for each. As with other design parameters, EPA has concluded that the use of median values for existing similar technologies should result in cost estimates that will include a somewhat equal mix of cost estimates that are both lower and higher than what would actually be required with the producing a reasonable overall national estimate.

EPA disagrees that utilizing relocation of an intake as a type of "default" choice would "increase" the national cost estimate. As the Agency notes and the commenter quotes, the module was applied when no one module stood out as a clear choice. However, what the commenter has not noted is that there is practical basis for this approach and that this approach is in concert with the commenter's recommendations for the Agency to account for cases of uncertainty about species variability and site-specific conditions. Additionally, the commenter has not noted that the Agency applied a hierarchy decision making process for selecting the appropriate technology prior to relying on any form of default in order to narrow down the available options for a particular model-site. By narrowing down the modules that might apply through hierarchy of selection, the Agency applied all available data in a reasonable manner to the selection of the technology costs. Finally, the commenter has not noted that the cases in which the Agency applied the supposed "default" choice were rare. Therefore, because of all these factors, the Agency contends that the commenter's assertions relating to likely increases in the national cost estimate are not accurate.

EPA agrees with the commenter that all offshore intake technologies would provide “location” benefits and the final rule accounts for this fact in its analysis of in-place and potential retrofit technologies.

Organization EPRI

Subject Matter Code 9.07

Cost Modules

Module 8 – Add Velocity Cap at Offshore Inlet

-We agree with EPA that a velocity cap, in and of itself, may not meet the required reduction in impingement, but does provide a benefit based upon location. Velocity caps should be designed for entrance velocities much higher than 0.3 ft/sec (referenced in the NODA as the design velocity for the one manufacturer of prefabricated steel velocity caps). Fish will be unable to detect and avoid a velocity cap designed with entrance velocities not significantly different than the velocities of ambient currents in the vicinity of the cap. Velocity caps should be designed with velocities (1-2 ft/sec) that can be detected and avoided by fish, thereby reducing entrainment.

-Velocity caps have been constructed from concrete. The formulas for the stainless steel and carbon steel velocities cap costs are associated with the wrong graphs.

EPA Response

EPA disagrees that a 1-2 fps inlet velocity is required in order to for fish to detect the velocity cap intake. EPA notes that the primary problem that velocity caps are intended to resolve involve the relative inability of fish to detect changes in vertical velocities. EPA notes that it is just as important that the intake velocity be low enough to allow slow swimming fish be able to escape. For screen type systems EPA has selected a through-screen velocity of 0.5 fps as suitable for new systems to allow for most fish species to escape. Corresponding approach velocities are even lower. The velocity caps at the St Lucie Nuclear Power Plant have an inlet velocity of about 0.5 fps (FPL 2002). If the commenter's assertion were true, then all velocity caps would perform poorly whenever the system was withdrawing water at a flow rate much lower than the design value.

Module 9 – Add Passive Fine Mesh Screen at Inlet of Offshore Submerged Intake

-Same comments as Module 7 above.

EPA Response

EPA notes that although the commenter references their comments from 316b.EFR.306.049, that those particular comments regarding relocating an intake (and the Agency's application of module 7) do not necessarily apply to adding passive screens to offshore submerged intakes. The Agency notes that application of module 9 (adding wedgewire screens to an existing offshore inlet) was dictated primarily by whether or not a facility had an existing offshore intake, the type of intake controls in-place, and the requirements that applied to the facility. Relocating an intake is different than retrofitting the offshore intake.

Nonetheless, the Agency has responded to the referenced comments at 316b.EFR.306.049.

Comment ID 316bEFR.306.052

Subject Matter Code 9.07
Cost Modules

Module 10 – Add / Modify Shoreline Technology for Submerged Offshore Intake

-EPA did not use this module. Unless an onshore screen exists, it is unlikely that any facility would add one as a retrofit, since more cost-effective options are available. The exception may be where they may be an economic benefit to moving the intake offshore that is associated with a reduced heat rate that will improve facility performance associated with colder source water.

EPA Response

EPA agrees with the comment. EPA did not use this module because it required site-specific information concerning the presence of onshore screens and an assessment of whether retrofitting the onshore system would effectively resolve the problem. Rather EPA chose to retrofit at the inlet where improvements in impingement and/or entrainment were deemed necessary. The comment concerning moving the intake offshore to access cooler water applies to module 7. The benefit of greater turbine efficiency would be difficult to predict and therefore was not given any monetary value. This can be viewed as another situation where a conservative approach (tending towards higher net compliance costs) was used.

Subject Matter Code 9.07

Cost Modules

Module 11 – Add Double-Entry Single-Exit with Fine Mesh, Handling and Return

EPA applied dual-flow screens to facilities that need to reduce velocity but lack the space required to expand the intake. Retrofitting to dual-flow screens within an existing screenwell does not increase screen surface area over standard once through traveling water screens and, therefore, will not decrease velocity at the screen face. To achieve uniform flow through a retrofitted dual-flow screen, the ascending and descending faces are approximately half the width of the through-flow screen baskets. The baskets in a dual-flow retrofit are shorter to avoid non-uniform flow through the screens. If a dual flow screen is located too close to the pump bellmouth, the uneven flow caused by the water jet exiting the screen may result in cavitation of the pump. To prevent possible cavitation, the pumps should be located no less than 15 ft (and preferably > 20 ft) downstream from the screen exit. EPA used the dual flow module at 59 facilities. The dual-flow option will not decrease velocity as EPA contends, thus other technologies will need to be used to achieve the desired 1 ft/s velocity. Since all other velocity reducing modules are more expensive, the national costs will be greater than EPA estimated.

EPA Response

After conducting additional research EPA agrees that dual flow screens have a limited ability to reduce through screen velocities. As such, EPA has reduced the number of facilities requiring dual flow screens particularly those with higher through-screen velocities. The greatest single advantage of dual flow screens is that they significantly reduce the problem of debris blinding and carryover. One of the problems encountered when coarse mesh screens are replaced with fine mesh (e.g., fine mesh overlays) is that the amount of debris captured by the screens increases resulting in operational problems. All else being equal, this problem increases with increasing screen velocity. As the commenter has noted many installations can operate effectively at through-screen velocities >1.0 fps. Thus, EPA has concluded that at model facilities identified as requiring dual flow screens where the through-screen velocity does not vary far from the desired through-screen velocity, it is reasonable to apply dual flow screens as the compliance technology.

Considering the operational benefits of dual flow screens, EPA has decided to use dual flow screens instead of through flow screens as the screening technology used in conjunction with the new larger intakes module.

As such, the Agency has changed its application of the module for the final rule. The Agency has utilized other technologies in-place of the dual-flow screens for some of the 59 cases cited by the commenter. The Agency no longer applies the dual-flow technology for the majority of situations that call for decreased velocity in its costing module application methodology.

Technology Efficacy Database

VII. Performance Standards

A. Technology Efficacy Database (TED) to Support Performance Standards

The following comments are submitted by EPRI as supported by experts with Alden. EPRI believes that the EPA TED is a notable effort that should provide valuable information to support both the resource agencies and permitted facilities in determining compliance options with the proposed rule. EPA has made a good start compiling available data on the effectiveness of fish protection technologies for application at CWIS. However, there are some shortcomings and limitations to the database as currently configured that should be addressed as subsequently discussed. EPRI would be pleased to work with EPA in further developing its content and utility.

-There are more studies and data available in both peer reviewed and gray literature that could be added to the TED. Additional reports and information on technologies for the protection of fish at cooling water intake structures can be found in the comprehensive review of the subject prepared for EPRI in 1999 (Fish Protection at Cooling Water Intakes: Status Report) (EPRI 1999b). EPRI is currently engaged in updating this report with the latest developments in technology research and the latest information on the cost of retrofitting the technologies to existing CWIS. The new report will be available by December 2003. The new report will be a web-based document for our members that will allow for efficient continual updating as new information becomes available. EPRI would welcome the implementation of collaborative efforts with EPA that extend the content and utility of the EPA TED.

EPA Response

Please see response to comment 316bEFR.325.004.

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Subject Matter Code 7.02.03

Technology Efficacy Database

The TED presents data using varying metrics. In many cases, this is unavoidable as data may have been presented differently in individual papers. EPA should be aware of the inconsistency in reporting of the data and exercise caution when comparing effectiveness estimates between two sites. In addition, the biological efficacy of a technology has to be measured differently depending upon that technology's mode of action. For example, a behavioral barrier acts to illicit a physiological response in adult or juvenile fish that repels them from the CWIS (or in some cases attract them toward a safe location). With such a technology, the benefit lies in a reduction in the total number of fish impinged. Behavioral barriers do not improve impingement survival (i.e., those fish that are not repelled will experience the same survival as they would in the absence of the technology). By contrast, a collection system (such as a Ristroph screen) improves the survival of impinged organisms over a conventional screen, but does nothing to prevent organism impingement. The database needs to clearly distinguish impingement reduction from improved impingement survival.

EPA Response

EPA agrees with the commenter that the high degree of variability between the data in the TED warrants caution from those who use it. The data summarized in the database is not intended to be used in direct comparison between studies but rather to provide an abstract that will guide users to the appropriate original documentation. EPA has modified the database contained in the docket to clarify the data contained therein to distinguish between impingement survival and impingement reduction.

Technology Efficacy Database

The structure of the TED should be altered to be more user-friendly. Currently, a user can only view one record at a time. Queries should be designed to allow users to sort data into meaningful groups (such as by technology or waterbody type).

EPA Response

EPA has modified the database to allow queries and other functions as mentioned by the commenter. EPA also notes that the underlying data tables are available for use as needed by the user.

Comment ID 316bEFR.306.058

Subject Matter Code 7.02.03

Technology Efficacy Database

Author Name Doug Dixon & Kent Zammit

Organization EPRI

The EPA should conduct a Q/A program to standardize the method of reference used throughout the TED. The current inconsistent reporting of bibliographic information makes it difficult to ascertain the ultimate source of the data. In addition, there are inconsistencies in the way authorship is attributed. For example, in some cases EPRI reports are attributed to EPRI, while in other records they are cited by the Principle Investigator. For example, EPRI's most recent technology evaluation (Fish Protection at Cooling Water Intakes: Status Report) (EPRI 1999b) is attributed to E. P. Taft. The inconsistencies of the citations make it difficult to acquire and assess the accuracy and relevance of the data. Fifty-eight records in the database have either no source given or they are from secondary sources. In general, very little of the data is from peer-reviewed literature.

EPA Response

EPA has rectified the discrepancies noted by the commenter. Please see DCN 6-5000 in the docket.

Comment ID 316bEFR.306.060

Author Name Doug Dixon & Kent Zammit
Organization EPRI

Subject Matter Code 7.04
Streamlined Technology Option

Streamlined Technology Option For Certain Locations

The following comments are submitted by EPRI as supported by experts with Alden. EPA's attempts to identify a non-burdensome technology approach for both industry and the regulators is notable. EPRI is also willing to collaborate with EPA to further develop streamlined technology options including establishing the criteria for technologies to be so identified.

EPA is seeking comment on two possible streamlined technology options. Under the first option, EPA would evaluate the impingement mortality or entrainment reduction expected for a specific technology based on review and analysis of available data, studies, and literature. In addition, EPA would assess the site-specific characteristics under which technologies are most effective (e.g., location, flow, velocity, species, life stage, etc.). EPA would promulgate new regulations that would allow the use of approved technologies for complying with Phase II section 316(b) requirements.

Currently EPA believes that there may be sufficient data to use the streamlined approach for wedge wire screens in certain water bodies and under specific water hydraulic conditions. EPA is considering the inclusion of the following words:

"Use of submerged wedge-wire screens where the cooling water intake structure is located in a freshwater river or stream, sustained countercurrents exist to promote cleaning of the screen face, and the design intake velocity is 0.5 feet per second (ft/s) or less."

We offer the following comments relative to this approach:

-This version of the streamlined technology option may work with some modifications to meet the entrainment reduction standard. Most importantly, the slot size should be selected in accordance with the size of eggs and larvae to be protected at the site. In general, while existing research indicates that a slot size of 0.5 to 1.0 mm may be protective in all cases; in some situations, it may be over-protective. In many cases, slot sizes of 1.5 mm and higher will afford the same level of protection as the narrower slot sizes. Given the direct relation between slot size and intake flow, wider slots will minimize unnecessary retrofit costs. We do note that screens configured as noted in EPA's wording (including a slot width of 1.75 mm as assumed from EPA cost analyses) should virtually eliminate impingement of juvenile and adult fish. The uncertainty regarding entrainment reduction may be lowered with additional research.

-For all wedge wire screen options throughout the NODA, EPA over-emphasizes the importance of ambient currents. Recent laboratory studies of wedge wire screens (EPRI 2003d) have shown that currents as low as 0.25 ft/s are sufficient to provide protection for many life stages and species tested. Currents of this magnitude occur commonly in all water body types and should be sufficient to protect fish eggs and larvae, as well as juvenile and adult fishes.

EPA Response

For EPA's response to the comment regarding slot size, please refer to comment 316bEFR.306.003. With regard to the role of ambient currents in the Approved Technology Option, § 125.99(a)(1)(ii) requires that the cooling water intake structure be situated such that sufficient ambient counter currents exist to promote cleaning of the wedgewire screen face. EPA has not specified a uniform ambient current velocity, as the Director will be responsible for determining whether ambient currents are sufficient for the technology to be effective. Please refer to EPA's responses to comments 316bEFR.017.003 and 316bEFR.063.005 for additional details of how the Director will determine compliance. EPA therefore disagrees that it has placed excessive emphasis on the ambient currents: ambient currents are one of several site conditions that must be present for the wedgewire screen technology to perform as required.

Streamlined Technology Option

The second option would establish the criteria and process for approving cooling water intake structure control technologies for complying with Phase II section §316(b) requirements. This option would allow the development of information demonstrating the effectiveness of other technologies to meet the impingement mortality and entrainment performance standards when operated under defined conditions. Our comments are as follows:

-The second option differs from the first in that it calls for the systematic development of criteria for the approval of technologies to meet §316(b) rather than through the inappropriate use of available data.

-If EPA adopts scientifically sound criteria for approving technologies and sufficient input is solicited from resource agencies, industry, and stakeholders, this approach could lead to the development of a functioning streamlined approach to implementing §316(b).

EPA should recognize the efforts of industry to develop technologies and not penalize them for good faith efforts to improve fish survival at their facilities. EPA should also make every effort to ensure that these regulations do not inhibit the development of new, more efficient technologies that could further enhance fish protection.

EPA Response

EPA believes that the second Approved Design and Construction Technology Option described in § 125.99(2)(b) provides an opportunity for industry and other interested parties to develop innovative technologies to protect aquatic life from cooling water intake structures. The option allows any interested individual or group to submit a technology for review as a means of complying with today's final rule. If the Director approves the technology, it will thereafter be available to all applicants in the region to use as a means of compliance. EPA believes that the inclusion of such an option will foster creativity and cooperation among industry and State representatives. EPA anticipates that this compliance option will generate a number of new Regionally-approved technologies that will be both protective and efficient.

Biology – Supporting Information

Entrainment Survival

EPRI previously commented that we disagree with the results of EPA’s analysis of entrainment survival and we continue to disagree with EPA’s additional analyses. We believe that the scientific data demonstrates with 100% certainty that entrainment survival can be significant for many fish and shellfish species. In the following paragraphs we offer some comments on the details in EPA’s analysis. However, more importantly, we would like to point out that EPA sets a standard of rigor in their analysis of entrainment survival that is inconsistent with all other analyses conducted to support the proposed rule. For example, EPA’s review of the results of 36 entrainment survival studies and subsequent rejection of them for various study limitations (which will always exist) is in sharp contrast to EPA’s use of a single contingent valuation study (Peconic Bay Study) to estimate nonuse benefits for the entire North Atlantic Region. It is scientifically and economically questionable if EPA’s use of this study is appropriate (see comments by Dr. Strand); in fact, the authors of that study would likely disagree with its use in the EPA context. It is readily apparent that in this instance EPA rejects information that was developed from peer reviewed, state-of-the art methods (which reduce national losses and associated benefits) while also embracing non-standard approaches with highly uncertain data and potentially inappropriate use of that data to estimate economic benefits (which inflate benefits by nearly an order-of-magnitude). We recommend that EPA attempt to be as consistent as possible in dealing with data set analysis and use. Furthermore, we recommend quantitative uncertainty analysis (at least sensitivity analyses) that reasonably bound all types of estimates EPA derives. This could be easily accomplished for entrainment survival. Reasonable entrainment survival ranges have been reported in the EPRI Entrainment Survival Report (EPRI 2000b).

EPA Response

Please see response to comment 316bEFR.305.001 with regard to entrainment-based performance standards. Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis. Please see the response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule.

EPA did not use the Peconic Bay study mentioned by this commenter to determine non-use values in the benefits assessment for today's final rule. Please see response to comment 316bEFR.307.061.

Entrainment survival chapter

As part of it's efforts on the issue of entrainment survival, EPA has revised Chapter A7: Entrainment Survival of the Case Studies document, but the revised version, similar to the initial version, suffers from a lack of perspective for the realities of entrainment survival programs. In the revision, EPA has selectively used the available literature to promote a position that the current state of knowledge is insufficient to utilize the existing data. EPA has relied heavily on some of the oldest entrainment survival literature, which used the most primitive sampling methods, and on literature that contains speculation about entrainment survival, while not reviewing literature that presents updated information that would contradict EPA's analysis, addresses concerns raised by EPA, or identifies the sampling biases and speculation contained in some of the early reports. Specific comments on the revised Chapter A7 are as follows:

- A7-1.1 Fragility of Entrained Organisms – EPA states "For these reasons, entrained eggs and larvae are believed to experience high mortality rates as a result of entrainment." EPA provides no reference to support this statement. EPA could have cited the work of it's own consultants from the 1970's which demonstrated that many species of larval fish can survive the entrainment stresses, despite early speculation that they must be too fragile to do so. EPA could also have cited later reviews that identified which of those early reports on entrainment survival contained no quantitative information or lacked valid controls (Jinks et al. 1981)<FN 2>. In fact, numerous scientific studies have since demonstrated that fish eggs and larvae do survive entrainment, in some cases in very high percentages. The preponderance of this information was sufficient to convince even early skeptics of the reality of entrainment survival, yet EPA chose to introduce their review with the same speculative impressions on fragility that preceded thorough scientific study.<FN 3>

Entrainment survival chapter

A7-1.2 Thermal Stress - EPA relies primarily on two reviews of the thermal effects literature (Schubel et al. 1978 and Stauffer 1980) which omit the majority of the studies designed to address thermal effects of the entrainment process. EPA could have accessed more recent literature that presents a more comprehensive and up-to date view of thermal stresses, such as EPRI (1981)<FN 4> and Kellog et al. (1984).<FN 5> In addition, EPA makes no mention of approaches that have been developed to use thermal effects information obtained from laboratory studies to evaluate thermal effects (and relationships to CWS flow) during entrainment. Predictions of temperature effects during entrainment have been found to be in reasonable agreement with temperature effects observed in field studies of entrainment survival (Jinks et al. 1978)<FN 6>.

An approach for the analysis of striped bass entrainment survival at Hudson River power plants, in Proceedings of the Fourth National Workshop on Entrainment and Impingement (L. D. Jensen, ed.), pp. 343-350. EA Communications, Sparks, MD.

EPA Response

EPA did not use analyses of thermal effects from laboratory studies because the Agency believes thermal stress is not the only stress that leads to entrainment mortality as organisms pass through a cooling water intake structure. EPA's chapter on Entrainment Survival in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule, also examines chemical and physical stress. Entrained organisms perish due to a variety of reasons due to stress within and after discharge from a cooling water intake structure. Therefore, laboratory studies which isolate thermal stress have only limited utility.

Please see the updated chapter, Entrainment Survival, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule.

Entrainment survival chapter

A7-1.3 Mechanical Stress – Again, EPA has relied upon very old information. While it may be true that "mechanical mortality is the dominant cause of entrainment mortality at many facilities", the references cited (Marcy 1973 and Marcy et al. 1978) leave an impression that mechanical mortality is nearly 100%. Marcy (1973) reported on studies conducted from 1970-1972 at the Connecticut Yankee plant using plankton nets, which themselves would have induced a considerable degree of mortality to the primarily alewife and blueback herring larvae (97.6% if the total catch). Studies during the 1970's clearly showed that high discharge velocities were the primary source of mortality observed using net sampling in early entrainment survival studies (NYU 1972, 1973; Lauer et al. 1974). Marcy et al. (1978) reviewed studies published no later than 1977, and did not consider advances in sampling techniques that were being developed at the time, which demonstrated much lower mechanical stress for some species. EPA's conclusion that "the only effective method of minimizing adverse effects to entrained organisms is to reduce the intake of water (Marcy 1975)" does not accurately reflect the source, which actually stated "…it may be possible to increase condenser ΔT's while lowering intake volumes, especially since the mechanical damage component of the mortality appears to dominate." Marcy's suggestion to increase, rather than maximize ΔTs, indicates a consideration of both thermal and mechanical stresses. In addition, Marcy was working from the perception at the time that mechanical entrainment mortality was generally high. Subsequent data showed that for many species, mechanical mortality could be quite low and that the potential for thermal effects at reduced CWS flow needed to be carefully evaluated (Jinks et. al. 1978; Steen and Schubel 1986). More detailed examples of flow reduction strategies that incorporate the both types of stress are found in the more recent literature.<FN 7>

Footnotes

7 Steen, A. E. and J. R. Schubel. 1986. An application of a strategy to reduce entrainment mortality. Journal of Environmental Management 23:215-228.

EPA Response

EPA reviewed studies that indicated that mechanical stress was the primary cause for mortality and other studies with indicated that temperature stress was the primary cause. These inconsistencies between the studies reviewed gave EPA further indication that entrainment survival was unpredictable and variable. EPA contends that entrained organisms perish due to a variety of reasons due to stress within and after discharge from a cooling water intake structure.

Entrainment survival chapter

A7-1.4 Chemical Stress – EPA continues to assert that biocides are routinely used, even though many facilities do not use biocides in the condenser cooling system at all, and those that do often have strict limitations on the amount of time during which biocides may be used. Typical usage, for those facilities that do employ biocides, would be on the order of a few hours per week. One of EPA's primary sources for this chapter (Marcy 1973) reported no increase in mortality due to biocide use.

EPA Response

EPA included information on biocide use because some facilities continue to use biocides. The typical usage cited by the commenter of a "few hours per week" is exactly what EPA meant by stating that biocides are "routinely" used. Several studies EPA reviewed indicated that during times when biocides are added to the water flow through a cooling water intake structure, 100 percent mortality can be assumed. Please see the chapter, Entrainment Survival, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule.

Entrainment survival chapter

A7-2 Factors Affecting the Determination of Entrainment Survival – In this section, EPA has confused empirical and theoretical issues. In several instances, EPA has cited a modeling exercise intended to examine the potential biases that would result with particular types of sampling errors as evidence that these errors do, in fact, exist:

"Some species are extremely fragile and disintegrate during collection or when preserved, and are thus not documented when samples are processed (Boreman and Goodyear, 1981)." [Page A7-3]

"The loss or damage of organisms beyond identification during plant passage causes overestimations of the true fraction of live organisms in the discharge samples, because the disintegrated organisms are extruded from the sampling device (Boreman and Goodyear, 1981)." [Page A7-3]

"Additionally, the initial survival estimates may be overestimations of survival due to the disintegration of entrained organisms and their subsequent extrusion through the sampling gear (Boreman and Goodyear, 1981)." [Page A7-4]

A detailed reading of Boreman and Goodyear (1981) shows that none of these statements are actually attributable to them. Their paper is a theoretical analysis of the potential sources of error in survival studies and any statements about error sources should be interpreted in a hypothetical rather than empirical context. Several lines of evidence, none of which are discussed by EPA, indicate that disintegration of larvae from transit through the CWIS is not extensive and is not a significant source of bias in the entrainment survival studies. First, laboratory studies using power plant CWIS simulators have exposed a variety of fish eggs and larvae to hydraulic regimes, shear forces, and pressures designed have to duplicate exposures typically occurring during transit through operating steam-electric plants. These controlled studies indicated no extensive destruction or loss or test organisms exposed to such stresses (Poje et al. 1978; Ginn et al. 1978; Coutant and Kedl 1975; Kedl and Coutant 1976; Cada et al. 1981).

Second, entrainment survival gear development studies have been conducted in which known numbers of entrainable life stages of several species were entrained through a variety of types of pumps and small (3-6") diameter piping (ESEERCO 1978). Similarly gear tests and calibration studies conducted on pump/larval table collection systems have passed known numbers of striped bass larvae through 4" diameter trash pumps and through 4" diameter tubing at high velocity. These studies generally gave no evidence of wholesale disintegration or destruction of organisms.

Third, a number of entrainment survival studies conducted by Ecological Analysts enumerated larval fragments in intake and discharge collections as a quality control check on potential for extensive damage from entrainment and/or gear effects. These studies typically showed relatively low and similar amounts of fragments in intake and discharge samples.

Fourth, direct release studies using very large numbers of striped bass larvae (which were stained with dye prior to release) introduced into power plants intakes showed no evidence of mass destruction of larvae in discharge collections. (In fact in one direct release study, EPA's own consultant from ORNL observed over 90% survival of stained striped bass larvae swimming vigorously in the sample container after collection from the Bowline Point high velocity diffuser and immediately called ORNL to report that the high survival being reported by the utility studies was real).

Fifth, a number of entrainment survival studies have sampled from high velocity (10 ft/s) diffusers or locations of high turbulence in condenser outfalls. There would be little chance for dead fish or fish fragments to settle out in the discharge under such hydraulic conditions, yet survival percentages were relatively high for a number of species in these studies. If extensive destruction were occurring, high percentages of dead and dismembered fish would have been expected to occur in the discharge samples.

EPA Response

Please see the updated chapter, Entrainment Survival, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule. The citations to the Boreman and Goodyear paper after the statements made by EPA were intended to give that paper credit for highlighting the fact that organisms may be extruded through the sampling gear and not counted in entrainment survival calculations. The extrusion of organisms through the gear is only partly due to the velocity of the flow through the sampling gear. The main reason why organisms are extruded is that they are smaller than the size of the mesh in the sampling gear.

Entrainment survival chapter

EPA also indicated concern for settling of dead organisms: "There is also evidence that dead organisms may even sink to the bottom of the water column after entrainment (Marcy, 1975)." [Page A7-46] Marcy (1975) stated that dead organisms would settle out rapidly but provided no reference in support of this claim. However, Marcy (1973) found decreasing densities of dead fish along the 1.8 km discharge canal of the Connecticut Yankee station. Although, as Marcy speculated, dead organisms may possibly settle out in this physical setting, a long discharge canal is not necessarily a typical situation. In a study that EPA reviewed for this analysis, samples from both surface and bottom of the Indian Point discharge canal did not find significant settling<FN 8>. Plants with discharge pipes, rather than canals, typically have very high water velocities that would preclude settling. Many of the entrainment survival studies intentionally sampled from high velocity sections of discharges, including high velocity diffusers, specifically to minimize the potential for settlement to affect the results.

Footnotes

8 EA Engineering, Science & Technology. 1989.

EPA Response

Based on its examination of the data, EPA concludes that dead organisms have the potential to settle out of the water column and may not be included in the samples. This is one of many challenges that need to be addressed when attempting to design a proper entrainment survival study. Please see response to comment 316bEFR.002.015 for the discussion regarding the inclusion of entrainment survival in site-specific benefit analyses.

Entrainment survival chapter

EPA also expressed concern that “sampling conditions be nearly identical at intake and discharge locations (Marcy, 1973).” This concern is always relevant, but is much harder to achieve, especially with respect to water velocity through the sampling device, when using plankton nets, as did Marcy (1973) and other early studies, than when using more advanced sampling gear developed in later years.

On page A7-4 EPA discusses the mathematical calculation of mortality rates and raises concerns that control mortality may be higher than 5%-10%, sample sizes may not be equal at intake and discharge, and that sampling mortality and entrainment mortality may not be independent. EPA therefore recommends that mortality data from the discharge not be adjusted for intake mortality. In making these recommendations, EPA has not considered the work of its own former consultants who reviewed the mathematical calculations and developed formulae to estimate confidence bounds and power levels for mortality estimates. <FN 9> Those results do not require equal sample sizes at intake and discharge, nor do they require that intake mortality be less than 10% as EPA has suggested. They do correctly point out that lower intake mortality rates and higher sample sizes will lead to more precise estimates of entrainment mortality, and EPRI agrees with this conclusion.

Footnotes

9 Vaughan, D. S. and K. D. Kumar. 1982. Entrainment mortality of ichthyoplankton: detectability and precision of estimates. Environmental Management 6(2):155-162.

EPA Response

EPA is concerned that in many studies reviewed high intake mortality rates (nearing 100 percent) are used to offset only slightly lower discharge mortality rates, and thereby, give the impression that 100 percent of organisms survive entrainment. When looking at the data behind these estimates of entrainment survival, the reality is that few organisms are alive in either sample. It is for this reason why EPA recommends that discharge samples not be corrected for intake mortality. Please see the response to comment 306.0073.

Entrainment survival chapter

Previous comments submitted on the proposed rule (UWAG 2002) presented reasons why no fixed standard for intake mortality rates can be established, similar to the "rules of thumb" used for bioassay studies (Newman 1995). Those reasons include 1) test organisms are those naturally occurring in the source water body rather than organisms intentionally selected because they work well for laboratory testing; 2) test organisms will vary greatly in lineage, age, size, and physical condition rather than being relatively uniform in all of these characteristics as can be expected with bioassay organisms; 3) sampling organisms from the environment will necessarily impose more stress than using laboratory-reared organisms. In addition, as was pointed out by EPA, recirculation of the discharge will result in the sampling of previously entrained organisms at the intake. For all of these reasons, it is unrealistic to expect that intake mortality should or can be reduced to levels that are typical of bioassay studies.

EPA Response

EPA acknowledges receipt of this comment. This submission highlights the fact that studies to accurately document entrainment survival rates are extremely difficult to conduct. Please see response to comment 316bEFR.002.015 for the discussion regarding the inclusion of entrainment survival estimates in site-specific benefit analyses.

Entrainment survival chapter

On the issue of non-independence of sampling and entrainment mortality, USEPA hypothesizes a situation in which sampling mortality would be lower at the discharge due to weaker organisms dying during entrainment. An alternative scenario could also be hypothesized in which sampling mortality is higher in the discharge due to the combination of entrainment and sampling stress; i.e., larvae that would have survived entrainment die in the sampling gear as a result of the combined stresses. It is clear that no definitive position on the independence of entrainment and sampling mortality is possible at the present time, however, EPA has considered only one of the possible directions for the bias.

EPA Response

EPA disagrees with this commenter. The stresses encountered by the organisms by entrainment occur first so the weakest organisms will most likely die from entrainment before encountering stresses associated with sampling. In addition, the stresses from entrainment are also generally considered to be of a higher magnitude than the stresses associated with sampling.

Entrainment survival chapter

On page A7-8 EPA states “These small sample sizes may not be sufficient to provide accurate estimates of entrainment survival given that these facilities entrain organisms on the order of millions to billions per year.” This statement seems to indicate a fundamental misunderstanding of the statistical concepts involved. The size of the sample is the only relevant issue. The numbers actually entrained, whether the number is in the thousands, millions, or billions is not relevant to the accuracy of the estimate.

EPA Response

Both the EPA document and the commenter may be confusing accuracy with precision.

Accuracy (or statistical bias) can be related to sample size and population size, depending on the details of sampling. No sweeping generalizations can be made - accuracy depends on how the details of sampling relate to the population.

Precision increases with sample size (the number sampled) but is also related to the fraction of the population sampled. However usually the dependency on sampling fraction is influential only at small sample sizes, and as sample size increases the precision (or the confidence limits for a population estimate) will depend almost entirely on sample size and will effectively be independent of population size.

The importance of the quoted statement on page A7-8 is that sample size needs to be reckoned in appropriate units of sampling. If there is substantial variation among days, operating conditions, and seasons in entrainment survival, then sampling on a small number of days risks both inaccuracy and imprecision. Inaccuracy could result because of failure to design the sample to properly reflect the temporal distribution of physical conditions, organism sizes and species, and operating conditions. Imprecision could result because the sample size is small in terms of the relevant scales of variation (days or hours). Some studies assume that a single binomial distribution adequately describes variability of survival. Unless temporal variation (i.e. heterogeneity of proportions) in the proportion surviving is correctly accounted for, variability will be underestimated. A sample size adequate for a given precision, and an unbiased sampling design, cannot be specified until temporal variation in survival has been characterized and accounted for on relevant time scales.

RFC: Documented entrainment survival rate studies

In addition to their value in site specific analyses, the entrainment survival studies provide background information (EPRI 2000b) that is useful for planning and conducting prospective analyses of benefits of intake alternatives, including that: 1) biocides, if they are used at all, are used infrequently, thus the chemical component of entrainment stress is typically non-existent; 2) at many stations, the combinations of cooling water flow rate and heat rejection rate actually observed do not result in significant thermal mortality for many of the commonly entrained taxa; and 3) survival rate depends on species sensitivity to the physical stresses of entrainment, which should be relatively similar for closely related species. Significant proportions of entrained organisms from taxonomic groups that are relatively hardy (e.g. Serranidae, Ictaluridae) might be expected to survive passage through some cooling systems, while only a small percentage of more sensitive taxonomic groups (e.g. Engraulidae, Clupeidae) would be expected to survive passage through a cooling system regardless of thermal and chemical stresses.

EPA Response

RFC: Entrainment vs. entrainment mortality

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Assuming that entrainment survival is considered in the BTA assessment, existing survival data may be useful in:

- Screening of intake alternatives—a screening study of all available management options can be used to identify and prioritize intake alternatives for detailed evaluation. As part of this screening, existing entrainment survival studies can be used to identify intake alternatives that would be most beneficial and to qualitatively evaluate their potential for reducing entrainment losses.

- Selection of representative species—if representative species are the basis for the assessment, one of several possible criteria for their selection is that they be susceptible to effects of the intake. Existing entrainment survival data can be used to help assure that the focal species selected for assessment adequately represent a range of species' sensitivities to entrainment.

- Detailed evaluations of fish protection benefits— the use of existing entrainment survival data is necessary for calculating the potential reductions in entrainment mortality that may be achieved by installation of technology or operating alternatives. Where site-specific survival data for the existing intake technology and operation is not available, it may still be desirable to conduct evaluations of entrainment losses for the existing intake using survival estimates appropriately selected from studies at other sites. Such evaluations help to evaluate the relative reductions in entrainment mortality each of the feasible alternatives is likely to provide. Later verification of the assumptions used in the evaluations, including entrainment mortality rates, can still be performed, if necessary.

Where significant site- and species-specific data exist, or could be developed, it may be possible, now or in the future, to protect more organisms by specifying operating conditions that will minimize the numbers of organisms killed by entrainment rather than minimize the number entrained. Development of a site-specific operation plan will depend upon the species involved and their particular phenology, the flow control capabilities of the station, generation levels, ambient temperatures, and design of the cooling water system. Stations that have good entrainment survival data should be permitted to incorporate those data into their plan for compliance with entrainment criteria.

EPA Response

Please see response to comment 316bEFR.305.001 with regard to entrainment-based performance standards. Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis.

Entrainment survival chapter

Although entrainment survival studies are difficult and expensive to conduct, the EPA review of existing studies in the Case Studies Chapter A7 was overly pessimistic on several issues:

- Taxa covered – Typically only a few taxa are entrained at high densities at any particular station. Studies of entrainment abundance have shown that the 5 most abundant taxa will comprise on the order of 90% or more of entrained ichthyoplankton. For instance, at the Yorktown Station (York River, VA) a study in 1977 reported that entrained fish larvae were 68% Anchoa mitchilli, 15% Gobiosoma sp., 7% Menidia menidia, 4.5% Microgobius thallisinus, 1.5% Syngnathus fuscus, and approximately 4% others<FN 10>. In a 4-year study of entrainment at the Fort Calhoun Station on the Missouri River, freshwater drum (Aplodinotus grunniens) and suckers (Catastomidae) comprised 95.4% of all larvae collected<FN 11>. Because most species are entrained at low levels, it is neither possible nor necessary to derive empirical estimates of entrainment survival for every species that may be encountered.

Footnotes

10 Virginia Electric Power Corporation, Yorktown Power Station, Yorktown, VA. Environmental Studies- 1977.

11 King, R. G. 1977. Entrainment of Missouri River Fish Larvae through Fort Calhoun Station. Pages 45- 56 In L. D. Jensen (ed) Fourth National Workshop on Entrainment and Impingement. EA Communication, Melville.

EPA Response

EPA was referring to the number of taxa with regard to attempting to develop predictions of entrainment survival for national benefits and not site-specific determinations.

Entrainment survival chapter

Temporal extent of sampling -- Seasonal patterns of entrainment, particularly in northern states with large seasonal temperature variation, are typically very peaked, with a high proportion of total entrainment occurring over a short period of time. The timing of the peak varies depending upon the environmental conditions and taxa present in the source water body. At the Fort Calhoun Station, peaks occurred in June through early July, reflecting the spawning period of freshwater drum and suckers<FN 12>. Similarly peaked temporal distributions have been found in other freshwater and estuarine systems<FN 13> <FN 14>. Thus, it is not necessary to conduct year-round studies of entrainment survival. A much more cost-effective and relevant study would be done over the periods of peak abundance.

Entrainment survival chapter

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Inconsistent methodology – The methods employed in the studies reviewed by EPA in Chapter A7 and in the NODA varied among sites and sometime among years at a given site because of site-specific deployment issues and/or the rapid evolution of sampling technology during the period when most of the studies were conducted.<FN 15> Preferred sampling gear changed from plankton nets to pumped flumes to rear-draw and pumpless flume systems, with more reliable results as each advance in gear design reduced the effects attributable to the sampling itself. However, the rear-draw and pumpless systems appeared in the late 1970s and early 1980s, about the time when most entrainment survival studies were discontinued. Only 2 of the studies reviewed by EPRI were more recent than 1985.<FN 16> Future studies would benefit from this evolution in methods and would be expected to provide even more useful information for the facility-specific assessment of benefits. Moreover, while inconsistent methodology may be a valid objection for using the existing data to establish national benefits for the rule, it is not necessarily a reason to reject facility specific use of the data. That is, valid data may be obtained by alternate methods, the principal requirement being that the methods used at any facility provide estimates of entrainment mortality rates that are acceptable in terms of their accuracy and precision.

Entrainment survival chapter

Sample size – EPA criticized the relatively small sample sizes that were reported in many of the entrainment survival studies. It is true that many single-year studies had low sample sizes for many of the species collected. However, this was generally a reflection of the fact that only a relatively small percentage of the total number of species resident in the waterbody have significant susceptibility to entrainment. Many species are not susceptible to entrainment because of their life history and behavioral characteristics and habitat preferences. Sample size is often relatively high for the species most susceptible to entrainment, which are the logical focus of protection measures. In addition, it may be quite reasonable to combine information across years at a facility to obtain the most precise estimate of the entrainment survival rate. Loss reduction estimates made on the basis of multiyear averages in entrainment survival would not be inconsistent with management objectives that seek to protect the long-term health of the fish populations.

EPA Response

Please see response to 316bEFR.306.073. It may be necessary to combine data from different years at a facility. However, only like data should be combined.

Entrainment survival chapter

Latent effects –EPA criticized the latent effects component of the studies for not providing realistic or comprehensive assessment of sublethal effects. Although the artificiality of the latent observation period is undeniable, the critical issue is whether the entrained organisms collected from the discharge experience the same conditions as the unentrained organisms collected from the intake. On this issue, EPA had no comment. In other regulatory efforts, EPA employs similarly artificial test settings to determine the effects of contaminant exposures.

EPA Response

EPA disagrees. The issue is not whether the entrained organism collected from the discharge experience the same conditions as the unentrained organisms collected from the intake in the latent effects studies. Control and experimental samples must always experience identical conditions in any laboratory scientific study. The issue is whether the artificial laboratory setting in which the latent effects studies are conducted accurately reflects the conditions in the field that the discharged organisms are subjected to post-entrainment.

RFC: Entrainment vs. entrainment mortality

In its final rule EPA may wish to consider using entrainment survival (mortality) in the compliance assessment, thereby aligning the entrainment metric with the impingement mortality metric. It is entrainment mortality, not mere entrainment, that constitutes potential impact. Allowance of the opportunity to factor valid estimates of survival into the estimate of reduction from baseline levels (which assume 100% mortality) may stimulate the collection of better information than presently exists, particularly where some of the hardier taxa are the most commonly entrained. This additional information, even if it does not ultimately demonstrate high survival rates, will nevertheless be useful in understanding the factors which contribute to entrainment stresses and could ultimately lead to improved design of once-through cooling systems or entrainment protection technologies and techniques.

EPA Response

Please see response to comment 316bEFR.305.001 with regard to entrainment-based performance standards.

RFC: Entrainment vs. entrainment mortality

EPA has also requested comment on how to design entrainment survival studies to properly account for organisms that may be destroyed during passage through the condenser system. Destruction of organisms is a concept that is difficult, although not impossible to address. Although comparison of sample densities at the plant intake and discharge would be the simplest approach, this usually will not be sufficient because ichthyoplankton may exhibit distribution patterns at the intake that are typically removed in the discharge sample due to turbulence. Thus, the intake sample may have a systematic bias that is usually not found in the discharge sample. Even so, if properly designed, a comparison of net or pump samples at intake or discharge, in terms of density of organisms and their length-frequencies, can provide valuable information with which to address this question.

Much additional information on destruction can be obtained from use of state-of-the-art survival sampling at intake and discharge stations. By comparing the frequency and types of damage at both locations, some information can be obtained on the severity of organism destruction. If organisms are being completely destroyed during plant passage, then it is also likely that the occurrence of damaged, but still recognizable, organisms will be significantly higher also. Thus a finding of low and roughly similar frequencies of damaged organisms in both intake and discharge samples would suggest a low degree of destruction. However, a significantly higher frequency of damaged organisms in the discharge samples would suggest that organism destruction could be a factor that must be considered.

Direct release studies, in which large quantities of hatchery-reared organisms are released into the cooling system, are perhaps the most effective way to assess organism destruction. Release of a few hundred hatchery-reared organism directly into the intake sampling device, and larger numbers (order of 105) into the intake structure for subsequent sampling in the discharge using state-of-the-art survival gear can provide a direct estimate of damage that is not confounded by the unknown state of wild organisms. Direct release studies are probably most informative if the hatchery-reared organisms can be released somewhat out of the natural period of abundance so that there is no possibility of wild organisms of the same species and life stage appearing in the sample. These direct release studies have been used at plants on the Hudson River.

The approach to assessing destruction of organisms promoted by EPA in the revised Chapter A7, measurements of DOC and POC at the intake and discharge, seems unlikely to yield definitive results. Typical entrainment densities are less than 1 fish egg or larvae per m3, and even very high densities during peak periods at most stations would typically not exceed 10 organisms per m3. The amount of carbon that would be converted from POC to DOC, even if all entrained organisms were to be dissolved during passage through the cooling system, would be on the order of parts-per-billion (ppb), and would not be exclusively assignable to destruction of fish eggs and larvae.

EPA Response

Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis.

RFC: Performance/effectiveness of restoration

Restoration

Peru's comments relative to restoration have been previously noted in our first section of this comment report and are contained in detail in the our report Enhancement Strategies for Mitigating Potential Operational Impacts of Cooling Water Intake Structures (EPRI 2003b) included in this comment filing. We recommend that the states or the permitted have the flexibility to determine the need for independent peer review. Many states have existing restoration programs and extensive expertise on restoration design and performance thereby negating the need for independent peer review. Descriptions of uncertainty associated with proposed restoration projects is a reasonable and prudent scientific approach.

EPA Response

In the final rule, permitting authorities have the flexibility to determine the need for external peer review. The final rule includes a requirement for uncertainty analysis.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

RFC: Performance/effectiveness of restoration

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Adaptive management is also reasonable and scientifically prudent; however, we recommend that conditions that trigger adaptive management exercises be clearly articulated in restoration plans otherwise all groups involved in the project could abuse the process with constant project course direction changes. This is especially important, given the long-term nature of environmental restoration projects and the time lags between action and response, since frequent adjustment of management actions based on monitoring data can be counterproductive. Implementation of adaptive management should apply active, rather than passive, adaptation (Walters and Holling 1990)<FN 17>. Active adaptation explicitly chooses management actions to enhance learning and attempts to balance expected short-term performance with the long-term value of improved understanding of system behavior.

Footnotes

17 Walters, C. J., and C. S. Holling. 1990. Large-scale management experiments and learning by doing. Ecology 71(6): 2060-2068.

EPA Response

EPA agrees with the commenter that adaptive management should include active adaptation approaches.

The final rule requires creation of an adaptive management plan by the permit applicant and approval of the plan by the permitting authority. EPA believes this process will allow for strong communication between the permitting authority and the permit applicant about plans and expectations for the restoration measure.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

Any restoration measure must meet all of the requirements described in the final rule.

RFC: Documented entrainment survival rate studies

Request for Impingement and Entrainment Data

EPRI submits its recently completed report: Evaluating the Effects of Power Plant Operations on Aquatic Communities: Summary of Impingement Survival Studies (EPRI 2003c). This report provides a summary of impingement survival studies conducted at steam-electric power plants since 1970, along with guidance for their interpretation and use. This information will be of value in estimating impingement effects, evaluating the potential fish protection benefits of technologies, operational measures, and habitat restorations/enhancements, and designing future impingement survival studies. The report is a companion to the EPRI Entrainment Survival Review (EPRI 2000b), which summarizes entrainment survival information, and complements EPRI reports TR- 112013 (Catalog of Fish Population Assessment Methods) (EPRI 1999a), 1005176 (Guidance for Selection of Fish Population Assessment Methods) (EPRI 2002a), and 1005337 (Ecological Risk Assessment Framework for Section 316(b)(EPRI 2002b), which describe the assessment framework and methods and depend, in part, on impingement survival inputs.

Available impingement survival study reports were identified and accessed from several existing holdings, search of the open literature, questionnaires soliciting impingement survival information that were sent by EPRI to its members, and direct requests to several companies thought to have completed impingement survival studies. All documents thus obtained were reviewed and a database of relevant study descriptors and impingement survival estimates was compiled. The study descriptors included in the database provide information on important variables that may influence impingement survival or the interpretation of impingement for each study. To facilitate access to the reported details of the impingement survival studies, the source documents were scanned, compiled on CD and cross-referenced to tables contained in the report. The report discusses the general methodology used in the impingement survival studies; the coverage of species, waterbodies, and screen system characteristics provided by the studies; the factors influencing impingement survival; and factors to consider when using existing impingement survival data for §316(b) planning and assessments.

The review included 65 reports covering impingement survival studies at 29 steam electric plants located in 15 states and the province of Ontario. These studies covered all four of the major waterbody types for which EPA has proposed §316(b) performance requirements. The studies include survival data for three major types of traveling screens (angled, dual-flow, and single-flow) and the majority of studies have tested some form of modification to screen design and/or operation intended to enhance impingement survival. These studies have reported survival data for over 300 different taxa, most identified to the species level, although for many species sample size was small.

Various biological, CWIS, and water body factors have been shown to influence impingement survival rates, but no generally applicable mechanistic models for predicting impingement survival have been developed. Species type appears to be the primary biological factor influencing impingement survival, although growth transitions and seasonal changes in condition may also play important roles. Survival rates vary widely among species, but over 50% of the taxonomic families of fish and shellfish studied to date appear to have the potential for impingement survival rates of 80%

or higher with adequate screen design and operation.

The survival data indicate that the hardier species tolerate the stresses of impingement so well that they exhibit high survival rates under virtually all screen design and operating conditions. For moderately tolerant and sensitive species, the data suggest that modifying screenwash operation to a continuous mode may be the single most effective means for enhancing impingement survival. Screen rotation speed and the use of additional Ristroph-type modifications generally also improved survival of these species. Water temperature and, in the case of estuaries, salinity have been found to be important environmental variables influencing impingement survival, with higher survival at lower temperature and higher salinities.

The uses of impingement mortality rate estimates in §316(b) compliance assessments are discussed and general guidance is provided on factors to consider in using impingement survival data in planning studies and assessments.

EPA Response

EPA thanks the commenter for this submission.

Regional Benefits Approach

National Benefits

There are two major issues embodied in EPRI's comments on this section. First is the methodologies employed by EPA. Relative to this issue, we have solicited expert comments from Drs. Lawrence Barnthouse and Webb Van Winkle relative to the soundness of the methods used to estimate impingement and entrainment losses. Relative to converting avoided losses to economic benefits, Dr. Ivar Strand is our expert. Details on their comments are presented in Appendices A, D, and B, respectively. Summary comments are presented below. The second issue relates to verifying the calculations performed by EPA and the source of data used in those calculations, as should be found either directly in the NODA or in supporting documents in the Water Docket. Our findings relative to this issue are discussed in the following section.

Case Study Clarifications and Corrections

Essentially, we found verification of the calculations presented in the NODA to be extremely difficult, in some cases, impossible. The following are examples of some of clerical errors identified and some of the calculations we could not verify.

Section X - Clerical Errors

- EPRI and our experts identified at least six separate errors in data entry in these tables, indicating a lack of QA/QC on the effort. For example, (1) Table X-13: The number for the Before Discount column for No Target Species should read 161,685.22 not 151,685.22. In the Discounted using 7% column, the Bottom Fish value should read 77,608.91 not 77.608.91; (2) Table X-24: The number for the Reduced impingement and entrainment as % of total catch column for Bottom Fish should read 6.577 not 6.595; and (3) Table X-25: The number for the Change in recreational losses from impingement and entrainment as % of total catch for Bottom Fish should read 5.010 not 5.024.

- Table X-27: Missing #'s denoted as NA are found in the 316 (b) Regional Case Studies: Chapter F5: Recreational Fishing Benefits. The number for the Boat mode column for Other Fish should read 276. The numbers for the Shore mode column for Sturgeon should read 12,185 and for Big Game, 7,173.

- Table X-28: The number for the 3% discount rate column for No Target should read 417,034 not 471,034. The number for the 7% discount rate column for No Target should read 380,994 not 390,994.

EPA Response

The errors that the commenter notes were only errors in transcribing output from estimation programs to the document, and did not affect other uses of the data. EPA noted this submission and corrected the identified clerical errors in the final Phase II Regional Studies Document (DCN # 6-0003), as appropriate.

EPA methods: age 1 equiv, yield, prod foregone

Questions on validity of I&E values for All Ocean Facilities in the North Atlantic Region

Our main question is this: there are only 2 Ocean Facilities in the North Atlantic Region - Seabrook and Pilgrim. Both I&E data sets are found in the 316(b) Case Studies, Chapter G3: Evaluation of I&E Data. Therefore, one would assume that the Total Annual I&E losses for all Ocean Facilities in the North Atlantic region expressed as Age 1 Equivalents, Foregone Fishery Yield, and Production Foregone, would mirror the combined values located in Chapter G3. This holds true for the entrainment data for Age 1 Equivalents. If you sum the mean Annual Entrainment at Pilgrim, by Species, Expressed as Age 1 Equivalents (Table G3-15) and the mean Annual Entrainment at Seabrook, by Species, Expressed as Age 1 Equivalents (Table G3-7) you get the values found in Table X-9 (page 13554) of the NODA.

The above assumption does not hold true for any other calculation. For example, the entrainment values of Total Yield and Production Foregone found in Table X-9 do not equal the summed entrainment values for the two facilities found in Tables G3-8 and G3-9 for Seabrook, and Tables G3-16 and G3-17 for Pilgrim. The values in Table X-9 of the register are higher.

See Hard Copy for Tables

EPA Response

The commenter has noted some apparent discrepancies among tables reported in the Case Study Document presented at proposal (DCN #4-0003) and analogous tables reported in the NODA. EPA revised aspects of the proposal I&E analyses for the NODA and therefore results from proposal and the NODA do not necessarily agree. General changes to EPA's I&E analyses are presented in the NODA and in Chapter A5 of Part A of the Regional Analysis Document (DCN #6-0003) prepared for the final Phase II rule. Any changes in the life history data used by EPA are provided in the life history appendix provided with each regional study report in the Regional Analysis Document.

The tables are in agreement with respect to age 1 equivalents, as expected. The tables disagree with respect to foregone yield for two reasons: (a) EPA revised many growth-related parameters (such as weight-at-age) between the time that the two separate reports were issued, which affects estimated weight-at-harvest; and (b) the tables listing foregone yield in the NODA include so-called "secondary yield", i.e. the augmentation of foregone yield flowing from the trophic transfer model (see Chapter A5 of the Regional Analysis Document), whereas the table reported in the initial Case Study Document (DCN #4-0003)presented at proposal do not include secondary yield.

Organization EPRI

Subject Matter Code 10.02.07

Regional Benefits Approach

As best we can determine, there have been no major changes in the calculations for Total Yield and Production Foregone. In the NODA it states that the Yield Equation contains a typographical error in the Case Study document, but EPA verified that the correct equation was used for the case study analysis. EPA did increase the "net trophic transfer efficiency" from 2.5% to 20% in the model used to calculate Production Foregone. But then EPA states that," although this change in transfer efficiency increases the portion of total yield attributable to the consumption of forage fish, the net effect is insignificant because the trophic transfer pathway accounts for a very small portion of the total foregone yield." If this statement were true, we would not expect to see changes in the values for Total Yield and Production Foregone from the case study analysis to the NODA.

None of the impingement data found in Table X-8 of the Federal Register mirrors the summed impingement values for Seabrook (Tables G3-3, G3-4, and G3-5) and Pilgrim (G3-11, G3-12, and G3-13). This increase is due to the fact that in the case studies EPA assumed that all impinged fish were age 1. The current NODA assumes instead that the ages of impinged fish are age 1 and older.

For example:
Below are the values for Mean Annual Impingement, Expresses as Age 1 Equivalents

(See hardcopy page 44 for table)

EPA Response

EPA used a trophic transfer efficiency of 10% for its final analysis, based on information in Pauly and Christensen (1995) (see DCN #6-1004). EPA notes that any changes in values for Total Yield and Production Foregone will depend on numerous other variables in addition to the trophic transfer efficiency (e.g., growth and mortality rates of life stages and species impinged and entrained).

EPA methods: age 1 equiv, yield, prod foregone

Author Name Doug Dixon & Kent Zammit

Organization EPRI

We also tried to verify age 1 equivalent data, but were unable to reproduce the numbers in the NODA or even the docket documents DCN 5-1002 and DCN 5-1003 (Outline of 316(b) Case Study Evaluation of Impingement and Entrainment Data). We believe that the equation for Feffective found in these two documents is incorrect. Also, to be able to verify I & E values in the NODA, the following information is needed:

- Which facilities are the case study facilities for the new regional study? (We assume Millstone and Brayton Point for the North Atlantic Region, Estuary/Tidal River Facilities, but it is never clearly stated)

- What is the flow at the case study facilities? (We know 822 MGD for Brayton Point, Millstone-?)

- Total Flow in the region?

- The NODA contains a statement that Average Annual Results for facilities with I & E data were averaged and extrapolated on the basis of operational flow to facilities without data. Our question is, were all years for which data were available used for the extrapolation, or were certain years excluded due to low operation/shutdown, etc?

EPA Response

The commenter believes that the equation defining F(effective) is incorrect, but does not elaborate on how it is incorrect. Without more description of the supposed problem, EPA is unable to respond to this comment.

The commenter is uncertain about the model facilities used to generate regional estimates. The commenter is correct that Millstone and Brayton Point are the model facilities for estuary/tidal river facilities in the North Atlantic Region. Information on the facilities with I&E data that were evaluated in each region are presented in the Regional Analysis Document (DCN# 6-0003).

The commenter asks for information about flow rates at several facilities. This information is considered by some facilities to be Confidential Business Information, so it is intentionally omitted from the Regional Analysis Document

The commenter questions EPA's timeframe (use of years in which data were collected). EPA selected representative years of operation through consideration of representative plant operations. In order to establish a meaningful baseline, in some cases loss rates from the year of collection were adjusted by a scalar reflecting changes in installed protective technologies or other plant characteristics between the time of data collection and current conditions. EPA did not use data from years in which plant operations were known to be atypical, such as years with significant shutdowns.

Subject Matter Code 10.02.07

Regional Benefits Approach

Dr. Lawrence Barnthouse in his review of the regional analyses also concluded the following:

“I was greatly impeded in my review by the poor documentation provided in the NODA and in the docket. I was unable to reproduce any of the age-1 equivalent loss, foregone yield, or production foregone estimates provided in the North Atlantic and Northern California case studies. For this reason, I cannot evaluate the quantitative importance of the errors and overly conservative assumptions I identified. In addition to the problems I found in my review, some of the values provided in the benefits tables for these new case studies appear suspicious, (e.g., the extremely high value of tautog production foregone in Table X-7, FR page 13553), however, the information needed to confirm whether errors have been made is unavailable.”

The above are likely only a few of the errors and/or lack of clarification/guidance for verifying EPA’s calculations. Without extensive conversations with EPA regarding their development, much as occurred during the proposed Phase II rule comment period, EPA’s calculations cannot be verified.

EPA Response

EPA has conducted extensive QA/QC of results presented in its final analysis and believes that any errors or inconsistencies in earlier drafts have been eliminated. See EPA’s QA/QC plan for a general discussion of its procedures (Docket #6-1002).

EPA has also made a concerted effort to document its analyses as completely as possible. Nonetheless, because these analyses are complex and involve multiple data sets and analytical methods, EPA recognizes that some reviewers may find it difficult to duplicate all of EPA's calculations.

Regional Benefits Approach

Regional Approach to Developing Benefits Estimates

Drs. Lawrence Barnthouse and Webb Van Winkle prepared detailed comments on behalf of EPRI on the methods used to convert I & E losses into age 1 equivalents, fishery yield and biomass production foregone. Their comments can be found in Appendices A and B, respectively. The following are summary comments from each of their reviews.

Dr. Barnthouse:

- In the NODA, EPA announced a change in the assumptions made concerning the age distribution of impinged fish and concerning the fraction of forage fish biomass that is converted to harvestable predator biomass (termed "trophic transfer efficiency"). In reviewing the NODA itself and the supporting information provided in the docket, I found significant problems with both of these methodological changes.

- The new assumption concerning impingement age distributions is clearly wrong, is contradicted by data already in the docket, and would greatly overstate the benefits of reducing impingement. Monitoring data collected throughout the U.S. demonstrate that impinged fish are generally age 0.

- The new assumption concerning trophic transfer efficiency is inconsistent with the most recent scientific literature and would overstate the benefits of reducing entrainment and impingement of forage fish.

EPA Response

Few facility studies provide information on the age distribution of impinged fish. In EPA's original case studies, EPA assumed that all impinged fish were age 1. Based on comments on this assumption and a review of available information on the ages of impinged fish (e.g., the 1992 monitoring report for the Millstone facility (DCN #5-2307) and New York's Draft Environmental Impact Statement for the State Pollutant Discharge Elimination System Permit Renewal for Bowline Point, Indian Point 2 & 3, and Roseton Steam Generating Stations (DCN #4-3100)), EPA's final analysis for the 316b Phase II rule assumed that impinged fish range in age from juvenile to age 5 and that the age distribution of impinged fish is species specific and follows a fixed distribution as indicated by the set of stage-specific survival rates for each species. In all cases, this method leads to an assumed age distribution that is dominated by juvenile stages, followed by age 1-age 5 fish, each in decreasing relative abundance.

In its final analysis, EPA used a trophic transfer efficiency of 10% as recommended by the commenter and supported by Paul and Christensen (1995) (see Docket #6-1004).

Fish Population Modeling

Dr. Van Winkle:

Benefits expected by EPA are not realistic. The benefits expected by EPA in their 316(b) rule making for Phase II existing facilities are not realistic for two reasons. First, empirical evidence is not available from any field study during the past three decades indicating I&E losses are the sole cause, or even the primary cause, of changes at the population, community or ecosystem levels. Second, theoretical considerations and real-world experience relating to direct mortality losses, such as I&E and fishery losses, clearly indicate that managing fish populations by managing direct mortality on early life stages is not as effective as managing fishing mortality Thus, detecting effects at the population and higher levels (much less, economic benefits for humans) caused by reductions in I&E losses seems highly unlikely, even with extensive multi-year monitoring studies.

EPA Response

EPA agrees with the commenter that it is extremely difficult to detect effects at the population and higher levels of biological organization (see the book by Schmitt and Osenberg, "Detecting Ecological Impacts", DCN 2-019A-R21). For this reason, EPA did not base its section 316b benefits analysis and regulatory decision-making on such analyses. EPA also notes that its analysis was not concerned with determining the relative efficiency of minimizing I&E and reducing fish harvest. EPA is concerned with all stressors on fishes in U.S. waters. EPA also notes that control of harvest alone can be insufficient for stock recovery, as indicated in the case of winter flounder in Mt.Hope Bay, Massachusetts. In addition, for the 98% of I&E losses that are not of commercial and recreational fishery species, harvest control is obviously not an option.

Methods to Evaluate I&E

EPA's assumptions concerning entrainment survival and compensation are not appropriate in the context of EPA's regional—national cost-benefit analysis. Two assumptions made by EPA in its regional-national cost-benefit analysis are not supportable because we know, with 100% certainty, that they are both inconsistent with scientific evidence. EPA assumes 0% entrainment survival for all life stages of all fish species at all facilities under all operating and environmental conditions for all years. EPA also assumes zero compensatory offsets of I&E losses for any population of any species at any facility under any operating or environmental conditions in any year. Furthermore, adoption of these two assumptions, without any characterization of uncertainty, results in providing decision-makers, all stakeholders and the public with inflated estimates of I&E losses and inflated estimates of benefits of reducing these losses. In the context of site-specific 316(b) determinations, these two assumptions may be reasonable. However, for EPA's regional-national analysis these two assumptions apply to ~550 facilities and hundreds of fish populations under all conditions, and in this context EPA's two assumptions are not scientifically supportable.

In estimating regional I&E losses and benefits of reducing these losses, the focus is on a population of 550 facilities and hundreds of fish populations under a broad range of conditions. EPA's analysis is designed to compare the national benefits and national costs of the proposed rule as applied to this population of facilities and associated fish species. As part of such an analysis, EPA is mandated by its own policies to characterize the uncertainties in both benefits and costs. EPA did not do this in either the proposed rule or the NODA. EPA's assumptions concerning entrainment survival and compensation are two of the most troubling examples.

Having calculated total regional impingement and entrainment losses by waterbody type and species or species group, EPA's next step should have been to consider uncertainty relating to entrainment survival and compensation. Use of fuzzy numbers is an effective and simple method for representing uncertainty in entrainment survival and compensation in EPA's benefits analysis. For both entrainment survival and compensation, the fuzzy-number approach provides for acknowledging EPA's reasons for adopting the simplistic and convenient assumptions of 0% entrainment survival and 0% compensatory offset. However, the approach also acknowledges that:

- EPA has an obligation to characterize uncertainty.

- With 100% certainty we know that some entrainment survival and some compensatory offset will occur among the hundreds of fish populations experiencing I&E losses at the 550 facilities covered by EPA's rule making for Phase II existing facilities.

- Ignoring these realities results in inflated estimates of I&E losses (especially entrainment losses) and benefits of reducing these losses.

EPA Response

EPA did a thorough analysis of available entrainment survival documents. For EPA’s conclusions about entrainment survival see Chapter A7 of the Phase II Regional Analysis Document (DCN #6-0003). See also EPA's response to Comment 316bEFR.306.506.

For a discussion of EPA’s assumptions about compensation see the response to Comment 316bEFR.025.015.

For a discussion of omissions, biases, and uncertainties in relation to EPA’s analysis, see Chapter A6, Chapter A10 and the regional reports contained in EPA's the Regional Analysis Document (DCN #6-0003) for the final rule.

Methods to Evaluate I&E

EPA has failed to adequately characterize uncertainties. EPA's regional and national benefit analysis is unavoidably based on many decisions, assumptions and information sources, and it involves many computational steps. In addition, the analysis requires extrapolation on a grand scale both ecologically and economically. Uncertainty, whether due to unavoidable variability or other sources of uncertainty, is associated with every decision, assumption, and information source incorporated in the analysis and with every additional computational step and level of extrapolation. Consequently, uncertainty is guaranteed to monotonically increase throughout EPA's analysis.

I propose seven inequalities involving I&E losses, complexity of EPA's analysis framework, benefits, costs, and uncertainty. These inequalities have several advantages over a detailed quantitative uncertainty analysis that attempts to cope with the many individual steps in EPA's analysis. They are simple and easy to understand, and they all make a macro-level claim. In addition, they are not likely to be controversial because in the context of EPA's analysis they can be easily verified or, in the case of the uncertainty inequalities, are likely to be accepted. Alone or in combination, these inequalities highlight important issues and make powerful statements in the simple manner that should appeal to decision-makers and nontechnical people. Based on these inequalities, it is clear that EPA's cost-benefit analysis for reducing entrainment losses is less convincing than its case for reducing impingement losses. This is an important conclusion to be able to reach because it should condition the vigor with which EPA is justified in requiring costly technological requirements to reduce entrainment losses compared to impingement losses.

Methods to Evaluate I&E

EPA Inflates Benefits of Reducing I&E Losses by Compounding Precautionary Assumptions. EPA has made precautionary assumptions at multiple steps in both its biological evaluation of I&E losses and its estimation of the benefits of reducing these losses. Several biological examples are highlighted elsewhere in my review, including 0% entrainment survival and 0% compensatory offset. Without these multiple precautionary assumptions, the economic benefits analysis would be very different. However, EPA has not acknowledged that it is relying on a precautionary approach, has not justified the need for this approach, and has not quantified the magnitude of the inflationary bias created by adopting this approach.

EPA Response

Please see Chapter A7 of the Phase II Regional Analysis Document(DCN #6-0003)and response to Comment 316bEFR.306.506 for a discussion of EPA's reasons for assuming zero entrainment survival. See response to Comment 316bEFR.025.015 for a discussion of EPA's assumptions regarding biological compensation. Please see response to Comment 316bEFR.005.026 regarding the term "precautionary approach."

EPA methods: age 1 equiv, yield, prod foregone

North Atlantic Regional (NAR) Study

In addition to some of the errors or lack of clarity in the EPA analyses, as noted above, we also attempted to verify the NAR equivalent loss calculations that are presented in the NODA to see if they are reasonable. Unfortunately, EPA does not provide sufficient information in either the NODA or original Case Studies to duplicate their answers. For example, EPA does not provide estimates of the duration of each life stage nor the breakdown of the total entrainment by life stage. Even without such data, we identified a few points that do not look correct:

- The production foregone values for tautog for the North Atlantic (NODA Table X-7) appear totally inconsistent with the number of Equivalent Age 1 and estimated Yield Foregone. By assuming that most (~80%) of the entrainment was eggs, we were able to get Age 1 numbers comparable to EPA's for Brayton Point from the Case Study. When we ran the production foregone model for this species, we came up with more than 12 million pounds. This appears to be unreasonably high. We then looked at the life history values used for tautog (Case Study Table F1-13) and found that they assumed each egg weighed ~1 gram (0.00022 lbs) and each larvae weighed ~10 grams (0.022 lbs). These would be very big eggs and larvae! (Note: for comparison, a 3 inch (75 mm) striped bass weighs just over 5 grams). To see if this might be the reason for the high EPA production foregone values, we re-ran the production foregone model using more reasonable weights for eggs and larvae (typical for cunner). This one change dropped the production foregone for tautog from more than 12 million pounds to less than 2,500 pounds. Clearly, the production foregone model is very sensitive to values used for weight in the early life stages when mortality is high.

- Based on these results, we looked at other weights used in the Brayton Point Case Study. We found that they used unreasonably high weights for eggs and/or larvae for many other species. For example, weakfish larvae were assumed to weigh 30 grams each and winter flounder larvae were assumed to weigh 2 - 10 grams each. For many of the other species, larvae were assumed to weigh 0.5 to 1 gram each. Even these values are way too high. Larval fish are most typically in the range of hundredths of grams each.

Clearly, the EPA did not apply reality check tests to the values used in these calculations. The likely result is that the production foregone values are likely to be substantial overestimates for many of these species. Unfortunately, without more information from the EPA it will prove difficult to further evaluate the estimates presented in the NODA. In addition, the recreational fishing valuation results (X-C-4) presented in this section probably grossly overstate flatfish losses. We were not able to locate DCN-1271 in the docket. This document describes the species groupings on which economic values for four broad species groups are based. These groupings likely have little or no relationship to the species actually constituting the entrainment and impingement counts used for the fisheries analyses. For example, Table 1 (below) shows the species groupings EPA used when compiling entrainment data for Seabrook. Entrainment numbers reported as winter flounder by EPA actually encompassed taxa designated in the entrainment database as Atlantic cod/witch flounder, cunner/yellowtail flounder, Pleuronectidae, winter flounder, witch flounder, and yellowtail flounder. Figure 1 shows the estimated entrainment for these taxa at Seabrook. Note that winter flounder was only a small fraction of entrainment attributed to winter flounder by EPA. Furthermore, the vast majority of the entrainment in the cunner/yellowtail flounder category was actually cunner. The facility report describing the entrainment data clearly states that "A comparison of cunner and yellowtail flounder larval abundance indicated that most of the eggs in the cunner/yellowtail flounder group were likely cunner, assuming a relatively similar hatching rate between the two species." (Normandeau Assoc. 1999: p 4-45)<FN18>. While the ratio of cunner to yellowtail flounder larvae varies from year to year, it can be as large as 408:1 (1997: Normandeau Assoc. 1998)<19> Clearly, entrainment numbers for all flounders and especially winter flounder have been grossly overstated. This problem is compounded when the higher per-fish value associated with winter flounder is assigned to these entrainment numbers.

(See Graphs and Tables on Pg 49 - 51)

EPA Response

The commenter has noted several results that appear unreasonable. These results were associated with several biological parameters, such as larval weights, that EPA has revised in its analyses subsequent to receipt of these comments and others on similar topics. Please see response to Comment 305.003 for discussion of EPA's production foregone analysis. EPA has also revised its species aggregation scheme, and cunner are no longer aggregated with winter flounder.

Regional Benefits Approach

Northern California Regional Study

Because of the limited time available, we were unable to evaluate to the same level of detail the calculations for the Northern California Study. Based on results of our NAR analyses, we are not confident that we could verify them nor are we confident that they represent a reasonable estimate of I&E losses for the region. Before moving forward with analyses for other U.S. regions, we recommend the development of standard QA/QC procedures to be followed as well as the use of direct and indirect reality checks on the reasonableness of input parameter values and calculations derived from them.

EPA Response

The commenter is incorrect to assume that EPA did conduct QA/QC analyses or "reality checks" of its input data and results. In fact, extensive review was conducted on all aspects of EPA's analyses. See EPA's QA/QC plan for a general discussion of its procedures (Docket #6-1002).

Nonuse Benefits

The following are the major summary comments by Dr. Ivar Strand on EPA's nonuse benefits analyses. Dr. Strand's detailed comments are in Appendix B:

In correcting the flaws in the previous analysis, EPA's two applications, as presented in the NODA, make clear the importance of properly estimating non-use values of fish and shellfish populations and also the complete inadequacy of existing research on the topic. The use values associated with the North Atlantic and Northern California regions contained in the NODA are believable and they highlight the fact that nonuse values must be around 20 to 30 times larger than the use values in order for benefits to equal costs. With non-use or passive use values being so pivotal, it is critical that they be estimated well.

EPA Response

The Agency agrees that estimating non-use values is critical to obtaining comprehensive estimates of total resource value such that the resulting total value estimates may be compared to total social cost. Given that ninety eight percent of organisms affected by I&E are not evaluated directly in the commercial and recreational benefits analysis, and the population of nonusers is larger than the populations of users, it is not unrealistic for the total non-use values to be many times greater than use values. For additional details regarding this issue, please see response to comment #316b.EFR.306.315.

Peconic-based approach

Author Name Doug Dixon & Kent Zammit

Organization EPRI

EPA's estimates of non-use value in the North Atlantic region raise substantial concerns, the most prominent among them are:

- There is no research that addresses the non-use value inherent to fish and shellfish stocks affected by the proposed regulations. Does the non-use value change with decreases in numbers of fish and shellfish impinged and entrained? Or is it more akin to existence value, with a threshold effect? No one knows but EPA assumes that non-use value changes with decreases in numbers of fish and shellfish impinged and entrained;

Regional Benefits Approach

Regional-Level Benefit Cost Analysis

The following summarizes Dr. Strand's comments on the regional-level analyses. Details can be found in Appendix B.

Another potential problem in the NODA is the merging of all facilities into an aggregate regional analysis so that benefits are only dependent on the sample of facilities in a region. While a region-based analysis is probably superior to the original EPA method, the heterogeneity in rivers, estuaries and oceans in combination with differences among facilities makes the regional expansion based on a few facilities quite tenuous. If the facilities chosen in the sample are not representative of the region, then a serious bias will exist. Because the data that exist are most likely associated with facilities that have high I& losses, the bias will upward. [detailed comments on extrapolating facility-level impingement and entrainment losses and the effects of multiplicity of conservative assumptions have been previously reviewed and discussed in detail by Drs. Barnthouse and Van Winkle in Appendices A and D, respectively]

EPA Response

It is not true that only "a few" facilities were evaluated in each region. In fact, I&E data from multiple facilities in each region were used to develop each regional estimate. In some cases, all of the facilities with I&E data in a region were evaluated (e.g., Northern California).

It is also not true that EPA's analysis was based only on facilities with high losses; in fact the magnitude of losses varied widely at the facilities evaluated. EPA was, however, limited in its analysis by a lack of facility I&E monitoring data. As facilities go through the permitting process and permitting authorities collect more I&E data, it will become possible to develop more precise regional estimates.

Given that the goal of EPA's analysis was to develop estimates of impacts and benefits at the national scale, EPA believes that it's regional approach provided a reasonable basis for extrapolation. Please see response to Comment 316bEFR.041.041 for additional discussion of EPA's extrapolation approach.

Author Name Doug Dixon & Kent Zammit
Organization EPRI

Subject Matter Code 10.02.04
Valuing Forage Species (incl non-use and non-landed)

In the North Atlantic and Northern California regions, the use values associated with impingement and entrainment losses appear miniscule in comparison to the costs of closed-cycle cooling. If this is also true in the remaining regions, then the estimates of the non-use or passive values are critical. However, EPA has not undertaken a stated preference study that will directly address them. Although monetary and time constraints are used to justify the inaction, substantial funds have been devoted to more studies associated with use values. If the use values continue to remain so small relative to costs in the remaining six regions, then EPA should initiate a process to obtain a better understanding and better estimates of non-use values associated with fish and shellfish populations. The traditional way to approach this is a state of the art stated preference analysis.

EPA Response

As this and several other commenters have noted – and as EPA itself has stated throughout – the best (and only direct) method available for developing reliable and defensible 316b-specific estimates of nonuse values is through the careful design and implementation of a stated preference (SP) research method. This could take the form of a contingent valuation method (CVM) survey or other notable forms of SP research (e.g., conjoint analysis).

SP methods of primary research entail the careful design of survey instruments (e.g., questionnaires) that are administered according to quality-assuring protocols to a scientifically-based sample of individuals. The survey instruments are used to elicit respondents' willingness to pay (or other indications of values or preference rankings) for the physical outcomes that are anticipated from the 316b rule.

While there is broad recognition and acceptance that SP methods are the primary research technique available to estimate nonuse values, there are several important practical reasons why EPA has not pursued such an effort for the 316b rulemaking. The design, implementation, and data analysis associated with conducting a high quality SP method application can be complex, time-consuming, and expensive. The method applied to measuring passive use values is controversial within some portions of the economics profession. Any results generated by a 316b application would most certainly generate as much controversy as it added to measuring the desired values.
In addition to the practical realities that make implementation of a state-of-the-art SP research method difficult and expensive, there also are administrative constraints that a federal agency has to address under the Paperwork Reduction Act to develop and field-implement any survey instrument and sampling design. Overall, the expense, administrative burden, and calendar time associated with an Agency effort to develop and field an SP method for 316b was considered to be beyond what was feasible within the various constraints the Agency faces.

The result of the Agency's choice not to pursue a quality SP primary research effort is the approach used to evaluate the high proportion of unlanded fish that are left out of the recreational and commercial benefits analysis. This approach is based on secondary applications and interpretations of other existing research.

As a result of this dilemma, several commenters have either critiqued the various second best methods the Agency has tried to apply in lieu of a primary SP study, or they have suggested the Agency do the primary SP research required, or both. Ideally, the Agency would have the time and resources to pursue a state-of-the-art SP study. Perhaps time and other resources will be available in the future to enable EPA to develop more primary research for benefits analyses of rulemakings under the Clean Water Act.

Please note that for the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. See Chapters A12, Non-use Meta-analysis Methodology, and A9, Economic Benefit Categories and Valuation Methods of the final Phase II Regional Studies Document (DCN # 6-0003). Please see Chapter D1 of the final Phase II EBA document regarding break-even analysis.

Subject Matter Code 10.02.04

Valuing Forage Species (incl non-use and non-landed)

Break-Even Analysis

The following summarizes Dr. Strand's comments on the break-even analysis. Details can be found in Appendix B.

Perhaps because of difficulties in obtaining relevant non-use values in the North Atlantic, EPA decided to approach this question from a different angle when evaluating the Northern California region. For Northern California, EPA calculated "break-even" nonuse value, the dollar amount of non-use value that would equate the total economic value with the costs of Northern California investment in closed-cycle cooling systems. While this may be useful information, it is not a substitute for credible estimates of the non-use value of the changes in fish and shellfish stocks associated with lower impingement and entrainment in CWIS. We know what the non-use values would have to be, but we still do not know what they are.

EPA Response

The commenters are correct in that the break-even approach does not answer the critical question of how high the values are, but rather indicates how high the values would need to be in order for benefits to equal costs. Ideally, primary research would be available to help answer the "how high are the benefits" question more directly. However, given the reality that such research does not exist and was not feasible for the Agency to pursue within the context of this rulemaking, the break-even approach provides a useful way to provide some "context" within which decision making process.

As EPA's analysis indicates, the direct use benefits estimated for recreational and commercial fishery impacts reflects only a very small portion of the physical injury associated with impingement and entrainment (i.e., EPA's direct use benefits analysis reflects landed fish, and the I&E assessments reveal that these account for less than 2% of the age 1 equivalent fish lost to I&E are fish not landed by recreational or commercial anglers). Accordingly, a comparison of the estimated direct use benefits alone to compliance costs provide an incomplete and potentially misleading. Taking account of the beneficial values (to reflect the value of protecting the predominant share of the I&E-impacted fish) thus becomes a critical component of the benefit-cost analysis for this rulemaking.

As noted throughout EPA's documents and acknowledged by many commenters, estimating nonuse or other values as may be associated with the unlanded fraction of fish loss is an extremely challenging and uncertain exercise, particularly when primary research using stated preference methods was not performed. In lieu of primary research using stated preference methods, the Agency explored other options. EPA described and applied multiple approaches for developing nonuse benefit estimates based on benefits transfer and associated methods. Each of these secondary approaches has conceptual and empirical limitations as recognized and acknowledged by the Agency. Given the uncertainty about the magnitude of values estimated by these or other means, EPA also developed and applied the "break-even" analysis to provide an alternative context with which to consider the potential likelihood that total benefits (including a reflection of values as may be associated with unlanded fish) might justify the regulation's cost.

While this approach of backing out the "breakeven" value per household does not directly answer the question of what nonuse or related values might actually be worth for the 316b rulemaking, these results do frame the question with a useful perspective that appeals to common sense and facilitates policy-making decisions. The break-even approach poses the question: "are the implicit non-use WTP estimates per household plausible, given empirical evidence available from the existing body of empirical research?" The available literature was then reviewed and reported in a manner that EPA believes does provide decision makers with some useful benchmarks and context for considering whether the benefits might equal or exceed costs. That is, the decision makers were not left to guess how high benefits were – rather, they were given some relevant information from the literature to help them place the results in perspective relative to established valuation benchmarks.

Please also see results from the break-even analysis reported in Chapter D1 of the EBA (DCN #6-0002).

Determination of compliance

Implementation and Other Regulatory Refinements

Definition and Methods for Determining the “Calculation Baseline”

EPA refinement of the theoretical ‘calculation baseline’ definition is an improvement from proposal. Establishing such a baseline provides a reasonable theoretical metric against which credits for existing fish protection can be ascertained. We have only a few comments relative to the proposed definition, as subsequently discussed. We do note, however, that this baseline calculation should likely be an optional and not prescriptive compliance metric. As later discussed, some applicants may wish to pursue the “as built” approach, therefore, provision for flexibility in conducting compliance monitoring should be provided.

The location, orientation, configuration and mesh size all are reasonable theoretical baseline definition components. We suggest EPA consider adding to this definition that flows operate a full capacity, year round. This addition will allow facilities that have scheduled outages for maintenance in accordance with peak entrainment periods to obtain such credit. Some plants may also reduce flows during certain periods as a fish protection approach. Incorporation of the full-flow operation criteria provides a metric against which flow reductions for fish protection can be measured.

EPA Response

EPA has clarified its definition of calculation baseline in today’s final rule (see §125.93). For additional explanation of EPA’s definition of calculation baseline, please refer to EPA’s response to comment 316bEFR.034.013 and the preamble to the final rule.

Comment ID 316bEFR.306.108

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Subject Matter Code 21.04

Determination of compliance

We also suggest that regulators have additional flexibility to add components to the definition to account for other measures that may have been implemented or installed for improved fish protection. For example, intake screen system operation varies among facilities in ways that significantly affect impingement mortality, including:

- Debris collection from the screenwash sluiceways for disposal before return to the waterbody, thus resulting in complete mortality of impinged fish;

- Debris return to the waterbody through a variety of screenwash and return system designs that may vary widely in the mortality they induce; and

- Operation of traveling screens over a wide range of schedules, ranging from very frequently to very infrequently, resulting in wide variations in the mortality rate of impinged fish (EPRI 2003).

Under the proposed definition of the baseline, a regulator could impose a baseline that includes survival of impinged fish based on existing information about impingement survival rates and factors influencing survival (e.g., EPRI 2003c). This would prevent applicants from receiving credit in the compliance demonstration for existing design and operations that reduce impingement mortality. An unambiguous definition of the baseline should either specify that the baseline intake is one without a fish return system or is one that yields 100% impingement mortality. This baseline definition would be consistent with the intake screen design standards that were in place when §316(b) was enacted in 1972. At that time, fish protection factors were largely unknown, fish protection modifications were not employed, and regulatory emphasis was focused on removal and disposal of debris by water intake screens as a mechanism for improving water quality, not on fish return.

EPA Response

EPA agrees that operational measures are an important part of achieving compliance. Therefore, EPA has included the authority to use operational measures throughout today's final rule as a means of achieving compliance. EPA has clarified its definition of calculation baseline in today's final rule (see §125.93). For additional explanation of EPA's definition of calculation baseline, please refer to EPA's response to comment 316bEFR.034.013and the preamble to the final rule.

Comment ID 316bEFR.306.109

Subject Matter Code 21.04

Determination of compliance

Author Name Doug Dixon & Kent Zammit

Organization EPRI

The “As Built” approach to assessing compliance is a reasonable approach where the efficacy of a technology can be assessed by direct measurement of entrainment and/or impingement survival. Although the use of this approach is more likely for entrainment compliance, there could be instances where the approach would also apply to impingement and its potential application should not be foreclosed. Such an example is direct installation of modified Ristroph screens with a fish return system separate from debris return. In this situation, survival can be directly measured relative to the 80-95% impingement mortality reduction requirement. In general, because of site-specific issues and the nuances of technology deployment and operation, EPA may wish to consider providing maximum flexibility in the design and timing of such studies in accordance with the mitigation option pursued and the information needed to assess fish protection performance.

EPA Response

EPA agrees that the “As-Built” approach is an acceptable method for establishing the calculation baseline. Therefore, a facility may choose to use the current level of impingement mortality and entrainment as the calculation baseline (see EPA’s definition of calculation baseline at § 125.93).

Options for Evaluating Compliance with Performance Standards

EPA's clarification that the proposed performance standards do not apply to "all species and life stages" reflects that such an approach would be virtually impossible to implement. Alternative approaches proposed and for which EPA requests comments are a major improvement; our comments on each are discussed below. In the absence of a definition of AEI that involves protection of aquatic populations and communities, we note that there is not a 'scientifically correct' approach relative to total numbers, total biomass, or the same for some subset of representative important or indicator species (RIS), including the number of RIS selected for assessing technology effectiveness. As we have discussed throughout this set of comments and the comments we have previously submitted, the 'all species approach', the 'representative species approach' and whether total numbers or total biomass should be the metric is a site-specific issue. EPRI recommends that each of these approaches be retained as possible approaches for measuring technology performance on a site-specific basis. As such, maximum technical flexibility will be provided to both the regulator and the permit applicant. Some brief comments on technical issues associated with each are noted below.

EPA Response

In today's final rule, EPA has chosen to not define the term "adverse environmental impact." EPA does not believe that such a definition is necessary for the successful implementation of today's final rule. EPA agrees that Directors should have flexibility in deciding how to determine compliance. In addition, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003.

Determination of compliance

Author Name Doug Dixon & Kent Zammit

Organization EPRI

All Species Versus Representative Species

EPRI has consistently commented that in order to understand the impacts of a CWIS one must understand the local biology. Therefore, relative to baseline characterization, some variation of the 'Representative Species' approach is the most technically defensible. Consultation with state and federal agencies and tribes could identify species of potential concern (recreational or commercial) or that are representative of different fish guilds or life history strategies could be identified for enumeration. Such an identification would support technology selection and would be a requirement for ascertaining the potential benefits that could be derived as a result of installing a technology. There is a long history with such an approach and it can likely be efficiently implemented.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Subject Matter Code 21.04

Determination of compliance

Assessing the performance of a technology, once installed, can be fundamentally different from the baseline characterization. Now the focus is on overall reduction in impingement mortality and, when applicable, entrainment relative to the proposed standards. Baseline characterization may find that potential CWIS impacts are dominated by one or a few species (or life stage), and measuring numbers or biomass for 'all species' could be an appropriate measure. This would avoid a potentially burdensome process of identifying individual fish and calculating technology performance for each species, or even representative species. Essentially, the all species approach would integrate technology performance across all actual species present. For some technologies that are potentially highly protective (e.g., cylindrical wedge wire screens and aquatic filter barriers) and can be deployed at the site, assessing performance relative to 'all species' would be an efficient and logical process.

EPA Response

EPA disagrees that the focus of the rule is exclusively on overall reduction of impingement mortality and entrainment. In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see the preamble to the final rule and EPA's responses to comments 316bEFR.017.003 and 316bEFR.063.005. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble section IX for a discussion of the Technology Installation and Operation Plan. For explanation of EPA's definition of calculation baseline, please refer to EPA's response to comment 316bEFR.034.013 and EPA's definition of calculation baseline at § 125.93.

RFC: Performance/effectiveness of restoration

As a result of the baseline characterization and technology assessments, some permit applicants may identify and volunteer a restoration project as the compliance approach. To support such proposals and to later monitor performance, the 'all species' approach with a measure of biomass lost to CWIS versus biomass ultimately replaced by habitat restoration would also be an efficient and logical metric. As a practical matter, direct weighing of eggs and larvae will be very difficult; however, this can be overcome by counting eggs or larvae in a representative density (#s/volume) sample then convert to biomass based on egg and larvae weights reported in the literature. In the absence of literature data for specific species or life stages, direct measurement on representative sub samples could obtain the needed weight data to support the biomass scale up process.

EPA Response

EPA does not require any particular methodology in the final rule. For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

Determination of compliance

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Relative to establishing the list of 'representative species' or 'critical aquatic organisms', the number of inclusive species should be driven by the distribution of species in the baseline characterization and whether or not they are of commercial and recreational concern to the resource agencies and tribes. This would avoid arbitrarily specifying the number of inclusive species, such as the 10 to 15 noted by EPA. For example, if 99% of the species impinged or entrained were for one species, collecting additional information for other species would be unnecessary relative to eventually assessing the performance of a technology (or for supporting a restoration proposal). Generally, most impingement and entrainment samples (whether by numbers or biomass) are dominated by only a few species. If EPA allows flexibility in selecting inclusive species, EPRI believes that the regulator, resource agencies, applicants and other stakeholders can reach informed decisions relative to target species on which baseline characterization and technology performance can be assessed.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan. Determination of compliance

Numbers of Organisms or Biomass

Some of our comments relative to numbers of organisms or biomass have been noted in the previous section. Additional technical points are subsequently noted such that EPA can consider providing additional options for assessing technology performance. Of particular note, entrainment samples will be overwhelming dominated by eggs and early life stages; however, the vast majority of these will die because of natural mortality. Protecting these early life stages may be extremely difficult, extremely expensive and, in some cases due to site-specific condition, impossible. Relative to our recommendations for an AEI definition, we recommend, relative to measuring effectiveness of impingement and entrainment reduction technologies, that the standard metric of ‘equivalent loss’ be an option in the assessment process. EPA’s proposed regulations requiring substantial reductions in entrainment and impingement losses at existing CWIS are based on the presumption that such losses pose an unacceptable risk to the continued health and well-being of aquatic populations and communities in the water bodies that serve as the source of the cooling water. Consequently, we believe that the measure used to determine compliance with the regulations be a scientifically valid measure of the risk posed by the cooling water intakes. By using such a measure, one can then presume that the reductions in entrainment and impingement loss achieved at a CWIS correspond to a comparable reduction in risk to the aquatic ecosystem.

Equivalent loss models are based on well-accepted scientific principals (life tables) and have a long history of use for assessing the risk of CWIS. In fact, they form the basis for the economic benefits assessment for the current Phase II rulemaking efforts. Equivalent loss provides a mechanism for combining estimates of entrainment and impingement loss across life stages and ages into a common currency (number of adults, number at Age 1, biomass, etc.). Reduction in equivalent loss can then be used to measure the performance of potential intake alternative. Just such an approach is currently embodied in evaluation of an aquatic filter barrier that is a component of a New York State SPDES permit for the Lovett Generating Station. Equivalent loss estimates provide a measure of risk that is more closely linked to the protection objectives of the CWA and §316(b). Yet the information needed for estimation of equivalent losses is more readily available or more easily obtained than other measures of entrainment and impingement risk, such as fractional loss estimates (EPRI 2002a, 2002b). Equivalent loss measures provide applicants with the additional advantage that they are amenable to valuation in the event that cost versus benefit assessment is a desired or necessary part of the compliance demonstration.

Conversion of life stage- or age-specific estimates of entrainment and impingement loss to measures of equivalent loss requires estimates of life stage specific mortality and, in the case of production foregone, growth rates. Fortunately, such information is readily available from prior §316(b) assessments for many of the commonly entrained and impinged species throughout the country. For other species, such information could be obtained from the scientific literature or from other species with similar life history characteristics. Because the assessment of compliance with the entrainment and impingement loss reductions is a comparative one (i.e., alternatives versus a baseline case), the precision of life-stage specific mortality and growth estimates is not as critical for the analysis of compliance with the loss reduction criteria as it might be for assessing adverse environmental impact. Such equivalent loss input parameters should be defined and accepted by both regulatory agency and permit applicant prior to the intake alternatives evaluation. This was the approach used for the permitting of the Lovett Generating Station.

We believe that the approach described above provides a technically sound optional method for determination of compliance with entrainment and impingement reduction requirements under §316(b). This approach will help to ensure that protection is directed towards those species and life stages that are most important for the continued health of the aquatic ecosystems in the source waterbodies. While such an approach might seem technically cumbersome and difficult to employ, this is not the case. Once the input parameters for each of the equivalent loss models are established, generation of equivalent loss estimates is a simple spreadsheet exercise. Further, model input parameters for each representative species can be transferred from site to site. While such an approach necessitates collection of the biological data (e.g., entrainment and impingement monitoring) on a species-specific basis, the cost for such are a relatively small component of the overall sample collection and sorting costs. We believe that such additional costs are more than warranted by the gains in alternative intake evaluation process.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see the preamble to the final rule and EPA's responses to comments 316bEFR.017.003 and 316bEFR.063.005. Determination of compliance

Additional Comments

Site-specific variability in the physical sciences and biology, CWIS operation, and performance of fish protection technologies, as we have long noted in our comments and reports, indicates the importance of providing flexibility in the determination of the species and metrics to be used during both baseline characterization and technology performance assessment. The following additional points are noted for consideration relative to providing flexibility in determining technology performance or in setting standards of performance:

- Exclusion of fish that are moribund or dead on arrival, as discussed in the NODA, is notable and logical. CWIS will act as ‘filters’ and collect moribund and dead fish that occur in the water due to natural causes (e.g., cold shock, low dissolved oxygen) and these organisms should be excluded from performance assessments. Not only should they be excluded, the technology should not be expected to perform at ‘normal’ standards because of clogging of screens, fish return troughs, etc. Essentially, expectation of technology performance to ‘target’ standards should not be expected during episodic fish kills. Standards for determining/identifying moribund and dead fish can be ascertained on a site-specific basis.

EPA Response

With regard to EPA’s approach to the exclusion of moribund or dead organisms from determining compliance, it is generally EPA’s position that naturally dead or moribund organisms should not be factored into the impingement or entrainment rates of a facility. However, EPA has left the final determination on methodology employed to the Director. EPA has included a provision in the Verification Monitoring Plan which allows a facility to exclude moribund or dead organisms. The facility may submit a proposal the Director as part of the Verification Monitoring Plan, that details how naturally moribund fish and shellfish that enter the cooling water intake structure would be identified and taken into account in determining compliance with the performance standards in § 125.94.

Organization EPRI

Subject Matter Code 21.04

Determination of compliance

EPRI recommends that in addition to exceptions for moribund and dead fish, similar performance exceptions be made when other episodic physical and biological events occur such as corn shuck loading during harvest seasons, leaf load during fall, woody debris and sediment load during high flow events, and SAV (e.g., eelgrass) loads following storm events. No technology can be expected to perform at expected standards during such events. Similar standards for determining/identifying conditions under which a technology cannot be expected to perform can be established on a site-specific basis.

EPA Response

EPA acknowledges that natural factors may affect the efficacy of any technology. For EPA's position on upset and bypass provisions please see EPA's response to comment 316bEFR.034.017.

Organization EPRI

Interannual variability in the numbers and assemblage of aquatic organisms impinged and entrained present challenges for assessing technology performance. Flexibility should be provided in the rules such that the challenges can be addressed. Our previous comments have noted how common it is for fish populations to vary in number and types of species on an annual basis (Sissenwine 1984, Winemiller and Rose 1993, Rose et al. 2001). For example, when performance monitoring is initiated (following collection of baseline data in previous years), the species assemblage and their relative distributions may be completely different than that observed during the baseline characterization. For technologies that reduce the impingement rate it will be difficult to directly demonstrate that the rate, in fact, has been reduced. The technologies that reduce the rate of impingement include, for example, cylindrical wedge wire screens, aquatic fabric barriers, barrier nets, and behavioral barriers (light, sound). This challenge can be overcome using indices of inter-annual relative abundance (such as reviewed at the EPA CWIS Conference, May 6-7, 2003 by Dave Bailey of Mirant Mid-Atlantic for their barrier net performance assessment at the Chalk Point Station on the Patuxent River, Maryland). Other approaches are also possible, the key point, however, is that provision of flexibility in the development and use of metrics will allow the development of technically defensible methods and metrics.

Flexibility will allow for innovation as well as adaptive approaches that address unanticipated conditions. Provision of maximum flexibility, essentially by limiting prescriptive requirements, will allow permit applicants, resource agencies, regulators and other stakeholders to derive scientifically informed approaches toward meeting the objectives of the rule.

EPA Response

EPA understands that natural populations will vary in abundance over the course of a year. For EPA's position on upset and bypass provisions please see EPA's response to comment 316bEFR.034.017. For a discussion of how compliance is to be determined, please see the preamble of the final rule, including its discussion of the availability of TIOPs with the approval of the Director, as well as, EPA's responses to comments 316bEFR.017.003 and 316bEFR.063.005.

Permit applications/implementation schedule

Compliance Timelines, Schedules, and Determination

EPRI has only a few comments relative to the compliance timeline and schedule. These included:

- Impingement and, when applicable, entrainment monitoring data will need to be collected and analyzed to support baseline calculations of fish losses. This information will then be used to assess technology and restoration options. This process can take a minimum of one year and considerably longer depending upon complexity of site-specific issues. EPA needs to consider the time required for developing baseline data and analyses relative to the compliance timeline and schedule.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

Comment ID 316bEFR.306.121

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Subject Matter Code 21.09

Permit applications/implementation schedule

EPRI previously noted that a 6-month compliance schedule is not a realistic timeframe for the design and installation of even the simplest impingement reduction technology. Retrofitting traveling screens with fish removal features or fish return systems would require more than 6 months. Efforts would include detailed design, preparation of construction and fabrication drawings and specifications, procurement and fabrication of components, and complete installation. At least one year would be required to complete even simple modifications.

EPA Response

See response to comment 316bEFR.002.021 for a discussion of installing technologies and see the preamble for a discussion of compliance alternatives.

Comment ID 316bEFR.306.122

Author Name Doug Dixon & Kent Zammit
Organization EPRI

Subject Matter Code 21.09
Permit applications/implementation schedule

Finally, as we verbally noted at the EPA CWIS conference in Arlington, VA (May 6- 7, 2003), there simply is insufficient consulting capacity to address the likely demand for impingement and entrainment monitoring, fish identification (particularly early life stages), assessing, designing and installing technologies, and performing economic analyses in response to the new rule requirements. It may take several years before sufficient capacity exists to meet the demand that will arise. This lack of consulting support capacity should also be considered when establishing the compliance timeline and schedule.

EPA Response

EPA disagrees with the commenter and believes that due to the varied compliance alternatives available to the facilities, demand for consulting support is not expected to occur simultaneously. Additionally, EPA has clarified timing requirements for the submittal of application studies. Please see response to comment 316bEFR.034.066 for a discussion.

Methods to Evaluate I&E

In its comments on the benefits case study, PISCES claimed that EPA had underestimated entrainment and impingement loss rates, underestimated the impact of impinging age-1 and older fish, used inappropriately low survival rates to scale entrainment losses to age-1 equivalent losses, and underestimated the economic value of entrained and impinged fish. In addition, PISCES argued that habitat restoration and replacement projects should not be used to satisfy the requirements of Section 316(b) because in-kind replacement of entrained and impinged fish cannot be guaranteed.

In reviewing Pisces' comments, I identified several significant errors and misinterpretations, and I find that most of Pisces' major conclusions are incorrect.

-In its analysis of entrainment and impingement loss rates, Pisces used an inapplicable data set and misinterpreted cooling water withdrawal data for the Salem Generating Station. I found no evidence that EPA had underestimated these losses.

-Pisces' assertion concerning the impact of impinging fish older than one year-of age is partially correct. However the conclusion that impingement loss rates, when expressed as age-1 equivalent losses, are nearly as large as entrainment loss rates is based on invalid reasoning and is incorrect.

-Pisces' analysis of variability and bias in estimates of natural survival rates for early life stages of fish is invalid and the conclusion that survival rates for all species should be increased by 25% is incorrect.

-Pisces' "reproductive value" approach to estimating the economic value of fish that die of natural causes ignores density-dependence and would be expected to greatly overstate the actual economic value of unharvested fish.

-Pisces' critique of habitat restoration and replacement projects is one-sided and substantially understates the potential environmental benefits of these projects.

EPA Response

EPA notes this review of comments submitted by Pisces. In regards to the issue of reproductive value, please see response to Comment 316bEFR.206.065.

Subject Matter Code 10.01.02.01

EPA methods: age 1 equiv, yield, prod foregone

Author Name Doug Dixon & Kent Zammit

Organization EPRI

In the NODA, EPA announced a change in the assumptions made concerning the age distribution of impinged fish and concerning the fraction of forage fish biomass that is converted to harvestable predator biomass (termed “trophic transfer efficiency”). In reviewing the NODA itself and the supporting information provided in the docket, I found significant problems with both of these methodological changes.

-The new assumption concerning impingement age distributions is clearly wrong, is contradicted by data already in the docket, and would greatly overstate the benefits of reducing impingement.

-The new assumption concerning trophic transfer efficiency is inconsistent with the most recent scientific literature and would overstate the benefits of reducing entrainment and impingement of forage fish.

EPA Response

The commenter expresses concern about the method used to interpret impingement records with respect to age distributions. Upon further review, EPA has revised its assumptions about the ages of impinged fish, as detailed in the response to Comment 316bEFR.029.105. For a discussion of EPA's trophic transfer model, please see response to Comment 316bEFR.305.004.

Organization EPRI

Subject Matter Code 10.01.02.01

EPA methods: age 1 equiv, yield, prod foregone

I was greatly impeded in my review by the poor documentation provided in the NODA and in the docket. I was unable to reproduce any of the age-1 equivalent loss, foregone yield, or production foregone estimates provided in the North Atlantic and Northern California case studies. For this reason, I cannot evaluate the quantitative importance of the errors and overly conservative assumptions I identified. In addition to the problems I found in my review, some of the values provided in the benefits tables for these new case studies appear suspicious, (e.g., the extremely high value of tautog production foregone in Table X-7, FR page 13553), however, the information needed to confirm whether errors have been made is unavailable.

EPA Response

The commenters do not specify exactly where they had difficulties in reproducing EPA's results, so EPA is unable to respond to their critique. The difficulties may lie in the fact that there were changes in input data between proposal and the NODA. Regarding the commenters' assertion that EPA's analysis includes "overly conservative assumptions," please see EPA's response to Comment 316bEFR.074.201.

Overview of I & E effects on organisms

Review of Comments by Pisces, Ltd. on EPA's 316(b) Case Study Methodology

I have reviewed Pisces' analysis with respect to technical accuracy and relevance to the rulemaking process. My comments are organized around five major issues raised by Pisces that directly challenge the basis for EPA's proposed rule. Brief comments are also provided concerning some secondary issues that do not directly challenge EPA's analyses or conclusions but that support the Riverkeeper Organization's contentions concerning the importance of minimizing entrainment and impingement losses.

Major Issue 1: Underestimation of losses due to underestimation of expected future water withdrawal rates.

Pisces argued (Section 1.4) that impingement and entrainment vary nonlinearly with flow, and that, because of recent increases in flow rates, EPA's estimates of future entrainment and impingement loss rates are biased low.

Pisces cited a paper by Kelso and Milburn (1979) as support for the proposition that impingement and entrainment are nonlinearly related to flow. These authors examined entrainment and impingement data for 37 power plants located on the Great Lakes, and developed empirical equations relating flow rate, entrainment, and impingement. Both equations are both power functions, implying that entrainment and impingement increase exponentially with flow. Clearly, since the data relate to the Great Lakes and are more than 25 years old, the equations themselves are irrelevant to evaluation of EPA's analysis. Moreover, as is shown in Figure 1, the quantitative significance of the nonlinearity described by Kelso and Milburn (1979) is trivial. Figures 1a and 1b plot entrainment and impingement rates calculated from the equations provided in the Pisces analysis over an arbitrary range of 500 to 1600 gallons per second (the actual range of flows used is irrelevant – the plots would look the same over any range of flows). Along with curves calculated using the power functions from Kelso and Milburn (1979), each plot shows a linear approximation calculated by drawing a straight line connecting the two ends of the curves. It is clear that the degree of non-linearity is small. For any given flow rate, the differences between the curves and the lines are probably much smaller than the uncertainty (not discussed by Pisces) in the impingement or entrainment rate expected at any given flow. Moreover, at every flow rate, the linear approximations overestimate the loss estimates obtained using the power functions.

Pisces also stated that EPA underestimated losses by failing to account for increases in the mean flow at many plants. The report illustrates this contention through an analysis of withdrawal rate data for Salem. According to Pisces, EPA should have used the estimated withdrawal rate for 1998, which was very high, rather than a long-term average withdrawal rate. This particular example is clearly inappropriate, because the principal use for these data in EPA's analysis was to calculate entrainment and impingement loss rates, measured as fish per unit flow. The loss rates were then scaled to other facilities using estimated withdrawal rates for those facilities. In any case, 1998 withdrawals are probably not representative of future operations at Salem, because this particular year immediately followed a two-year shutdown of both units for a major facility upgrade. Representative future withdrawal rates would have to be adjusted for periodic refueling and maintenance shutdowns.

[see hard copy for figure]

EPA Response

Please see response to Comment 316bEFR.041.037 regarding the assumption used in EPA's benefits analysis that I&E are proportional to flow. EPA agrees with the commenters' conclusion that the data in the paper cited by Pisces indicate that for any given flow rate, the difference between the curves and the lines are probably smaller than the uncertainty in the I&E rate expected at any given flow. EPA also agrees with the commenters' observation that EPA used Salem flow data to calculate average annual I&E rates as fish per unit flow and that 1998 flow data were not appropriate for this purpose.

Subject Matter Code 10.01.02.01

EPA methods: age 1 equiv, yield, prod foregone

Major Issue No. 2: Underestimation of impingement due to age 1 assumptions

Pisces claimed that EPA underestimated effects of impingement losses “both in terms of their impact on the populations and relative to entrainment” by assuming that all impinged fish are age 1. Pisces supported this argument with a series of calculations (sections 1.5 and 1.6) in which, instead of assuming that all impinged fish are age 1, actual age distribution of the impingement counts provided in the Salem filing (as reproduced in EPA’s input spreadsheet for Salem) were used to convert age 1 and older impingement losses into age-1 equivalents. The results of these calculations were especially dramatic for white perch, because white perch up to eight years old are impinged at Salem.

Pisces is correct in stating that the appropriate approach for calculating age-1 equivalents is to scale all of the age groups to age 1 using estimates of the fraction of fish expected to survive from age 1 to the age at which impingement occurred (e.g., for eight-year-old fish, the fraction expected to survive from age 1 to age 8). I was able to reproduce Pisces’s calculations, and in doing so I found that Pisces’s survival rates for age groups 1 through 7 are incorrect. These values were apparently taken from EPA’s input data spreadsheet for Salem. This spreadsheet contains an erroneous formula for calculating total mortality rates from estimates of age-specific natural mortality and fishing mortality rates. The error inflates the total mortality rate estimates for adult fish, and consequently inflates the estimated numbers of age-1 equivalents for fish that are age 1 and older.

Although the calculations presented in Pisces’s analysis are correct in principle, the interpretation of the results by Pisces is incorrect. For the purpose of impact assessment and benefits analysis, scaling older fish backwards to age 1 is not equivalent to scaling younger fish forward to age 1. For age 0 fish, the scaling adjusts losses of eggs, larvae, and juveniles to a common future age, prior to the age at which the fish may be expected to reproduce or to be harvested. These estimates can then be used to calculate expected harvest or reproduction that would have occurred at future ages, had these fish not been entrained or impinged. The same procedure cannot be applied to age-1-equivalent estimates derived from backward-scaling of losses that occur at older ages. The reason for this is that no reproductive potential or opportunity for harvest is lost prior to the age at which a fish is actually impinged. For example, each eight-year-old white perch is, according to Pisces, equivalent to 13,572 age-1 white perch (the correct value is 5,961 EPRI APPENDIX A 6 age-1 equivalents). This means that, for every 13,572 (5,961) white perch alive on their first birthday, only 1 would be expected to survive to age 8 years. The 13,571 (5,960) fish that did not survive would have died of natural causes (most likely due to consumption by predators) or would have been harvested prior to the age at which the impinged fish was lost. No foregone yield or reproduction would accrue due to the deaths of these fish.

In Table 6 of its analysis, Pisces calculated numbers of equivalent 1-year olds, by age group, for the total numbers of all RIS fish species collected over all available years of sampling at Salem. Figure 2 of my comments compares estimates of equivalent 1-year olds (recalculated using correct mortality rates), yield foregone, and production foregone for each white perch age group. The following equations were used to make these calculations:

[see hard copy for equation]

All parameters in the above equations except for the loss rates were taken from Appendix L, Tab 18 of the Salem filing (PSEG 1999). Figure 2 shows that white perch impinged at an age of eight years, which account more than 75% of the age-1 equivalent losses as calculated using Pisces' method, account for only 7% of the total yield foregone and for less than 2% of the total reproduction foregone. It is true that assuming that age 1 and older fish are impinged at age 1 underestimates the yield and reproduction foregone due to impingement, however, the magnitude of the bias is much smaller than is implied in Pisces' analysis. Pisces's assertion that impingement losses – when measured in terms that are relevant for impact assessment and benefits analysis – are similar in magnitude to entrainment losses is erroneous.

[see hard copy for figure]

EPA Response

Regarding EPA's assumptions on the age distribution of impinged fish for its final analysis for the Phase 2 rule, please see response to Comment 316bEFR.029.105

EPA methods: age 1 equiv, yield, prod foregone

Major Issue No. 3: Effect of survival rate on age 1 equivalent calculations

In Section 1.6.2, Pisces argued that survival rates used by EPA in scaling losses of early life stages to age-1 equivalents were too low. Support for this argument included (1) a comparison of striped bass and cunner survival rates used by EPA to other published values (2) a sensitivity analysis demonstrating that increasing the assumed survival fractions increases the estimates numbers of age-1 equivalents, (3) an assertion that EPA's survivorship estimates already include effects of power stations and therefore are probably biased high, and (4) an assertion that for this reason all of the survivorship estimates should be increased by 25%.

The fact that survival rates of early life stages are highly variable and difficult to measure is well known. Table 1 compares empirical estimates of survival rates from five different studies of bay anchovy, one of the most frequently studied of all fish species vulnerable to entrainment and impingement. This table shows that the actual range of variation in estimated values is much greater even than is suggested in Pisces's comments. This variability does not imply, however, that EPA systematically underestimated or overestimated survival rates as compared to published studies.

It is definitely not true that the estimates used by EPA in general include station mortality. This could be the case only for survival estimates derived from site-specific studies of populations susceptible to station impacts. However, survival estimates used in 316(b) demonstrations are only rarely based on site-specific data. In the great majority of studies, survival estimates are derived from available scientific literature.

Even if the estimated survival rates did include station mortality, it is not true that conditional mortality rates are "often in the 10%-25% range." Such rates have been observed only at a few sites (most notoriously, the Delaware Estuary and the Hudson River) and for only the most susceptible species at those sites. Values this high are not representative of all sites or species nationwide. Hence, there is no justification for increasing the survival rate estimates used in the age-1 equivalent calculations.

[see hard copy for table]

EPA Response

EPA agrees with most of this comment. However, with respect to conditional mortality rates, EPA notes that such rates are unavailable for most facilities and species. Therefore, it is unknown how representative rates of 10-25% may be.

Commercial Fishing Benefits

Major Issue No. 4: Calculating the worth of commercial species impinged and entrained

Pisces asserted that EPA had underestimated the economic value of entrained and impinged fish species by neglecting to value those fish that would have died of natural causes rather than being harvested. Pisces's argument is based on "reproductive value," defined as the expected contribution of a fish at any given age to future generations of fish. If the reproductive value of each egg is defined to be 1.0 (since at equilibrium one egg will be produced in each generation for each egg produced in the previous generation), then the reproductive value of a fish at any given age is given by:

(See Appendix A pg 8 for Formula)

For age a = 1 year, Equation (3) calculates the number of eggs expected to be produced over the lifetime of each age-1 equivalent fish. When applied to age-1 equivalent fish, reproductive value as defined in Equation (3) is identical to reproductive potential as defined in Equation (2) divided by the age 0 survival rate.

As noted by Pisces, the economic benefits model used by EPA calculates the expected lifetime yield from each 1-year-old equivalent fish, and then assigns an economic value to that yield. Pisces used Equation (3) to assign values for those fish that die of natural causes rather than being harvested. Pisces calculated the number of eggs that would have been produced by the unharvested fish, multiplied this value by the fraction of eggs expected to survive to age 1, and then calculated the value of these second-generation 1-year-olds using EPA's model.

Pisces provided numerical calculations for striped bass and for 11 species entrained and impinged at Pilgrim. The survival and fecundity values for striped bass appear to have been taken from Setzler-Hamilton et al. (1980) and do not match values used by EPA or by PSEG (1999). It is not clear whether the age-specific fecundity values were adjusted to account for sex ratio (which they should have been). However, the principal problem with the approach is with the validity of the multi-generational extrapolation. Pisces's approach assumes that recruitment is directly proportional to egg production, i.e., there is no density-dependence. Numerous recent studies, as reviewed by Rose et al. (2001), have shown that density-dependent recruitment in marine fish species is the rule rather than the exception; evidence for density-dependence in striped bass is especially strong. For this reason, Pisces's approach should overestimate next-generation reductions in harvest. In a population that is relatively stable from generation to generation, there would be little or no net loss to the next generation because reduced egg production due to the losses would be balanced by improved reproduction or survival of those fish that were not entrained or impinged. Even if a reduction in recruit production due to entrainment and impingement did occur, any reduction in value assigned to these foregone future fish would have to be converted to net present value using an appropriate discount rate.

Pisces's comment simply reflects an alternative and highly conservative assessment approach, not an error on the part of EPA.

EPA Response

EPA comments on the general issue of reproductive value in responses to Comment 316bEFR.206.065.

RFC: Proposed use of restoration measures

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Major Issue No. 5: Biological issues implicit in habitat replacement

Section 5.1 of Pisces' comments consists primarily of a one-sided value-based argument (non-scientific) against Peg's Estuary Enhancement Program and other similar restoration projects. However, three important and arguably valid points are raised on page 55:

- Habitat equivalency analysis is primarily aimed at offsetting past losses or damage, rather than continuing loss

- Considerable uncertainty exists as to whether equivalence can be focused on actual species harmed; and

- Sufficient habitat to offset losses or damage may often be unavailable.

The first two points raised by Pisces are technically correct but irrelevant. Since cooling water withdrawals do not affect the ability of habitat to perform its normal ecological function, the concept of habitat equivalency is inapplicable to 316(b) issues, regardless of whether the damage is past or continuing. In addition, it should be obvious that habitat restoration projects cannot possibly be designed to provide specific numbers of specific fish species. Successful projects can enhance the productivity and diversity of entire ecosystems, however, the numbers or biomass of individual species that will be produced by any given project cannot be confidently predicted. Even the most aggressive proponents of habitat restoration make no such claims. In raising the issue of in-kind replacement as a defect in EPA's proposed rule, Pisces has simply erected a convenient straw man to knock down.

With regard to point no. 3, Pisces is probably correct that lack of suitable quantities of habitat will often prevent companies from using restoration as a means of satisfying the rule. However, this does not mean that these activities should not be pursued where feasible.

Regardless of the objections raised by Pisces, habitat restoration is a worthwhile activity that can provide a wide variety of tangible environmental benefits. The most obvious of these benefits include enhanced production of all types of aquatic biota, provision of habitat for wildlife, and increased opportunities for aesthetic enjoyment and education. Benefits of restoration can be expected to continue long after the retirement of all of the facilities subject to the proposed rule. In contrast, long-term monitoring studies have provided at best equivocal evidence that fish populations have been adversely affected by entrainment and impingement losses. Reducing those losses may produce no measurable environmental benefits.

EPA Response

For a discussion of uncertainties associated with restoration measures, see EPA's response to comment 316bEFR.206.055.

For a discussion of the use of out-of-kind restoration in the context of the final rule, see EPA's response to comment 316bEFR.206.055.

EPA agrees that although space limitations may make restoration infeasible for some permit applicants, for other permit applicants, this will not impede their consideration of restoration measures.

For a discussion of the role of ancillary benefits, see EPA's response to 316bEFR.032.011.

For a discussion of adverse environmental impacts deriving from impingement and entrainment by cooling water intake structures, see EPA's response to comment 316bEFR.207.015.

Impacts to T&E species

Author Name Doug Dixon & Kent Zammit
Organization EPRI

Other issues

Impacts on threatened and endangered species. The need for additional reductions in losses to protect T&E species is raised in Section 7.1 of Pisces' comments. However, these species are already protected by the Endangered Species Act. Operators whose facilities have the potential to entrain or impinge T&E species are already required to have consultations with the appropriate agencies, and to obtain certification that they are not harming these species.

EPA Response

EPA agrees that the requirements of today's rule should not be construed to preclude or deny the protection of Threatened and Endangered species by the Endangered Species Act.

Data Issues

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Trends in abundance of fishes. Section 1.7 (pages 22-26) notes that, because of improved water quality and in some cases improved fisheries management, the abundance of some fish species has increased. Any such increases would likely result in increased entrainment and impingement losses. This, according to Pisces, means that the economic benefits of reducing the losses might have been underestimated if the available data were collected in the 1970s. On the other hand, some species have declined since the 1970s (Atlantic tomcod in the Hudson River is cited as an example). In these cases, using older data means that the potential impacts of entrainment and impingement on the declining species may have been underestimated. This comment is clearly an example of "spin" and not a technical comment on the benefits analysis. Since the benefits analysis is a national aggregate, as long as the increases and decreases are roughly balanced there would be minimal effects on the net results.

EPA Response

EPA's estimates of current (baseline) I&E may be over- or underestimated if fish abundances have declined or increased since the data used by EPA were obtained. It is unknown if potential increases or decreases would be roughly balanced and therefore would have minimal effects on EPA's results. Unfortunately, EPA's analysis was constrained by the available data, which rarely provide information for determining if and how fish stocks may have changed as a results of I&E.

Data Issues

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Increased species richness and fish/crustacean abundance following plant closure. I have previously read through the Henderson et al. Hinkley Point monitoring report that is cited in Section 1.7.2 as support for the proposition that reducing losses through plant closures is beneficial to fish populations. Effects of reduced withdrawal of cooling water from the Bristol Channel are confounded with effects of improved water quality and regional oceanic temperature increases that have occurred over the same time period. Although the authors claim that within two more years they will be able to test whether station closures have contributed to the observed increases, they provide no indication of how they will perform the test.

EPA Response

EPA would be interested in any data that could resolve this question. Unfortunately, long-term monitoring before and after an impact at both control and impacted sites is usually required to detect ecological effects, particularly at the population or higher levels of biological organization (see Schmitt and Osenberg, "Detecting Ecological Impacts," DCN # 2-019A-R21). Such data are seldom available and are difficult to obtain.

EPA methods: age 1 equiv, yield, prod foregone

Inflated estimates of foregone yield due to impingement

In the NODA, EPA states that:

In the case studies prepared for proposal, EPA determined that all impinged fish are age 1 because of a lack of data on the actual ages of impinged fish. As several commenters pointed out, this biases estimates low because impinged fish may include older individuals that are closer to harvestable age. This is confirmed by data on the ages of impinged fish presented in studies conducted at Salem (PSEG, 1999) and Millstone (Northeast Utilities Environmental Laboratory, 1992). To address this concern, the current studies relax the assumption that all impinged fish are age 1, and assume instead that the ages of impinged fish are 1 and older, and follow an age distribution that is implied by the associated survival rates. This approach takes into consideration the common observation that relatively few older, larger fish are impinged. The effect of this adjustment is that a higher proportion of impinged fish are assumed to survive until harvest. As a result of this adjustment, the estimate of foregone yield associated with impingement increases by a factor ranging from about three to ten, depending on a species' age-specific survival rates. [NODA, section X.B.3.b(4), 68 Fed. Reg. 13,546, col. 2]

The adjustment made by EPA is based on erroneous assumptions concerning the age composition of typical impingement collections. Because of these errors, EPA's adjusted estimates greatly overstate the expected foregone yield due to impingement. Studies of the ages of impinged fish have consistently shown that:

-Most impinged fish are younger than one year of age, and not one year old or older as assumed by EPA.

-The vulnerability of most species to impingement decreases with age, so that EPA's use of survival rates to estimate the age composition of impinged fish usually overstates the relative contributions of older fish to impingement losses.

The importance of these errors is demonstrated below, using the data for Salem provided in Docket No. 4-2051 to the Proposed Rule. The Salem data are used for this demonstration because, unlike the other input data files provided by EPA, the impingement data for Salem include a breakdown by life stage and age class. Figure 3 plots age distributions of fish impinged at Salem from 1990 through 1998 for three representative species: weakfish, striped bass, and white perch. The actual age distributions are compared to the distributions implied by EPA's original (proposed rule) and revised (NODA) assumptions concerning the age distributions of impinged fish. For all three species, the impingement totals are comprised primarily of fish in the juvenile 1 and juvenile 2 life stages. Only 0.2% of weakfish, 15% of striped bass, and 26 % of white perch were age 1 or older. For only one of the species listed in the Salem input file, bay anchovy, do age 1 and older fish make up more than half of the total impingement losses. Figure 3 shows that, contrary to EPA's assumption in the NODA, no weakfish older than age 1 and no striped bass older than age 2 were reported in impingement collections at Salem from 1990 through 1998. White perch up to age 8 are impinged at Salem, however, even for this species EPA's assumed age distribution greatly overstates the proportion of fish impinged at ages older than age 1.

As in my comments on the Pisces report (above), I used Equation (1) to calculate the foregone yield due to fish impinged at each age or stage. This is the same yield equation used by EPA [see NODA, section X.B.3.b(1), 68 Fed. Reg. 13,545-46]. The total foregone yield due to impingement is obtained by summing the stage and age-specific values over all stages and age classes. Results of these calculations are shown in Figure 4. For all three species, foregone yield estimates calculated using the NODA assumptions are inflated compared to estimates calculated using actual age distributions For weakfish, the NODA value is inflated by a factor of 70 times over the value calculated using actual age distributions. For striped bass and weakfish, assuming that all impinged fish are age 1 also greatly overestimates foregone yield. Only for white perch does the age-1 assumption underestimate foregone yield, and the difference in this case is only about 20%.

The age distribution of fish impinged at Salem is probably typical of estuarine facilities, and perhaps most facilities. Very small fish have lower swim speeds and smaller energy reserves than larger fish, and are therefore more vulnerable to being trapped and impinged. Moreover, a large fraction of the species impinged in high numbers at Salem and other estuarine facilities spend most of their life cycles at sea. These species include anadromous species such as striped bass, American shad, alewife, and blueback herring; and estuarine-dependent species such as weakfish, spot, Atlantic croaker, and Atlantic menhaden. For all of these species, EPA's original approach to calculating foregone yield due to impingement almost certainly would have overstated the potential reduction in harvest; EPA's revised approach greatly overstates this reduction.

Relatively few of the species addressed in the case studies (e.g., white perch and bay anchovy) are estuarine-resident throughout their life cycles and, therefore, vulnerable to impingement at all ages. However, the revised approach still would overestimate foregone yield because it assumes that all impinged fish are at least one year old.

The extent to which the above comments apply to EPA's estimates of production foregone due to impingement is unknown, because EPA has provided no documentation of the method used to calculate production foregone for harvested species. Although Chapter 5 of the original case study report states that the production foregone model was applied only to forage species, both the original case study and the new regional case studies documented in the NODA (Tables X-6, X-8, X-20, and X-22, 68 Fed. Reg. 135,52-53, 13561-62) include estimates of production foregone for impinged fish belonging to harvested species. If the same assumptions used to calculate yield foregone for these species were also used to calculate production foregone, then the production foregone estimates would be similarly biased.

[see hard copy for figures]

EPA Response

Please see EPA's response to 316bEFR.029.105 concerning EPA's assumptions about the age of impinged fish.

EPA revised its trophic transfer assumptions for its final analysis for the Phase 2 rule. Please see response to Comment 316bEFR.305.004.

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Estimation of Trophic Transfer Efficiency

In the case study performed to support the proposed 316(b) Phase II Existing Facilities Rule, EPA used a trophic transfer model to estimate the yield of harvested species foregone due to entrainment and impingement of forage species. EPA's model assumed that 20% of forage species biomass is directly consumed by harvested species. EPA assumed that the remaining 80% is consumed by intermediate predators, which are then consumed by harvested species. EPA assumed that the trophic transfer efficiency for the direct pathway is 9%, and that the transfer efficiency for the indirect pathway is 0.9%. These values imply a net transfer efficiency, considering both direct and indirect pathways, of 2.5%.

In the NODA (section X.B.3.b(2), 68 Fed. Reg. 13,546, col. 1), EPA stated that it had revised the trophic transfer model and was now assuming a net trophic transfer efficiency of 20%. The change, according to the NODA, was "based on an additional review of the scientific literature." The change reflects a questionable review of the scientific literature and could lead to overestimation of the estimated benefits of reducing entrainment and impingement of forage fish.

The following issues are relevant:

-The trophic transfer efficiency is derived from an unreferenced source and is at the high end of the range of accepted values.

-The modified approach assumes that 100% of forage fish biomass is consumed by economically valuable species.

With regard to the first issue, the only citation provided in the NODA to support the new value is to "Reed et al. (1994)." The reference cited by EPA is the documentation report for NOAA's Type A Natural Resource Damage Assessment model for the Great Lakes. This model was developed to facilitate calculation of natural resource injuries and service losses cause by spills of oil or hazardous substances. Rather than providing a detailed review of the literature on trophic transfer efficiency, the NOAA report simply states that a range of values between 10% and 30% has been estimated by various authors, provides a brief list of citations, and states that the "preferred" value is 20%. The most recent of the papers cited in the report was published in 1987. Pauly et al. (1995) published a more recent and more thorough review of the literature on trophic transfer efficiency. These authors compiled 140 estimates of trophic transfer efficiency from 48 trophic models of aquatic ecosystems. They found that, although the range of values was very wide, the mean value was 10% and only a few of the values were 20% or higher. It appears from Pauly and Christensen's study that the value chosen by EPA is at the upper end of the range of accepted values and probably overstates the average trophic efficiency across all aquatic ecosystems.

With regard to the second issue, although the actual percentage of forage species that are consumed by harvested species is unknown, it is certain that a large fraction of forage species production goes to unharvested species, including invertebrates such as jellyfish. In the Lake Turkana food web described by Pauly and Christensen (1995), for example, approximately 60% of pelagic forage fish biomass is directly consumed by the top-level predators (tigerfish and Nile perch). The remaining forage biomass is consumed by catfish, which are then consumed by Nile perch. EPA's original assumption concerning the fraction of forage fish biomass directly consumed by economically valuable species may be either an underestimate or an overestimate of the actual average value; the new assumption clearly is an overestimate.

EPA claimed in the NODA that the effect of the change in trophic transfer assumptions insignificant because foregone yield attributable to losses of forage fish is only a small component of the total foregone yield due to entrainment and impingement. EPA has not provided supporting analyses to verify this claim. However, the change in assumptions results in a factor-of-eight increase in all estimates of yield foregone due to losses of forage species. The difference might well be significant for facilities at which entrainment and impingement losses consist primarily of forage species.

EPA Response

Please see EPA's response to Comment 316bEFR.305.004 regarding trophic transfer efficiency.

Valuing Forage Species (incl non-use and non-landed)

Although the NODA is incomplete (the new "regional analyses" has only two of the eight regions completed), it does make a number of general methodological statements that will presumably guide future analyses of the remaining six regions. My comments therefore are limited to USEPA's methodological statements and to the analyses of the two regions.

There are several promising changes in the methodological statements, including the recognition of stated preferences as the only generally accepted method with a potential for estimating nonuse values of reduced impingement and entrainment (I&E) losses. Implicit in this seems to be a rejection of the Habitat Replacement Cost and the Societal Revealed Preference approach to estimating total value. Discounting future gains and proper accounting for harvest changes in improved commercial and recreational stocks are clearly actions that make USEPA's analysis better.

In correcting the flaws in the previous analysis, the NODA's two applications make clear the importance of properly estimating non-use values of fish and shellfish populations and also the complete inadequacy of existing research on the topic. The use values associated with the North Atlantic and Northern California regions contained in the NODA are believable and they highlight the fact that nonuse values must be around 20 to 30 times larger than the use values in order for benefits to equal costs. With nonuse or passive use values being so pivotal, it is critical that they be estimated well.

EPA Response

In the cost-benefit analysis for the cost-benefit analysis for the final 316(b) Phase II rule, the non use benefits do not need to be 20 to 30 times larger than use values in order for benefits to equal costs. As reported in Chapter D1 of the EBA, in the North Atlantic use benefits are estimated to be $3 million with total social costs of $31.7 million. In California use benefits are estimated to be $6.9 million with total costs of $22.8 million. Thus, in final analysis non-use benefits would need to be approximately 2 to 9 times larger than use benefits in order for benefits to equal costs.

Please see response to EPA's response to comments on the feasibility of doing original state preference work in the response to comment #316EFR.306.105.

Organization EPRI

Subject Matter Code 10.02.04

Valuing Forage Species (incl non-use and non-landed)

USEPA's estimates of non-use value in the North Atlantic region raise substantial concerns, the most prominent among them are:

-There is no research that addresses the non-use value inherent to fish and shellfish stocks affected by the proposed regulations. Does the non-use value change with decreases in numbers of fish and shellfish impinged and entrained? Or is it more akin to existence value, with a threshold effect? No one knows but USEPA assumes that non-use value changes with decreases in numbers of fish and shellfish impinged and entrained;

EPA Response

As part of the final 3169(b) rule analysis, EPA conducted a literature search of the Natural Resource Damage Assessment (NRDA) Literature in order to identify studies where: (a) respondents expressed non-zero willingness-to-pay (WTP) to prevent the mortality of individual aquatic or bird species resulting from "human-activity;" and (b) the valuation scenario indicated that species population-level effects were not expected as a result of the hazard(s) described in the valuation scenario; or respondents were told that it is unclear whether or not the hazard(s) may result in population-level effects.

In NRDA cases, there are often short-term losses to species with large populations, such as seabirds, shorebirds, or fish. The dollar values of interim losses pending natural recovery or restoration must be estimated. In some cases, there may also be losses to endangered species, which would affect long-run populations of these species. Consequently, while some NRDA studies estimate values for losses to threatened or endangered species, where population-level effects are significant, the majority of studies focus on estimating people's willingness to pay for short-term losses of small numbers of fish or birds.

In the case of impingement and entrainment (I&E) at power plants, there are ongoing losses of individual fish. However, it is possible that there are no population-level effects on some fish species. If I&E were eliminated, these species would likely recover naturally in a time period similar to the recovery of equivalent losses of fish caused by an oil or chemical spill. Therefore, the damage assessment approach of valuing short-term losses to individual species that will recover naturally is also appropriate to estimating I&E losses for fish species that do not suffer population-level losses.

The findings of the NRDA studies indicate that people have significant values for small, temporary losses to bird and fish species that are not threatened or endangered. This implies that people responding to these surveys are willing to pay to prevent the loss of individual birds or fish, when the loss of these individuals do not affect the long-term population level of the species. In addition to short-term losses of individuals, with no population effect, respondents to some of the studies presented here were asked to value losses to endangered species where these losses would negatively impact species population. As one would expect, people were also willing to pay for population-level losses.

Valuing Forage Species (incl non-use and non-landed)

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Perhaps because of their difficulties in obtaining relevant non-use values in the North Atlantic, the USEPA decided to approach this question from a different angle when evaluating the Northern California region. For Northern California, the USEPA calculated "break-even" non-use value, the dollar amount of non-use value that would equate the total economic value with the costs of Northern California investment in closed-cycle cooling systems. While this may be useful information, it is not a substitute for credible estimates of the non-use value of the changes in fish and shellfish stocks associated with lower impingement and entrainment in CWIS. We know what the nonuse values would have to be, but we still do not know what they are.

EPA Response

For EPA's response to comments on the break-even analysis, please see the response to comment #316bEFR.306.106. Please also see Chapter D1 of the EBA (DCN #6-0002).

Use of Replacement Costs (HRC and hatchery-based)

The NODA has reopened the comment period on all aspects of the April 9, 2002 proposal. Given the uncertainty regarding how the remaining six regions are to be analyzed, I thought that it might be useful to reiterate my concerns regarding the Habitat Replacement Cost (HRC) and Societal Revealed Preference (SRP) methods. Even though USEPA states "Stated preference methods, or benefit transfers based on stated preference studies, are the only generally accepted techniques for estimating non-use values" (Tudor, et al., March 12, 2003a; Tudor et al., March 12, 2003b), the NODA contains no direct repudiation of HRC or SRP methods. For the numerous reasons previously discussed in my comments and those of others (e.g., Stavins 2002) on the proposed rule, the HRC and SRP method should not be advocated nor used by the USEPA as they are conceptually incorrect and could lead to extremely inefficient policy choices. USEPA
should make this clear for the record.

EPA Response

While EPA acknowledges that believes that analyses of replacement costs do not provide benefits estimates, EPA does believe that they are useful tools for evaluators to use in the decision-making process.

However, EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule. Please see the document entitled "Habitat-based Replacement Cost Method" (Docket # XX) for additional discussion of the HRC method. Please also see EPA's response to comment #316bEFR.005.035.

EPA does not use the Societal Revealed Preference (SRP) method in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the SRP, please see the response to comment #316bEFR.005.006

Regional Benefits Approach

Another potential problem in the NODA is the merging of all facilities into an aggregate regional analysis so that benefits are only dependent on the sample of facilities in a region. While a region-based analysis is probably superior to the original USEPA method, the heterogeneity in rivers, estuaries and oceans in combination with differences among facilities makes the regional expansion based on a few facilities quite tenuous. If the facilities chosen in the sample are not representative of the region, then a serious bias will exist. Because the data that exist are most likely associated with facilities that have high I& losses, the bias will upward.

General Comments on Valuation Approaches

In the North Atlantic and Northern California regions, the use values associated with impingement and entrainment losses appear miniscule in comparison to the costs of closed-cycle cooling. If this is also true in the remaining regions, then the estimates of the non-use or passive values are critical. However, USEPA has not undertaken a stated preference study that will directly address them. Although monetary and time constraints are used to justify the inaction, substantial funds have been devoted to more studies associated with use values. If the use values continue to remain so small relative to costs in the remaining six regions, then USEPA should initiate a process to obtain a better understanding and better estimates of non-use values associated with fish and shellfish populations. The traditional way to approach this is a state of the art stated preference analysis.

I believe that developing a defensible stated preference analysis of non-use values associated with individual stocks of fish is critical to the USEPA. I realize that carrying out such a survey may not be possible because of the deadlines imposed by the court. However, the NODA makes clear that the USEPA proposal rests on the estimation of non-use values, a grossly inadequate part of the NODA analysis.

EPA Response

EPA does not agree that it is essential to conduct an original stated preference study of non-use values. For EPA's response to the issue of conducting an original stated preference survey, please see response to comment number 316bEFR.306.106.

General Comments on Valuation Approaches

Author Name Doug Dixon & Kent Zammit

Organization EPRI

EPA has issued the Notice of Data Availability associated with the standards for the location, design, construction and capacity of cooling water intake structures (CWIS) of existing power plant facilities. USEPA has revised substantially its approach to estimating benefits from the preferred option of closed-cycle cooling associated with two regions (the North Atlantic and Northern California) and briefly outlined its approach to the other regions.

While the NODA has made substantial improvements in the use of valuation concepts (such as using discounting and not using costs as benefits) over the original proposal (Proposed Regulations for Cooling Water Intake Structures at Phase II, Existing Facilities, EPA ICR No. 2060.01), the empirical data supporting the NODA are grossly inadequate. The major problem is in USEPA's attempt to quantify non-use values associated with reduced losses from impingement and entrainment in CWIS. I will go through the complete benefit section of the NODA, but focus on its non-use valuation aspects.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values. The Agency, however, has explored several methods that indicate the potential significance of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Commercial Fishing Benefits

Use Benefits from Marketed Goods

The change in the return to commercial fishers (from a range of 40-70 % of new revenues to 0-40 % of new revenues) when there is no expected change in fish price from the proposed action is reasonable (NODA, page 107). Fisheries are substantially different but what is likely common among them is that the immediate return will be larger than the more distant (in time) returns. While the immediate effect might be higher than the new range, the long-term effect might be lower and approach 0. USEPA's approach is probably a reasonable compromise, given the fisheries involved.

For cases when there is an expected price change, the Bishop and Holt approach (2003) appears promising even though the final results need peer review and the illustrations seem terribly dependent on having a fishery with a transferable quota. Without the transferability, there is good reason to believe that the long-run average costs of fishing will increase as an "Olympic" fishery races to get the new fish. This eliminates both the long-run surplus to the fishermen and the consuming/post-harvesting participants.

Regarding the general problem of incorporating fisheries management regimes into the analysis, I would recommend that this is a continuing problem for many EPA regulations and requires a specific study that would extend beyond the time line of this proposed regulation.

EPA Response

This comment does not disagree with the approaches taken by EPA to analyze commercial fishing benefits for the final rule. For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits, please see the response to comment 316bEFR.005.029.

Regional Benefits Approach

Indirect Use Benefits from Non-Marketed Goods

The process suggested uses a 5-year historic catch per hour as the measure of abundance and measures the value of fish from an estimated coefficient (say θ) associated with how the catch rate influences site choice. In the Northeast analysis, the USEPA may use the formula for the value of additional fish based on (See Appendix B pg 6 for Formula) , where Δq is total new fish and $\beta\$$ is the coefficient on cost. If this is used, then the fish per hour changes must be considered differently from total fish changes. You have to reduce the coefficient on the fish per hour by the average number of hours fished. This is the only way that the monetary units (which are on the basis of trips) are in same units as the number of fish. An alternative way of looking at it is that the additional fish are going to increase the hourly catch in proportion to the average number of hours fished. An original catch of 100 fish in 5 hours (20 fish per hour) is augmented with say 10 additional fish from the proposed regulations. Although the total goes up by 10 fish, the catch per hour only goes up by 0.2 fish/hour. The Northern California analysis appeared correct but the North Atlantic analysis was unclear to me.

EPA Response

The commenter states that EPA's approach to calculating the measure of fish abundance and the value of fish presented in the NODA was not clear to him.

EPA's analysis uses fish per hour values for catch rates and for increases in catch rates. All catch rates in the models are average number of fish caught per hour for each site and species. The only exception is the North Atlantic model developed by Hicks et al. (1999, DCN #4-1603). Hicks et al.(1999) uses a 5-year historic catch per trip as a measure of fish abundance at a given site.

In calculating welfare estimates for increases in catch rates, EPA estimated the change in utility for a given percent change in catch rates. Thus, a percent change in catch per hour was applied to each site and each species. For example, if catch rates were estimated to increase by ten percent, the catch per hour for each site was multiplied by 1.10. Since catch rates were already in the model as catch per hour, no additional adjustment is necessary. EPA used the same method for the North Atlantic region. The only difference is that the percent change in catch rate is applied to historic catch per trip.

When EPA calculated welfare for an increase in catch of one fish per trip, the one fish per trip was divided by the average duration of a trip before being added to the average catch rate per hour. For example, if the average trip was four hours long, EPA added .25 fish (1 fish/4 hours) to each site's catch rate. In calculating welfare for an increase in catch of one fish per trip for the North Atlantic region, no adjustment was necessary; EPA simply added one fish to the average catch per trip. See Chapter 4 in Parts B through H of the Regional Case Study Report (DCN #6-0003) for detail.

General Comments on Valuation Approaches

Non-use Valuation

USEPA's statements in the NODA such as "Stated preference methods, or benefit transfers based on stated preference studies, are the only generally accepted techniques for estimating non-use values" (Tudor, et al., March 12, 2003a; Tudor et al., March 12, 2003b) are reassuring. In concept, the approaches to address nonuse values used in the NODA are a major improvement over the original proposal. They do not use costs as benefits. Unfortunately, they still do not provide adequate information regarding non-use values of reduced I&E losses. The studies used for the North Atlantic region simply are too inaccurate and the error inherent in USEPA's manipulation of the data renders the results meaningless. The break-even analysis in the Northern California region does not yield any information on household's non-use values. What is missing from the NODA is an credible assessment of the non-use value of reduced losses from impingement and entrainment in CWIS.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values for national benefits analysis. The Agency, however, has explored several methods that indicate the potential significance of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

North Atlantic

EPA's Approach to Non-Use Valuation

I will not address in detail the recreational and commercial harvest benefits estimates in the North Atlantic because they are miniscule in comparison with either the costs of closed-cycle cooling or the non-use values estimated for the North Atlantic. The use benefits are 1/22 of the CWIS costs and 1/30 of the non-use values (NODA, Table X- 46). The small ratio of use to non-use value is derived in a large part because the USEPA's per-household non-use value of a wetland or eelgrass acre is about 20 times the per-household use value (NODA, Table X-34). This is somewhat shocking when taken in comparison with values reported by Tudor et al. (2003b). In a summary of existing studies reporting both use and non-use values, Tudor et al (Appendix A) show that around 90 % of the nearly 30 studies estimate a non-use value/household that is less than 3 times the use value/household. The average ratio of non-use value/household to use value/household is around 1.8 the use value/HH, one-tenth of the value that is presented for the North Atlantic. The three largest relative non-use values are from one study (Croke et al. 1986). When that study is dropped, the average falls to about 1.3.

Given that total non-use values are pivotal and that the relative non-use values appear out of character with the literature, focus will be given to how the non-use values were created and the pitfalls in the analysis. The process uses the estimate of non-use value/ (reduced I&E loss) times the reduced I&E losses to produce a total non-use value (Tudor, 2003a). But the process of obtaining an estimate of non-use value/ (reduced I&E loss) is complex and requires detailed explanation.

The USEPA uses existing literature, Opaluch, et al. (1998) and Johnston et al. (2001), in an attempt to estimate the expressions of equation (5.). Both studies are fundamentally stated preference studies although one is called contingent choice (Opaluch et al.) and the other is called conjoint analysis (Johnston et al). USEPA uses the data and results from these two studies to develop their non-use values.

The analysis begins using the data in Opaluch et al. (1998) to estimate the total non-use value per household per acre of wetlands and eelgrass. This is despite an explicit warning by the authors: "we believe that the resource priorities or relative values of resources are more reliable than are the dollar estimates of values and recommend that relative values, rather than dollar values, be used in the process of selecting management actions (p. 5, Opaluch, et al., 1998)".

There are likely a number of reasons for this warning but it is particularly meaningful given the use that USEPA intends to make of the data. Opaluch et al. warned of using the wetlands and eelgrass values/acre but USEPA's intended use goes beyond that to an estimate of a value per fish and shellfish arising from a wetland change. There was no information given to the respondents regarding how these wetlands on eastern Long Island affected fish populations. When choosing to allocate money between a policy to protect wetlands and one to protect eelgrass, the respondents had only a rudimentary picture of a heron and marsh grass as information about the wetland and a fish in water as information about eelgrass. To assume, as USEPA does, that that respondents can translate that drawing of wetland or eelgrass bed into the same amount of fish as biololgists have now done is technically indefensible. However, there are other problems, perhaps as serious as this one.

(See Appendix B ph 7-8 for tables and formulas)

EPA Response

For EPA's response to comments regarding using habitat values to estimate values for fish and similarity between the study and policy resources, please see the response to comment #316bEFR.307.061.

For EPA's response to comments regarding the connection between values for habitat and values for fish and shellfish and respondents perception of the role of habitat in fish production, please see the response to comment #316bEFR303.020.

For EPA's response to comments regarding the soundness of the original study for benefit transfer, please see the response to comment #316bEFR.304.002.

Given that ninety eight percent of organisms affected by I&E are not used, and the population of non-users is larger than the population of users, it is not unrealistic for total non-use values to be many times greater than use values. In general, it is not unreasonable to expect that non-use values greatly exceed use values for some resources. For example, non-use value losses from the Exxon Valdez oil spill greatly exceed use value losses. (For detail see (1) Carson, Richard T., Robert C. Mitchell, W. Michael Hanemann, Raymond J.Kopp, Stanley Presser, and Paul A. Ruud. "A Contingent Valuation Study of Lost Passive Use Values Resulting from the Exxon Valdez Oil Spill," A Report to the Attorney General of the State of Alaska, November 10, 1992; and (2) Molly McCommon. "Evaluation of Environmental Damages of the Exxon Valdez Incident." Presented at the conference on Issues Concerning Incidents on Tanker Routes, Tokyo, Japan, February, 2003.)

Organization EPRI

Definition of Non-users

The definition of non-users is absolutely critical when developing non-use values. A definition of users that is too restrictive causes a serious overestimation of non-use benefits. It arises because the difference between the total value of the non-user group and the total user group is reduced when users are switched to the non-user group. Because use value is the difference between the total value of the two groups, by placing users into the non-user group the estimate of non-use value increases. The upward bias is spread across everyone because everyone is assumed to have the same non-use value.

USEPA derives a total value of wetlands (willingness to pay for all wetland services, Tudor et al. 2003a, p.10) for users and nonusers. Definitions of nonusers and users of wetlands are made; users are residents/second-home owners who fish or shellfish and non-users are all others. No information on the number of respondents in each category is provided. However, going back to original report on which the data was based, the authors state "almost all of the respondents (97%) participate in at least one of the listed activities (fishing, shellfishing, walking/hiking, swimming, other beach use, boating, artwork, other), and 81% participate in at least one activity in the Peconic estuary. Swimming is the most popular activity. (Opaluch et al. p. 108-109)." Fishing (40.4%) is the fourth most popular activity in the Peconic and shellfishing (27.0%) is the fifth most popular. Because I do not have the data, I can but venture a guess that less than 50% of the respondents are considered users. I would also venture a guess that at least 80% of the respondents consider themselves users of the wetlands. Simply driving by and enjoying a gorgeous expanse of wetland would be a use. Hikers and swimmers are certainly wetland users.

If the USEPA definition of a user is too restrictive, then it is not surprising that the values per household for non-users are almost equal to the values of users. It is also probable that this error in judgment will make the ratio of non-use to use values per household out of line with the literature. That non-use value dominates the use value may be a matter of definition of the groups.

Consider an example using four categories with 100 respondents whose willingness to pay for wetland protection is known:

(See Page 9 Appendix B for Table)

If a correct definition of user is used that includes swimmers along with fishers and shellfishers, then the total non-use value is $100 [100x1.] while the total use value is $360 [40x4. +50x4.]. The ratio of non-use to use value per respondent is .25 [1/4].

Now suppose that we take the USEPA approach and define fishers/shellfishers as the only users of the wetland. With this definition, the average respondent's total value is $5 for users and is $4.33 [260/60] for non-users. The $4.33 is also the average non-use value for the user group. The total non-use value over all respondents is then $ 433 [100x4.33]. The use value per respondent is defined as the difference between the average user's total value and the average non-user's total value. The user value per respondent is $.67. The total use value for the sample is only $26.80 [40x.67]. The ratio of non-use to use value per respondent is 16.2 [433/26.8].

This illustration underscores how critical the definition of non-user is. In the illustration, the ratio of nonuse to use values per respondent changed from .25 to 6.5 and the ratio of total non-use to total use values go from .03 to 16.65. In essence, the ratios go from being similar to those in the literature to being substantially higher. By narrowly defining the user category, the difference in total value between user and nonuser is reduced. Because the nonuse value is directly related to the difference between the two while the use value is inversely related to that difference. Without the data, I cannot tell specifically the effect of the narrow definition of use; however, I expect that it is great.

EPA Response

The comment states that the definition of non-users is critical when developing non-use values. The comment implies that EPA's estimates are biased upwards because by their definition of non-users. EPA disagrees. For EPA's response to comments regarding the definition of users vs. nonusers, please see comment #316bEFR303.020.

Peconic-based approach

The Share of Wetland Non-use Value Attributable to Fishing and Shellfishing

The nonuse value of a wetland, as described above has to be reduced to the share that is attributable to fish and shellfish. USEPA uses data from Johnston et al. to determine that share. Their model uses responses from Rhode Island residents<FN 2> that stated their preferences regarding plans for wetlands that improved bird populations, fish habitat, shellfish habitat, and mosquito control. In deriving the share associated with gains to fish (0.256) and shellfish (0.278), USEPA assumes that the only products of wetland restoration are the four just listed. A fifth category of services (such as storm protection) was not specified but was assumed to capture any residual share. USEPA apparently also ignores the fact that they are determining the share of total value, not nonuse value, of a wetland. Each assumption raises concerns.

By assuming so few uses of wetland restoration, a serious overestimate of the share of value attributable to fish and shellfish can arise. That is, if 30% of the value was attributable to other factors (such a scenic amenities), then the share that should be attributed to fish is 0.179 (0.256*(1-0.3)). This is something that USEPA might want to consider.

By not addressing the issue of non-use values, I believe that the share that USEPA attributes to fish and shellfish is irrelevant. Consider the illustration in the previous section. The share of total value associated with fish and shellfish users is about 36% but we have no information about the contribution that fish and shellfish make to the non-use value. It is unfortunate but the information in Johnston et al. (2001) does not address the share of non-use value associated with fish and shellfish.

Footnotes

2 The sample was selected from individuals who were willing to be respondents in a survey associated with environmental issues. The lack of random selection of the sample undoubtedly influences the results.

EPA Response

Regarding the allocation of wetlands values to different services, this comment by the authors is based on arbitrary assumptions unsupported by the focus groups that supported the Johnston et al. (2002) survey and results, upon which the value proportions are estimated (DCN #6-3151). For EPA's response to comments regarding the allocation of values for various wetland services using the Johnston, et al. study, please see the response to comment #316bEFR.303.021.

Peconic-based approach

General Impression of the Non-use Valuation Process

If USEPA is going to rely, as they should, on stated preferences, then the current process is indirect and fraught with the potential for error. The notion that the original respondent in the Peconic Bay study (Opaluch et al. 1998) had the non-use values per fish that arise from USEPA's process is not technically defensible and would not pass professional review. I've discussed the problems with the economic parameters but the error in them may be small compared with the error in determining ecological link between wetlands and fish production. Are we to believe that these respondents knew the number of fish (as determined by USEPA) an acre of wetland would provide? A well designed contingent valuation study directed to determining the non-use values related to I & E losses would help resolve many of these problems.

EPA Response

Please see EPA's response to comment #316bEFR.307.061 regarding using habitat values to estimate values for fish.

Valuing Forage Species (incl non-use and non-landed)

The Northern California Study

Once again, the estimated use values are extraordinarily small compared with a non-use value that would equate benefits with costs. Non-use values would have to be over 30 times greater than use values for benefits to equal costs. Recognizing the issue and recognizing “the uncertainties of providing estimates of the magnitude of non-use values (NODA, page 188)”, the USEPA chooses to compute a break-even value per household in the Northern California region. One presumes that decisions makers use this information by judging whether the break-even value is within the realm of possibility for households in the region.

While it is information, I am not sure that decision makers are more able than anyone else to decide the non-use values. USEPA loses technical credibility when it ignores the complete lack of relevant non-use data and ask others to determine it in some haphazard manner. A defensible contingent valuation of non-use values associated with reduction in impingement and entrainment is critical to the USEPA’s proposed Phase II rule. It will require great care because of the possibility that non-use values per household in this situation may be quite small. Eliminating the “good feeling” or “warm glow” associated with stating a preference (and willingness to pay) for environmental improvement is critical as is determining the extent of the market. It will also have to have sufficient spatial variation to capture regional and waterbody influences on the nonuse values. Addressing whether or not the size of fish and shellfish stocks influence the willingness to pay is critical. USEPA is under court order with regard to timing but I think USEPA will have made an enormous mistake if it does not approach this difficult but essential task. As I wrote in my last set of comments eight months ago, I believe that developing a defensible contingent valuation of non-use values associated with reduction in impingement and entrainment at power plants is critical to the USEPA Phase II rule. It might require pooling talent from consultants with experience in designing non-use studies (such as Michael Hanemann, Ian Bateman, Ron Cummings or Bill Devousges) to get an objective study. It is doubtful that use value studies will make the case for using the closed-cycle cooling option. At the same time, the current analysis of non-use values
does not make the case.

EPA Response

Closed cycle cooling is not required by the regulation.

As noted in the response to comment 316bEFR.306.301 and in Chapter D1 of the final EBA (DCN #6-0002), in the final cost-benefit analysis non-use benefits would need to be on the order of 4 times use benefits to equate total social benefits and costs.

EPA concurs that the estimation of nonuse values is an extremely challenging, complex, and controversial matter.

For EPA’s response to the issue of conducting an original stated preference survey, please see response to comment number #316bEFR.306.105. Recreational Fishing Benefits

Regarding the recreational fishing analysis for Northern California, it is far better than previous RUM models done by USEPA for the proposed rule. I do have a concern about using the catch rate of all species for non-targeting anglers. This presumes that the value to a non-targeting angler for an additional striped bass is the same as for a white croaker. The biased introduce by this assumption is not clear to me, though.

EPA Response

In the coastal region RUM models, EPA used average catch rates for all species caught by no target anglers to model the "no target" catch rate. Therefore, each no target angler is assumed to face a catch rate at each site that is the average for all species that have been caught in the past by no target anglers at that site. Intuitively, this makes sense, as no target anglers, by definition, will catch whatever bites. This implies that, in the model, all fish caught by no target anglers are assigned equal values, based on the assumption that no target anglers choose a site based on average catch rates for fish caught by no target anglers at that site. Presumably, if no target anglers had a preference for a particular species, they would target that species.

In terms of welfare estimation, using a single average catch rate for no target anglers does result in equal value estimates for different species, so that, as the comment states, the value for an additional striped bass is the same as that for an additional white croaker. However, calculating an average value does not introduce statistical bias to the model, it simply means that it is not possible to estimate differences in value across species for no target anglers. It is possible that striped bass and white croaker have the same value for no target anglers. It is also possible that one species is more valuable than another. However, the model estimates an average value for all species caught by no target anglers, rather than values for individual species. While the model is not biased, it might result in slightly different total values for I&E reductions than a model with separate catch rates by species for no target anglers, depending on the species affected and how each species affects the average value per fish for no target angler. In addition, by using average catch rates for no target anglers for each site, EPA's model allows for more substitute sites with positive catch rates for each no target angler. This is likely to result in lower values than a model with fewer substitute sites per angler. EPA believes that it has chosen the best model for no target anglers. Overall, this is a minor issue, and estimating separate values by species for no target anglers is not likely to improve the model or results.

Cooling system costs (e.g., dry, wet, recirculating)

The outage times required for units to install recirculated cooling are not trivial, and certainly could have impact on grid reliability in the case of the All Cooling Tower Option.

EPA Response

The Agency acknowledges that the outage times from recirculating cooling tower retrofits are not trivial. The Agency does not base the requirements of the final rule, in part, based on the potential for impacts on grid reliability due to construction downtimes.

Organization EPRI

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

In typical retrofit circumstances, the cooling tower would have to be sized for the higher flow rates associated with once-through cooling. Redesign and conversion of the cooling system to accommodate the lower flows and smaller towers of a typical recirculating system would entail extensive revisions to the plant cooling system, more extensive outages, and an overall increase in capital cost over the unoptimized system.

EPA Response

The Agency agrees with the comment regarding the sizing of retrofit cooing towers to higher flow-rates associated with once-through cooling.

Comment ID 316bEFR.306.404

Dry Cooling

EPA was prudent in its determination that wet cooling is not a reasonable alternative for retrofit to existing facilities. In addition, I would add that the retrofit of dry cooling to existing plants would be even more problematic, increases technical complexity, costs, and efficiency penalties, and most assuredly would require extended outages.

EPA Response

The final rule is not based on dry or wet cooling tower technologies. Therefore, the commenters concerns have been met.

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

However, the additional point that “there is insufficient non-CBI<FN 1> information to allow any detailed plant or firm-specific assessment of the analyses provided by EPA” is worthy of comment and relevant to much of what follows.

It is most important to recognize that costs of major retrofit projects at existing, operating power generating facilities are fundamentally site specific in nature. In the absence of detailed studies at individual sites, which are often appropriately held to be privileged in the current competitive utility business environment, it is impossible to make generalized statements about the costs of retrofit with any degree of precision. EPRI was able to obtain access to such studies for the purpose of commenting on the proposed rule and the results of that analysis [3] demonstrate the high degree of variability in the costs resulting from site-specific factors.

Therefore, it is not particularly useful or illuminating to debate modest disagreements in cost or to put a great deal of weight on the importance of small differences between individual site costs and cost estimates derived from generalized algorithms or correlations. It is only major differences, supported by consistent trends over a wide range of plants, which can be expected to be significant. In this light, many of the points raised in Synapse document, particularly those in Section 6, "Cost Estimates," are of little importance

Footnotes

1 "Confidential Business Information"

EPA Response

The Agency agrees with the principle of the comment that precision of cooling tower retrofit cost estimates cannot be made with a great deal of precision. The Agency knows of only four cases where cooling tower retrofit project has been conducted. Of these four, the Agency was only able to obtain details on the costs incurred at two cases. Each of these cases is significantly less in cost than those presented by the commenter for the 50+ cases of "hypothetical" planned retrofits included in their appendix C (see response to comment 316b.EFR.208.002). Thereby, it can be inferred that the range of costs likely for cooling tower retrofit projects would be extremely wide, should the costs in the referenced comment prove to be true, as those have been for the two documented cases in EPA's record (see DCN 4-2526).

The Agency disagrees with the assertion by the commenter stating, "it is not particularly useful or illuminating to debate modest disagreements in cost...derived from generalized algorithms or correlations." While broad-brush reviews of costs are extremely important, it is sometimes in the analysis of and debate over "modest disagreements in cost" that important facts can be revealed and learned. In the context of the point to which the commenter is referring, that made by Synapse that "there is insufficient non-CBI information to allow any detailed plant or firm-specific assessment of the analyses provided by EPA," the Agency disagrees. Other commenters have pointed out that sufficient information was provided in the NODA, and sufficient publicly available information exists in the Energy Information Administration databases that allows for thorough review of the Agency's

NODA cost estimates. Also, sufficient information was provided for other commenters to critique in detail EPA's revised approach to costing in the NODA, to which the referenced commenter (Synapse) provided no substantial comments.

Comments on Material in “Section 4: Reliability Impacts”

Outage Time Required for Wet Tower Retrofits

EPA asserted in the Technical Development Document [4] that much of the preparatory and construction work required to retrofit a once-through cooled plant to a cooling tower could be performed while the plant is on-line, requiring outage time only for the final tie-in of the circulating water lines to the new tower. therefore, it was assumed (and it was alleged to be a conservative assumption) that the parts of the retrofit activity that required the plant to be off-line could be accommodated during the course of routinely scheduled maintenance outages extended by one month.

While this may be the case in some instances, there are numerous documented studies in which the anticipated outage time was expected to be much longer. These include studies performed by experienced A&E firms for PSE&G’s Salem Plant [5], as well as four other plants. Table 1 below lists these several stations and the estimated extended outage time determined to be required for a retrofit.

(See Table, Appendix C Page 6)

Reasons for the necessity for required outages beyond the one-month extension include

- The installation of underground circulating water lines frequently encounters interferences with existing utilities which must be disconnected during the installation period

- The need to reinforce existing condenser water boxes renders the condenser inoperable for long periods The need to reinforce existing circulating water lines renders the condenser inoperable during the work period.

- Existing cooling water intakes and discharge facilities may need to be shut down in order to reconfigure them to accommodate the lower flow rates. In most situations these activities are extensive and time-consuming.

While it is not possible to estimate realistically the average amount of lost capacity during the several years over which the many retrofit operations would take place given an “all cooling towers” option, it is reasonable to expect that, in a region such as the West which has recently experienced capacity shortfalls, that an extended outage of a major facility (such as San Onofre) for several months could exacerbate an already marginal situation.

EPA Response

The final rule is not based on cooling tower technologies, in part, due to the uncertainty inherent in construction downtimes. Therefore, the commenters concerns have been met.

Cooling system costs (e.g., dry, wet, recirculating)

Outage Time Required for Dry Cooling Retrofits

The Synapse report goes on to extend the outage time discussion to include dry cooling and asserts that such retrofits would also have little effect of available system capacity.

Two points are noteworthy. First, in the context of effects on national capacity, this is not an issue worth discussing. EPA has already quite correctly determined that dry cooling is not “a reasonable option for a national requirement not for sub-categorization under this proposal” and that such a requirement “would have a significant detrimental effect on electricity production…” [9]

This is an appropriate conclusion, in my view, even for new facilities, but especially so for retrofits at existing plants for several reasons, specifically:

- Retrofit to dry cooling at an existing plant would require the use of indirect dry cooling (where the steam is condensed in conventional water-cooled condensers and the hot cooling water is circulated through an air-cooled heat exchanger) rather than direct dry cooling where the steam is condensed directly in an air-cooled condenser (ACC).

- The use of direct systems in retrofits is precluded due to the extreme difficulty of modifying the turbine exhaust area, removing the existing shell-and-tube condenser, and ducting the large volume of steam out to an ACC.

- Indirect systems carry severe economic penalties, even in comparison to direct dry cooling, because of the additional temperature differences between the condensing steam and the ambient air imposed by the heat transfer resistance of the existing condenser and the temperature rise of the circulating cooling water. This is evidenced by the fact that direct systems are always the system of economic choice among dry systems at new facilities where the freedom to choose an appropriate turbine and to optimize the cooling system for plant characteristics is available.

- Existing plants, originally designed for once-through cooling are almost certainly equipped with steam turbines for which the maximum allowable turbine back pressure is 5 in Hga or less corresponding to a condensing temperature no greater than 134 F. For an indirect dry cooling system, with a condenser terminal temperature difference of 7 F, a cooling water temperature rise of 20 F and a probable minimum temperature difference across the air cooled hear exchanger of 25 F, the plant would be required to curtail load at ambient temperatures above 82 F. At new plants, where extended back pressure turbines and the use of ACC’s may permit operation at temperatures well over 100 F, the capacity and operating penalties can be important. Under retrofit constraints, they would be completely unacceptable.

EPA Response

EPA agrees with the comment, which supports its conclusion to not include dry cooling technology as a basis for the final rule.

Comment ID 316bEFR.306.411

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

Second, it remains to consider whether retrofit to dry, although unacceptable as a national requirement, might be the “appropriate cooling technology for some facilities” as EPA suggests, for example “facilities that are repowering and replacing the entire infrastructure…”

Several considerations are important.

- Even under the most favorable conditions, the costs are significantly higher than for a comparable plant with recirculating wet cooling. A few plants, both actual and proposed, are sometimes offered as examples of situations where dry cooling has been or could be the cooling technology of choice. However, even in those situations such as Morro Bay (an ocean-side plant in Central California), Athens (a plant on the Western bank of the Hudson river in upstate New York) or Crockett (a plant on the San Francisco Bay), where the conditions for dry cooling are as favorable as they can ever be (low annual average temperatures, low maximum temperatures during cool, fog-shrouded summer months; combined cycle plants where only 1/3 of the plant capacity requires cooling for steam condensation; and plants designed and optimized from the beginning for dry cooling with extended back pressure turbines), the estimated cost differentials are significant ($52 million more for dry cooling vs. once-through cooling out of $800 million at Morro Bay; and $20 million more for dry cooling vs. hybrid cooling (already a significantly more costly option than wet cooling at Athens). If similar comparisons were applied at steam plants (not combined cycle) with existing (not optimized) turbines and in less favorable climates (as would be the case for most inland plants in most parts of the country), the differentials would be much greater.

- Finally, to return to the question of outage times, attempts to retrofit to direct (ACC) systems would entail very long outages to accommodate the removal of the existing condenser and the installation of the steam duct under the turbine exhaust shroud, the structural modification to the turbine hall and the removal, relocation and reinstallation of much of the major equipment such as feedwater pumps----none of which can be done while the unit is on-line. Since such retrofits, if done at all, would be extremely rare, it is likely true that the effect on national generating capacity would be small. However, for the individual plant it would represent an important revenue loss and, in the unlikely event that it were done on a large base-loaded facility, the effect on local capacity could be important. A retrofit to an indirect system might well require outage times more comparable to those needed for wet cooling tower retrofits, but with unacceptably high cost and performance penalties.

EPA Response

EPA agrees with the comment, which supports its conclusion to not include dry cooling technology as a basis for the final rule.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

Percent capacity simultaneously out of service

Synapse calculates that only 0.5% of the national generating capacity would be out of service at any one time during the 5 year period allowed for compliance. This figure derives from the EPA estimate that approximately 33% of the capacity would be subject to retrofit requirements, that additional outage periods of only one month would be required to accomplish the retrofit and that the projects would be scheduled to take place uniformly over the five year period. Therefore, 33% for one month spread over 60 months (33% divided by 60) approximates 0.5% at any one time.

These assumptions are questionable. The examples given in Table 1 above suggest that an average of 6 months of retrofit-related outage time rather than one month might be required. This alone would increase the average simultaneous outage rate to 3%. Furthermore, reason dictates that perfectly uniform scheduling is unattainable. During likely occurrences where the affected capacity was only 2 to 3 times the average, the affected percentage would rise to 6 to 9%, which, if it occurred during peak periods, would be an important consideration for system reliability.

EPA Response

EPA notes that for the NODA analysis, EPA changed from 1 month to 7 months, the length of the outage period for nuclear facilities estimated to install a cooling tower. EPA therefore agrees that the estimate of 0.5% probably understates retrofit-related outage time. EPA also agrees that a perfectly uniform schedule of compliance and outages is highly unlikely. However, EPA notes that whether an affected percentage of 6% or 9% might cause reliability concerns will depend on the timing of the outages (i.e., if it is during peak or off-peak times) as well as the reserve margin in the NERC region.

Comment ID 316bEFR.306.413

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

Preferential scheduling to off-peak seasons

Synapse further suggests that rather than assuming "that the extra downtime needed to connect the new cooling towers would be spread evenly throughout the year…it is far more likely that the extra downtime would be preferentially scheduled to occur during the off-peak seasons when system loads are lower and capacity reserves are reserve margins are significantly higher."

This is likely true, but the argument cuts both ways. If all the outages are scheduled during off-peak periods (say, for simplicity, during one-half of the year) then the 60 month period shrinks to 30 months and the percent of capacity simultaneously out of service doubles (on average assuming one month outages) from 0.5% to 1%. Assuming the more realistic outage duration of six months and the inevitability of non-uniform scheduling, the expected simultaneous outage percentages given above increase from 6 or 9% to 12 or 18%. Even during off-peak seasons, these numbers have important reliability implications.

EPA Response

The Agency has not based the final rule on cooling towers, in part, due to the uncertainty associated with connection outages and the potential impact on electricity reliability. However, the Agency disagrees with the commenter that it would be feasible or likely that a coincidence of construction projects would all occur simultaneously. The Agency notes that construction schedules would in large part be influenced by the time when permits are renewed. Because of this fact, it is improbable, in the Agency's view, that mass-simultaneous outages would occur. Further, the Agency has allowed considerable flexibility in permit compliance schedules for the final rule precisely to accommodate concerns about the small potential outages expected for the intake technology retrofits associated with the technologies forming the basis of the final rule. The Agency refers to the Chapters B-1 and B-3 of EBA for the final rule for results of the Agency's assessment of compliance years and modeling of the energy market.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

Net plant capacity reductions

Synapse asserts, based on Table B8-3 of EPA's Economic and Benefits Analysis (EBA) [6] that the implementation of the All Cooling Towers Option reduces the total national generating capacity by only 0.4% (3,380 MW out of 922,740 MW) and suggests that this "would not have a significant impact". However, it should be noted that Table B8-3 displays the aggregate result of "closures, additions, repowerings and energy penalties" which tends to obscure the effect of energy penalties from cooling system retrofits. If the individual contributions are tabulated separately using information available on Tables B8-2, B8-4 and B8-5 from the same EBA [6], one finds that the 3,380 MW deviation from the base case results from the sum of the energy penalties plus

7,120 MW more additions (125,990 vs. 118,870 base),
4,120 MW more re-powering (22,650 vs. 18,530 base) and
3,640 MW more closures.

These items would lead to an increase of 7,600 MW {7,120 + 4,120 -3.640 = 7,600} implying a decrease due to energy penalties of 10,980 MW (7,600 + 3,380 = 10,980) or 1.2% of national installed capacity rather than 0.4%. This is consistent with the energy penalty analyses presented in Chapter 5 of EPA's Technical Development Document. [4]

While this amount may also be considered small on a national average basis, one additional point should be considered. The energy penalty used to develop this estimate is an annual average penalty. (See Table B1-1 from [6].) Therefore, this penalty is consistent with the performance of the plant at the annual average wet bulb climate conditions at the individual sites. During the hottest and most humid times of the year when the power demand is at its peak in most regions, the wet bulb temperature is typically 10 to 15 F higher than the annual average value. Using the graphs in the EPA Technical Development Document [4], this corresponds to a turbine backpressure increase of 0.5 to 0.75 in Hga (Fig. 2, Chap. 5, Ref. [4]) and an accompanying 1 to 2% loss in output. (Fig. 1, Chap. 5, Ref. [4]). Therefore, if the annual average penalty is 1.5 to 1.75%, the penalty at peak load times could be 2.5 to 3.75%. In some parts of the country, this shortfall could be important to system reliability.

EPA Response

The commenter is correct in pointing out that energy penalties are responsible for reductions in available capacity. EPA agrees that energy penalties should be included in an overall assessment of the impact of section 316(b) policy options.

EPA also agrees that use of an annual average penalty might have underestimated the loss in output. For more information on this topic, please refer to the response to comment 316bEFR.041.822 in subject matter code 9.03.

Finally, EPA notes that whether certain penalty might cause reliability concerns will not only depend on the load but also on the reserve margin in the NERC region.

Cooling system costs (e.g., dry, wet, recirculating)

Condenser upgrades

Synapse suggests that credit for improved plant and hence system reliability should be taken for the result of condenser upgrades. This is alleged on the basis that plants which upgrade their condensers as part of the cooling system retrofit will experience fewer tube failures and lower forced outage rates in the years after the retrofit than had previously been the case.

In fact, the opposite may be true. Although condenser problems are not a major source of forced outages at any time, it is the case that they are more likely to experience problems just after installation and initial operations than later in their operating life. Most of the early problems are leaks in tube-to-tube sheet joints resulting from flawed assembly. Once these are detected and repaired, the condenser operates extremely reliably in most cases for the remaining life of the plant. [7]

EPA Response

EPA agrees with the comment. In addition, the Agency responds to the suggestion by Synapse to credit condenser tub improvements in response to comment 316b.EFR.404.058.

Comments on Material in “Section 5: Capacity Retirements”

Economic benefits from investment in plant

In Section 5, Synapse expresses doubt that the cost of retrofit would lead to the retirement of plants. As evidence, it is noted that a $36 million investment at the Vermont Yankee Power Plant, which increased the power level by 13%, would result in a net present value benefit of $56 million. However, the situation for cooling system retrofit is quite different. The estimated cost to retrofit Vermont Yankee [8] is $77.4 million and results not in power level increase but a modest (1 to 2%) output decrease leading to a net present value loss.

It might be argued that a cooling system retrofit would extend the operating life of pants that would otherwise not be allowed to continue operation under some regulatory scenarios. While it is likely that plants with long remaining life, high efficiency and high capacity factor will elect to retrofit, older plants with little utilization and poor efficiency would be unable to realistically expect to recover the investment required to retrofit over a limited remaining life and would be retired. Such plants may represent a relatively small fraction of the existing fleet. However, they are also likely to be precisely those plants called upon at periods of peak demand or under exigent circumstances when other more efficient base load plants are in forced outage or to provide voltage support during conditions of unusual grid operation. While difficult to quantify, the loss of these plants may have important effects on system reliability out of proportion to their fraction of installed capacity.

EPA Response

EPA agrees with this comment. EPA notes that this comment refers to retrofitting cooling towers. The final Phase II rule does not require the retrofit of cooling towers. EPA notes that whether the loss of generating capacity might cause reliability concerns will depend on the reserve margin in the NERC region.

Economic impacts on consumers/households

Comments on Material in “Section 6: Cost Estimates”

Costs of compliance are minor

In Section 6, it is asserted that the costs of retrofit are minor in comparison to overall costs; specifically that the annual (2001) cost of $2.3 billion established by EPA for the All Cooling Tower option amounts to only 0.1¢/kWh out of an average cost of 8.46¢/kWh and adds only $0.28 per month to the average residential electricity bill. While the arithmetic is correct, several points are noteworthy. The annual cost of $2.3 billion is made up of (from Table B7-12 in [6])

(See Table 2 Appendix C pg 12)

Other studies, analyzed and reported by EPRI [3] consistently define capital costs in the range of 2 to 2.5 times those estimated by EPA. As discussed above, probable outage times range from 2 to 10 time the one month outage assumed in the Connection Outage costs in the table above. Using an average outage of 6 months, these costs approach $700 million.

Accepting the recurring and permitting costs as given, this would raise the annual cost to approximately $3.8 billion. On a consistent basis this raises the monthly increase in residential bills to $0.46. While this is still a minor monthly expense for nearly all households, in aggregate, it represents a considerable sum.

It is misleading, we believe, to dismiss the importance of truly large sums spent by an industry or by society as minor by spreading them over a large population. For example, current debate over competing tax bills argue over differences of $100. billion over 10 years. While this difference amounts to less than $4.00 per capita per month, it is alleged to have critical impact on the future of the Nation’s economic health.

Organization EPRI

Subject Matter Code 9.01

Facility & firm-level costs/Econ. Practicability

Cost of compliance are overstated

In the remaining parts of Section 6, Synapse argues that the costs of compliance that have been dismissed as “minor” are nonetheless overstated and several instances are presented to support this contention.

Amortization period

EPA amortizes the capital costs of cooling towers over a 30-year life. Synapse argues that they have a longer life and that a longer amortization period should be used which would significantly reduce the annualized cost. Two points are noteworthy.

- People in the field commonly speak of 20-year towers or 30-year towers---not 40- or 50-year towers. The CTI literature has many discussions of tower rebuilds or even collapses for towers less than 30 years old. Economic analyses of the lifetime cost of cooling systems routinely include substantial refurbishment costs for wet towers at 10-year intervals. While it may be that the current generation of FRP towers will have longer life with less maintenance, there is no currently available data to confirm this.

- Even if one accepts a longer amortization period of, say, 50 years, the effect on annualized cost is small. From p. B1-15 of the EBA [6].

Annualized Cost = Capital Cost x {[r x (1 + r)^n]/[(1 + r)^n – 1]}

Using a discount rate of r = 7%, the amortization factor for n = 30 years is 0.0806 and for n = 50 years is 0.0725 or about 10% less. Since the capital cost represents only about 30% of the total cost (see Table 2 above), the reduction would less than 3% of an amount already asserted to be minor.

EPA Response

EPA notes that the final Phase II rule does not contain requirements to retrofit cooling towers.

EPA generally agrees with this comment and notes that it supports EPA’s analyses. EPA’s cost estimates included O&M costs to refurbish cooling towers at approximately 10-year intervals. This assumption was generally supported by industry comments.

Circulating water flow in closed cycle cooling

In a second point, Synapse correctly points out that EPA sized the cooling tower for retrofit to the same circulating water flow used in the pre-retrofit once through cooling system. This results in a tower that is larger and more expensive than if the entire cooling system were re-configured at a circulating water flow rate which had been optimized for a re-circulating cooling system with a wet cooling tower. Indeed, EPA did not re-optimize the cooling system nor did any of the individual plant studies with a very few exceptions. The reasons are these.

Although Synapse apparently fails to recognize it, re-configuring the cooling system to an optimized flow rate, requires major changes throughout the cooling system. Reducing the flow rate, while allowing the use of a smaller cheaper tower, requires that the condenser be modified in order to maintain tube side water velocities and the corresponding heat transfer performance. This normally requires changing the tube bundle from a one-pass to a two pass arrangement with an accompanying major re-arrangement of the inlet and outlet nozzles and piping connections. Doing this frequently requires significant structural work on the turbine building in order to gain access to the condenser, disconnecting, removal and reinstallation of major equipment and a significant extension of the outage time while the condenser is being modified.

Performing such a re-optimization of the design will reduce future operating costs but at the expense of substantially increased capital costs for the retrofit. As a result, it would only be considered on large, base-loaded plants with long remaining life and would be wholly inappropriate for smaller, older plants with lower capacity factors. In the case of the Salem Nuclear plant for which a retrofit cost analysis was conducted and published [5], the re-optimization was recommended and added $70 million to the initial cost of the retrofit.

EPA Response

The Agency agrees with the comment. See response to comment 316b.EFR.404.058 for the Agency's response to the referenced comment by Synapse.

Costs

Tower materials of construction

Synapse notes that EPA cost data shows that fiberglass reinforced plastic (FRP) are slightly less expensive than the redwood towers chosen by EPA as the basis for their cost estimates. Examination of the cost curves on Chart 2-1 of the Technical Development Document [4] demonstrates that this is a “distinction without a difference”. The difference in cost between the two fitted curves is approximately 2.3% and, by inspection, less than the fine structure scatter in the data points from which the curves were derived. Since the cost of the tower itself is typically 20 to 30% of the total retrofit cost (Appendix B in [3]), this difference, even if it were assumed to be consistent and robust, would lead to a total cost difference of only about 0.5%. This is equivalent to the difference in national capacity that Synapse dismissed as inconsequential in their discussion of system reliability. We suggest that you can’t have it both ways. If a difference is insignificant when it opposes an argument, then it should be insignificant when it supports an argument.

EPA Response

The Agency agrees with the comment and finds that it is an accurate description of the Agency’s data. See response to comment 316b.EFR.404.058 for the Agency's response to the referenced comment by Synapse.

Costs

EPA estimates vs. case studies

Synapse observes “the equations used by EPA to quantify the capital cost of a new cooling tower produce cost estimates that ‘in almost all cases’ exceeded the actual project costs.” They then suggest that EPA should either revise their correlating equations to “more accurately reflect the actual costs of building a tower” or “not apply a 20 percent ‘retrofit factor’ when quantifying the cost of adding a cooling tower at an existing facility.” Several points should be considered.

- An agreement between correlating equations derived from generalized cost algorithms and actual project costs of the level of accuracy displayed in Chart 2-7 [4] is remarkably good. No correlation of any type should be expected to capture project-to-project differences for activities as complex as power plant construction with great precision.

- The decision of whether to adjust the correlation to represent some lower bound, a best fit or a likely upper bound is a judgment to be made based on the objective of the correlation. EPA’s choice reflected a choice to display a likely upper range of costs that would be encountered in installing recirculating cooling systems at new facilities and was identified as such.

- However, to suggest that this choice of correlating equation for new plants should in some way replace the “retrofit factor” for installing similar systems at existing plants is to misunderstand the reason for the retrofit factor. It is not a “contingency” margin intended to allow for project-to-project variability, which, although expected, cannot be specifically identified and planned for at the outset. Rather, it is intended specifically to account for the obvious differences between conducting a project at a “greenfield” site and at an operating facility where existing structures, utilities and necessary activities interfere with access, erection, installation, delivery, storage and all other aspects of the project.

- Finally, whereas Synapse suggests that “the combined use of both the existing equations and the 20 percent retrofit factor leads to unreasonably high estimates for the capital costs of adding a new cooling tower at an existing facility”, quite the contrary is true. Comparisons with both data from site-specific case studies at 50 sites and with other correlations developed by skilled, experienced engineering firms show clearly that the EPA estimates for retrofits underpredict site-specific estimates in essentially every case and on the average by a factor of more than x2.

EPA Response

The Agency generally agrees with the commenter’s conclusions regarding the EPA new facility cooling tower cost curves. In addition, the Agency agrees with the commenter's statements about the purpose of a retrofit factor and the inappropriateness of Synapse’s suggestion to remove the factor from cooling tower estimates (see response to comment 316b.EFR.404.058).

The Agency notes that it is has not based the requirements of the final rule on cooling tower retrofits for existing facilities. See response to Comment ID 316bEFR.208.002.

Location of cooling tower

Synapse asserts that the assumption that 2,000 to 4,000 feet of piping for make-up and blowdown to the cooling tower is excessive and would “apply in only a limited number of cases”. While there are doubtless sites at which shorter lines world be adequate, the assumption does not appear to be unreasonable. One of the major issues in any retrofit is the siting of the cooling tower itself. At plants originally designed for once-through cooling the site could often be arranged quite compactly. There would have been no need to allow for unimpeded air flow to a tower or to protect switchgear from drift and plumes from a tower. Therefore, when a tower must be added, it is often necessary to locate it quite far from the main plant buildings for the above reasons. In a brief survey of utilities reported by EPRI [3], at 46 out of 56 plants surveyed said that extensive separation distance between the plant and turbine hall would be required in a retrofit. Additionally, 31 of the 56 plants indicated that they would have to acquire additional property in order to have a place to locate a tower. In specific studies at large nuclear stations, the siting of the tower over 2,000 feet from the turbine hall was required in three out of four cases. [5, 6, 8]

EPA Response

The Agency notes that the commenter’s conclusions regarding the distance of make-up and blowdown piping distances supports the Agency’s rebuttal of the same comment (see response to comment 316b.404.058).

Facility & firm-level costs/Econ. Practicability

Cost of foregone Sales

Synapse objects to the use of “annual average sales figures and annual average wholesale prices” to calculate the cost of foregone electricity sales during the connection outage. It suggests that this overstates the outage costs and that sales and price data from off-peak seasons should be used.

First, earlier in their comments Synapse urges that the outages be spread evenly over the 60-month period allowed for retrofit in order to minimize the effect on system reliability. Again, you can’t have it both ways.

Nonetheless, if it were to be assumed that all retrofits would be done during off-peak seasons, then the use of off-peak data would be appropriate. However, these distinctions are insignificant compared to the understatement of outage costs which results from the use of a one month outage duration when numerous detailed studies (See Table 1 above) indicate that outages of two to ten times this long will realistically be required.

EPA Response

EPA generally agrees with this comment. While EPA acknowledges that the difference in average prices and off-peak prices can be important, it is not clear that all installation downtimes could realistically be scheduled during off-peak times. This is especially the case in regions where more than one facility might experience an installation downtime during the same year. As a result, EPA developed an estimate that recognizes that some retrofits might occur during times that are not considered off-peak. This will especially be the case for downtimes that have longer durations. For example, for the NODA analysis, EPA revised its assumption of the downtime required to install cooling towers at nuclear facilities from one month to seven months. Clearly, a seven month downtime cannot be scheduled during off-peak times alone. EPA also revised its downtime assumptions for compliance technologies other than cooling towers. For the analysis supporting the final rule, such downtimes range from 2 to 11 weeks. Again, it would be difficult to assume that an 11-week downtime can be scheduled during off-peak times only in all cases. EPA therefore believes that its approach to estimating the cost of downtime is appropriate.

Fish Population Modeling

Benefits expected by EPA are not realistic. The benefits expected by EPA in their 316(b) rule making for Phase II existing facilities are not realistic for two reasons. First, empirical evidence is not available from any field study during the past three decades indicating I&E losses are the sole cause, or even the primary cause, of changes at the population, community or ecosystem levels. Second, theoretical considerations and real-world experience relating to direct mortality losses, such as I&E and fishery losses, clearly indicate that managing fish populations by managing direct mortality on early life stages is not as effective as managing fishing mortality. Thus, detecting effects at the population and higher levels (much less, economic benefits for humans) caused by reductions in I&E losses seem highly unlikely, even with extensive multi-year monitoring studies.

EPA Response

Assumptions about I&E survival

Author Name Doug Dixon & Kent Zammit

Organization EPRI

EPA's assumptions concerning entrainment survival and compensation are not appropriate in the context of EPA's regional—national cost-benefit analysis. Two assumptions made by EPA in its regional-national cost-benefit analysis are not supportable because we know, with 100% certainty, that they are both inconsistent with scientific evidence. EPA assumes 0% entrainment survival for all life stages of all fish species at all facilities under all operating and environmental conditions for all years. EPA also assumes zero compensatory offset of I&E losses for any population of any species at any facility under any operating or environmental conditions in any year. Furthermore, adoption of these two assumptions, without any characterization of uncertainty, results in providing decision-makers, all stakeholders and the public with inflated estimates of I&E losses and inflated estimates of benefits of reducing these losses. In the context of site-specific 316(b) determinations, these two assumptions may be reasonable. However, for EPA's regional-national analysis these two assumptions apply to ~550 facilities and hundreds of fish populations under all conditions, and in this context EPA's two assumptions are not scientifically supportable.

In estimating regional I&E losses and benefits of reducing these losses, the focus is on a population of 550 facilities and hundreds of fish populations under a broad range of conditions. EPA's analysis is designed to compare the national benefits and national costs of the proposed rule as applied to this population of facilities and associated fish species. As part of such an analysis, EPA is mandated by its own policies to characterize the uncertainties in both benefits and costs. EPA did not do this in either the proposed rule or the NODA. EPA's assumptions concerning entrainment survival and compensation are two of the most troubling examples.

Having calculated total regional impingement and entrainment losses by waterbody type and species or species group, EPA's next step should have been to consider uncertainty relating to entrainment survival and compensation. Use of fuzzy numbers is an effective and simple method for representing uncertainty in entrainment survival and compensation in EPA's benefits analysis. For both entrainment survival and compensation, the fuzzy-number approach provides for acknowledging EPA's reasons for adopting the simplistic and convenient assumptions of 0% entrainment survival and 0% compensatory offset. However, the approach also acknowledges that:

- EPA has an obligation to characterize uncertainty.

- With 100% certainty we know that some entrainment survival and some compensatory offset will occur among the hundreds of fish populations experiencing I&E losses at the 550 facilities covered by EPA's rule making for Phase II existing facilities.

- Ignoring these realities results in inflated estimates of I&E losses (especially entrainment losses) and benefits of reducing these losses.

Methods to Evaluate I&E

Author Name Doug Dixon & Kent Zammit

Organization EPRI

EPA has failed to adequately characterize uncertainties. EPA's regional and national benefit analysis is unavoidably based on many decisions, assumptions and information sources, and it involves many computational steps. In addition, the analysis requires extrapolation on a grand scale both ecologically and economically. Uncertainty, whether due to unavoidable variability or other sources of uncertainty, is associated with every decision, assumption, and information source incorporated in the analysis and with every additional computational step and level of extrapolation. Consequently, uncertainty is guaranteed to monotonically increase throughout EPA's analysis.

I propose seven inequalities involving I&E losses, complexity of EPA's analysis framework, benefits, costs, and uncertainty. These inequalities have several advantages over a detailed quantitative uncertainty analysis that attempts to cope with the many individual steps in EPA's analysis. They are simple and easy to understand, and they all make a macro-level claim. In addition, they are not likely to be controversial because in the context of EPA's analysis they can be easily verified or, in the case of the uncertainty inequalities, are likely to be accepted. Alone or in combination, these inequalities highlight important issues and make powerful statements in the simple manner that should appeal to decision-makers and non-technical people. Based on these inequalities, it is clear that EPA's cost-benefit analysis for reducing entrainment losses is less convincing than its case for reducing impingement losses. This is an important conclusion to be able to reach because it should condition the vigor with which EPA is justified in requiring costly technological requirements to reduce entrainment losses compared to impingement losses.

EPA Response

See Chapter A6 and Chapter A10 and the regional reports contained in the Phase II Regional Analysis Document (DCN #6-0003)for discussions of omissions, biases, and uncertainties in relation to EPA's analysis.

The commenters don't define the "seven inequalities" they refer to, so EPA is unable to respond to this part of the comment.

Ecological Evaluation Methodology

EPA Inflates Benefits of Reducing I&E Losses by Compounding Precautionary Assumptions. EPA has made precautionary assumptions at multiple steps in both its biological evaluation of I&E losses and its estimation of the benefits of reducing these losses. Several biological examples are highlighted elsewhere in my review, including 0% entrainment survival and 0% compensatory offset. Without these multiple precautionary assumptions, the economic benefits analysis would be very different. However, EPA has not acknowledged that it is relying on a precautionary approach, has not justified the need for this approach, and has not quantified the magnitude of the inflationary bias created by adopting this approach.

EPA Response

Please see Chapter A7 of the Regional Analysis Document (DCN #6-0003) and response to Comment 316bEFR.306.506 regarding EPA's conclusions about entrainment survival.

Please see EPA's response to Comment 316bEFR.025.015 regarding compensation.

Also, please see response to Comment 316bEFR.074.201, which refutes the claim that EPA has included "multiple conservatisms" in its analysis, and response to Comment 316bEFR.005.026 regarding the term "precautionary approach."

Methods to Evaluate I&E

Benefits Expected by EPA Are Not Realistic

To set the stage for addressing this concern, I cite EPA text from four EPA documents that characterize the environmental and economic benefits that EPA expects will follow from its rule for Phase II existing facilities.

NODA, Summary of Proposed Rule for Existing Facilities. Key phrases used by EPA to characterize its expectations for environmental benefits are: reducing harmful effects of entrainment and impingement; decrease in expected mortality or injury to aquatic organisms; protect ecosystems in proximity to CWIS; preserve aquatic organisms, including T&E species and the ecosystems they inhabit; and benefits may [emphasis added] also accrue at multiple ecological scales including population, community, or ecosystem levels.

Case Study Analysis, Chapter A9: Economic Benefit Categories and Valuation Methods. EPA postulates the following chain of 'potential' or 'expected' benefits [emphasis added]:

"Valuing the changes in environmental quality that arise from the §316(b) regulations for existing facilities is a principle desired outcome for the Agency's policy assessment framework. Changes in the CWIS design or operations reduce I&E rates. These changes in I&E can potentially yield significant ecosystem improvements in terms of the number of fish and other aquatic organisms that avoid premature mortality. This in turn is expected to increase the numbers of individuals present, increase local and regional fishery populations, and ultimately contribute to the enhanced environmental functioning of affected waterbodies (rivers, lakes, estuaries, and oceans) and associated ecosystems. The economic welfare of human populations is expected to increase as a consequence of the improvements in fisheries and associated aquatic ecosystem functioning" (p. A9-1).

Economics and Benefits Analysis (EBA), Chapter A2: Need for the Regulation. In support of these expectations, EPA comments as follows:

"Review of the available literature and section §316(b) demonstration studies has identified numerous documented cases of impacts associated with I&E and the effects of I&E on individual organisms and on populations of aquatic organisms. [EPA cites three cases in terms of direct E&I losses (numbers or weight).] The yearly loss of billions of individuals is not the only problem. Often, there are impacts to populations as well. [EPA cites one study involving population projections from a computer simulation model. EPA cites a second study (San Onofre Nuclear Generating Station (SAIC, 1993)) quantifying both losses at the individual level and decreases in the densities of two fish species within three kilometers of the facility relative to densities in control areas.]" (p. A2-8)

Case Study Analysis, Part F: Brayton Point, Chapter F1: Introduction. Although only I&E impacts are to be considered under Section 316(b), EPA indicates its awareness that fish and shellfish populations in the vicinity of a power plant may be exposed to major environmental stresses in addition to I&E

losses. In addition to surface water withdrawals by CWIS and discharge of heated water, EPA discusses habitat alteration (e.g., water pollution, dredging, coastal development, and other environmental stressors that have nearly eliminated eelgrass in Mount Hope Bay), overfishing, pollution (e.g., Narragansett Bay and Mount Hope Bay must assimilate high levels of industrially derived toxic pollutants, nutrients, and wastewater from the area's 33 wastewater treatment facilities), and weather patterns (e.g., warmer winter water temperatures resulting in loss of the usual winter-spring diatom bloom and perhaps contributing to increased predation rates by shrimp on larval winter flounder) (pp. F1-6 & F1-7).

Benefits expected by EPA are not realistic for the following two reasons:

(a) Lack of empirical evidence. Empirical evidence is not available from any field study during the past three decades indicating that I&E losses are the sole cause, or even the primary cause, of changes at the population, community or ecosystem levels. This lack of empirical evidence does not mean that I&E losses are not having any negative effects at the population and higher levels. It does mean, however, that for any existing facility some variation of the Brayton Point story (mentioned above) involving other major environmental changes has and is continuing to occur. In some situations, reductions in other stresses will complicate interpretation of monitoring data (e.g., substantial improvements in water quality and the ban on commercial and recreational fishing for striped bass in the Hudson River, NY). EPA's one and only example of effects of empirical evidence I&E losses at the population level (i.e., San Onofre Nuclear Generating Station, cited above) is misleading. While the observed decreased densities of two fish species within three kilometers of the facility relative to densities in control areas likely was due to operation of this facility, the fundamental problem was the negative effects of the thermal discharge on the kelp beds in the vicinity of the facility. The resulting reduction in suitable habitat for these two fish species was the primary cause of the observed spatial differences in densities of these two species.

(b) Theoretical considerations and real-world experience relating to direct mortality losses. I&E losses are examples of direct mortality losses, analogous to losses associated with fishing mortality.<FN 1> Examples abound illustrating that overfishing can be a primary cause of decline in fish populations, in some cases with observable effects at the community level and even the ecosystem level. Examples also abound that regulating fishing mortality is an effective tool for managing fish populations and that a reduction in fishing mortality can allow an overfished population to recover. However, theoretical considerations and real-world experience relating to direct mortality losses, such as I&E losses, clearly indicate that managing fish populations by managing direct mortality on early life stages is not as effective as managing fishing mortality. The logic underlying this claim is simple. First, by the time a fish enters the fishery, natural mortality rates are much lower compared to the high natural mortality rates of age-0. Typically, annual probability of survival for age-0 fish compared to fish in the fishery differ by a factor of 10^4 to 10^7.<FN 2> Second, the ratio of age-specific annual instantaneous fishing mortality rate to age-specific annual instantaneous total mortality rate is much higher than the ratio of age-0 annual instantaneous I&E mortality rate to age-0 total annual instantaneous mortality rate. Thus, reducing age-specific fishing mortality a given percentage, compared to reducing age-0 I&E mortality a given percentage, results in a greater percent reduction in total mortality and thus an increased probability of increasing abundance.

EPA's 'potential' and the 'expected' outcomes have a low probability of being realized. The combination of items (a) and (b) above strongly suggests that detecting effects at the population and higher levels (much less, economic benefits for humans) caused by reductions in I&E losses seems highly unlikely, even with extensive multi-year monitoring studies.

Footnotes

1 Assessing direct mortality losses versus habitat loss involve different ecological conceptual frameworks. Assessing consequences of direct mortality losses requires evaluating the cause-effect linkage from the individual level up to the population level, and possibly up to the community and ecosystem levels. Assessing the consequences of habitat loss requires evaluating the cause-effect linkages between direct impacts at the ecosystem level and subsequent effects down to the community, population, and individual levels. The first conceptual framework is bottom-up, while the second is top-down.

2 See EPA's Appendix 1: Life History Parameter Values Used to Evaluate I&E in the North Atlantic Region.

EPA Response

It is difficult to determine the relative importance of multiple environmental stressors on populations, communities, or ecosystems, and therefore the impact of any one stressor can be difficult to determine. However, contrary to the commenter's assertions, EPA notes that there are cases in which the evidence suggests that there are significant population-level impacts of I&E and thermal discharges. For example, fish populations in Mt. Hope Bay, Massachusetts have declined substantially, and extensive analysis by EPA Region 1 indicates that this results in large part because of the operation of the Brayton Point Station. Despite decreased fishing, many species have shown no sign of recovery. The San Onofre case is another example. Contrary to the commenter's assertion, facility reports demonstrate that decreased fish densities were not simply due to the negative effects of the thermal discharge on kelp beds.

Difficulties with detecting ecological effects at higher levels of biological organization, including power plant impacts, are discussed in detail in a recent book by Schmitt and Osenberg, "Detecting Ecological Impacts" (DCN #2-019A-R21). The authors note that a "before-after-impact-control" study design is the best way to detect such effects.

Assumptions about I&E survival

EPA's Assumptions Concerning Entrainment Survival and Compensation Are Not Acceptable in the Context of EPA's Regional—National Cost-Benefit Analysis<FN 3>

Two assumptions made by EPA in its regional-national cost-benefit analysis (CPA) are not supportable because we know, with 100% certainty, that they are both inconsistent with scientific evidence. EPA assumes 0% entrainment survival for all life stages of all fish species at all facilities under all operating and environmental conditions for all years. EPA also assumes zero compensatory offset of I&E losses for any population of any species at any facility under any operating or environmental conditions in any year. Furthermore, adoption of these two assumptions, without any characterization of uncertainty, results in providing decision-makers, all stakeholders and the public with inflated estimates of I&E losses and inflated estimates of benefits of reducing these losses.

For site-specific 316(b) determinations, it may not be reasonable to expect the permitting authority to accept an applicant's claim of entrainment survival greater than 0% for a life stage and species unless supported by credible results from a credible entrainment survival study at that facility, including an evaluation of variability and other uncertainties. Similarly, it is not reasonable to expect the permitting authority to accept an applicant's claim that I&E losses for a specific population have been offset by compensation unless long time series of credible monitoring data exist from both the facility and source waterbody, including annual estimates for spawning stock, recruitment, and other factors that may be affecting that population. Thus, for site-specific determinations and in the absence of monitoring data indicating otherwise, EPA's two assumptions may be justified. However, for EPA's regional-national analysis these two assumptions apply to ~550 facilities and hundreds of fish populations under all conditions. In this context EPA's two assumptions are not supportable or acceptable.

EPA justifies these two assumptions in chapters A6 and A7 (March 2003 version) of the Benefits Case Studies. EPA's justification for assuming 0% entrainment survival is based on its review of 36 entrainment survival studies suggesting that:<FN 4>

- Proportion alive in the samples is highly variable and unpredictable among species, among facilities, and among years at a given facility;

- Some species are more sensitive than others (e.g., herrings and bay anchovy compared to striped bass);

- Few studies could conclusively document and quantify the specific stressors causing the observed mortality, and no rigorous, validated method or model was put forward that would allow survival rates to be accurately predicted;

- Studies cover very few species, primarily in a single geographical region of the country, thus providing no basis for prediction to other species in other parts of the country;

- A finding for one facility cannot be considered to be valid for another facility, since many site-specific and facility-specific factors can affect the magnitude of mortality that occurs;

- Usefulness of all the findings is further compromised by the numerous factors that can influence the representativeness, accuracy, and precision of the survival estimates presented and that are often not rigorously accounted for in the studies (e.g., high control mortalities, omission of fragmented or unidentifiable organisms, and uncertainty regarding post-discharge survival).

In spite of the above reservations, EPA does concede that “it may be true that not all organisms are necessarily killed as they pass through the cooling systems of all facilities under all operating conditions” (p. A7-50). Given this admission, however, EPA’s final conclusion remains (Benefits Case Studies, Part A: Evaluation Methods, Chapter A7: Entrainment Survival, March 11, 2003, p. A7-51):

“Overall, the unreliability, variability and unpredictability of entrainment survival estimates evident from EPA’s review of the entrainment survival studies supports the use of the assumption of zero percent survival in the benefits assessment because there is no clear indication of any defensible estimate of survival substantially different from zero percent<FN 5> to use to calculate benefits for this rule.”

See Item II. A for additional comments on entrainment.

EPA’s justification for assuming no compensation is based on the low predictive capabilities of fish population models, the difficulty of identifying specific mechanisms of density dependent response, and the difficulty of estimating the magnitude and timing of compensation for specific populations in specific waterbodies. As indicated below, however, one does not need to use fish population models and does not need to know specific mechanisms or magnitude and timing of compensation for specific populations in specific waterbodies in the context of estimating regional and national E&I losses and benefits. See Item II.B for additional comments on compensation.

In estimating regional I&E losses and benefits of reducing these losses, the focus is on a population of 550 facilities and hundreds of fish populations under a broad range of conditions. EPA’s analysis is designed to compare the national benefits and national costs of the proposed rule and its various options as applied to this population of facilities and associated fish species. As a component of such an analysis, EPA is mandated by its own policies to characterize the uncertainties in both benefits and costs. EPA did not do this in either the proposed rule or the NODA. EPA’s assumptions concerning entrainment survival and compensation are two of the most troubling examples.

Clearly, in calculating impingement and entrainment losses by waterbody type and species or species group for its regional case studies, EPA assumed that absolutely no entrainment survival or compensation occurs. This is evident from the information in Table X-6 through Table X-9 for the North Atlantic Region (NAR). The values in these four tables, for age-1 equivalents, fishery yield foregone, and production foregone, represent EPA’s estimated impingement and entrainment losses for the 21 in-scope facilities in the NAR (19 estuarine, 2 ocean), calculated assuming 0% entrainment survival and 0% compensatory offset.

Having calculated total regional impingement and entrainment losses by waterbody type and species or species group, EPA's next step should have been to consider uncertainty relating to entrainment survival and compensation. Use of fuzzy numbers is an effective and simple method for representing uncertainty in entrainment survival and compensation in EPA's benefits analysis:

"A fuzzy number represents an uncertain number, i.e., a number whose value is not precisely known….Fuzzy numbers arise as a refinement of intervals which are rather crude encapsulations of uncertainty. For instance, intervals seem to imply that, although we cannot give a number's value exactly, we can give exact bounds on the number. Fuzzy numbers generalize intervals in a way that eases this paradox. A fuzzy number can be thought of as a nested stack of intervals at infinitely many levels of confidence about uncertainty. These levels of confidence range between 0 (corresponding to the most conservative, widest interval) and 1 (the narrowest interval, which assumes we're really [relatively] good at making measurements). By definition, all fuzzy numbers must reach [a confidence level of] one and must be convex (single humped). The [Y-axis] scale between 0 and 1 is said to measure the possibility [or confidence, consensus or belief] that a number is within the interval at a particular [possibility] level. This introduces the notion that possibilities can be graded…. Fuzzy numbers and their arithmetic provide a simple and workable methodology that is valid for handling non-statistical uncertainty in calculations….Triangular fuzzy numbers [are specified by] three scalars. For example, the fuzzy number [1, 2, 3] represents a number whose value is certainly somewhere between 1 and 3 and about which our best guess is 2. Trapezoidal fuzzy numbers…are specified by…four scalars….The fuzzy number [1, 2, 3, 4], for instance, represents a number whose value we optimistically think is somewhere between 2 and 3, but we know for certain is between 1 and 4" (EPRI, 1999, p. 5-21).<FN 6>

For entrainment survival, I propose that EPA define a trapezoidal fuzzy number of the form [0, p2, p3, p4], where p is % entrainment survival. Figure 1 illustrates the general shape for such a fuzzy number. I have not suggested specific values for p2, p3 or p4 in order to focus attention on the method. Note that p1 = 0 is EPA's assumption of 0% entrainment survival; it is the lower bound and correctly has a possibility of zero. Alternatively, it would be more realistic to define two such trapezoidal fuzzy numbers. Based on life history, taxonomy, and a critical evaluation of results of existing entrainment survival studies, each species or species group could be classified into one of two classes: relatively low risk and high risk of mortality if entrained. The two fuzzy numbers could differ in some or all of the values for p2, p3 and p4.

(See Graph on Page 10 of Appendix D)

Figure 1. General shape for a trapezoidal fuzzy number for % entrainment survival. To avoid controversy and focus attention on the method, values for p2, p3 or p4 are not proposed. Note that p1 = 0 is EPA's assumption of 0% entrainment survival; it is the lower bound and correctly has a possibility of zero.

For compensation, I propose that EPA define a trapezoidal fuzzy number in a similar manner, where in this case p is % compensatory offset of I&E losses. In this case, p1 = 0 is EPA's assumption of no compensatory offset, and again p1 is the lower bound and correctly has a possibility of zero. Again it would be more realistic to define two such fuzzy numbers as I propose for entrainment survival, although for different reasons. In the case of compensation, one fuzzy number would apply to entrainment losses and the second to impingement losses. More specifically, entrainment losses are more likely to be offset by compensation than impingement losses because a longer period of time remains during which compensatory mechanisms are most likely to be operative [see Item II.B.1, EPA's quote from Myers (2001)]. For both entrainment survival and compensation, the fuzzy number approach provides for acknowledging EPA's reasons for adopting the simplistic and convenient assumptions of 0% entrainment survival and 0% compensatory offset. However, the approach also acknowledges that:

EPA has an obligation to characterize uncertainty.

With 100% certainty we know that some entrainment survival and some compensatory offset will occur among the hundreds of fish populations experiencing I&E losses at the 550 facilities covered by EPA's rule making for Phase II existing facilities.

Ignoring these realities results in inflated estimates of I&E losses (especially entrainment losses) and benefits of reducing these losses.

If EPA adopts this suggestion, EPA needs to carefully consider selecting a credible process for determining values for these fuzzy numbers.

Footnotes

3 See Item II.A for additional comments on entrainment and Item II.B for additional comments on compensation.

4 These six concerns, while not unreasonable, set a very high standard for acceptance/rejection of results for field studies. EPA did not apply analogous standards to all its own analyses, EPA's extrapolations from case study facilities to the regional level being a prime example.

5 EPA's standard for substantially different from zero percent [sic; substantially greater than zero] is not indicated.

6 EPRI. 1999. RAMAS Risk Calc: Risk Assessment with Uncertain Numbers. EPRI, Palo Alto, CA. CM-113048.

EPA Response

To calculate the environmental benefits associated with the reduction of entrainment due to the implementation of technology to comply with this rule, EPA used the assumption that all organisms passing through a facility's cooling water system would experience 100 percent mortality. EPA believes that this assumption is supportable.

The benefits assessment used a regional approach which relied on data from several facilities within each region. A lack of facility-specific data relating to entrainment survival was the impetus of this assumption. Given the lack of facility-specific entrainment survival data, EPA conducted a detailed review of 37 entrainment survival studies conducted at 22 individual power producing facilities in order to determine if entrainment survival was generally predictable and if the various results could be synthesized in a manner to apply the general results to the facilities used in the regional benefit estimates. The review of the studies showed that while a few individuals may be alive in samples collected near the discharge of the facility and may survive entrainment, the proportion surviving is highly variable and unpredictable. These studies did not support predictions of entrainment survival for the range of species, life stages, seasons, regions and facilities involved in EPA's benefits estimates. In addition, the methods employed in the studies had the potential for high bias such that the survival estimates reported by the studies were most likely overestimates. If the potential for high bias was eliminated from these studies, then the proportion of organisms shown to survive entrainment would most likely be indistinguishable from zero. Also, in the studies reviewed the majority of organisms entrained appear to experience little to no survival. The conclusion of this review was that the reported study results do not provide support for the selection of an estimate of entrainment survival substantially different from zero percent to be used as a defensible and nonarbitrary assumption to calculate benefits for this rule.

EPA agrees with the commenters that this conservative assumption does simplify the national benefits assessment. EPA agrees that presenting sensitivity analysis and discussing uncertainty is generally important, however, due to the high variability and unpredictability in the entrainment survival estimates from the studies the Agency reviewed, EPA saw little utility in performing a sensitivity analysis using unreliable, and thus arbitrary, numbers as the commenter suggests with such a large range of possible entrainment survival values (essentially from 0 to 100 as reported by the studies).

Chapter A7: Entrainment Survival from the Case Study Analysis for the Section 316(b) Phase II Existing Facilities Rule provides more detailed information on the scientific basis for this position. For information regarding compensation assumptions in the benefits analysis, please see the response to comment 316bEFR.025.015.

Methods to Evaluate I&E

EPA Has Failed To Adequately Characterize Uncertainties

In its regional—national cost-benefit analysis, EPA has failed to adequately characterize uncertainties. EPA's benefit analysis is unavoidably based on many decisions, assumptions and information sources, and it involves many computational steps and levels of extrapolation. This situation is not qualitatively unique to 316(b) rule making for Phase II existing facilities. However, this situation perhaps is quantitatively unique in the extent to which the analysis requires extrapolating from a small sample to a more heterogeneous large population. The small sample consists of EPA's nine case studies with facilities located on nine different waterbodies in different regions of the United States and the fish populations experiencing I&E losses at these facilities. In addition, the quantity and quality of I&E monitoring data among the facilities in the nine case studies is variable. The more heterogeneous large population consists of ~540 additional facilities located on many different waterbodies throughout the United States and the hundreds of fish populations experiencing I&E losses at these facilities. The only site-specific datum used in estimating I&E losses for the additional 540 facilities, other than region and waterbody type, is the design intake flow or capacity (MWE). Thus, ecologically, EPA's benefit analysis requires extrapolation on a grand scale.<FN 7>

Economically, EPA's benefits analysis also involves extrapolation and assumptions on a grand scale. The analysis requires estimating the dollar value of regional E&I losses and of reducing these losses. The methods used to convert 'fish currencies' (number and pounds) to dollars range from direct methods (e.g., market value per pound of fish for commercial fisheries) to indirect methods relying on estimates of human behavior, benefits transfer, and stated preferences for recreational fisheries and nonuse benefits.

Uncertainty, whether due to unavoidable variability or other sources of uncertainty, is associated with every decision, assumption, and information source incorporated in the analysis and with every additional computational step and level of extrapolation. Consequently, uncertainty is guaranteed to monotonically increase throughout EPA's analysis (Figure 2).

In spite of this reality, EPA has avoided quantitatively or even qualitatively characterizing the uncertainty in its estimates. EPA is providing decision-makers and all stakeholders (including the public) with a package of single-number estimates of benefits and costs at the regional and national levels for various regulatory options. Is it acceptable for EPA to not characterize the uncertainty associated with estimates produced by this complex multi-tiered edifice? Even for EPA the answer to this question has to be "No," because EPA's most recent policies clearly require that the agency characterize uncertainty associated with analyses designed to support agency decisions.

(See Graph on Page 12 of Appendix D)

Figure 2. Framework for qualitatively visualizing proposed inequalities involving EPA's cost-benefit analysis. The left Y axis applies to the inner triangle and represents the cumulative increase in the

complexity of EPA's analysis framework. Complexity includes number of computational and extrapolation steps and number of decisions, assumptions and information sources used in the analysis. The right Y axis applies to the outer triangle and represents the cumulative increase in uncertainty. The bottom point of both triangles represents the starting point for the analysis, i.e., the raw/original I&E monitoring data for EPA's nine case studies.

Note that, because of compounding effects, the cumulative increase in uncertainty accumulates faster than the cumulative increase in complexity.

I propose the following inequalities involving I&E losses, complexity of EPA's analysis framework, benefits, costs, and uncertainty. Figure 2 is designed to help the reader better visualize and understand these inequalities.

Definitions:
U = uncertainty
N = complexity of EPA' analysis <FN 8>
B = benefits ($)
C = costs ($)
E = entrainment losses (number, lbs.)
I = impingement losses (number, lbs.)
RE = reduced entrainment losses (number, lbs.)
RI = reduced impingement losses (number, lbs.)
BRE = benefits of reducing entrainment losses ($)
BRI = benefits of reducing impingement losses ($)

E&I losses (as age-1 equivalents):
E > I, i.e., estimated losses due to entrainment are greater than estimated losses due to impingement.
Complexity of EPA's analysis framework:
NE > NI, i.e., greater complexity for entrainment than impingement.

Benefits and costs:
BRE > BRI, i.e., estimated benefits of reducing entrainment are greater than estimated benefits of reducing impingement.
CRE > CRI, i.e., estimated costs of reducing entrainment are greater than estimated costs of reducing impingement.
Uncertainty:
UE > UI, i.e., uncertainty in estimated entrainment losses is greater than uncertainty in estimated impingement losses.
UB,RE > UB,RI, i.e., uncertainty in estimated benefits of reducing entrainment losses are greater than uncertainty in estimated benefits of reducing impingement losses.
UB > UC, i.e., uncertainty in estimated benefits is greater than uncertainty in estimated costs.

Many methods are available for characterizing uncertainty, as summarized in a recent EPRI report (EPRI 1999).<FN 9> Although EPA's analysis could be classified as between a "best-estimate analysis" and a "worst-case analysis," or labeled as a "precautionary-approach analysis," EPA has not characterized the uncertainty associated with its single number estimates of benefits and costs. Interval analysis, fuzzy arithmetic, what-if analysis, and sensitivity analysis are methods that could be considered (EPRI 1999). However, it is not obvious to me that this would be particularly constructive, given the complexities and multiple sources of uncertainties most of which reflect ignorance rather than variability.<FN 10>

The above inequalities have several advantages over a detailed quantitative uncertainty analysis that attempts to cope with the many individual steps in EPA's analysis. These inequalities are simple and easy to understand, and they all make a macro-level claim. In addition, they are not likely to be controversial because in the context of EPA's analysis they can be easily verified or, in the case of the three uncertainty inequalities, are likely to be accepted.

Alone or in combination, these inequalities highlight important issues and make powerful statements in the simple manner that should appeal to decision-makers and non-technical people. The following sequence is one statement that uses all seven inequalities:

E > I, and thus BRE > BRI.
However, UE > UI (because NE > NI), and CRE > CRI.
Furthermore, UB,RE > UB,RI, and UB > UC.

In words, estimated losses (as age-1 equivalents) due to entrainment are greater than estimated losses due to impingement, and thus estimated benefits of reducing entrainment are greater than estimated benefits of reducing impingement. However, uncertainty in estimated entrainment losses is greater than uncertainty in estimated impingement losses (because more steps for E than I), and estimated costs of reducing entrainment are greater than estimated costs of reducing impingement. Furthermore, uncertainty in estimated benefits of reducing entrainment losses is greater than uncertainty in estimated benefits of reducing impingement losses, and uncertainty in estimated benefits is greater than uncertainty in estimated costs.

Bottom line: Based on the above reasoning, EPA's cost-benefit analysis for reducing entrainment losses is less convincing than its case for reducing impingement losses. This is an important conclusion to be able to reach because it should condition the vigor with which EPA is justified in requiring costly technological requirements to reduce entrainment losses compared to impingement losses.

(See Appendix D page 13 for variables)

Footnotes

7 See Items II.G and III.E for concerns related to EPA's extrapolation method and reliance on precautionary assumptions.

8 Complexity represents number and type of decisions, assumptions, information sources, computational steps, and extrapolation levels.

9 EPRI. 1999. RAMAS Risk Calc: Risk Assessment with Uncertain Numbers; EPRI, Palo Alto, CA. CM-113048.

10 EPRI (1999) describes two basic kinds of uncertainty. Ignorance includes measurement error, indecision about the mathematical form of an equation or model, and confusion about the appropriate level of abstraction in formulating the problem. Ignorance is a subjective kind of uncertainty but has the potential of being reduced. Variability includes temporal stochasticity, spatial variation, and heterogeneity among individuals. Variability is objective (i.e., it exists whether or not humans observe it); it cannot be reduced, although it can be better characterized (p. 2-11).

EPA Response

Ecological Evaluation Methodology

EPA Inflates Benefits of Reducing I&E Losses by Compounding Precautionary Assumptions

EPA has made precautionary assumptions at multiple steps in both its biological evaluation of I&E losses and its estimation of the benefits of reducing these losses. Several biological examples are highlighted elsewhere in my review, including 0% entrainment survival and 0% compensatory offset. Without these multiple precautionary assumptions, the economic benefits analysis would be very different. However, EPA has not acknowledged that it is relying on a precautionary approach, justified the need for this approach, or quantified the magnitude of the inflationary bias created by adopting this approach.

How much difference can compounding of precautionary decisions and assumptions make? A lot, just as it does with compounded taxes and fees. As an example, for a sequence of 10 decision points with the same inflationary bias associated with each decision, the final inflation factor is 260% for a 10% bias (= 1.10^10) and 620% for a 20% bias (= 1.20^10). Others have brought this problem to EPA's attention.<FN 11>

Additional Comments Relating to Entrainment

EPA retained inflated entrainment losses in calculating regional losses. EPA inflated entrainment losses based on greater than 0% entrainment survival from the case study facilities in order to extrapolate to other facilities in the region with no entrainment survival studies. I accept this as a reasonable approach. However, it appears that EPA retained these inflated entrainment losses when summing over all facilities in the region to estimate regional losses. EPA neither mentions nor quantifies this bias.

EPA Response

Please see Chapter A7 of the Phase II Regional Study Report (DCN #6-0003) for a discussion of EPA's position on entrainment survival and response to Comment 316bEFR.306.506..

Option 3--Site-specific determination

Credible entrainment survival studies. For site-specific determinations, EPA notes that the proposed rule language does not preclude the use of estimates of entrainment survival when presenting a fair estimation of the monetary benefits achieved through the installation of BTA, instead of assuming 0% survival. This statement implies that EPA is aware that credible entrainment survival studies are possible. Thus, if EPA is going to allow results from such studies to be included in permit applications, they are obligated to set minimum data quality objectives and standards.

EPA Response

For information about the consideration of entrainment survival in determining compliance, please refer to sections VIII and IX in the preamble to the final rule. In the final rule, EPA does not intend to set minimum data quality standards for these studies and expects the Director to perform such reviews on a case-by-case basis.

Fish Population Modeling

Additional Comments Relating to Compensation

EPA's justification for not representing compensation in its regional—benefits analysis is not adequate (Case Study Analysis, Chapter A6). I start by extracting material from four sections of Chapter A6 to characterize EPA's mindset regarding compensation and fish population modeling. I have italicized selected text in each section and then added my comments on the italicized text at the end of each section. I have indicated by "(Ref.)" when EPA supports its text with references.

Section A6-1. Background. "Compensation refers to the theoretical ability of a population to offset (compensate for) increased mortality (Ref). While considered likely to operate in most biological populations, compensation and other density dependent processes are difficult to observe and measure. When modeling population dynamics, this makes it difficult to identify underlying mechanisms of density dependent response and to estimate the magnitude and direction of population changes…."

My comment: Compensation is operative in the long term in every population or the population will become extinct. In addition, it is not necessary to model population dynamics, identify underlying mechanisms, or estimate the magnitude of population changes in order to represent both the consequences and uncertainty of compensation in EPA's regional—national benefits analysis. See Item I.B above for possible approach.

EPA Response

Fish Population Modeling

Section A6-3. Use of Stock-Recruitment Models to Evaluate CWIS Impacts. "In a recent paper prepared for the Utility Water Act Group for the §316(b) rulemaking, Myers (2001) noted that the life stage at which power plant mortality occurs in relation to the timing of any compensatory response will strongly determine the degree of impact. If compensation operates in a population and power plant mortality occurs before compensation, the impact on equilibrium spawner biomass and fishery yield may be small. However, if power plant mortality occurs after compensation on juveniles, there can be a more rapid decrease in equilibrium spawner biomass with plant mortality."

My comment: I agree with Myers' point concerning the importance of the timing of any compensatory response relative to the life stage at which entrainment or impingement losses occur. This is why in Item I.B, I recommend specifying two fuzzy numbers for % compensatory offset, one for entrainment losses and the second for impingement losses.

EPA Response

Fish Population Modeling

Section A6-4. Uncertainty in Stock-Recruitment Models. "In practice the use of stock recruitment curves to set fish levels, or to determine how much I&E a population can withstand, is complicated by the many physical and biological factors that can cause the stock-recruitment relations and potential compensatory reserve to vary over time (Ref.)….Because the relationship between spawners and recruits may itself vary, applying fixed rules for achieving constant fisheries yields or taking of young by CWIS can have very different effects, depending on whether population size is high or low."

My comment: Applying fixed rules for taking of young by CWIS at a specific facility is not the issue in EPA's regional—national benefits analysis. Again, what is at issue in EPA's analysis is representing the consequences and uncertainty of compensation. See Items I.B and I.C.

EPA Response

Fish Population Modeling

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Section A6-5. Precautionary Approach. “EPA is concerned that even in fish populations where compensatory processes are thought to operate, it has proven extremely difficult to estimate the magnitude of compensation and the form of compensatory response (Ref.). This is a particular concern for commercially exploited marine species….Given the many [commercially exploited marine] fish stocks are at risk, EPA has adopted a “precautionary approach” in evaluating CWIS impacts because of the many uncertainties associated with modeling compensation and stock-recruitment relationships….In the context of the §316(b) rulemaking, EPA notes that most CWIS cause substantial losses of aquatic organisms, and EPA believes that it is not appropriate to assume that these impacts are unimportant unless population-level consequences can be demonstrated….EPA believes that the many uncertainties associated with modeling stock recruitment relationships and potential compensation justify this approach, in keeping with a precautionary approach to environmental decision-making.”

My comments: First, that many commercially exploited marine fish stocks are at risk is a weak justification for adopting a precautionary approach for all fish species in all waterbody types, especially forage species. Second, population-level consequences primarily because of overfishing have been demonstrated numerous times. Population-level consequences primarily because of I&E losses have never been demonstrated. This difference suggests that a lower level of risk applies to consequences of I&E losses compared to fishing and again calls into question EPA’s justification for adopting a precautionary approach. See Item 1.D.

Fish Population Modeling

Author Name Doug Dixon & Kent Zammit

Organization EPRI

EPA's regional—national benefits analysis ignores two realities concerning compensation. We know with 100% certainty that the assumption of no density-dependent compensation in response to I&E losses for any population of any fish species at any of the 550 Phase II existing facilities at any time is incorrect. It is a simplifying assumption and eliminates the need to further consider a difficult, but critically important, reality. Based on both empirical evidence and theory, we know that compensation in fish populations usually occurs during early life stages. More specifically, entrainment losses are more likely to be offset by compensation than impingement losses. See Item 1.B.

EPA Response

General Comments on Valuation Approaches

Need for Regional Analyses for Entrainment Alone and Impingement Alone

For each of its eight regions, EPA should provide benefits analyses for entrainment alone and impingement alone, before combining results. Results from analyses structured in this manner will better allow all parties to compare the cost effectiveness of reducing impingement losses vs. reducing entrainment losses.

EPA Response

EPA disagrees that regional analyses should be conducted for entrainment and impingement alone. Some of the EPA analyses rely on non-linear valuation functions (e.g., recreational fishing benefits). Thus, estimating benefits for impingement and entrainment alone first and then combining these results would produce different benefit estimates compared to the total entrainment and impingement reduction approach used by the Agency in the final 316b regulation.

RFC: Performance/effectiveness of restoration

Need for Peer Review of Ongoing Restoration Projects

The practice of having a restoration plan undergo an independent peer review prior to the plan's submission to the Director is appropriate (Section IX.B.3). I would suggest, in addition, that independent peer reviews be required at 5-year intervals after the start of any restoration project. Without such periodic reviews it is unlikely that the successes and failures of restoration projects as a mitigation measure can be evaluated in a credible manner. Costs for such reviews should be included in EPA's cost-benefit analysis.

EPA Response

The final rule gives the permitting authority the flexibility to determine the need for an independent peer review. EPA encourages the use of independent peer review to bring current expertise to bear on consideration of a restoration measure.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

For a discussion of EPA's costing of restoration measures, see the preamble to the final rule.

Regional Benefits Approach

Uncertainty for Extrapolations in the Interior Region

EPA identified eight study regions based on similarities in the physical characteristics of the affected water bodies, aquatic species present in the area, and characteristics of commercial and recreational fishing activities in the area (Section X.B.2). The Interior region contains 372 of the 548 facilities. EPA needs to characterize the high heterogeneity that unavoidably must exist among these 372 facilities and evaluate the extent to which this heterogeneity may compromise credibility of extrapolations.

EPA Response

In an attempt to expand its coverage of this region, EPA's final analysis contains information on facilities in the Inland Region in addition to those evaluated for proposal. In addition, the recreational benefits analysis is now specific to the Inland Region. See the Regional Analysis Document for further information (DCN # 6-0003).

Methods to Evaluate I&E

Sensitivity Analysis of Representative Life History Parameters Is Needed

EPA acknowledges that life history data are very limited for many of the species that are impinged and entrained (Section X.B.3.a). To overcome this limitation, EPA uses the available life history data for closely related species to construct tables of representative life history parameter values for different species groups for each region.<FN 12> EPA's approach seems reasonable.

However, uncertainties associated with this approach should be addressed. Regional estimates of impingement and entrainment losses and benefits will be sensitive to the representative life history parameter values selected, especially to the life-stage-specific values for eggs, larvae and juveniles. Consequently, a sensitivity analysis for this step in the computational chain of estimating regional losses and economic benefits is needed.

Footnotes

12 As an example, see Life History Parameter Values Used to Evaluate I&E in the North Atlantic Region. Appendix 1 to §316(b) Regional Case Studies, Part B: North Atlantic.

EPA Response

Regional Benefits Approach

Precautionary Bias in Extrapolation Method for I&E Losses Should Be Evaluated

EPA's equation for I&E extrapolation within each region is [Section X.B.3.b.(3)]:

(Total losses @ case study facility/Flow @ case study facility) * Total flow in region = Total regional losses.

Implicit in this simple model is the assumption that, on average, the ratio of total I&E losses to intake flow at a case study facility (or facilities for some regions) is similar to that for all the other facilities in the region where I&E losses are estimated using the above equation. For the North Atlantic Region, Brayton Point is the only estuarine case study facility, results from which are extrapolated to 18 other estuarine facilities using this equation. Thus, the opportunity for bias in either direction is evident.

However, EPA's use of this simple model is likely precautionary because the case study facilities are all examples of sites where impingement and entrainment loss rates (number lost/MGD intake flow) were relatively large. Because these large losses were of regulatory concern, these facilities were required to monitor the losses, which in turn created the data sets that resulted in EPA selecting these facilities for case studies. The likely bias resulting from this assumption would result in an overestimate of regional losses and benefits. EPA should seek appropriate data sets to evaluate the extent of this likely bias.<FN 13>

Footnotes

13 Appropriate data sets are available from select facilities on the Hudson River, Chesapeake Bay, and perhaps other regions. The Atlantic States Marine Fisheries Commission's Power Plant Panel is evaluating this same potential concern in its study of cumulative impacts of power plant impingement and entrainment: a case study for Atlantic menhaden.

EPA Response

Please see response to Comment 316bEFR.041.041 on EPA's regional extrapolation procedures. EPA has discussed numerous types of uncertainty associated with its analysis, including the possible problems associated with regional extrapolations. Please see Chapter A6, Chapter A10, and the regional reports contained in the Regional Analysis Document (DCN# 6-0003) for a discussion of uncertainty in the context of EPA's analysis. Please see response to Comment 316bEFR.005.026 regarding the term "precautionary approach."

EPA's Preferred Option Would Reduce I&E Losses Less Than 30% in NAR

For the North Atlantic Region (NAR), the values in Table X-10 indicate that EPA's preferred option would reduce I&E losses less than 30% (Section X.C.4). I was expecting EPA's preferred option to reduce I&E losses 50 % or more. Using the values for flatfish, however, the decrease is less than 30% (3.64%/12.5% = 91,995 fish/315,703 fish = 29.1%). The values in Table X-40 illustrate a similar pattern. Presumably, the explanation lies in the definition of the baseline. EPA needs to clarify this issue. EPA's proposed rule is indeed an expensive solution, especially for reducing entrainment, if it removes only 30% of an impact that EPA views as being so environmentally damaging.

Benefit Estimation Methodology

Fish Currencies, Monopoly Money, and Justification for EPA's Rule

EPA uses three models to characterize I&E losses at case studies facilities (Chapter A5). I&E losses and reductions in these losses for EPA's preferred alternative are expressed in three fish currencies: age-1 equivalents, foregone fishery yield, and forage fish production foregone. These three fish currencies facilitate comparison and ranking of alternative regulatory options and decisions—on a relative scale. The conversion of any of these fish currencies to monetary benefits in dollars unfortunately camouflages the reality that one is now dealing with monopoly money, especially when ~99% of the total economic benefit is due to nonuser benefits. Although among alternative regulatory options the relative dollar rankings for benefits may still be reasonably valid, it is the absolute dollar value for these benefits that are compared to costs in the final cost-benefit analysis used by EPA to justify their rule for Phase II existing facilities.

EPA Response

EPA agrees with the commenter that the metrics used to evaluate I&E (age 1 equivalents, foregone fishery yield, and production foregone) "facilitate comparison and ranking of alternative regulatory options and decisions on a relative scale." The Agency, however, points out that the cost-benefit analysis (i.e., comparison of the absolute value of costs and benefits) yield results that cannot be used, in isolation, for decision-making, because the calculations of benefits are often incomplete.

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to uncertainty in monetizing national benefits associated with non-use values for the final rule. Thus, the Agency was not able monetize benefits for 98.2% of the age 1 equivalent losses of all commercial, recreational, and forage species (with the exception of some indirect benefits of forage on harvestable species production). (The percentages by region are as follows: California 95.2%, North Atlantic 99.0%, Mid Atlantic 98.4%, South Atlantic 98.1%, Gulf of Mexico 95.8%, Great Lakes 99.8%, and Inland 99.9%.) This means that the benefit analysis represents the benefits associated with less than 2% of the total age 1 equivalents lost due to impingement and entrainment by cooling water intake structures (CWISs)." Thus, the Agency considered all of the relevant data in the § 316(b) rulemaking process, not just absolute value of costs and benefits.

The Agency has explored several approaches that indicate the potential significance of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapter A12,Non-Use Meta-Analysis Methodology, and Chapters C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment

#316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. See also DCN # 6-2500 for the peer review report. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

For EPA's response to comments on the use of benefit cost test in the context of the 316(b) regulation please see the response to comment #316bEFR.005.020.

Subject Matter Code 10.03.05

Brayton Point

Author Name Doug Dixon & Kent Zammit

Organization EPRI

Logic for Omitting the Last Decade of I&E Data at Brayton Point Is Faulty.

Pisces argues (Section 1.2) that EPA was reasonable in omitting the most recent decade of I&E data at Brayton Point because fish populations were severely depressed, numbers impinged steadily declined, and thus mean I&E values will be underestimates. Such an omission might be defensible if I&E losses at Brayton Point were considered one of the primary causes of the decline in fish and shellfish populations. However, they are not.

Why have the fish and shellfish populations in Mount Hope Bay declined over the past decade? EPA (Case Study Analysis, Part F: Brayton Point, Chapter F1: Introduction) indicates its awareness that fish and shellfish populations in the vicinity of Brayton Point are exposed to major environmental stresses in addition to I&E losses. In addition to surface water withdrawals by CWIS and discharge of heated water, EPA discusses habitat alteration (e.g., water pollution, dredging, coastal development, and other environmental stressors that have nearly eliminated eelgrass in Mount Hope Bay), overfishing, pollution (e.g., Narragansett Bay and Mount Hope Bay must assimilate high levels of industrially derived toxic pollutants, nutrients, and wastewater from the area's 33 wastewater treatment facilities), and weather patterns (e.g., warmer winter water temperatures resulting in loss of the usual winter-spring diatom bloom and perhaps contributing to increased predation rates by shrimp on larval winter flounder).

Although I&E losses at Brayton Point cannot be ruled out as a contributing cause, the clear regional trend in warming water temperature and decline in many fish and shellfish populations suggests other primary causes for the decline. Thus, a less protective and more realistic analysis would have been to include all the years for which data were available, rather than disregarding the last decade's I&E losses. Omitting the past decade of data inflates I&E losses at this case study facility, and this inflationary effect is magnified in EPA's process of extrapolating from Brayton Point to the other 18 estuarine facilities in the North Atlantic Region. See Item II.G.

EPA Response

EPA concurs with the analyses and conclusions of EPA Region 1 that there have been significant declines in finfish populations in Mt. Hope Bay as a result of the operation of BPS.

EPA disagrees with the commenters assertion that the omission of the past decade of data inflates EPA's estimate of average annual I&E at BPS. EPA only evaluated 1974-1983 data for this facility for several important reasons: (1) year-round entrainment sampling of all species began in 1972 and ended in 1984; BPS began entrainment monitoring again in 1993, but only for winter flounder, (2) 1984 and 1985 were not considered because of the use of "piggyback" cooling during some of this time, (3) Unit 4 did not go into service until 1974, so data from 1972 and 1973 were not included, and (4) this time period is prior to a dramatic decline in fish populations beginning in 1985. EPA believes all of these reasons justify its selection of data to evaluate for the purposes of estimating the total average annual I&E at BPS.

EPA methods: age 1 equiv, yield, prod foregone

Correction of EPA's Assumption Concerning Age at Impingement Is One-sided

EPA assumed at proposal that all fish killed by impingement were age 1 at time of death. Pisces (Sections 1.5.1 and 1.6) is correct in principle in pointing out that this assumption results in an underestimate of age-1 equivalents because impingement losses include older fish for some species. However, Pisces' one-sided approach to correcting EPA's assumption that all fish killed by impingement were age 1 at time of death. The majority of fish killed by impingement at most facilities are age 0. Assuming that all age 0 impingement losses were actually killed at age 1 likely results in a much greater overestimate of impingement losses, and of monetized benefits of reducing these losses, than the underestimate caused by not considering impingement losses of older fish.

EPA Response

Please see EPA's response to 316bEFR.029.105 concerning the age of impinged fish.

EPA methods: age 1 equiv, yield, prod foregone

Sensitivity Analysis of Effect of Survival Rates on Age-1 Equivalents

Pisces raises a valid point in Section 1.6.2, i.e., estimates of age-1 equivalent losses are sensitive to the survival rate estimates used to calculate age-1 equivalents. However, they illustrate this point in a biased manner. First, they select two examples where published estimates of age-specific survival were available that were higher than those used by EPA. For striped bass at Salem the EPA values on average are 48% of the NOAA values (Table 10), and for cunner at Seabrook the EPA values on average are 72% of the values quoted by Horst (Table 11). Pisces makes no effort to evaluate why these differences might exist, but rather assumes that the non EPA values are the standard. Second, Pisces then proceeds in Table 12 to present the results of a unidirectional sensitivity analysis for striped bass, weakfish, and croaker. Column 1 is labeled “Variation in estimate” and the table caption states “The effect of changing estimates of survival….” Column 1 should be labeled “Increase in estimate” and the table caption should state “The effect of increasing estimates of survival….”

EPA Response

Please see Chapter A6 of Part A of the Regional Analysis Document (DCN# 6-0003) for a discussion of uncertainty in the context of EPA’s analysis.

EPA methods: age 1 equiv, yield, prod foregone

Two Overly Precautionary Suggestions

Two examples of Pisces' conservation precautionary approach are as follows:

- In the final paragraph of section 1.6.2, Pisces proposes that "…it would seem reasonable to err on the side of caution [emphasis added] and increase all the estimates [of I&E losses] by 25%."

- Pisces' thesis is that EPA's method of calculating the worth of commercial species impinged and entrained "only considers the immediate loss and places a value on only a proportion of the number killed. This is felt to be an extremely significant omission, liable to underestimate the value of fish killed severely" [i.e., underestimate severely, not killed severely] (Section 2). Pisces then proposes a model and includes examples of how to estimate future losses into the next generation.

Both of Pisces' suggestions are examples of a precautionary approach. See Item I.D above.

EPA Response

Please see response to Comment 316bEFR.330.028 regarding the first point made by the commenter. In regard to reproductive value, please see EPA's response to Comment 316bEFR.206.065.

Extrapolation Methods

Examples of Implications of Extrapolations from Case Studies to Other Facilities

Pisces' bottom line, effectively illustrated by the bar graphs in Figure 6 through Figure 9, is: "As can be seen from these examples, extrapolating the catch of fish from one station is prone to many errors" (Section 1.8, last paragraph). Pisces chose to highlight an example that would significantly underestimate the number and value of the fish killed, i.e., extrapolating from Salem in the Delaware Estuary to power plants in the Hudson Estuary. A more balanced presentation by Pisces would have acknowledged that extrapolation can also result in significantly overestimating the number and value of the fish killed. See Item II.G above.

EPA Response

EPA agrees with the commenter that extrapolations can under- or overestimate true values. However, EPA also notes that such under- or overestimates may not be significantly different from the true estimate.

RFC: Proposed use of restoration measures

Two Conceptual Frameworks for Considering Habitat Replacement As a Mitigation Measure

Pisces' lengthy evaluation of habitat replacement (more than 20% of its report) is informative and raises issues of legitimate concern that require further discussion and evaluation. Pisces lists methods of aquatic habitat creation and restoration/modification, and labels each method as a "habitat measure," a "species-related" measure, or both. Only six of the 19 methods are species related measures, while 14 are habitat measures, including wetland creation and restoration. I&E losses constitute a direct source of mortality, analogous to fishing mortality. Thus, I&E losses represent a species-related impact, and the most direct and equivalent approach for mitigating a species-related impact is with species-related measures, not habitat measures. It can be argued that indirectly such losses constitute a potential impact on a fish community and perhaps the habitat (and the same applies to commercial & recreational fisheries). However, the primary focus of 316(b) assessments in the past has always been on the species experiencing the losses, whether estimating the risk of AEI or the economic value of these losses.

Much of the appeal of habitat-related measures for many stakeholders (and not just the permit applicant) is the opportunity to provide (in the words of PSEG) "long-term, broad-based benefits for the natural resources and people of the region" (p. 59). Pisces comments that "these are valid and valuable ideals, but it is far from certain that they are a true replacement for losses, and so it can be argued that they should not be used as a bargaining chip to enable utilities to reduce their commitment to solving the primary environment problems [emphasis added], impingement and entrainment."

Bottom line: Pisces' conceptual framework for evaluating habitat replacement as a mitigation measure for I&E losses leads to the answer that true ecological equivalence is impossible, and thus habitat replacement is not an acceptable mitigation measure for I&E losses. An alternative conceptual framework for evaluating habitat replacement as a mitigation measure for I&E losses is as follows:

- Empirical evidence over three decades is weak from a scientific perspective in indicating that I&E losses are primary environmental problems or that reducing I&E losses will result in any of the population, community or ecosystem level benefits predicted by EPA's analysis;

- Empirical evidence over three decades is strong in indicating that I&E losses are a primary environmental problem for some stakeholders and thus for many regulators, including EPA;

- Empirical evidence is steadily increasing to indicate that habitat replacement can enhance the productivity and diversity of entire ecosystems; and

- Ecological equivalency can be viewed as a scientific, sociopolitical, and regulatory issue, and not just a scientific issue.

Bottom line: By saying 'Yes' to some form of habitat restoration as an appropriate mitigation measure for I&E losses, rather than focusing solely on reducing I&E losses, EPA's rule making for Phase II existing facilities has the potential of going from an overall lose-lose policy to a potential overall win-win for regulators, Phase II existing facilities, other stakeholders, and more importantly for aquatic resources and society.

EPA Response

For a discussion of the uncertainties associated with restoration measures and the use of restoration measures to address species other than those that are impinged and entrained, see EPA's response to comment 316bEFR.206.055.

EPA disagrees with the commenter's statement about the nature of empirical evidence available on the environmental problems associated with impingement and entrainment losses. For additional discussion of adverse environmental impact from cooling water intake structures, see EPA's response to comment 316bEFR.207.015.

EPA agrees with the commenter that impingement and entrainment losses are a primary environmental problem for some stakeholders. EPA also believes that habitat restoration can enhance the productivity and diversity of some ecosystems.

For the purpose of the requirements for restoration measures described in the final rule, including sections 125.94 and 125.95, ecological equivalency is viewed as a scientific issue.

For additional discussion of the role of restoration measures in the final rule, see EPA's response to comment 316bEFR.060.023.

Valuing Forage Species (incl non-use and non-landed)

EPA’s estimates of the national and regional costs and benefits of the proposed rule have improved in some ways but are still inadequate. EPA’s analysis vastly overstates the non-use benefits of the proposed rule. But EPA’s apparent abandonment of the Habitat Replacement Cost (HRC) and Societal Revealed Preference (SRP) methods is a great improvement and ought to be confirmed.

EPA Response

EPA does not use the Habitat-based Replacement Cost (HRC) or Societal Revealed Preference (SRP) methods in the cost benefit analysis for the final Section 316(b) Phase II rule.

Please see the document entitled "Habitat-based Replacement Cost Method" (Docket # XX) for additional discussion of the HRC method.

Please also see EPA’s response to comments on the HRC (#316bEFR.005.035) and the SRP (#316bEFR.005.006).

Methods to Evaluate I&E

EPA's estimates of how many fish would be saved by the proposed rule have errors in both the weights and ages of fish.

EPA Response

Without examples, EPA cannot respond to this comment other than to say that EPA believes that it is incorrect and misleading to describe the weights and ages of fish used by EPA as "errors." In fact, EPA has made considerable effort to identify the best available biological data for its evaluations of impingement and entrainment. EPA consulted with local fisheries experts and conducted as thorough a review of the biological literature as possible to obtain the best available life history data. When possible, EPA used life history data recommended by local technical advisory committees and provided in current facility studies (e.g., EPA used the same life history data used by Salem and by Brayton Point in their recent permit renewal applications). However, the fact remains that despite this considerable effort to obtain the best available data, parameters such as fish weights and ages are not well known for many species.

Comment ID 316bEFR.307.007

Subject Matter Code 21.0
Implementation

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

Implementation requirements should state clearly that reductions in entrainment and impingement by species or life stage are not required. On other implementation issues, UWAG believes flexibility is called for.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see EPA's response to comment 316bEFR.017.003. For an explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble section IX for a discussion of the Technology Installation and Operation Plan. EPA believes that providing flexibility in the means by which compliance is determined will encourage facilities and Directors to cooperate to find the best means of protecting their source waterbodies from adverse environmental impact.

Subject Matter Code 7.01

RFC: Three-option framework for determining BTA

Section I: General Information

At the heart of the proposed rule are "performance standards" that call for reducing impingement mortality by 80-95% and, for many facilities, entrainment by 60-90%. EPA has looked at available intake structure technologies and concluded that some of them can achieve these standards. The candidate technologies are wedge wire screens, fine mesh screens with fish return systems, and aquatic filter barriers.

The proposed rule could conceivably be read, incorrectly, to suggest that, if wedge wire screens, fine mesh screens with fish return systems, or aquatic filter barriers could not achieve the performance standards at a particular site, cooling towers (closed-cycle cooling) might be required.

Clearly it is not EPA's intent to require cooling towers, as several passages in the NODA reveal. For example, EPA deliberately did not include costs for cooling towers in its economic analysis for the "preferred" option. As EPA said in the original proposal:

[A]lthough closed-cycle, recirculating cooling is not one of the technologies on which the presumptive standards are base[d], use of a closed-cycle, recirculating cooling system would achieve the presumptive standards.

67 Fed. Reg. 17,142 col. 2.

To make it clear that cooling towers are not a "default" option to be required whenever the other alternatives cannot achieve the numerical standards, EPA should revise the rule as follows.

§ 125.94 How will requirements reflecting best technology available for minimizing adverse environmental impact be established for my Phase II existing facility?

(See hardcopy page 4)

§ 125.95 As an owner or operator of a Phase II existing facility, what must I collect and submit when I apply for my reissued NPDES permit?

(See hardcopy Page 5)

EPA Response

Subject Matter Code 3.06.01

Withdrawal threshold of 50 MGD

As UWAG said in its comments of August 7, 2002<FN 2> , the rule should not apply to emergency intakes. The “existing facilities” to which the proposed rule would apply are facilities with a design intake flow of 50 million gallons per day (MGD) or more. Proposed § 125.91(c)(4), 67 Fed. Reg. 17,220 col. 2. In applying this 50 MGD threshold, EPA should distinguish between ordinary cooling water intakes and emergency service water intakes. An emergency service water intake may operate only a few hours each month, enough to ensure that it stays in working order. It may have a capacity greater than 50 MGD, but the design flow of an intake that is used only rarely should not be counted in determining whether a facility is subject to the § 316(b) rule.

RFC: Regulating limited capacity facilities

Capacity Utilization Factor

In number 7 of its "major changes," discussed in Section III of the NODA, EPA says that it may refine its definition of "capacity utilization rate" in proposed § 125.93. The definition is important because a facility must reduce entrainment of all life stages of fish and shellfish by 60 to 90% from the calculation baseline if the facility has a capacity utilization rate of 15% or greater and withdraws cooling water from a tidal river or estuary, an ocean, or one of the Great Lakes, or if the facility's design intake flow is greater than 5% of the mean annual flow of a freshwater river or stream. 67 Fed. Reg. 17,221 col. 2. Hence, it is important to be clear about when a facility has a capacity utilization rate of 15% or greater. The old proposed definition of capacity utilization rate is "the ratio between the average annual net generation of the facility (MWH) and the total net capability of the facility (MW) multiplied by the number of available hours during a year. The average annual generation must be measured over a five-year period (if available) of representative operating conditions." 67 Fed. Reg. 17,220 col. 3.

EPA now proposes to change the definition to reflect use of only the steam electric part of a facility. For the NODA, EPA uses the capacity utilization of only the steam electric generators at Phase II facilities so that its updated economic analyses include this potential refinement (68 Fed. Reg. 13,525 col. 2-3).

As explained in Section XI.H of these comments, UWAG supports adding "steam electric part" to the definition. But UWAG is troubled that the proposed definition of "capacity utilization rate" may unfairly penalize facilities that are out of service for a large part of a year. Also, UWAG proposes modifying the five-year period to avoid inflating capacity factors in uncharacteristically dry years when some generating units operate more than is normal.

EPA Response

EPA notes that the commenter agrees with the Agency's decision to base the definition of capacity utilization on steam electric capacity.

However, the Agency disagrees with the commenter's suggestion to modify the five-year period for calculating the capacity utilization rate. See response to comment 307.084.

Subject Matter Code 9.06

Burden to facilities (general)

Costs of Demonstrations and Monitoring

EPA addresses in Section III its prior inclusion of costs associated with demonstrations and monitoring in cases where the permittee has recirculating cooling (68 Fed. Reg. 13,525). EPA says that it should not have included those costs, because the proposed rule does not require any studies or monitoring. UWAG agrees with EPA's conclusion and hopes EPA will make this clear in the rule.

EPA Response

The Agency notes that there is an omission in the following statement made in the comment: "EPA says that it should not have included those costs, because the proposed rule does not require any studies or monitoring." The Agency notes that the correct summary would include a clarification that the proposed rule does not require any studies or monitoring for facilities "with recirculating cooling."

Regarding the commenter's request that EPA clarify the point in the final rule, the Agency has done so for the final rule, and, therefore, the comment has been met.

Costs

Engineering Cost Analysis

UWAG welcomes the more detailed cost analysis in the NODA. We agree that no generic analysis of this kind can capture all site-specific factors that would determine the choice of "best technology available" or its cost. That is why it is important to have a cost-cost test that allows permittees and permit writers to compare the cost of the technology EPA assumed a facility would use with the cost of the technology a facility actually proposes to use. UWAG has not been able to critique EPA's analysis in detail, however, because EPA has not provided the data, citing constraints due to confidentiality.

The new data EPA has provided on cooling tower costs and other factors shed important light on the technical feasibility (or, for some sites, infeasibility), cost, and environmental side-effects of recirculating cooling. It is apparent, in light of the Department of Energy (DOE) documents referred to in the NODA and contained in the docket, that EPA's original cost estimates for closed-cycle conversions were far too low. DOE's initial review of site-specific factors resulted in cost estimates that were between 65% and 104% larger than EPA's. Further site-specific information received by DOE after this analysis was completed revealed that actual costs of construction at the four studied facilities could be 230% to 310% greater than EPA's cost methodology would suggest. We also believe that EPA's decision to revise its estimates for downtime for nuclear facilities to seven months, while leaving the outage time for non-nuclear facilities unchanged, is arbitrary and unrealistic. If more realistic outage times were considered, the impact of a closed-cycle option would increase even further.

UWAG thinks that all of this information, taken together, confirms that EPA should reject any option that requires cooling towers of any kind for existing facilities. <FN 03>

Footnotes

3 In fact, for the reasons explained in our preious comments, UWAG seriously questions EPA's authority to impose a closed-cycled cooling requirement on any facility. See UWAG August 2002 Comments, Section IV.B.

EPA Response

EPA notes that the cost-cost test is included in the final rule. As such, this portion of the comment is met. The Agency responds as follows to the assertion of the commenter that it was not been able to critique EPA's NODA cost analysis because EPA did not provide sufficient data due to confidentiality to be an insufficient reason for not reviewing and critiquing the detailed cost analysis provided by the Agency in the NODA: The Agency notes that it provided in the NODA pertaining to the revised cost analysis the detailed cost algorithms and equations for each of the technologies forming the basis of the NODA analysis, the methodology for applying these cost technologies to model facilities, and the results of the costing analysis in the most detailed format permissible by the restrictions of protecting confidentiality. The Agency notes that other comments to the NODA, for instance comments 316bEFR.306.002, 316bEFR.306.009, 316bEFR.306.023, and 316bEFR.306.030

through 316bEFR.306.053 were able to critique the Agency's revised cost methodology and estimates suitably with the data provided in the NODA.

The Agency has reviewed the study (An Investigation Site-Specific Factors for Retrofitting Recirculating Cooling Towers at Existing Power Plants, January 22, 2003)prepared on behalf of the Department of Energy and finds the principles and concepts behind the analysis to be sound. The Agency notes that it did not base the requirements of the final rule based on cooling tower retrofits. Also see response to comment ID 316bEFR.208.002.

Proposed standards for tidal rivers and estuaries

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

As to the specific option EPA considered, i.e., the waterbody/capacity option, we do not believe the rulemaking record provides any valid biological basis for the assumption, on which that option depends, that facilities on estuaries and oceans merit such dramatically different treatment as a group. The distinction between facilities on estuaries and oceans and other facilities is fundamentally arbitrary.

EPA Response

With respect to the standards for tidal rivers and estuaries, please refer to the response to comment 316bEFR.025.014.

With respect to the standards for oceans, please refer to the response to comment 316bEFR.032.014.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

IPM Analyses

In footnote 8 at 68 Fed. Reg. 13,530, EPA says its two base case scenarios were used to analyze the impacts associated with the preferred option and the waterbody/capacity-based option. It is difficult to compare the results of EPA's two analyses of the preferred versus the watershed/capacity (i.e., cooling tower) alternatives, because EPA used different assumptions to run the base cases for the two analyses. EPA says it is rerunning the analyses to make them more comparable, but we have not seen the re-analyses. UWAG believes it is important that we be allowed time to comment on the re-analyses.

EPA Response

EPA notes that the re-analyses were added to the docket on June 19, 2003.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

Other Economic Analyses

The Edison Electric Institute has prepared a more detailed review of EPA's revised IPM runs and other aspects of EPA's economic analyses. EPA says that those analyses are intended to estimate the economic impacts of the rule on electricity consumers (i.e, the average electricity price and average household cost impact analyses) and to electric power sector investors (i.e., the cost-to-revenue test and the electricity market impact analysis). As that review <FN 4> shows, EPA provides no explanation of how the results of these analyses will be used to inform the broader cost-benefit analysis it has undertaken. Moreover, EPA's economic analyses still suffer from a number of flaws that are likely to result in understatement of the economic implications of the rule at all levels.

Footnotes

4 Edison Electric Institute's review will be submitted with its comments on the NODA.

EPA Response

EPA notes that the "other economic analyses" are measures of the magnitude of compliance costs. They are not intended to "inform the broader cost-benefit analysis". For a response comments on the average electricity price and average household cost impact analyses, please refer to subject matter code 9.02. For a response to comments on the cost-to-revenue test, please refer to subject matter code 9.02.

Subject Matter Code 9.03

Mkt-level impacts/Reliability/EO 13211: Energy Effects

Even assuming that EPA's economic analyses were correct (which DOE's and EOP's reviews suggest they are not), EPA's revised economic analysis shows that the cost implications of the proposed rule for the power industry, and for reliability, are serious even for the preferred alternative. EPA tends to dismiss the effects as trivial, but even a 1% effect on profits is important in a newly competitive industry with as small a margin and as many financial challenges as the power industry. A greater than three percent effect, which EPA estimates for at least one region, is very large.

EPA Response

EPA disagrees with this comment. EPA notes that the percentage effects cited by the commenter are a reduction in absolute profit, not a reduction in the percentage profit margin. Even in a "newly competitive industry," profit changes of 1% and, in one region, 3% would be considered very small, particularly within the context of ordinary variations in profit performance.

Technology Efficacy Database

Database

UWAG has reviewed the comments on EPA's database prepared by EPRI and agrees with EPRI's conclusions. According to EPRI, the studies show that the technologies EPA has identified will be deployable at appropriate sites and are capable of achieving appreciable reductions in impingement and entrainment. The technologies probably can meet the proposed performance targets, provided those targets are properly and reasonably interpreted, at many but not all sites. As the studies in EPA's database show, technology performance has been evaluated in many different ways, using a wide variety of metrics and monitoring approaches adapted to the features of the technology and the site. Later in these comments we discuss in greater detail (1) important principles that EPA should follow in interpreting and applying the performance standards, and (2) the important connection between a performance standard or target and the means of assessing whether it has been achieved.

EPA Response

For a more detailed discussion of the efficacies of some of the technologies documented in the database, the commenter should refer to Chapter 3 of the Technology Development Document (TDD). The studies detailed in the TDD contain a more robust set of data that EPA was able to analyze when developing the performance standards. EPA agrees that the studies contained in the database are varied in many ways, including the study protocols and metrics, but maintains that the data discussed in the database and the docket support the performance standards in today's rule.

General: cost tests

While we believe that there may be some sites for which the performance standards are not achievable, the cost-cost and cost-benefit tests offer an appropriate – in fact, an essential – means of setting alternative targets for those sites. Unlike a maximum intake flow requirement, which could be met by cooling towers or other equipment but which is not the same as a proportional reduction in entrainment or impingement, there is no technology, even wet recirculating cooling systems, that (1) can feasibly be deployed at each and every existing facility and (2) would always meet the proposed numerical reductions in impingement mortality and entrainment at all sites.

EPA Response

The Agency agrees with the comment and notes that the cost-cost and cost-benefit tests have been included in the final rule.

Subject Matter Code 7.04

Streamlined Technology Option

The NODA, unfortunately, does not address a critical issue in the rulemaking: how the permittee and the permit writer are to select the most cost-effective technology or alternative for purposes of setting a site-specific performance target from the range specified by the rule (80-95% reduction in impingement mortality and 60-90% reduction in entrainment). For a facility where not just one but several alternatives will produce reductions that are within the specified ranges, what technology or option should be chosen? While UWAG believes that, under § 316(b), EPA should set BTA performance standards that maximize net benefits, the use of performance ranges inherently departs from strict application of that principle. In fact, in many cases, hitting the minimum levels of the ranges may provide for a level of control that is excessive if viewed solely from the position of maximizing net benefits. However, use of specified ranges can be justified as a streamlining measure, because it can reduce uncertainty and transaction costs for both regulators and the regulated community by providing a “safe harbor” for those able to obtain performance in the range at reasonable cost. The most appropriate way to apply the ranges, consistent with this purpose, is to allow the permittee to choose among technologies that it can demonstrate will achieve performance within the range. To do otherwise would defeat the purpose of the ranges by a cost-benefit calculation (and a review of the calculation by EPA) in every case.

Allowing the technology choice to fall anywhere within a range does not mean that permittees will choose technologies that provide the lowest acceptable level of protection. Selection of technologies will be driven largely by what will work under the conditions of a site, and permittees will err on the side of caution and choose a level of performance that will ensure compliance through the lifetime of the facility, in order to avoid the risk of noncompliance.

EPA Response

EPA agrees that Directors and permit applicants will require guidance when it comes to setting alternate performance standards and BTA in the event that a facility qualifies for a site-specific determination of BTA. EPA intends to develop a model permit and permitting guidance to assist Directors in implementing the requirements set forth by today’s rule. In addition, the Agency intends to develop implementation guidance for owners and operators to address how to comply with the application requirements, the sampling and monitoring requirements, and the record keeping and reporting requirements in these final regulations. In addition, see preamble section III.C. for a description of the guidance documents already available to Directors and permit applicants.

Streamlined Technology Option

Streamlined Technology Option

Part B of Section VII of the NODA addresses a "Streamlined Technology Option for Certain Locations" (68 Fed. Reg. 13,539 col. 2). EPA asks whether the following technology would qualify for streamlined application requirements:

Use of submerged wedge-wire screens where the cooling water intake structure is located in a freshwater river or stream, sustained countercurrents exist to promote cleaning of the screen face, and the design intake velocity is 0.5 feet per second (ft/s) or less.

68 Fed. Reg. 13,540 col. 1. The concept of a streamlined compliance option is sound and should be adopted. UWAG has long supported alternatives that simplify the approval of technologies that have proven themselves. <FN 6>

Footnotes

6 EPRI's June 2003 comments on the NODA will provide additional details on the criteria that should be specified as part of a streamlined option based on cylindrical wedgewire screens.

EPA Response

EPA appreciates Utility Water Act Group's support of EPA's Approved Design and Construction Technology option.

Comment ID 316bEFR.307.027

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

Subject Matter Code 7.04

Streamlined Technology Option

EPA also proposes language that would implement two variations on the streamlined compliance option. Under the first variation EPA would evaluate the effectiveness of a technology under specific circumstances (68 Fed. Reg. 13,539 col. 3). Based on such an assessment, if EPA identified technologies that are sufficiently protective and for which applicability conditions could be defined, EPA would promulgate regulations that allows for their use as a means of complying with Phase II § 316(b) requirements. Such a technology would be used to treat the entire cooling water intake flow and would not be used in combination with restoration measures to meet the performance standards. Monitoring would be required as necessary to verify that the technology was in fact achieving an acceptable level of performance.

This concept is sound but can be implemented in a manner that has a better probability of success. First, it is doubtful that requiring agencies to go through a rulemaking process to approve each technology will prove practical or expedient in all cases. Just the process of promulgating a regulation under § 316(b) will be difficult, and burdensome for the regulatory agencies. A better approach would be to approve the technology by issuance of a Technical Support Document or similar technical document. Second, monitoring should be conducted for informational purposes, not compliance purposes (as UWAG argues should be the case whether or not a streamlined approach is used). If the technology has been established as BTA, then the permittee should not be liable if he has properly installed and maintained the technology, even if monitoring demonstrates that the performance standard percentages are not met (although further technology refinements could be required in appropriate cases).

The second variation would allow the approval process to be carried out by the permitting agency, perhaps with EPA oversight or approval. The rule would define the criteria that a control technology must meet to be approved and the process for approval, but the permitting agency would determine whether the preferred technology satisfied the performance criteria. If so, the technology would be approved for use by any eligible party (that is, any facility that met the applicability criteria) within the agency's jurisdiction.

We recommend that the approval process for the second variation be implemented through technical guidance and kept separate from the formal regulatory process. If that is not possible, the approval criteria should be set up on a statewide basis similar to the criteria for a general NPDES permit. These approval criteria would be subject to the public participation process. Once the approval criteria were approved, the regulatory agency then could issue an approval certificate (or denial) to each applicant who qualified. As with the first variation, monitoring should be conducted for informational purposes, not compliance purposes. Once a technology was established as BTA, the permittee should not be liable if monitoring demonstrated that the performance standard percentages had not been met.

Any regulatory language in proposed § 125.94(a)(4) and § 125.95(c) should reflect the above concepts, especially the idea that monitoring should be for informational purposes and not to assess compliance for enforcement purposes. If a permittee is required to monitor a preapproved technology for compliance with the performance standards, then the "streamlined" compliance option may be undermined, because most permittees will not install a preapproved technology if they could face civil or criminal liability should the technology fail to meet the performance standards.

Finally, the language of 125.94(a)(4)(ii) is awkward:

Any interested person may submit a request that a technology be approved for use under the compliance option in § 125.94(a)(4). If the Director approves, the technology may be used with compliance option § 125.94(a)(4) by all facilities under their jurisdiction. Requests for alternative technologies for compliance under § 125.94(a)(4) must be submitted to the Director and include the information in paragraphs (A), (B), and (C) below:

- A detailed description of the technology;

- A list of design criteria for the technology and site characteristics and conditions that each facility must possess in order to ensure that the technology can consistently meet the appropriate impingement mortality and entrainment performance standards in § 125.94(b); and

- Information and data sufficient to demonstrate that all facilities under the jurisdiction of the Director can meet the applicable impingement mortality and entrainment performance standards in § 125.94(b) if the applicable design criteria and site characteristics and conditions are present at the facility.

68 Fed. Reg. 13,540 col. 2-3. Paragraph 125.94(a)(4)(ii) should read as follows:

Any interested person may submit a request that a technology be approved for use throughout the Director's jurisdiction. If the Director approves, the technology may be used to establish best technology available for minimizing adverse environmental impact by all facilities under the Director's jurisdiction. Requests for approval of alternative technologies under this 125.94(a)(4)(ii) must be submitted to the Director and include the information in paragraphs (A), (B), and (C) below: . . . .

While EPA is considering "streamlined" approaches, it should consider also the expedited § 316(b) permitting process that UWAG has recommended before for facilities that have already performed a successful § 316(b) demonstration in the past and show that their present intake is already "best technology available." See UWAG August 2002 Comments, at 10-11. In such cases the permitting agency should be empowered to reapprove the existing intake unless there has been a material change in the facility or the waterbody.

EPA Response

EPA disagrees that approval for an alternate streamlined technology should be based upon Technical Support Documents as opposed to a regulatory process. The benefit of codifying an alternate approved technology is that once approved, the technology will be available to all applicants in the region to use as a means of compliance. EPA anticipates that this mechanism will expedite the application process in the future, and result in time and money saved for both applicants and State permitting agencies.

In response to the comment that monitoring should be used only as a means of gathering data and not to evaluate compliance, EPA disagrees. In today's final rule, meeting the performance standards is the benchmark for determining a facility's compliance, with the exception of facilities that choose to comply through a Technology Operation and Installation Plan (see EPA's response to comment 316bEFR.063.005).

EPA has set a monitoring minimum of two years in today's rule for those facilities that must demonstrate the efficacy of their design and control technologies, operational measures and/ or restoration measures through a Verification Monitoring Plan. EPA believes that this is a reasonable amount of time by which to determine if a facility's technology or operational or restoration measures are indeed achieving the performance requirements. A facility may demonstrate compliance within a shorter timeframe, while others may need additional time. Because of the site-specific factors affecting the speed with which a facility is able to come into compliance, EPA has determined that the Director will be the appropriate authority over determining how much monitoring, if any, should be conducted by a facility beyond the mandatory two-year minimum. Facilities that have reduced intake flow commensurate with closed-cycle recirculating systems are exempt from monitoring requirements. In addition, facilities that reduce intake their velocity to 0.5 fps or less under § 125.94(b)(1)(ii), will not be required to demonstrate compliance (through monitoring) with the performance standards for impingement mortality. Facilities not demonstrating compliance through the Verification Monitoring Plan must conduct monitoring in accordance with their Technology Installation
and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5). The Director may consider additional monitoring requirements as well. Specific study parameters may be proposed by the applicant for review and approval by the Director.

An additional means by which a facility can reduce its biological study requirements is to prove that conditions at the facility and in the waterbody have not changed. EPA has provided this option to give facilities the ability to have reduced Comprehensive Demonstration Study (CDS) requirements when they apply for a permit renewal. For details on how facilities may reduce their CDS burden, refer to EPA's response to comment 316bEFR.034.005. Generally, facilities will be required to review whether conditions, such as biological, chemical or physical conditions, have changed. If conditions have changed, facilities will be required to submit all of the relevant CDS components when they submit the application for permit renewal. □
□□□
For an explanation of why EPA did not choose UWAG's recommended approach, please refer to the final rule preamble section VII. E., Major Options Considered for the Final Rule and Why EPA Rejected Them.

Subject Matter Code 10.1

General: cost tests

Cost Tests (68 Fed. Reg. 13,541)

In Section VIII of the NODA (68 Fed. Reg. 13,541 col. 1) EPA asks for comment on its “significantly greater” cost tests. Under the proposed rule, a facility may choose the site-specific alternative if the costs of complying with the performance standards would be “significantly greater” than either (1) the costs considered by EPA when establishing the performance standards or (2) the benefits of complying with the performance standards (68 Fed. Reg. 13,541 col. 1).

As a threshold matter, UWAG reiterates that these two tests are absolutely essential components of EPA’s proposal, without which EPA’s approach (using numerical performance standards) would be insupportable. We believe strongly that the two cost tests must be retained in any final rule, with certain refinements necessary to make them fairer and more workable.

EPA Response

The Agency notes that the cost-cost and cost-benefit tests have been retained in the final rule. As such, the commenter's recommendation has been met.

Subject Matter Code 10.07.02

RFC: Appropriateness of “significantly greater”

How much greater is “significantly” greater? As explained below, UWAG believes that when applying the cost-benefit test, the cost should be viewed as significantly greater than the benefit whenever the cost is greater than the benefit by any amount at all. The purpose of this formulation is to prevent the requirement of a technology that will do more harm than good to society’s overall interest. The “significantly” could be interpreted to require enough evidence to provide confidence that the cost really is higher than the benefit.

EPA Response

See responses to 316bEFR.006.003, 018.009 and 045.012.

Comment ID 316bEFR.307.030

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

Subject Matter Code 10.1

General: cost tests

One thing that would not be appropriate for either test would be to impose a simple percentage test, by declaring, for example, that 1.10% of EPA's costs would be "significantly greater" than those costs (or 1.10% of actual costs would be greater than actual benefits). A percentage test would be inequitable because it would penalize precisely the facilities for which costs are estimated to be highest (either by EPA or the discharger, depending on the test used). The greater the costs assumed by EPA or estimated by the facility, the harder it would be for the facility to meet either test. This would be irrational.

EPA Response

The Agency agrees that implementation of the cost tests is not suited to application of a percentage test. As such, the cost tests in the final rule do not have percentage tests in the Agency's requirements or guidance for their implementation.

Comment ID 316bEFR.307.031

Subject Matter Code 10.07.03

RFC: Test: benefits should justify the costs

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

UWAG's position on the cost-benefit test is clear on the record and has not changed from our comments on the original proposed rule: The alternative that should be chosen from among several available intake technologies is the one that maximizes the net benefit to society. This is the only test that makes sense based on the principles of economics.

If EPA retains the "significantly greater" test, however, the test should be simply that the costs of compliance are "significantly greater" if they are greater than the benefits by any amount whatsoever. Otherwise, EPA will be requiring technology that does more harm than good, and this would be irrational. To date, EPA has offered no real justification for using the "significantly greater" test or indeed any test other than a break-even net present value of zero (meaning that benefits are equal to costs).

Possibly the "significantly" in the proposed "significantly greater" formula is designed to err in the direction of complying with the standards, instead of using an alternative, in the face of uncertainty. The "significantly" may be designed to provide a margin of safety for the performance standards to account for uncertainty.<FN 7>

If this is EPA's rationale, this safety margin could be accomplished by using, as UWAG suggests, the test that the costs of complying with the performance standards be greater than the benefits by any amount at all, but adding that there must be enough evidence, or a sound enough analysis of costs and benefits, to give the permitting agency confidence that the cost of compliance really would be greater than the benefits. The margin implied by "significantly," in other words, could be addressed considering both the magnitude of the difference between estimated benefits and estimated costs and considering the precision of the estimates. The precision of the estimates would be affected by amount of evidence or analysis underlying the estimates.

Footnotes

7 "Safety" is here a relative term, because erring in one direction is just as bad as erring in the other. Erring in the direction of preferring the performance standards over the site-specific alternative means erring away from doing the most good for the public in a larger sense. It is not really "safe" to err in favor of overprotecting fish, since this may underprotect society's larger interests

EPA Response

For EPA's response to comments on application of the cost-benefit test to assessing the value of alternative CWIS technologies, please see comment #316bEFR.005.020.

For EPA's response to comments on application of the "significantly greater then" test to assessing the value of alternative CWIS technologies, please see comment #316bEFR.006.003.

Comment ID 316bEFR.307.032

General: cost tests

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

Cost-Cost Test

Meaning of Significantly Greater

The rationale of the cost-cost test is somewhat different from the cost-benefit test. Rather than seeking to avoid decisions that do more harm than good, the cost-cost test tries to identify facilities where, because of site-specific conditions, the assumptions underlying EPA's rule do not fit. The question of what constitutes "significantly greater" for purposes of the cost-cost test deserves further development on the rulemaking record. The question is how much site-specific cost is "different enough" from EPA's assumptions to warrant an alternative standard. UWAG proposes that "significantly greater" should be defined, consistent with the cost-benefit test, as an amount that is any amount at all greater than the cost, once uncertainty and the precision of the estimates are taken into account. A variety of approaches to deciding how to account for uncertainty and precision might be used. We suggest that EPA should consider the following factors in deciding how far above EPA's estimated costs is "significantly greater": the range of and uncertainty in EPA's cost estimates, standard statistical tests for "outliers" in a data set, financial and accounting standards for what are significant expenditures in a business environment, and how cost overruns are treated in utility ratemaking.

Although EPA should provide guidance on how much excess cost is significant, ultimately the question of when a facility's individualized costs are so high that relief should be granted is one that ought to be addressed by the states, because it is tied up with how states value their resources and how they regulate their electric utilities. EPA should avoid setting a rigid numerical test for "significantly greater" in the cost-cost test.

EPA Response

EPA agrees with the commenter's request to EPA allow local authorities to determine what is the proper definition of significantly greater for the reason stated by the commenter (i.e., that local authorities should be responsible for valuing their local resources and regulate electric utilities).

See response to comment 316b.EFR.006.003.

The Agency has provided discussions of the "uncertainty" and precision of its cost estimates in the Technical Development Document for the final rule which addresses the principles outlined in the comment.

Comment ID 316bEFR.307.033

Subject Matter Code 10.1

General: cost tests

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

Applying the Cost-Cost Test

Since the cost-cost test depends on the costs EPA considered when it promulgated the regulation, EPA must be very clear about stating these costs in a way that makes comparison possible. First, EPA must make it clear that the cost to be compared is the cost that EPA actually assigned to a particular facility. <FN 8>

Second, EPA needs to make available information about what intake technology it chose for each facility, so that the facility can calculate EPA's estimated cost for that facility by starting with EPA's choice of technology and applying EPA's own costing method. To know what the cost assigned by EPA is, permittees and permit writers need to know (1) what technology (wedge wire screen, fine mesh screen, or aquatic filter barrier) EPA chose for each facility and (2) what EPA's costing method would estimate it to cost. EPA could provide this data quite simply by publishing a table listing the facilities for which costs were identified (using questionnaire numbers to assure confidentiality) and the costs it assigned to each facility. Most permittees will have a copy of their questionnaires; if not, EPA should be able to disclose the questionnaire number, at least to the permittee and permit writer, since the number itself is not the permittee's information, and it need not be linked to any other confidential business information provided by the permittee on its questionnaire.

Although less straightforward and simple, there is another approach. A permittee could obtain information about EPA's choice of technology for its facility by using the spreadsheets and other information referenced in EPA's Technology Costing Module Applications for Model Facilities (DCN 5-2504). The spreadsheets provide, for each facility that completed a detailed or short-form questionnaire, a code identifying the CWIS technology or technologies that EPA selected for the facility.<FN 9> Thus, the permittee and permit writer would need only the questionnaire number to learn what technology EPA chose for the facility. As discussed above, most permittees should have that number, or be able to get it from EPA. Knowing what technology EPA chose for the facility, the permittee then can use the algorithms EPA developed for that technology (described in DCN 5-2505), to calculate the cost EPA would have calculated for the facility.

This method requires some calculation, and possibly extrapolation, but it at least accounts for both key factors – the choice of technology and the cost of that technology scaled to a given site. It also allows use of the cost-cost test even when the technology proposed by a permittee (such as an aquatic filter barrier) is not an option applied by EPA in its national cost analysis

Footnotes

8 The other part of the comparison is the costs the permittee calculates based on its engineering analysis of what technology will work and what it will cost at the site. In the proposed rule, these costs are characterized as "your costs" based on "data specific to your facility" (proposed 40 C.F.R 125.94(c)(2)). In the preamble to the proposed rule, EPA goes to some length to describe the level of "empirical" information it proposes to require of permittees who wish to apply for site-specific requirements under either the cost-cost or cost-benefit test. 67 Fed. Reg. 17, 152. UWAG reiterates its view (UWAG August 2002 Comments, Section XII.E.1) that, while it is fair to require permittees to identify a reasoned basis for the

assumptions and calculations they make, if EPA intends by the term "empirical" to require a showing that the same costs have been incurred elsewhere, that is unreasonable. It is the very circumstances that make costs site-specific that also make direct empirical cost transfer impractical. Permittees must be allowed to make adjustments, which may involve assumptions or calculations or textbook values, to account for site-specific circumstances.

9 These spreadsheets were not placed in the docet until April 23, 2003, and may facilities may not be aware that they exist.

EPA Response

The Agency notes that the commenting organization (UWAG) provided additional (and somewhat different) recommendations on implementing the cost to cost test in comment 316b.EFR.410.001. The Agency has reviewed and considered, in depth, both sets of suggestions from the commenter and has determined a methodology that meets both sets of recommendations, to the extent possible, and balances the need for a flexible cost to cost test that is also easily implementable. See section IX.H of the preamble to the final rule.

General: cost tests

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

EPA also should explain what site-specific requirements are justified once the permittee has met the cost-benefit or cost-cost test. In the original notice of proposed rulemaking, EPA said that the applicant must propose less costly technologies "to the extent justified by the significantly greater costs." See 67 Fed. Reg. 17,146 col. 2. In some cases, EPA said, this might justify no additional technologies at all. This would be most likely where either (1) the monetized benefits at the site were very small (for example, a facility with little impingement mortality and entrainment, even in the calculated baseline) or (2) the costs of implementing any additional technologies or measures at the site were unusually high (67 Fed. Reg. 17,146 col. 2). EPA's suggestion that the benefits of the alternative should "justify" the costs raises many questions.

Based on the economic principle that benefits should exceed costs (the best choice being the alternative that "maximizes net benefits"), it seems clear to UWAG that no alternative site-specific technology should be chosen unless its benefits exceed its costs. If the benefits do not exceed the costs, then society will be no better off for having required the technology, and the decision to impose a different technology will be at best a waste of effort and at worst a bad decision, contrary to the public's interest. If no technology for reducing entrainment or impingement mortality that has benefits greater than its costs can be found, then none should be required.

But what if there is more than one technology that will reduce impingement mortality or entrainment and that has benefits greater than its costs? The ideal decision in this case, based only on economic principles, would be, again, to choose the alternative that has the maximum net benefit. To ensure that this approach works as intended, however, it is important that total costs be accounted for as accurately as possible.

An example will illustrate this point. Suppose an alternative with capital and O&M costs totaling $1 million dollars is deemed likely to produce benefits worth $1.1 million dollars (for a net benefit of $100,000), while a cheaper alternative has capital and O&M costs of $100,000 and is likely to produce a benefit of $190,000 (net benefit of $90,000). Maximizing net benefits would require that the more expensive of these be selected as BTA. If, however, the more expensive option would likely impose other types of costs (e.g., greater hazards to navigation or other uses of the waterbody, aesthetic effects, effects on air emissions) that had not been counted, or if the benefits of the more expensive option were less certain to occur than the other option, choosing the less expensive option could maximize net benefits.

EPA Response

Regarding the site-specific, alternative requirements, see section IX.H of the preamble to the final rule, which describes the implementation of the cost-cost and cost-benefit tests.

EPA disagrees with the commenter's assertion that benefits must exceed costs in order to be justified by them. Rather, EPA believes that the purpose of the cost benefit test is to lay out all of the options and evaluate them in relationship to each other. One difficulty evaluating the benefits is that they are not always monetize-able, another complication is that a cost benefit test does not specify any decision criteria on how benefits and costs should be weighted. Also, see response to comment 316bEFR.005.020 for a discussion of the Agency's approach to net benefits and the cost-benefit test.

RFC: Documented entrainment survival rate studies

Reliable Data on Entrainment Survival Should be Used for Compliance Determination

Some species of fish survive entrainment quite well. Although EPA is correct to assume no survival of entrained organisms for the “baseline” condition, in determining compliance it should not forbid the use of sound data that show some survival, where such data exist.

Reliable data on entrainment survival should be accepted to show compliance with the entrainment performance standard of 60-90% reduction. If a facility can show, based on reliable data for a given site, that the facility has less than complete entrainment mortality, or can demonstrate modifications that will lessen entrainment mortality, then EPA should allow that information to be taken into account. As Peru's June 2003 comments point out, scientific data demonstrate with 100% certainty that entrainment survival can be significant for many fish and shellfish species.

Although EPA is skeptical of past entrainment survival studies, EPA’s assessment of the shortcomings of existing studies as a basis for national standards does not lessen the value of site-specific studies that can quantify accurately with reasonable certainty the entrainment survival that might be expected for particular species at a particular facility.

In any event, EPA’s skepticism about entrainment survival studies is not entirely deserved. The comments submitted by EPRI address entrainment survival at some length. As EPRI points out, <FN 10> EPA sets a much more rigorous standard for entrainment survival studies than for contingent valuation studies and often criticizes entrainment survival studies that are outdated.

In fact, survival studies can be useful. Apart from their value in site-specific analyses, entrainment survival studies provide useful background information, such as the following:

- Biocides, if they are used at all, are used typically only a few hours a week. One of EPA’s primary sources (Marcy 1973) reported no increase in mortality due to biocide use. The chemical component of entrainment stress, where it occurs, typically is of limited duration.

- At many stations, the combinations of cooling water flow rate and heat rejection rate actually observed does not result in significant thermal mortality for many of the commonly entrained taxa.

- Survival rate depends on species sensitivity. Some taxonomic groups (e.g., Serranidae and Ictaluridae) are relatively hardy, and significant proportions of them might be expected to survive passage through some cooling systems. Only a small portion of more sensitive taxonomic groups (e.g., Engraulidae and Clupeidae) would be expected to survive passage through a cooling system.

RFC: Documented entrainment survival rate studies

As EPRI points out, where significant site-specific data exist or could be developed, it may be possible, now or in the future, to specify operating conditions that will minimize the numbers of organisms killed by entrainment instead of minimizing the number entrained.

Developing a site-specific operation plan will depend on the species involved, the flow control capabilities of the station, the generation levels, the ambient temperatures, and the design of the cooling water system. Stations that have good entrainment survival data or that can implement changes that will increase survival should be permitted to incorporate survival information into their plans for complying with the entrainment performance criterion.

Entrainment survival chapter

The Shortcomings in Survival Studies Have Been Overstated

As EPRI points out, although entrainment survival studies are difficult and expensive to conduct, EPA's review of existing studies in Chapter A7 of the Case Studies (DCN 5-4059) is overly pessimistic in several respects.

Taxa covered. Typically only a few taxa are entrained at high densities at any one station. Studies of entrainment abundance have shown that the five most abundant taxa compose about 90% or more of entrained ichthyoplankton. For instance, at the Yorktown Station (York River, Virginia) a study in 1977 reported that entrained fish larvae were 68% Anchoa mitchilli, 15% Gobiosoma sp., 7% Menidia menidia, 4.5% Microgobius thallisinus, 1.5% Syngnathus fuscus, and approximately 4% others.<FN 11> In a four-year study of entrainment at the Fort Calhoun Station on the Missouri River, freshwater drum (Aplodinotus grunniens) and suckers (Catastomidae) were 95.4% of all larvae collected.<FN 12> Because most species are entrained at low levels, it is neither possible nor necessary to derive empirical estimates of entrainment survival for every species that may be encountered.

Temporal extent of sampling. Seasonal patterns of entrainment, particularly in northern states with large seasonal temperature variations, are typically very peaked, with a high proportion of total entrainment occurring over a short period of time. The timing of the peak varies depending on the environmental conditions and taxa in the source waterbody. At the Fort Calhoun Station, peaks occurred from June through early July, reflecting the spawning period of freshwater drum and suckers.<FN 13> Peaked temporal distributions have also been found in other freshwater and estuarine systems.<FN 14> Thus, it may not be necessary to conduct year-round studies of entrainment survival. A more cost-effective and relevant study could be done over the periods of peak abundance.

Inconsistent methodology. The methods used in the studies reviewed by EPA in Chapter A7 of the Case Studies (DCN 5-4059) and in the NODA varied because of site-specific deployment issues or because the sampling technology was in a period of rapid evolution when most of the studies were conducted.<FN 15> Preferred sampling gear changed from plankton nets to pumped flumes to rear-draw and pumpless flume systems, with more reliable results as each advance in gear design reduced the effects attributable to the sampling itself. The most advanced rear-draw and pumpless systems appeared only in the late 1970s and early 1980s, about when most entrainment survival studies were discontinued. Only two of the studies reviewed by EPRI were more recent than 1985.<FN 16> Future studies using modern sampling gear would be expected to be substantially better than past studies.

Sample size. EPA criticizes the small sample sizes that were reported in many entrainment survival studies. It is true that many single-year studies had small sample sizes for many species. But this generally reflected the fact that only a relatively small percentage of the total number of resident species are significantly susceptible to entrainment. EPRI says that it may be quite reasonable to combine information across years at a facility to obtain the most precise estimate of entrainment survival rates.

Entrainment survival chapter

Latent effects. EPA criticizes entrainment survival studies for not providing a realistic or comprehensive assessment of sublethal effects. Although observation of latent effects does take place in artificial surroundings, the critical issue is whether the entrained organisms collected from the discharge experience the same conditions as the unentrained "control" organisms collected from the intake. On this issue the NODA does not comment. In other regulatory efforts, EPA uses similarly artificial test settings to determine the effects of exposing aquatic organisms to chemical contaminants.

EPA Should Allow the Use of Survival Studies

As Peru's comments recommend, in its final rule, EPA should explicitly allow using entrainment survival to determine compliance with the entrainment performance standard. Allowing permittees to factor in valid estimates of survival may stimulate the collection of better information on survival than presently exists, particularly where some of the hardier taxa are the most common ones. This additional information, even if it does not ultimately demonstrate high survival rates, will still be useful in understanding the factors that contribute to entrainment stresses and could lead to improved design of once-through cooling systems. Such improvement clearly would be consistent with EPA's goal of advancing technology.

Equally important, assessing survival of entrainable-sized organisms will be essential for purposes of evaluating the performance of one of EPA's BTA technologies, i.e., fine mesh traveling screens. Those screens and associated fish handling systems are designed to increase survival of entrainable-sized organisms that, with the decrease in mesh size, become impinged. It would be irrational for EPA to require facilities that use this type of technology to evaluate performance by assessing organism survival rates, while denying other facilities the opportunity to do the same.

Experience Teaches Lessons About How to Design Survival Studies

EPA has requested comment on how to design entrainment survival studies to account for organisms that may be destroyed during passage through the condenser system. As the EPRI comments point out, destruction of organisms is difficult but not impossible to address. Although comparing sample densities at the plant intake and at the discharge would be the simplest approach, this usually will not be sufficient, because ichthyoplankton may exhibit distribution patterns at the intake that are not found in the discharge sample because of mixing. Thus, the intake sample may have a systematic bias that is usually not found in the discharge sample. Even so, if properly designed, a comparison of net or pump samples from the intake and discharge in terms of species and length-frequencies can provide valuable information about what organisms are susceptible to entrainment and what ones are likely to be destroyed.

Additional information on destruction can be obtained from state-of-the-art survival sampling at intake and discharge stations. By comparing the frequency and types of damage at both locations, information can be obtained on the severity of organism destruction. If organisms are being completely destroyed during passage through the plant, then it is likely that the occurrence of damaged but still recognizable organisms will be significantly higher also. Thus, a finding of low and roughly similar frequencies of damaged organisms in both intake and discharge samples would suggest a low degree of destruction. However, a significantly higher frequency of damaged organisms in the discharge samples would suggest that organism destruction should be considered.

Direct release studies, in which large quantities of hatchery-reared organisms are released into the cooling system, are perhaps the most effective way to assess organism destruction. Release of a few hundred hatchery-reared organisms directly into the intake sampling device and of larger numbers (on the order of 10^5) into the intake structure for subsequent sampling in the discharge using state-of-the-art survival gear can provide a direct estimate of damage that is not confounded by the unknown state of wild organisms. Direct release studies are probably most informative if the hatchery-reared organisms can be released somewhat out of the natural period of abundance, so that there is no possibility that wild organisms of the same species and lifestage will appear in the sample.

EPA Response

RFC: Entrainment vs. entrainment mortality

In Summary, EPA Should Allow Entrainment Survival to Be Considered for Compliance Determinations Where There Are Reliable Data

EPA notes in the NODA that the language of the proposed rule does not preclude the use of estimates of entrainment survival when estimating monetary benefits. Likewise, the rule should not preclude the use of entrainment survival estimates for compliance determination, where reliable data on survival are available. There is no question that survival occurs and can be substantial for some species and circumstances. It would be irrational not to consider it where reliable information is available.

EPA Response

Organization Hunton & Williams obo Utility Water Act Group

Subject Matter Code 11.0

Role of Restoration

EPA's Proposal to Permit Voluntary Restoration is Justified by Congressional Intent

EPA has recognized the benefits of voluntary restoration and has proposed that a facility may implement restoration measures in lieu of or in combination with reductions in impingement mortality and entrainment. Proposed § 125.94(d). Restoration measures, alone or in combination with reductions from other sources, would be designed to maintain fish and shellfish at a level comparable or substantially similar to that which would be achieved by compliance with the rule's performance standards or with BTA on a site-specific basis.

One commenter, Riverkeeper, Inc., has complained that restoration measures are "wholly unrelated" to intake structure technologies and therefore cannot be BTA. Riverkeeper August 2002 Comments 1.76, p. 48. But EPA, in its discretion as the expert agency, has the right to accept mitigation or restoration measures instead of intake structure modifications, particularly given the site-specific nature of intake designs and their effect on the surrounding environment.

Moreover, Congress is firmly in favor of habitat restoration, including wetlands restoration. Many statutes passed by Congress over the past 30 years show that Congress' intent is to encourage the preservation, creation, restoration, and enhancement of wetlands. In particular, the U.S. Army Corps of Engineers issues nationwide permits under § 404 of the Clean Water Act for activities that cause only "minimal" adverse effects on the environment. "General Condition 19" says that "½-acre of created wetlands can be used to reduce the impacts of a ½-acre loss of wetlands to the minimum impact level in order to meet the minimal impact requirement associated with NWPs." 67 Fed. Reg. 2,092-93 (Jan. 15, 2002). This mitigation is authorized by § 404(e) of the Clean Water Act, 33 U.S.C. 1344(e), which was enacted at the same time as § 316(b). EPA would be inconsistent with § 404(e) if it were to prohibit wetlands restoration under § 316(b) to "minimize" adverse environmental impact, even while the Corps is using it under § 404(e) to ensure "minimal" adverse environmental effects.

Congress has consistently promoted creation and restoration of wetlands in a wide variety of statutes. The Water Resources Development Act of 1976 funds Corps of Engineers projects, including the creation of wetlands where the benefits justify the costs. 33 U.S.C. 59m, 426, 547a, 577, 579, 701e, 702a-12. The Estuary Restoration Act establishes an Estuary Habitat Restoration Council, which is charged with developing a national restoration strategy with a goal of restoring 1,000,000 acres of habitat by 2010.

The Magnuson Stevens Fishery Conservation and Management Act and the National Marine Fishery Service (NMFS) regulations require Regional Fishery Management Councils to "prevent, mitigate, or minimize any adverse effects from fishing." 50 C.F.R. 600.815(a)(2)(ii). If appropriate, "habitat creation may be a means of compensating for lost or degraded habitat." 67 Fed. Reg. 2,356 (Jan. 17, 2002).

The North American Wetlands Conservation Act provides that "wetland ecosystems provide essential and significant habitat for fish, shellfish, and other wildlife of commercial, recreational, scientific, and aesthetic values." 16 U.S.C. § 4401(a)(1) & (2) (1989). The Migratory Bird Conservation Act provided $200,000,000 to prevent loss of wetlands and other waterfowl habitat essential to the preservation of waterfowl. See 16 U.S.C. § 715-3k (1929). The Coastal Wetlands Planning, Protection and Restoration Act aims to protect, create, or enhance wetlands. 16 U.S.C. §§ 3951, 3956 (1990). So does the Coastal Zone Management Act, 16 U.S.C. § 1452.

Congress' enthusiasm for wetlands extends to the transportation laws as well. The Intermodal Surface Transportation Efficiency Act of 1991 authorized National Highway System funds to be used for wetlands mitigation efforts. 23 U.S.C. § 1006(b). The Transportation Equity Act for the 21st Century, 23 U.S.C. §§ 103(b)(6)(M), 133(b)(11) (Supp. V. 1999), clarified Congress' desire to favor wetland mitigation banking to offset adverse environmental impacts. And the Endangered Species Act allows restoration projects. In Southwest Center for Biological Diversity v. U.S. Bureau of Reclamation, 143 F. 3d 515 (9th Cir. 1998), procuring, restoring, and protecting an alternative nesting habitat was allowed to meet the threshold of "no adverse effect" on a species' habitat. Id. at 524. Even the National Environmental Policy Act (NEPA), though essentially a procedural statute, obligates EPA to improve its programs so as to enhance the quality of renewable resources. 42 U.S.C. § 4331(b). Incorporating restoration and enhancement of wetlands into its § 316(b) program would help fulfill this obligation.

EPA Response

For a discussion of EPA's authority to include restoration measures in the final rule, see the preamble to the final rule.

The final rule permits both "in-kind" restoration measures (those that address organisms impinged and entrained by the cooling water intake structure) and "out-of-kind" restoration measures (those that address organisms other than those impinged and entrained by the cooling water intake structure). The final rule also permits restoration measures to be used either in lieu of or as a supplement to design and construction technologies and/or operational measures. All restoration measures must adhere to the requirements for restoration described in the final rule, including those in sections 125.94 and 125.95.

For a discussion of the extent to which restoration measures are voluntary, see EPA's response to comment 316bEFR.060.022.

Subject Matter Code 11.0

Role of Restoration

EPA's Approach to Restoration Is Justified by Successful Precedents

It is not surprising that many NPDES permitting authorities have accepted restoration measures such as hatcheries, fish ladders, wetlands creation or restoration, and other types of habitat enhancements in fulfillment of § 316(b) requirements. Many restoration projects implemented under state § 316(b) rules have been very successful. Exelon's Quad Cities Station has stocked walleye and hybrid striped bass in the Upper Mississippi River since 1984. This program has produced over 4 million game fish fingerlings. Presently the program's production goals are 175,000 walleye fingerlings (2-5 inches in length) and 5,000 yearling hybrid striped bass (8-9 inches in length) per year (LaJeone 2003). The program uses native Mississippi River walleye as breeding stock. LaJeone and Pitlo 1989. Biological monitoring and trending of standing crop estimates in the Mississippi River pools stocked by Exelon have demonstrated a 30% recruitment in certain game species as a result of these stocking efforts. This project has strong support from the Illinois and Iowa Departments of Natural Resources.

Other successful § 316(b) restoration projects include the following:

- Chalk Point Station: Over 3.4 million striped bass were produced and released in the Chesapeake Bay watershed. Once the striped bass stocks rebounded, at the request of regulators the hatchery raised other species, including American shad, yellow perch, and sturgeon.

- Salem Station: The restoration projects undertaken at Salem are innovative and extensive. Through the Salem Estuary Enhancement Program, PSEG has: (1) restored and/or preserved more than 20,000 acres (32 square miles) of wetlands; (2) constructed eight fish ladders to help river herring and other species migrate over barriers and made plans to build four more; (3) supported artificial reef programs in both New Jersey and Delaware; and (4) conducted extensive biological monitoring that has greatly increased scientific knowledge about the estuary's ecosystem. <FN 17>

- Crystal River Energy Complex: A successful multispecies marine hatchery is being operated at the Crystal River site to culture and release twelve selected important organisms. The facility has released over 1.7 million fingerlings and 4 million larvae of red drum, spotted seatrout, pink shrimp, striped mullet, silver perch, and stone crab. The remaining targeted species will be phased in on a rotating basis as culture techniques are developed.

- John Sevier Station: Between 1982 and 1995, over 5 million hatchery-reared walleye, saugeye, and paddlefish fingerlings and over 1.5 million saugeye fry were stocked in the Cherokee Reservoir (below the plant) as mitigation for organisms lost to the cooling water intake structure. Throughout this period, paddlefish numbers in Cherokee continued to increase, and survival of the stocked fish was good. Saugeye (a walleye-sauger hybrid, selected by the Tennessee Wildlife Resources Agency) demonstrated good-to-excellent growth and survival, and a sport fishery was established. Stocked walleye also survived and grew to catchable size in Cherokee, and thereby a fishery also was established for that species. In 1995, the Station provided the Tennessee Wildlife Resources Agency

(TWRA) with five new rearing ponds to integrate into its fish propagation, stocking, and management programs and in which to propagate appropriate fish species for introduction into the Cherokee Reservoir and the Holston River (on which the plant is located). TWRA has managed and will continue to manage the rearing facility and stocking programs as it sees fit.

- Contra Costa and Pittsburg Stations: Mitigation activities at these stations included restoration of tidal flow by creating dike openings along the Sacramento River and the creation of additional tidal marsh zones.

In addition to these successful § 316(b)-specific projects, power companies have conducted many water-related restoration measures unrelated to § 316(b) compliance. For example, at Reliant Energy's Cedar Bayou Station, aquaculture ponds are used for growing redfish and to propagate wetland plants used for marsh restoration projects. Also, State resource agencies such as the Texas Parks and Wildlife Department and conservation groups such as the Coastal Conservation Association routinely catch fish from the plant's cooling pond to use as brood stock in their hatcheries.

Southern California Edison (SCE) operates an extensive mitigation project in connection with the San Onofre Station. SCE has provided $4.7 million for a white sea bass hatchery, which began operation in October 1996. See SCE, "SONGS Mitigation," available at http://www.sce.com/sc3/006_about_sce/006b_generation/006b1_songs/006b1c_env_prot/006b1c3_songs_miti/default.htm. When operating at design capacity, the hatchery is expected to produce 300,000 juvenile white sea bass per year. SCE also plans to construct a 150-acre artificial reef for the mitigation of kelp impacts. Id.

EPRI's new report on enhancement strategies describes many other successful restoration projects (EPRI 2003).

Subject Matter Code 11.0

Role of Restoration

Design and Management of Restoration Measures

EPA is considering whether to add requirements for the use of restoration measures. The three principal requirements EPA seeks comment on are the following:

- Documentation of sources and magnitude of uncertainty in expected restoration project performance,

- Creation and implementation of an adaptive management plan, and

- Use of an independent peer review to evaluate restoration proposals.

68 Fed. Reg. 13,542 col. 1.

Uncertainty. Uncertainty in project performance is related to natural variations both in the restoration project and in the ecosystem that is affected by the restoration project. It is recognized that this uncertainty exists and is inevitable. This uncertainty should be taken into account in determining the feasibility of a project, but the methods used to account for uncertainty should not impose an unreasonable burden.

Prescribing in detail how this uncertainty must be addressed would be needlessly inflexible and add an unnecessary burden to the process. We note, however, that the degree of uncertainty can be lessened by looking at biomass or at trophic levels rather than at specific species (especially when looking at lower trophic levels, e.g., forage fish). This is done when performing natural resource damage assessments and can result in significantly greater certainty that a given level of benefits will occur than can be obtained if individual species are examined.<FN 18>

Peer Review. EPA's discussion of the Independent Peer Review process is ambiguous. From the discussion, it appears that EPA is proposing to require permittees to consult with federal and state resource agencies and select a panel of multidisciplinary private individuals who would review the restoration project plan before submittal. Selection of reviewers and alternates, coordination of review timeframes, and consultation with federal and state resources agencies all would add expense and delay to the Comprehensive Demonstration Study, and the benefits are questionable.

The addition of all the proposed practices for restoration projects will require additional time and effort in the early stages of the process when the Comprehensive Demonstration Study is prepared. EPA should consider this burden when determining the amount of time needed to prepare the Study.

On the other hand, the three suggested approaches to assessing and managing restoration measures may be useful, depending on the nature and complexity of the proposed measure. In general, the formality and level of detail for each of the proposed requirements should be tailored to the specific project. For example, the application of these factors to a standard hatchery operation should be different from their application to a wetlands restoration project. For the hatchery, the magnitude of uncertainty will be much less than for wetlands restoration, and therefore the documentation and scrutiny of the uncertainty factors need not be extensive. Also, the hatchery project may not need a formal adaptive management plan. Instead, the hatchery could simply report its annual production numbers to the permitting authority.

For a wetlands restoration project, on the other hand, uncertainty analysis, adaptive management, and peer review may well require a higher level of effort. To manage and address the uncertainty of a restoration project, an adaptive management plan that calls for regular assessment of the restoration's progress may be appropriate. Peer review for a hatchery project could be handled informally by a local fish and wildlife manager or other official as part of the project's approval process. In contrast, for a large wetlands restoration project, it may be critical to the overall success of the project to have several peer reviewers from different disciplines provide written comments on the restoration plan, and then continue to review the data during the plan's implementation.

On the other hand, some types of restoration may be well established on the waterbody in question and not require intensive scrutiny. For example, if the restoration involves building a fish ladder on a river where several other fish ladders already have been installed and have proven useful in expanding habitat uses, then a lesser degree of scrutiny may be appropriate for the new ladder project.

In short, while UWAG agrees that all three factors (uncertainty analysis, adaptive management, and peer review) may be useful for designing, assessing, and managing restoration projects, each factor should be tailored to the individual project. Therefore, the rule should not require these factors or prescribe the details, but it should empower and encourage permitting authorities to apply them as necessary to ensure a successful project.

Footnotes

18 This point was made by Dr. Deborah French-McCay in her comments on behalf of PG&E NEG submitted in August 2002. See PG&E National Energy Group August 2002 Comments 1.60 Appendix XVII.

EPA Response

EPA acknowledges the commenter's assessment that uncertainty analysis, adaptive management, and peer review may be useful for designing, assessing and managing restoration measures. In section 125.95 of the final rule, EPA has included provisions relating to uncertainty analysis, adaptive management, and peer review. EPA believes the implementation of these requirements, along with the other requirements described in the final rule, including those in sections 125.94 and 125.95, will reduce the uncertainty associated with restoration measures and enhance their overall performance (see the discussion of uncertainties associated with restoration measures at 67 FR 17146-17148 and the discussion of the roles of uncertainty analysis, peer review and adaptive management at 68 FR 13541-13543). EPA believes the requirements in the final rule allow permittees and permitting authorities the flexibility to conduct analyses appropriate to the nature of the restoration measure under consideration. The final rule also contains provisions that EPA believes will provide facilities with sufficient time to develop the studies associated with restoration measures.

For additional discussion of the use of restoration measures to address aquatic organism species other than those impinged and entrained by a cooling water intake structure, see EPA's response to comment 316bEFR.099.034.

Regional Benefits Approach

An important part of the NODA, Section X, is devoted to EPA's reassessment of the estimated benefits of the rule. This section makes clear that commenters raised many questions and concerns about EPA's original estimates of both use and non-use values. In many respects, EPA has made commendable efforts to address those questions and concerns. On some points, the refinements EPA has made are clear improvements. But EPA leaves some key questions unresolved, and its revised analyses – particularly its estimate of non-use values – remain seriously flawed.

What EPA Did to Estimate Benefits

The NODA describes EPA's new regional methodology for estimating use and non-use benefits and presents use values it calculated for two regions (the North Atlantic Region and the Northern California Region) and non-use values it calculated for one region (the North Atlantic Regions). See 68 Fed. Reg. 13,543-80. EPA very generally describes the data sources it is considering using and the types of methods it may apply for another six regions, but it provides insufficient details to allow UWAG a meaningful opportunity to comment on the appropriateness of any such future analyses. See, e.g., 68 Fed. Reg. 13, 546-47, 13,575-76.

EPA's regional methodology uses species groupings to aggregate impingement and entrainment data from a subset of plants within the region for which EPA had such data. EPA then used the flow-weighted data to extrapolate losses for other facilities within the region, grouped by waterbody type. As with its previous methods, EPA assumes, but does not test, the representativeness of its data for other plants within the region.

EPA then converted annual impingement and entrainment losses for each species group into (1) Age-1 equivalents, (2) fishery yield, and (3) biomass production foregone. Each of these conversions requires EPA to use biological data or make assumptions that heavily influence the results. For example, in estimating production foregone, EPA used a revised trophic transfer efficiency that is eight times higher than the value it previously used. For purposes of this analysis, EPA assumed that no entrainment survival occurs and that compensatory mechanisms do not operate to offset losses in any way. See 68 Fed. Reg. 13,543-46, 13,552-54, 13,559-63.

EPA then estimated commercial and recreational use values for losses within the two regions. For both categories of use values, EPA made some changes in the methods it used. See 68 Fed. Reg. 13,546-48, 13554-58, 13,563-67.

EPA also estimated non-use values for the North Atlantic region, using a new benefits transfer approach that uses the results of a stated preference survey assessing the preferences for different kinds of aquatic habitat (wetlands and submerged aquatic vegetation (SAV) (i.e., eelgrass)) held by a study population of households near the Peconic Estuary in western Long Island. EPA used that study to derive a per-household value-per-acre of wetland or eelgrass. The Agency then estimated the amount of wetland and eelgrass habitat needed to produce the same number of organisms as it estimates were lost to impingement and entrainment within the region. Lacking any data on the productivity of wetlands for the species in question, EPA used abundance data collected for certain species near two power plants in the region.

Notably, the NODA does not mention the Habitat Replacement Cost (HRC) or Societal Revealed Preference (SRP) approaches for estimating non-use benefits. It also omits any response to objections raised by UWAG and many others opposed to EPA's wholly inappropriate use of those methods for benefits estimation. As UWAG's comments explained, those methods, even if applied perfectly, are capable only of estimating costs, not benefits. See UWAG August 2002 Comments, at 65-66 and Appendix 9; Stavins April 21, 2003 Comments (DCN 5-1.1).

If EPA's decision not to discuss these methods in the NODA means that it has decided to drop all use of those methods, then UWAG agrees wholeheartedly. We believe, however, that in the final rule, EPA should go further by recommending against any use of those methods for benefits estimation.

EPA Response

This comment is simply a general opinion about EPA's analysis without any specifics. Therefore, no specific responses from EPA is required. EPA notes that the HRC and SRP approaches were not used to estimate benefits for the final analysis for the 316b Phase 2 rule. However, EPA believes that studies such as these provide a potentially useful approach. For information on the HRC, please see the document entitled "Habitat-based Replacement Cost Method" (DCN # 6-1003) and responses to Comments 316bEFR.005.035. For additional information on the SRP, please see Part B of the Regional Analysis Document (DCN # 6-0003) and response to Comment 316bEFR.005.006. For a discussion of nonuse analyses, see response to Comment 316bEFR.307.061 on the Peconic habitat-based study, and responses to Comment 316bEFR.338.046 and Comment 316bEFR.338.047 on nonuse.

Regional Benefits Approach

A number of experts have reviewed some or all of the biological data and assumptions EPA used to estimate the extent of impingement and entrainment losses caused by power plants and the value of those losses. They include Drs. Larry Barnthouse and Webster Van Winkle, on behalf of EPRI; Gregory Seegert, M.S., on behalf of UWAG; and Dr. Douglas Heimbuch, on behalf of PSEG. Among the conclusions evident from their reviews are these:

- The regional approach, while an improvement over EPA's previous approach, is unlikely to compensate for site-specific differences that determine the nature and extent of impingement and entrainment losses;

- EPA's failure to account in any way for entrainment survival and compensation, both of which are known to occur, means that its estimates will overstate losses of Age-1 fish, yield, and production foregone;

- EPA made erroneous assumptions about the age of impinged organisms, many of which are young of year (YOY or Age-0 fish), rather than Age-1 or older, as EPA has assumed. This error also is likely to have resulted in a substantial overestimate of losses;

- EPA overestimated the weights of fish and larvae, again inflating loss estimates;

- EPA's new net trophic transfer rate is too high, which will result in overstatement of production foregone or any other summary metric for which it is used; and

- EPA incorrectly assumed that it could use species abundance as a proxy for wetlands productivity, resulting in vast overestimates of the amount of habitat needed to replace organisms lost to impingement and entrainment.

EPA Response

It was not the aim of EPA's analysis to develop facility-specific estimates of I&E for the over 550 facilities inscope of the Phase II rule. Rather, EPA used available I&E data to develop regional-scale estimates of I&E, which were then summed to obtain an estimate of the magnitude of I&E nationwide. Facilities will have an ample opportunity to collect facility-specific I&E data for their permit applications.

See Chapter A7 of the Phase II Regional Study Document (DCN #6-0003)for a discussion of EPA's conclusions about entrainment survival.

See response to Comment 316bEFR.025.015 for a discussion of EPA's assumptions about compensation.

Few facility studies provide information on the age distribution of impinged fish. See response to Comment 316bEFR.029.105 for a discussion of EPA's assumptions about the age of impinged fish for the purposes of the national benefits analysis.

The commenter provides no evidence to support his conclusion that EPA overestimated weights of fish and larvae. In fact, EPA consulted with local fisheries experts and conducted as thorough a review of the biological literature as possible to obtain the best available life history data. In addition, whenever possible, EPA used life history data recommended by local technical advisory committees and provided in current facility studies (e.g., EPA used the same life history data used by Salem and by Brayton Point in their recent permit renewal applications).

EPA's final analysis used a trophic transfer efficiency of 10% based on Pauly and Christensen (1995) (see Docket #6-1004).

EPA disagrees with the commenter that it is necessarily incorrect to assume that species abundance is a proxy for productivity. Please see response to Comment 316bEFR.029.113.

Commercial Fishing Benefits

EPA has made some clear improvements in its analytical approach (for example, by eliminating multi-market producer surplus) and some changes that appear likely to have improved its analysis but as to which further details on implementation would be helpful (e.g., using the regional aggregation approach, assuming proportionality between stock and harvest (rather than assuming that 100% of all fish spared by CWIS improvements would be harvested), <FN 19> and accounting for benefit timing with discounting);

Footnotes

19 This is not to suggest, however, that EPA has even considered, much less shown, that from a biological point of view reduction in impingement and entrainment losses will result in a proportional increase in harvest. Rather, it is simply to suggest that EPA's assumption in the NODA, while biologicaly unsupported, is less wrong than its original assumption

EPA Response

The commenter is incorrect that EPA assumes that 100% of all fish spared by CWIS improvements would be harvested.

The fate of fish spared by CWIS improvements is determined in the I&E model, as described in Chapter A5 of the Regional Study Document (DCN #6-0003).

For a discussion of the 98% of the saved fish that are not valued in the analysis because they are not harvested, please see EPA's response to comment #316bEFR.336.009.

As suggested by this commenter, improved documentation on these matters has been provided in the Regional Study Document and in the EBA for the final Section 316(b) Phase II rule.

Regional Benefits Approach

EPA intends to take a regional approach to benefits estimation, aggregating data within regions by species and again by waterbody type. In concept, this approach has the potential to offer better resolution both biologically and economically. On the biological side, however, there is no evidence that EPA has made any attempt to test its apparent assumption that the approach will produce more realistic impingement and entrainment values not only for facilities for which it has data, but for facilities for which it does not. Given the site-specific factors that drive entrainment and impingement, we believe EPA has an obligation to test its assumption.

EPA Response

While the commenter argues that EPA should test its assumption that I&E data can be extrapolated among like facilities in the same region, he provides no suggestions about how this could be done. Nevertheless, EPA believes that its approach was reasonable given the goals of its analysis. Please see response to Comment 316bEFR.041.041.

Assumptions about I&E survival

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

Failure to Account for Entrainment Survival and Compensation in Estimating Losses

Above we addressed why entrainment survival studies should be used at individual facilities to determine compliance with the entrainment performance standard. A related issue is whether entrainment survival estimates should be used in EPA's assessment of regional benefits of the new rule.

As Dr. Van Winkle points out,<FN 20> EPA's assumption of zero entrainment survival (along with its assumption of zero compensatory effect) is unsupportable. Even if it might be defensible to assume zero percent survivability at an individual facility where there are no reliable data, it is not defensible for regional or nationwide costs and benefits, for which zero survivability is clearly not true. What is needed, says Dr. Van Winkle, is a sensitivity analysis that illustrates the effect on estimated regional and national economic benefits of representing both the reality and the uncertainty of what is known about entrainment survival.

Footnotes

20 See Van Winkle Appendix to EPRI June 2003 Comments.

EPA Response

Please see the response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule. Please see the chapter, Entrainment Survival, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule.

Fish Population Modeling

Also, EPA continues to make no adjustment for the effects of compensation on Age-1 equivalents, production foregone, or yield. As Drs. Barnthouse and Van Winkle point out, and as UWAG has shown in its previous comments,<FN 21> there is no credible scientific doubt that compensation operates in aquatic populations. EPA's failure to make any adjustment for compensation is unreasonable, especially in light of EPA's willingness to make extravagant and wholly unfounded assumptions with respect to parameters it used for non-use benefit valuation, which we discuss below.

EPA methods: age 1 equiv, yield, prod foregone

EPA relaxes its previous assumption that all impinged fish are Age-1 and assumes instead that “the ages of impinged fish are one and older and that they follow an age distribution that is implied by the associated survival rates.” 68 Fed. Reg. 13,546 col. 2. <FN 22> EPA says that data collected at the Salem and Millstone facilities indicate that individuals older than Age-1 were collected and that EPA’s assumption that all impinged fish were Age-1 resulted in an underestimate. Id. As EPA notes, the adjustments it made increased the estimates of forgone yield by factors ranging from three to ten, depending on species-specific age survival rates. Id. This is so because older fish weigh more and thus contribute more biomass and because Age-1 and older fish have a higher probability of surviving to reproductive age.

EPA’s assumptions about the age distribution of impinged fish are in error and as a result greatly overstate the expected forgone yield due to impingement. As the Barnthouse report points out, studies of the ages of impinged fish have consistently shown the following:

- Most impinged fish are younger than one year of age, not one year old or older as assumed by EPA.

- The vulnerability of most species to impingement decreases with age, so that EPA’s use of survival rates to estimate the age composition of impinged fish usually overstates the relative contributions of older fish to impingement losses.

Using data from Salem for weakfish, striped bass, and white perch, Dr. Barnthouse shows that estimates using the NODA assumptions are inflated compared to estimates calculated using actual age distributions. For weakfish, the NODA value is inflated by a factor of 70 times over the value calculated using actual age distributions. For striped bass and weakfish, assuming that all impinged fish are Age-1 likewise greatly overestimates foregone yield. Only for white perch does the Age-1 assumption underestimate foregone yield, and the difference is only about 20%. Dr. Barnthouse says that the age distribution of fish impinged at Salem is probably typical of estuarine facilities.

The reasons for EPA’s overestimates are not hard to discern. A large fraction of the species impinged in high numbers at Salem and other estuarine facilities are anadromous and spend most of their life cycles outside the estuary. Many of the species included in EPA’s North Atlantic Region case study are anadromous, such as American shad, Atlantic menhaden, blueback herring, striped bass, weakfish, and winter flounder. For all these species, EPA’s original approach to calculating foregone yield due to impingement probably would have overstated the potential reduction in harvest. EPA’s revised approach in the NODA would overstate the reduction even more.

Relatively few of the species addressed in EPA’s case studies <FN 23> (for example, white perch and bay anchovy) reside in the estuary throughout their life cycles and are vulnerable to impingement at all stages. These are the only species for which EPA’s original approach might have caused an underestimation of foregone fishery yield due to impingement. The revised approach would still overestimate foregone yield, because it assumes that all impinged fish are at least one year old.

It is impossible to tell how much EPA's estimates of production foregone are affected by this error, because EPA has provided no documentation of the method used to calculate production foregone for harvested species. Dr. Barnthouse points out that, although Chapter 5 of EPA's original case study report says that the production foregone model was applied only to forage species, both the original case study and the new regional case studies documented in the NODA include estimates of production foregone for impinged fish belonging to harvested species. If the same assumptions used to calculate yield foregone for these species were also used to calculate production foregone, the production foregone estimates would be similarly biased.

As Mr. Seegert documents in Appendix A to these comments, it is clear that in freshwater rivers, as well as in lakes and reservoirs, impingement is typically dominated by YOY (young-of-year) fish. Mr. Seegert examined fewer estuarine studies, but dominance of YOYs at such sites also appears to be typical. At Great Lakes plants, the age distribution of impinged fish appears to vary considerably depending on the plant in question. However, even at sites where YOYs do not predominate, EPA's assumption that all fish impinged will be Age-1 and older is still erroneous. At such sites, EPA production foregone estimates will be "less wrong" than at sites where YOYs predominate, but still wrong.

In the NODA, EPA says it will assume that the ages of impinged fish will be Age-1 and older. Clearly, this approach is not supported by the data. Based on the studies reviewed in the Seegert report, it would be appropriate for EPA to assume that 80-90% of the fish impinged at sites situated on rivers, lakes, and reservoirs are YOYs, 10-20% are Age-1, and a very small percentage, no more than 1-2%, would be Age-2 and older.

For the Great Lakes, especially Lakes Michigan and Erie, the changes in species composition that have occurred over the past 20-30 years are great enough to make any assumption tenuous. Nonetheless, it is clear that impingement in the Great Lakes includes significant percentages of YOYs. EPA cannot ignore this documented evidence and should adjust its estimates accordingly.

Footnotes

22 We cannot tell what EPA means when it says that it will assume that the ages of impinged organisms "follow an age distribution that is implied by the associated survival rates." If it means that EPA will assume that impinged fish at facilities for which it has no data will survive or die at the same rate as impinged fish at facilities for which it has data, then EPA would seem to be omitting any consideration of the extent to which fish protection technologies or other site-specific factors may affect survival.

23 EPA is proposing to combine similar species into family groups or groups used by NMFS for landings data (68 Fed. Reg. 13,545). Species should be combined according to their taxonomic classification and not by their common names. For example, two widespread species whos distributions overlap are the trout-perch and the logperch. The trout-perch (Percopis omiscomaycus) is in the Order Percopsiformes, which is unrelated to the logperch's (Percina caprodes) Order Perciformes. These two species were erroneously combined in at least one of the case studies.

See Appendix A

See Barnthouse report (UWAG. Aug 2002).

EPA Response

The commenter expresses concern EPA's assumptions about the age distributions of impinged fish. For its analysis for the final rule, EPA revised the methods used to assume age distributions of impinged fish in a manner that acknowledges that YOY may be predominant among impinged fishes, as described in EPA’s response to Comment 316bEFR.029.105.

Erroneously High Weights of Fish and Larvae

Although the NODA does not provide enough data to allow duplication of EPA's equivalent loss calculations, an initial analysis conducted by Lawler, Matusky and Skelly Engineers (LMS) for PGE/NEG was able to identify unrealistically high weights that EPA appears to have used for eggs and larvae.

The production foregone values for tautog in the North Atlantic region (NODA Table X-7) appear totally inconsistent with the number of Equivalent Age-1 fish and estimated yield foregone. By assuming that most (~80%) of the entrainment was eggs, LMS was able to get Age-1 numbers comparable to EPA's for Brayton Point from the case study. When LMS ran the production foregone model for this species, it produced a result of over 12 million pounds, which appears unreasonably high. LMS then looked at the life history values used for tautog (Case Study Table F1-13) and found it assumed that each egg weighed ~1 gram (0.00022 lbs) and each larva weighed ~10 grams (0.022 lbs). By comparison, a 3-inch (75-mm) striped bass weighs just over 5 grams.

To see if these high weights might be the reason for the high EPA production foregone values, LMS re-ran the production foregone model using more reasonable weights for eggs and larvae. This single change lowered the production foregone for tautog from more than 12 million pounds to less than 2,500 pounds. Clearly the production foregone model is very sensitive to values used for weight in the early life stages when mortality is high.

Based on these results, LMS looked at other weights used in the Brayton Point case study. It found that EPA had used unreasonably high weights for eggs or larvae, or both, for many other species. For example, weakfish larvae were assumed to weigh 30 grams each, and winter flounder larvae were assumed to weigh 2 - 10 grams each. For many other species, larvae were assumed to weigh only 0.5 to 1 gram each, but even these values are far too high. Larval fish are most typically in the range of hundredths of grams each.

EPA did not use reasonable weight values in these calculations. As a result, the production foregone values are likely to be substantial overestimates for many species. Unfortunately, without more information from EPA, it is difficult to evaluate further the estimates presented in the NODA.

EPA Response

Please see EPA's response to Comment 316bEFR.305.003 regarding its production foregone calculations for the final rule.

Comment ID 316bEFR.307.056

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

Subject Matter Code 10.01.02.01

EPA methods: age 1 equiv, yield, prod foregone

Use of Inappropriate Net Trophic Transfer Rate

For the proposed rule, EPA used a trophic transfer model to estimate the yield of harvested species foregone due to entrainment and impingement of forage species.<FN 24> EPA's model assumed that 20% of forage species biomass is directly consumed by harvested species and that the transfer efficiency for this direct pathway is 9%. EPA assumed that the remaining 80% of forage fish are consumed by intermediate predators, which are then consumed by harvested species, with a transfer efficiency for this indirect pathway of 0.9%. These values imply a net transfer efficiency, considering both direct and indirect pathways, of 2.5%.

EPA now says that it is using a different net trophic transfer efficiency of 20%, "based on an additional review of the scientific literature." 68 Fed. Reg. 13,546 col. 1 (citing Reed et al. (1994)). Dr. Barnthouse has concluded that EPA's new, far higher net trophic transfer rate is unsupported for two reasons: (1) it is derived from an un-refereed source and is at the high end of the range of accepted values and (2) it assumes that 100% of forage fish biomass is consumed by economically valuable species.<FN 25> See Barnthouse Appendix to EPRI June 2003 comments. Dr. Barnthouse concludes, based on review of more recent, authoritative literature, that a net trophic transfer rate of 10% would be more reasonable, yet still quite conservative.

Although EPA says that the effect of the change in trophic transfer assumptions is insignificant because foregone yield attributable to losses of forage fish is only a small component of the total foregone yield due to entrainment and impingement, it provides no support to verify this claim. Given that the change in assumptions results in an eight-fold increase in all estimates of yield foregone due to losses of forage species, the difference might well be significant for facilities at which entrainment and impingement losses consist primarily of forage species.

Footnotes

24 While EPA says that it performed these trophic transfer calculations for purposes of the new estimated losses presented in the NODA it is less than clear about the results. We have been unable to find clear evidence of how those calculations were applied and what they yielded. Equally important, assuming the calculations were done and done correctly, it is not clear that they were used for the benefits estimate. If the calculations were done and are reflected in results for commercial and recreationally important fish, then assigning a non-use value to forage species would result in at least some double-counting.

25 Although EPA does say what percentage of biomass it assumes is consumed directly by top harvested species, it identifies only one trophic transfer rate (20%), which is the same single rate discussed in Reed et al. Had EPA assumed that different percentages were consumed via direct and indirect pathways, the collective net rate would have been different from 20%. Thus, Dr. Barnthouse concludes that EPA must have assumed that 100% of the forage biomass is consumed directly by the harvested species.

EPA Response

Please see EPA's response to Comment 316bEFR.305.004 regarding its trophic transfer analysis for the final rule.

Use of Replacement Costs (HRC and hatchery-based)

EPA's Erroneous Use of Abundance as a Proxy for Habitat Productivity

In addition to the erroneous biological assumptions detailed above, which undercut EPA's quantification of impingement and entrainment losses, EPA's method for estimating non-use benefits rests on other major biological errors that result in vast overestimates of the amount of habitat needed to replace those losses. An analysis prepared by ASA for PGE/NEG <FN 26> details these errors. By pointing out these errors, UWAG does not mean to suggest that it endorses the overall method EPA applied for non-use valuation, or that that method is salvageable if EPA corrects these errors. Rather, we raise them because they provide further evidence, if any is needed, that EPA's non-use value estimates are unreliable.

One of EPA's gravest errors is its assumption that limited surveys of species abundance in comparable habitat around two power plants in the region can be used as a legitimate proxy for the productivity of an acre of wetlands. As the ASA report shows, they cannot. EPA has made no effort to establish that habitat in that area can serve as a reference point for gauging the maximum, or even the minimum, productivity of an acre of wetland or eelgrass for any given species. In fact, it is highly likely that they cannot, given other conditions that are likely to affect the presence and abundance of organisms (most critically winter flounder, which the NODA (13,569 col. 1) says dominated the acreage determination) in that habitat.

Footnotes

26 The ASA report is appended to PGE/NGE's June 2003 comments

EPA Response

In regards to the commenter's assertion that it is incorrect to assume that species abundance is a proxy for productivity, please see EPA's response to Comment 316bEFR.029.113.

With respect to habitat restoration alternatives, EPA met with and received information from local experts with knowledge about which restoration alternatives would most efficiently address the majority of species being lost to I&E in the vicinity of the facilities. EPA believes that the information was sufficiently site-specific, and sufficiently reviewed by local experts to include the most relevant restoration alternatives that could address the majority of species in a practical, cost-effective approach. EPA deliberately avoided including highly experimental or uncertain restorations for species that had no obvious and practical restoration opportunities.

For additional information on the HRC method, please refer to the response to comment 316bEFR.005.053 and the document entitled "Habitat-based Replacement Cost Method" (DCN 6-1003).

Benefit Estimation Methodology

The attached report by Triangle Economic Research (TER), entitled "Comments on Benefit Estimation in EPA's Proposed Phase II 316(b) Rule as Summarized in the Notice of Data Availability" (2003) (Appendix B to these comments), addresses the revised estimate of benefits that EPA announces in the NODA. EPA has made major changes to the benefits analysis, including the following:

- Eliminating multi-market producer surplus;

- Replacing the case study-based benefit extrapolation with a regional approach;

- Accounting for the impact of benefit timing through discounting;

- Correcting the assumption that all fish spared due to CWIS modifications are harvested by recreational or commercial anglers;

- Exploring new options for calculating commercial benefits;

- Using regional random utility models (RUMs) to estimate recreational fishing benefits; and

- Developing a revised analysis of non-use benefits.

TER's review indicates that EPA has made improvements and potential improvements in estimating the amount and timing of benefits. However, while EPA has potentially corrected some problems, it has introduced new ones. Consequently, TER concludes that the resulting benefit estimates, especially the non-use benefits, are vastly overstated.

A comparison of benefit sources across the two analyses demonstrates the magnitude of the problem. In EPA's original benefit-cost analysis, benefit estimates for the Salem facility along the Delaware Estuary (comparable to the North Atlantic region) of approximately $23.2 million were distributed approximately 64% to commercial, 24% to recreation, and 12% to non-use. In the NODA, EPA estimates that the total benefits from reduction in entrainment and impingement for the North Atlantic region is $79 million per year. Of this, $0.3 million (0.4%) is due to commercial benefits, $3.1 million (3.9%) is due to recreational benefits, and the remaining $75.6 million (95.7%) is from non-use value.

This dramatic shift in the apportionment of benefits across categories is remarkable, and in particular the movement of benefits from use categories to the non-use category is troubling. Moreover, TER reports that its ability to evaluate some of the significant issues is limited because, in many cases, EPA's intentions are only partially developed and not completely implemented.

(See Appendix B)

EPA Response

EPA agrees with the commenter that the revised benefits analysis presented in the NODA is an improvement over the benefits analysis presented at proposal. The commenter, however, states that non-use benefit estimates presented at the NODA are "vastly overstated." The comment concludes with the implication that, because the magnitude of total non-use values has increased from EPA's original analysis to the NODA analysis, that it cannot be correct. The Agency disagrees.

First, EPA's original analysis only considered a very small fraction of non-use values – those non-use values that accrue to users of the resource for species that have use values. In the revised analysis, EPA has included additional species that do not have use values, or that have only indirect use values, and has included a more reasonable population who are likely to hold these values.

EPA has responded to concerns regarding the Agency's non-use valuation methods presented in the NODA in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services.

For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis.
For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Second, the Agency points out that comparing the apportionment of benefits across use and non-use categories between the Delaware Estuary case study presented and proposal and the North Atlantic Region case study presented in the NODA is not appropriate because commercial and recreational fish losses are much greater in the Mid Atlantic region compared to the North Atlantic region (for detail see Section XII, Benefits Analysis, of the preamble for the final rule).

For the final Section 316(b) Phase II regulation, the Agency presented only a qualitative assessment of the benefits of the environmental protections at issue in the final 316(b) benefit cost analysis given the unavoidable uncertainties in estimating non-use benefits at the national level.

Commercial Fishing Benefits

EPA still bases benefit estimates for commercial fishing on the gross revenue of lost commercial catch. EPA is now considering a range of 0% to 40% of dockside value. This adjustment is significant, but EPA's methodology inappropriately characterizes the source and nature of societal benefits.

EPA's approach reflects the misconception that the effect of entrainment and impingement reductions can be approximated as some portion of increased dockside value. This notion is rooted in short-run production theory, which has no place in the analysis of benefits rising from entrainment and impingement reductions.

TER's investigation indicates that societal benefits from § 316(b) regulations under open markets exceed gains observed with market restrictions. Using the assumptions of unit price elasticity and open markets, TER estimates that societal gains from the elimination of entrainment and impingement in the North Atlantic region are $0.72 million, as opposed to the EPA estimate of $0.28 million.

EPA Response

The estimates presented by the commenter assume some level of decrease in price as a result of the increased supply of fish. EPA assumes that the magnitude of changes in the commercial fishing harvest will not be large enough to affect prices. Thus, no change in consumer surplus is expected.

For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits, including short run vs. long run issues, please see the response to comment 316bEFR.005.029.

Recreational Fishing Benefits

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

EPA plans to use region-specific random utility models (RUMs) with participation components to estimate losses to recreational fishing. Random utility models provide the best opportunity for correctly valuing increased catch hypothesized to result from impingement and entrainment reductions. However, unadjusted data from the surveys cited by EPA may reflect an upward bias in benefits estimates caused by the sampling procedure, because anglers lead to an upward bias in benefit estimates. Another concern is that EPA incorrectly measures the opportunity cost of time; this also will result in an overestimate of benefits.

EPA Response

The commenter argues that using unadjusted data from the surveys cited in the NODA (the National Marine Fisheries Service (NMFS) Marine Recreational Fishing Statistics Survey (DCN #6-3189) and from the Michigan Recreational Anglers survey conducted by Michigan Department of Natural Resources (MDNR) (DCN #6-3176)) may lead to an upward bias in recreational benefits estimates (see DCN #5-1008 and #5-1009 for details regarding EPA's recreational fishing analysis presented in the NODA). EPA believes that NMFS and MDNR have adequately corrected for sampling bias through long-established and tested survey and statistical methods. In addition, EPA does not believe that the Agency's analysis incorrectly calculates opportunity cost of time in the RUM models. If anything, EPA's measure of opportunity cost of time would result in downward bias in estimates for regions where income was reported for extremely small numbers of respondents. For regions where income was estimated using median household income from the U.S. census, it is impossible to determine the direction of bias, if any, because, without collecting primary data, there is no way to compare the median income of anglers to the median income of all households in the region. EPA has followed standard, generally-accepted methods of RUM modeling.

Valuing Forage Species (incl non-use and non-landed)

Whether non-use benefits should be included in a benefit-cost analysis is somewhat controversial. Currently contingent valuation (CV) is the most widely used technique for attempting to measure non-use values.

Citing difficulties with regulatory scheduling and resource requirements, EPA employs a benefits transfer approach for non-use valuation. This approach assesses respondents' values for habitats that play a significant role in the production of fish and shellfish and then estimates the quantity of this habitat that would be required to replace fish and shellfish lost to entrainment and impingement. EPA then combines this information with population data to produce what it hopes will be an indirect estimate of aggregate human values for fish and shellfish lost to entrainment and impingement.

EPA concludes that $76 million or 95.78% of the benefits from entrainment and impingement reduction in New England fisheries is attributable to non-use values. However, EPA's approach to assessing non-use values is entirely inadequate. In particular, the assumption that values for eelgrass and wetlands can be transformed into non-use values for fish is unfounded and rests on a string of unsupported, and unsupportable, assumptions. Not only did EPA assume that the value respondents placed on habitat could be translated into a value those same respondents would place on the well-being of a fish stock, it went further. In essence, EPA assumed that it could convert that derivative value into a value respondents would place on the well-being of individual fish, which is what the Agency seeks to value here. <FN 27>

Throughout this proceeding, EPA has refused categorically to make any attempt to consider the implications of individual losses at a higher, more meaningful level (which UWAG has suggested is the population level).<FN 28> Yet the survey EPA relied on, and all of the other surveys it suggests it may consider using, elicits responses about the values non-users place on broader, resource-wide endpoints.

But EPA has done no analysis from which it could link any reduction in impingement or entrainment to any increase in well-being or decrease in risk to a resource, instead of an individual fish. UWAG submits that, even if further efforts to estimate non-use benefits more reliably were worthwhile, such efforts could succeed only if EPA framed the questions so that responses were directed to the values relating to the resource, not to individual fish.

In short, the vast difference between the transfer study's hypothetical valuation scenario and the § 316(b) policy context cannot be overcome. EPA's attempt to overcome this disparity leads to the remarkable conclusion that over 90% of benefits due to § 316(b) regulations can be attributed to growth in the stock of forage fish. TER concludes, in contrast, that non-use values for the proposed regulation are likely negligible.

A report prepared for EPRI by Ivar Strand <FN 29> agrees in large part with the TER analysis. Dr. Strand concludes that EPA's use values for the North Atlantic Region are probably within an order of magnitude of the truth. For non-use (passive use) values, on the other hand, some major progress in the case studies has been made, but substantial questions remain. Dr. Strand identifies these questions:

- To obtain non-use values of North Atlantic fish and shellfish changes, EPA bases its dollar value of willingness to pay per wetland (or eelgrass) acre on Opaluch et al. (1998). In this study, the authors specifically state "we believe that the resource priorities or relative values of resources are more reliable than are the dollar estimates of values and recommend that relative values, rather than dollar values, be used in the process of selecting management actions" (Opaluch and Grigalunas (DCN-5-1292), at 5).

- In transforming the questionable value per acre of wetlands in the North Atlantic into a value per change in fish population, EPA goes through a process that relies on numerous unsupported judgments, resulting in fundamentally arbitrary and excessively large non-use values.

- In developing information for the Northern California region, EPA develops a "break-even" analysis that calculates the dollar amount of non-use values that will equate the costs of Northern California investment in closed-cycle cooling systems with total economic value. While this may provide useful information, it is not a substitute for a credible study of the non-use value of the uncaught recreational and commercial fish plus the forage fish losses from impingement and entrainment.

Footnotes

27 This criticism is equally true for the other studies EPA has found through its literature review. EPA says it is considering using these studies individually or collectively in some fashion as its non-use benefits assessment proceeds. See 68 Fed. Reg. 13,575-76; DCN 5-1011. Those papers are not in the record, and, even if they were, a thorough review would have been possible in the time available. Nevertheless, based on what TER knows of the papers with which it is familiar and what EPA says of those papers in DCN 5-1011, it is clear that non of them probes respondents on individual-level values, which is what EPA is seeking to value here.

28 UWAG August 2002 Comments, Section III.B.1.

29 See Strand Appendix to EPRI June 2003 Comments.

EPA Response

The comment states that "EPA's approach to assessing non-use values is entirely inadequate." EPA does not agree.
For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values. However, the Agency has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

The benefit transfer method used by EPA was never intended to value specific quantitative changes in fish and shellfish based on WTP per acre of habitat. Rather, it was intended to value the habitat required to compensate for, or offset, losses of fish and shellfish. The relevance of this approach was approved, in principle, by Stavins in his comments on the National Pollutant Discharge Elimination System (NPDES) permit for Brayton Point. Stavins wrote "while mitigation, restocking, and/or habitat restoration may be acceptable approaches as alternatives to the installation of specific technologies in order to offset I&E losses, the cost of such alternatives is in no sense whatsoever a reasonable proxy for the value (that is the benefits) of reducing I&E". (R.Stavins. October 4, 2002. Review of Economic Analysis Supporting NPDES Permitting Determination for Brayton Point Station, pp. 6-7).

The above statement shows that commenters seem to agree with the assumption that the public would be willing to accept a one-to-one tradeoff between a unit of lost habitat services at one site (i.e., the CWIS) and a unit of habitat services at another site (e.g. a salt marsh). Thus, the main objection to the use of HRC in the proposed rule analysis and the economic analysis for the NPDES permitting determination for Brayton Point was based on distinction between costs and values.
A study by Milon and Dodge (2001; Bulletin of Marine Science 69) presents an application of a habitat valuation method to the assessment of economic losses resulting from damage to coral reefs. In addition, NOAA has allowed the use of this method as one means of compensating for lost interim values pending restoration, under the NRDA regulations of the Oil Pollution Act (Damage Assessment and Restoration Program (DARP), National Oceanic and Atmospheric Administration, 1997. Natural Resource Damage Assessment Guidance Document: Scaling Compensatory Restoration Actions (Oil Pollution Act of 1990) Available at: http://www.darp.noaa.gov/pdf/scaling.pdf). A paper by Mazzotta, Opaluch and Grigalunas ("Natural Resource Damage Assessment: The Role of Resource Restoration," Natural Resources Journal V. 34, pp. 153-178) describes a method for providing habitat restoration to compensate for the lost services of that habitat, rather than attempting to estimate dollar values for those services.
The commenter asserts that "non-use values for the proposed regulation are likely negligible." The commenter provides no empirical evidence for this assertion, which is simply an opinion. EPA has provided evidence to the contrary, indicating that non-use values are not negligible.

The comment includes a quote regarding the reliability of measured priorities versus that of measured dollar values in the Peconic Estuary study. At issue here is what level of precision of value estimates is required for this particular policy analysis. The results of the Peconic survey have been used by the Peconic Estuary Program to evaluate options and plan for preservation and restoration actions in the Estuary, under the National Estuary Program, programs that require expenditure of scarce public funds and thus have significant opportunity costs for the public.

The Peconic model was designed to both measure dollar values and develop priorities; the dollar values estimated through the PES study have been published in the peer-reviewed literature. As clearly stated by Johnston et al. (Johnston, R.J., J.J. Opaluch, T.A. Grigalunas, and M.J. Mazzotta. 2001. Estimating Amenity Benefits of Coastal Farmland. Growth and Change 32(summer): 305-325.) on page 313: "Contingent choice questions were designed to measure respondents' values for changes in the natural resources of the Peconic Estuary system…." Nearly identical text is found in Johnston et al. (Johnston, R.J., T.A. Grigalunas, J.J. Opaluch, J. Diamantedes, and M. Mazzotta. 2002. Valuing Estuarine Resource Services Using Economic and Ecological Models: The Peconic Estuary System Study. Coastal Management 30(1): 47-66).

The original Peconic study concludes that

the minimum conditions for economic rationality are met, with mixed results for the more rigorous tests. The estimated coefficients for all models have the correct sign and are statistically significant. Relative values and priorities are consistent across model specifications, and estimates of dollar values are not highly sensitive to specification. ….

Overall, there is no strong evidence that people are unable to make tradeoffs that express their priorities for resources. Open-ended comments and other qualitative evidence suggest that respondents were concerned about the issues, accepted the scenarios, and made an effort to provide thoughtful answers …

…[R]esponses provide robust estimates of people's priorities and relative values for the natural resources…. Although the dollar values may not be precise, they may be appropriately used to indicate the general magnitude of benefits of different programs as part of a decision-making process that considers a variety of factors, including economic benefits. (Mazzotta, 1996)

EPA recognizes that the Peconic study does not provide perfect estimates of dollar values. There is no study in existence that provides perfectly reliable dollar values for non-marketed goods. Every non-market valuation study contains some level of bias or uncertainty. However, the Agency believes that the values provided are useful for indicating the magnitude of benefits that would be provided by restoring fish habitat. EPA believes that the values provided, while not perfectly ideal, are adequately reliable for the context.

The comment further states that the benefit transfer "relies on numerous unsupported judgments." For EPA's response to comments regarding the connection between values for habitat and values for fish and shellfish, please see the response to comment #316bEFR303.020.

For EPA's response to comments regarding losses to individual fish vs. population losses, please see the response to comment #316bEFR.306.302.

For EPA's response to comments regarding the similarity of wetlands between the study area and the policy area, please see the response to comment #316bEFR303.020.

For EPA's responses regarding the relative magnitudes of use and non-use values, please see response to comment #316b.EFR.306.315.

For EPA's response regarding the soundness of value estimates from the Peconic study, please see the response to comment #316bEFR.304.002.

For EPA's response to comments regarding the allocation of values for various wetland services using the Johnston, et al. study, please see the response to comment #316bEFR.303.021.

For EPA's response to comments on the break-even method, please see comment #316bEFR.306.106.

Overview of I & E effects on organisms

According to Dr. Van Winkle,<FN 30> empirical evidence is not available from any field study during the past three decades showing that entrainment and impingement losses are the sole cause, or even the primary cause, of changes at the population, community, or ecosystem levels. This lack of evidence does not necessarily mean that entrainment and impingement losses are having no negative effects at the population and higher levels, but it does mean that for all existing facilities, environmental changes other than entrainment and impingement are implicated. An example is Brayton Point.

In addition to surface water withdrawal by cooling water intakes and discharges of heated water, fish populations may be stressed by habitat alteration (water pollution, dredging, coastal development, and other environmental stressors that have nearly eliminated eel grass in Mt. Hope Bay), overfishing, pollution (for example, Narragansett Bay and Mt. Hope Bay must assimilate high levels of industrially derived toxic pollutants, nutrients, and wastewater from the area's 33 wastewater treatment facilities), and weather patterns (for example, warmer winter water temperatures resulting in the loss of the usual winter-spring diatom bloom and perhaps contributing to increased predation rates by shrimp on larval winter flounder). In some situations, reductions in other stresses will complicate the interpretation of monitoring data. For example, substantial improvements in water quality and the ban on commercial and recreational fishing for striped bass have affected the fish population in the Hudson River.

EPA's one and only example of entrainment and impingement effects at the population level, the operation of the San Onofre Nuclear Generating Station, is misleading. While the observed decreased densities of two fish species within three kilometers of San Onofre, relative to densities in control areas, were likely due to operation of the facility, the fundamental problem was the effect of the thermal discharge on the kelp beds near the facility. The resulting reduction in suitable habitat for the two fish species was the primary cause of the observed spatial differences in densities.

In contrast, there are many studies showing that entrainment and impingement have not caused adverse impact. For example, a recent report of a 30-year study conducted by the Texas Commission on Environmental Quality examined two cooling water intake systems in the Houston Ship Channel.<FN 31> At one of the intakes, statistical analysis revealed an upward trend in total abundance, species richness, and diversity over 30 years, and no species demonstrated a statistically significant decline over the period of the study. The second intake also experienced an upward trend in diversity and no statistically significant change in species richness and abundance.
