Facilities not covered by today's proposal

It is ZCA's understanding that manufacturing facilities such as ours are not covered under the Phase II Rule, but may be covered under the upcoming Phase III Rule. This understanding is based language in the preamble and discussions with USEPA staff. Language in the proposed Phase II Rule preamble supports this understanding. For example, the following statement is made in preamble Section I.B., "Today's proposal would not apply to existing manufacturing facilities... ." 67 Fed. Reg. 17122, 17124. The preamble further states that ". . . certain existing manufacturing facilities. . . would not be subject this proposed rule . . ." 67 Fed. Reg. 17122, 17128. In addition, USEPA states in Section IV of the preamble, "Today's rule does not apply to facilities whose primary business activity is not power generation . . ." 67 Fed. Reg. 17122, 17135.

Although it does not appear to be the USEPA's intent to regulate non-utility manufacturing facilities the Phase II Rule, the proposed regulatory language is somewhat ambiguous. In order to clarify such ambiguity, ZCA requests that the USEPA modify the language of proposed 40 CFR 125.91(a)(2) to read as follows:

"Both generates and transmits electric power, or generates electric power but sells the majority of that power to another entity for transmission. A facility whose primary business activity is not power generation is not subject to this subpart."

ZCA further recommends a change to the last sentence of the first paragraph of Section IV of the preamble, 67 Fed. Reg. 17122, 17135. The new sentence would read as follows:

Today's rule does not apply to facilities whose primary business activity is not power generation, such as manufacturing facilities that produce electricity by cogeneration or for use in its own manufacturing operations (i.e., the rule does not apply to facilities whose primary SIC code is not 4911).

Incorporation of such language will eliminate confusion over the status of manufacturing facilities, and clearly delineate which facilities are subject to the Phase II Rule.

EPA Response

See response to 316bEFR.050.002.

Response to Public Comment

General statement of support

In general, CZM is supportive of the proposal for reducing entrainment and impingement existing facilities with cooling water intake structures (CWIS) by 60-90%, supports compliance monitoring for verifying the efficacy of technological modifications to CWIS, and supports giving the Director or Regional Administrator authority to require more stringent regulations in areas where it is deemed necessary (e.g., estuaries).

EPA Response

EPA notes the comment. No response necessary.

Benefit Estimation Methodology

CZM does not support any proposal that ignores the value of entrained and impinged organisms to ecological networks (e.g., evaluation schemes where the impact to entrained and impinged organisms is measured relative to only their commercial or recreational dollar value)

EPA Response

EPA disagrees that its analysis "ignores the value of entrained and impinged organisms to ecological networks." Although EPA has not included quantitative estimates of nonuse values for the final 316b rule, due to unavoidable uncertainty in monetizing non-use values, the valulation methodologies explored by the Agency suggest the potential for significant values. These methods include meta-analysis of surface water valuation studies and a benefit transfer method. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003).

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values. The Agency, however, did explore several alternative non-use valuation methods to appreciate the potential magnitude of non-use values, including meta-analysis and the benefit transfer method. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

RFC: Proposed use of restoration measures

CZM does not recommend that EPA implement habitat restoration or restocking as mitigation for CWIS impacts unless long-term scientific analysis suggests that these methods are effective at replacing the ecological role and function of entrained and impinged organisms.

EPA Response

EPA agrees with the commenter that long-term scientific analysis suggesting that a restoration method is effective at replacing the ecological role and function of entrained and impinged organisms is a useful tool for determining whether or not a restoration measure is feasible.

The final rule allows permitting authorities to make decisions on the feasibility of restoration measures on a site-specific, case-by-case basis. All restoration measures must meet the requirements described in the final rule, including those under sections 125.94 and 125.95. Permitting authorities and permit applicants should consider the ability of a restoration measure to replace the ecological role and function of entrained and impinged organisms when evaluating a restoration measure's feasibility.

RFC: Should EPA include impingement trading?

CZM does not support any form of trading of entrainment reduction credits.

EPA Response

Please see response to comment 316bEFR.034.027 regarding the role of trading in today's final rule.

Comment ID 316bEFR.002.005

Subject Matter Code 1.0
Introduction

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

CZM believes EPA regulation will be the best way to ensure that the greatest possible benefits to the environment are realized. CZM believes that this decision will be most effective when made by the Regional Administrators on a region-by-region basis.

EPA Response

Today's final rule has established national requirements, and gives State permitting authorities great discretion in implementing the rule.

Comment ID 316bEFR.002.006

Subject Matter Code 7.02
Performance standards

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

It is CZM's opinion that compliance monitoring should be required. CZM believes the Regional Administrator should reserve the right to reopen the permit to modify the permit conditions to require compliance with performance standards if the prescribed technology is not performing as expected.

EPA Response

EPA notes that with the exception of compliance alternative one (closed-cycle cooling), all compliance alternatives require verification monitoring to ensure adequate performance of the selected compliance options. The Technology Installation and Operation Plan (TIOP) allows a facility to select a suite of design and construction technologies, operational measures, and/or restoration measures and request that the implementation of the TIOP be considered compliance with today's rule. This option is available to the permittee with the approval of the Director.

RFC: Cost: benefit ratio for site-specific BTA?

CZM believes there is no evidence in this proposed rule (e.g., economic analysis) to validate EPA's belief that "it is appropriate to set a lower cost threshold in this rule to avoid economically impracticable impacts on energy prices, production costs, and energy production." A table of information such as Exhibit 3 on p. 103 would be helpful to identify if in fact the cost to existing facilities would be an unreasonable proportion of revenues. Furthermore, not all facilities would need to comply at the same time because existing permits will expire at different times. Therefore the impact to regional or nationwide prices of electricity should not be affected by individual facilities complying with a rule whose premise is that the BTA should not be wholly disproportionate to the costs EPA considered when proposing the rule.

EPA Response

For information regarding EPA's rejection of cooling towers, see the preamble to the final rule.

Comment ID 316bEFR.002.008

Subject Matter Code 10.02.03

Use of Replacement Costs (HRC and hatchery-based)

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

This will be affected by what costs are considered. For example, evaluating the commercial value of fish lost due to entrainment and impingement is not the same as enumerating the costs to successfully reintroduce those fish to the ecosystem. The latter might require creating viable habitat and could take a number of years, the costs of which would far outweigh a fish's economic value.

EPA Response

In the analyses for the NODA and the final rule, EPA no longer uses hatchery costs to estimate impacts on forage species. Instead EPA translates foregone production among forage species into foregone production among harvested species that are impinged and entrained using an assumed trophic transfer ratio, and then translates foregone production among these harvested species to foregone yield. Further information on the methods EPA used to estimate forage losses is provided in the regional study document prepared for the analysis for the final Phase II rule. See Chapter A5: Methods Used to Evaluate I&E (DCN #6-0003).

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule.

Please see the document entitled "Habitat-based Replacement Cost Method" (DCN # 6-1003) for additional discussion of the HRC method. Please also see EPA's response to comment #316bEFR.005.035.

Subject Matter Code 11.01

RFC: Proposed use of restoration measures

CZM recommends that additional information be required before a restoration measure alone, or in combination with control technologies and operational measures, is accepted by the Director. CZM requests that long-term site-specific data be collected, validated, and approved by the Director and appropriate Federal, State, and Tribal fish and wildlife management agencies before a restoration measure is accepted.

EPA Response

EPA believes the requirements for restoration measures described in the final rule under sections 125.94 and 125.95 allow permitting authorities the flexibility to request or conduct analyses appropriate to the nature of the restoration measures under consideration.

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

Subject Matter Code 11.06

RFC: Performance/effectiveness of restoration

CZM cautions against comparisons between fish restocking programs and performance standards for reducing entrainment and impingement because of the difference in the life stages affected by each. Restocking programs usually focus on the reintroduction of juveniles or adults whereas technological methods that reduce entrainment enhance egg and larvae numbers. These various life stages have very different ecological roles and importance.

EPA Response

The Agency agrees with the commenter that eggs and larvae of aquatic organisms have a different ecological role and importance than juveniles and adults and that restocking programs tend to focus on reintroduction of juveniles and adults. The final rule addresses impacts to eggs and larvae as well as to juveniles and adults. For some facilities, restocking might be a viable restoration alternative.

All restoration measures must meet the requirements described in the final rule.

Comment ID 316bEFR.002.011

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

Subject Matter Code 11.06

RFC: Performance/effectiveness of restoration

CZM believes that in most cases compensatory mitigation has failed to completely replace or restore impacted wetlands (Brown and Veneman, 2001). CZM believes that a restoration or mitigation method must be shown to reproduce the ecological value that was lost in order for the method to be counted as having "substantially similar performance" as technological or operational measures that reduce entrainment or impingement. To date, no restoration or mitigation measures that CZM is aware of in New England have been shown to adequately replace the ecological role or value of organisms killed through entrainment and impingement in cooling water intake structures.

CZM would not be able to endorse any taking or loss of existing marine resources that is not mitigated by a minimum goal of one-to-one. CZM also questions the efficacy of restocking measures. Because the conditions under which restocking organisms are grown will never be able to replicate the psychosensory environment found outside a controlled aquaculture environment, CZM is not convinced that restocking will be able to replace functioning ecological units that are lost through impingement or entrainment. For example, organisms raised in a laboratory or in a cage in the "wild" will not be exposed to predators and may not develop appropriate predatory escape behaviors. Laboratory- or cage-raised organisms may also not develop foraging behaviors that are appropriate for survival under natural conditions. In addition, replacing functional ecological units with organisms that belong to a different ecological unit will not achieve the goals of attaining "substantially similar performance technological or operational constraints at the facility. For example, replacing fish larvae through entrainment with a number of "equivalent adults" does not replace the ecological role of the larvae as a link within a complex food and energy web.

As a case in point, in the Commonwealth of Massachusetts Entergy Nuclear Generation Co, owner of the Pilgrim Nuclear Power Station (PNPS) in Plymouth, has attempted to mitigate its entrainment impacts by introducing hatchery raised young-of-the-year winter flounder to Plymouth Harbor. The company has proceeded despite concerns from the Commonwealth Division of Marine Fisheries and CZM on the hatchery growing techniques and the inability of the company to verify that hatchery-raised flounder survive long enough to contribute to the population that the company is depleting through entrainment of flounder larvae. In addition to our concerns about the practice of replacing millions of entrained fish larvae and eggs with of thousands of individuals from a different life stage (i.e., young-of-the-year), CZM is concerned that the Proposed Rule would encourage reintroduction of hatchery raised fish when there is no evidence that these fish possess the genetic structure, feeding and avoidance behavior, reproductive capability, survivorship, or natal homing ability to replace the ecological function of the organisms entrained at PNPS.

CZM believes that habitat restoration may be more beneficial than direct restocking because properly restored habitat may serve as a nursery area, providing shelter and foraging area for juvenile organisms (and for additional organisms other than the ones entrained or impinged). However, CZM believes that habitat restoration in and of itself can not be considered a replacement to technological or operational measures that reduce impingement and entrainment if the habitat can not be shown to directly increase the abundance of organisms and life stages (in the ratio in which they were entrained and impinged) within the ecosystem or localized areas that the facility occupies. The introduction of stocked organisms without investigating population dynamics (e.g., source/sink dynamics) or available niche space and resource availability at the point of reintroduction will not serve the purposes of this Proposed Rule or Section 316 of Clean Water Act.

EPA Response

If a permit applicant wishes to utilize a particular restoration measure, they will need to demonstrate to the permitting authority that these approaches will meet the performance standard.

For a discussion of the permitting authority's role in determining the nature of a restoration measure that is necessary to meet the requirements of the final rule, see EPA's response to comment 316bEFR.060.026.

For a discussion of the requirement to examine design and construction technologies and operational measures before choosing to implement restoration measures, see EPA's responses to comments 316bEFR.033.005 and 316bEFR.202.029.

Comment ID 316bEFR.002.012

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

Subject Matter Code 11.08

RFC: Habitat conservation as part of restoration

CZM in general supports habitat conversation, however, CZM does not believe that conservation of existing habitat will replace the ecological function of organisms that are entrained or impinged. As EPA has stated in the Proposed Rule, conserved habitat is already contributing to the relative productivity and diversity of an aquatic system, therefore conservation measures would not necessarily ensure a net benefit to the waterbody or watershed of concern. CZM maintains that reductions of entrainment and impingement through technological changes or reductions in flow are the most efficient means of reducing cooling water intake structure impacts.

EPA Response

Any restoration measure must meet all of the requirements in the final rule.

The final rule requires permit applicants who propose restoration projects to demonstrate to the permitting authority that they have sufficiently considered design and construction technology and operational options for their site. This will help ensure that all parties identify the most feasible means of addressing environmental impacts from cooling water intake structures.

Comment ID 316bEFR.002.013

Organization Office Environmental Affairs; Office of Coastal Zone Management

Subject Matter Code 12.02

RFC: Monitoring frequencies

CZM is concerned that this proposed monitoring scheme is not sufficient. For example, it is unclear from this document as to whether "biweekly" sampling means every two weeks or twice each week. CZM is concerned that these minimum sampling frequencies might be used not as the minimum amount of work needed to quantify entrainment and impingement, but as the required standard above which more sampling is not necessary. Without any explanation as to why frequencies were chosen, it is difficult to evaluate their merits.

Recently, EPA New England and the Commonwealth of Massachusetts Department of Environmental Protection have been requiring that existing power plants with CWIS monitor for impingement three times per week - often enough to capture at least one morning, one afternoon and one night sample. In addition, entrainment data must be collected three times per week (morning, afternoon, and night) every week from March to September and every two weeks in other months. These sampling periods cover times of spawning and recruitment for Representative Important Species (RIS) in such a way that impacts to the RIS can be determined without having to sample every day. Less frequent sampling would risk missing key impingement or entrainment events.

EPA Response

Please see EPA's response to comment 316bEFR.074.023.

Comment ID 316bEFR.002.014

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

Subject Matter Code 10.02

Benefit Estimation Methodology

Valuing fish that are part of a commercial fishery in the manner suggested in option 1 fails to recognize that these fish and their eggs and larvae have an ecological role before they are caught. Likewise, the valuation presented in option 2 addresses only the value of fish to recreational fisherman. Option 3 provides a valuation scheme that focuses narrowly on how much citizens are willing to pay (e.g., an increase in their electric bill) to prevent impingement and entrainment. The value of entrained and impinged fish to an ecosystem will always be underestimated if only their transient commercial or recreational value is considered. In addition, many respondents to the suggested surveys may not recognize how the types entrained and impinged fish contribute to ecological integrity or socioeconomic prosperity.

All three of these options fail to address the larger quality of life issues associated with ability to see, catch, eat, or sell fish in or from one's own watershed. The health of fish populations is intimately linked with the communities surrounding a watershed. Activities as disparate as bird watching and bait dealing and commercial ventures as varied as gas stations or seafood restaurants, all depend upon adequate fish populations and help strengthen the tax and the well-being of local communities. These issues are not factored into a simple survey looking narrowly at the dollar value of fish deemed recreationally or commercially important. CZM recommends that such valuation schemes not be used to quantify the benefits that would occur if a facility were to comply with the performance standards in this Proposed Ru1e. A combination of the above methodologies may be useful as a relative measure of the benefits of several different options or level of compliance with the performance standards. CZM does not recommend using any one of the proposed methodologies by itself to evaluate the benefits of reducing entrainment and impingement.

EPA Response

EPA agrees that the value of entrained and impinged fish to an ecosystem is underestimated "if only their transient commercial or recreational value is considered." For EPA's response to comments that the Agency's benefit estimates are incomplete, please see response to comment #316bEFR.206.047.

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values. The Agency, however, did explore several alternative non-use valuation methods to appreciate the potential magnitude of non-use values for this rule. These methods include meta-analysis and the benefit transfer method. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Comment ID 316bEFR.002.015

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

Subject Matter Code 12.03

RFC: Entrainment vs. entrainment mortality

CZM agrees with EPA that all estimates of entrainment and impingement mortality should be based upon scientific studies with quality assurance goals approved by local resource agencies and EPA. These studies should be conducted during times of high abundance of the organisms of interest, and at times when the facility is operating at full capacity, at times when biocides are in use, and at times that reflect current entrainment rates at the facility. In order for the results of these studies to be useful, it should be ensured that sample sizes are large enough to make inferences to the populations at large. Mortality rates for several different species within the ecosystem should be identified and sub-lethal effects after passing through the CWIS should be quantified for each of the RIS. CZM realizes that to accomplish all of these goals will be a large task and suggests that in the absence of the aforementioned data, 100% mortality of organisms should be assumed.

EPA Response

EPA agrees with this commenter. Designing studies to accurately determine whether entrainment survival occurs can be very difficult. At this point in time, it may even be impossible. In the interest of leaving the door open for the advancement of techniques to determine entrainment survival, today's final rule allows facilities to attempt to study this topic and use the results in their benefits assessments when seeking a site-specific entrainment requirements. However, the permitting authority must review and accept the study before the results may be incorporated into the benefits assessment. Permitting authorities also may want to see benefit analyses as a range with and without the incorporation of any entrainment survival estimates.

EPA encourages permitting authorities to use the chapter, Entrainment Survival, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule, as a guide when reviewing these studies. In general, EPA believes that the studies it has reviewed are not acceptable and should not be incorporated in any benefits assessment. EPA's review of these studies has shown that while some individual organisms may be alive in some of the discharge samples, the proportion of the organisms that are alive in the samples is highly variable and unpredictable. In addition, the studies contain various sources of potential bias which case the estimated survival rates to be higher than the actual survival rates. If the permitting authority determines that the facility's study does not support a defensible and reliable prediction of entrainment survival, then EPA would encourage the permitting authority to reject the study for the site-specific benefit analysis.

Comment ID 316bEFR.002.016

Subject Matter Code 13.0

More Stringent Requirements

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

CZM agrees that more stringent requirements than those that would be required based on the proposed performance standards in the rule (§ 125.94(b)), or based on the proposed site-specific determination of the best technology allowed under the rule (§ 125.94(c)), would be appropriate under the scenarios described above. CZM suggests that EPA evaluate the impact of multiple stressors, including multiple intakes within a waterbody, when evaluating demonstration studies.

EPA Response

EPA agrees with the commenter that cumulative stressors, including multiple intakes located in close proximity to each other, are of concern and should be considered when evaluating demonstration studies and permit requirements. Today's rule does not limit a State's authority to adopt more stringent requirements.

EPA notes that in considering a permit application, the Director must review the performance of the technologies implemented and require additional or different design and construction technologies, operational measures, and/or restoration measures, if needed, to meet the requirements of the rule. In addition, the Director may consider any other factors including chemical, water quality, and other anthropogenic stresses on the source waterbody and other factors in determining whether to impose more stringent conditions to comply with the requirements of the applicable State and Tribal law or other Federal law.

Please see response to comment 316bEFR.099.004.

RFC: Definition of "adverse environmental impact"

The working definitions of "significant" and "population" are very important to the identification of any impacts in this scenario. CZM would like clarification on EPA's definition of "significant" numbers of organisms. Does "significant" represent a certain fraction of the estimated local population (e.g. 5%)? Or does it refer to a statistically significant difference from some established baseline. If the latter, this definition would be constrained by the ability to detect statistical differences, which itself is constrained by the sampling techniques. Statistically significant differences may be very difficult to determine given the wide variation in larval and egg abundances even on short temporal scales and the amount of effort required to attain representative samples. Because of the difficulty involved in establishing baselines especially where waterbodies have historically been impacted by CWIS and the difficulty collecting enough plankton samples to detect statistically significant changes, CZM recommends that "adverse environmental impact" be assumed whenever there is entrainment or impingement as a result of a CWIS.

While CZM agrees that the health of critical aquatic populations or ecosystems is the endpoint of interest (and not necessarily numbers of individuals lost), CZM is not convinced that adequate metrics of population or ecosystem health have been developed for waterbodies affected by CWIS in New England. This is a goal to which resource agencies should strive, but the science has not yet been developed that would make this option implementable in the near-term. Furthermore, CZM is not convinced that biotic health metrics can adequately account for the compensatory reserve required for populations or subpopulations to rebound from major declines associated with catastrophic events, long-term climate or habitat changes, fluctuations in predators, prey, or other resources.

CZM suggests that EPA use local populations (or subpopulations) to determine adverse environmental impacts. The current definition of adverse environmental impact (described on p. 188 of the Proposed Rule) allows a facility to decimate the local population of an organism (e.g., that portion of a larger population that resides within a given embayment or river segment) so long as this reduction does not affect the larger population. CZM does not believe that it is the intention of the Clean Water Act to allow power plants with CWIS to decimate local populations of organisms.

EPA Response

EPA has elected not to define "adverse environmental impact" or "significant". Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define adverse environmental impact in today's final rule. The definition of significant has been left to the discretion of the permit director. However, EPA would like to be clear that by significant, the agency is not referring to statistically significant.

Subject Matter Code 18.01.01

UWAG definition of "adverse environmental impact"

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

UWAG contends that its recommended definition of "adverse impact" is scientifically sound and environmentally protective because it focuses on protecting populations or species and because it requires that the level of population protection be adequate to ensure protection of the integrity of the ecosystem (community structure and function). However, the UWAG definition would allow for the creation of metapopulations with local "sinks" (areas of net negative local population growth for certain species) around CWIS. As stated above, CZM is supportive of scientific approaches that protect subpopulations of organisms but feels that the UWAG proposal fails to recognize that holistic (i.e., inclusive of all sources of mortality) scientific approaches to determining long-term population or ecosystem health have not yet been developed or verified in New England and that the UWAG proposal does not differ from the site-by-site evaluation of CWIS that is currently being implemented under 316(b). Under the current system, determination of "adverse impact" is broad enough that it requires resource agencies to constantly redefine the term in each segment of a waterbody in which there is a CWIS. This has been proven to be neither expeditious nor cost-effective.

UWAG's protective decision criteria (e.g., Locational Criterion, Design Criterion Proportion of Flow or Volume Criterion, Percent Population Loss Criterion, No Significant Downward Trend Criterion; pp.190, 191) should be protective in many cases but will not be protective if a subpopulation is at such a low level that any entrainment or impingement at all may hinder recovery. The latter is likely the case for winter flounder in Mount Hope Bay. CZM opposes the proposed caveat that allows achieving only one of the UWAG criteria to demonstrate no risk of adverse environmental impact for a facility. CZM does however concur with UWAG that if population-based criteria are to be used, they should be applied independently to each RIS species, and each species should meet the criteria in order for the facility to demonstrate no risk of adverse environmental impact.

EPA Response

In today's final rule, EPA has elected not to define adverse environmental impact. EPA has rejected the UWAG, PSEG and "alternative" definitions of adverse environmental impact because they are too broad and dependent on proven damage on the community and population levels before controls on cooling water intake structures could be put in place as the best technology available. EPA does not view adverse environmental impact as limited to demonstrated community or population level effects. Damage on the community or population level is extremely difficult to quantify and attribute to a particular cooling water intake structure given the vast number of environmental factors which work concurrently on fisheries at that organizational level. In today's final rule, EPA seeks to simplify the section 316(b) determination process by requiring the reduction of impingement mortality and entrainment by a performance standard. These reductions will reduce stress on fish populations. Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

RFC: Use of previous demonstration studies

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

CZM believes that EPA should not allow a previous 316(b) demonstration to be used for determining whether there is no adverse environmental impact unless the applicant can demonstrate, through scientific studies, that the waterbody of interest and the biota therein have not changed since the previous 316(b) demonstration. Increases in water quality and restoration of habitat can increase the number of organisms near a CWIS and can lead to increases in a facility's effects on a population or subpopulation where none was demonstrated in the past. On the other hand, decreasing water and habitat quality and diminishing populations in the area of a CWIS can also increase the impact of a CWIS if a facility impacts a larger and larger proportion of organisms as populations decline. For this reason, CZM believes that an applicant, after consultation with local resource agencies on the appropriate detection methods, demonstrate to the satisfaction of EPA and the local resource agencies that no change has occurred to the ecosystem in which the CWIS is located.

EPA Response

EPA agrees with the commenter and has not allowed the use of historical determinations of BTA in today's final rule. Please see response to comment 316bEFR.040.001 for details.

Applicability to facilities subject to NPDES permit

CZM would like clarification as to the definition of compliance. Does it mean that the CWIS upgrade (if this track is selected) has to be completed before a NPDES permit is issued? Or does it mean that some sort of construction plan with a timetable has to be in place?

EPA Response

For a discussion of how compliance is to be determined, please see EPA's responses to comments 316bEFR.017.003 and 316bEFR.063.005. A facility will not have to complete upgrades to its cooling water intake structures prior to the issuance of its NPDES permit. For permits that expire within 4 years, EPA has allowed a facility to submit the required information in accordance with a schedule established by the Director. This information need not be incorporated into the permit application. For additional information on timing requirements please see EPA's response to comment 316bEFR.034.066.

Impacts of multiple intake structures on watersheds

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

CZM agrees that this is a wise approach. CZM asks for clarification as to who will be responsible for investigating the cumulative impacts of multiple intakes in a given area? Would it be the permit applicant? The Regional EPA office? National Marine Fisheries Service?

EPA Response

The permitting authority should consider the cumulative impacts of multiple intakes in a watershed as part of its section 316(b) decision making process.

Subject Matter Code 7.02

Performance standards

One problem with this approach, recognized by EPA in its discussion of the Ohio River (p. 78) is that waters that will experience greater aquatic life as they are cleaned up or as impediments are removed, may experience greater entrainment and impingement impacts and the CWIS may no longer be considered BTA because EPA made the BTA determination at a time when fewer organisms were to be found in the source waterbody.

CZM would like clarification on EPA's proposed technology-based approach freshwater in rivers or streams (p. 85). How will EPA determine if a control technology is BTA if the technology has not yet been implemented at a specific site? Will it be possible to issue a temporary BTA determination contingent upon the performance of the technology at a specific site? Further, what if a technology is expected to reduce entrainment and impingement studies following construction and implementation show that the target reductions are not met? Can EPA rescind a BTA determination? Will another technology be required? What if the combined cost of having constructed and implemented both technologies is greater than expected environmental benefits?

EPA Response

EPA recognizes that improvement of impaired waters is a goal of the Clean Water Act and will continue to be achieved over time. EPA also acknowledges that improvements to water bodies are the result of concerted efforts involving numerous factors, the results of manifest themselves over time. NPDES permits are valid for five years to allow the permitting authority to revisit issues and circumstances that may not have been present during the previous permit issuance. Improvements in water quality is one such issue that can be addressed during a permit reissuance. EPA believes it is unlikely that a water body would experience such a dramatic and unforeseen improvement in water quality within the term of a 5-year permit as to warrant a revised BTA determination.

EPA does not believe that a technology must be tested in situ in order to make a BTA determination for the facility in question. Sufficient data exist about several technologies and operational modifications to enable permitting authorities and facilities to select the optimal configuration meet the performance standards for the facility in question.

Because compliance monitoring occurs over several years, a temporary BTA determination is unnecessary. Insufficient performance of a technology or operational modification cannot usually be determined without several years worth of data. Thus, a decision whether it is necessary to modify a BTA determination would likely be made during the next permit reissuance rather than a mid-cycle revocation of BTA. In addition, today's regulation authorizes the permit writer to make site-specific determinations of BTA, taking into account cost-cost or cost-benefit considerations. Please see the preamble to today's rule for additional discussion.

Subject Matter Code 7.02

Performance standards

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

CZM would like clarification on this statement. Is EPA implying that it would prefer a lower reduction in entrainment and impingement (and therefore more organisms passing through the facility) when there is the risk that "fragile" organisms could be killed by a barrier mechanism? CZM questions why EPA is proposing the least amount of reduction in entrainment and impingement rates when the organisms of interest are most sensitive.

EPA Response

EPA does not believe that the presence of fragile organisms warrants a lower performance standard for either entrainment or impingement mortality. Today's rule adopts ranges for the performance standards to maintain the desired flexibility for facilities to determine the most appropriate and cost-effective means of meeting the requirements. EPA notes that care must be taken when developing an impingement mortality and/or entrainment reduction strategy to prevent unintended losses that may result from the final action. Fragile species, while they may require a more focused effort on the part of the facility, are not subject to less stringent requirements.

Comment ID 316bEFR.002.026

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

Subject Matter Code 7.02

Performance standards

CZM notes that it is not mentioned in this section that a reduction in flows could be counted as BTA. EPA has previously mentioned in this document that flow is directly related to entrainment and impingement but does not specifically include reductions in flow with existing or with additional CWIS upgrades as BTA. But “EPA believes that many facilities achieve further reductions (estimated at 15-30 percent) in impingement mortality) entrainment by providing for seasonal flow restrictions, variable speed pumps, and operational measures and innovative flow reduction alternatives” (p. 90).

EPA Response

EPA recognizes the potential reductions that can be achieved by reducing the overall intake flow to a facility. However, because of the increased cost associated with adopting a reduced flow (most likely the installation of some sort of closed-cycle system), EPA acknowledges the unlikelihood that many Phase II facilities would opt for flow reduction to meet the requirements of the final rule. This does not preclude any facility from selecting this option, either alone or in concert with other technologies or operational modifications, to satisfy the requirements of the final rule.

EPA has not predetermined any technology to be BTA for all facilities. Instead, EPA has opted left the determination of the means of compliance up to the facility and the responsible permitting authority.

Subject Matter Code 10.1

General: cost tests

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

CZM believes that allowing facilities the option for site-specific determination of BTA by establishing that the facility's costs are exceptionally high or the benefits are exceptionally low, depends upon such relative terms that a facility will always tend to overestimate the costs of reducing entrainment and impingement (e g, by including production value lost while installing technological upgrades). In addition, calculating the benefit to a population or ecosystem may also be subjective, especially if the current quality of the receiving waters, and the abundance the biota in these waters, have been affected by historical activities of the facility.

EPA Response

The only example given for how a facility might overestimate costs in a site-specific determination is not a valid example of an "overestimate" of costs, in the Agency's opinion. In fact, the Agency views valuating foregone electricity production due to a construction downtime for installing technology to comply with this rule to be a valid economic practice.

EPA agrees that current impacts will depend, in part, on the effects of historical conditions on current abundances of organisms in the vicinity of an intake. Historical conditions include whatever impacts the plant may have had in the past, as well as the effects of other potential stressors, including water quality. However, EPA believes it can be extremely difficult to detect effects at the population or ecosystem level without knowledge of the population or ecosystem before and after an impact at both control and impact sites (see Schmitt and Osenberg, "Detecting Ecological Impacts," Docket #2-019A-R21). This is a major reason that EPA has focused its analysis directly on impingement and entrainment, rather than attempting to determine the magnitude of potential population or ecosystem impacts.

See Sections V and IX of the preamble for a site-specific determination of best technology available for minimizing adverse environmental impact. For EPA's response to comments on application of the cost-benefit test to assessing the value of alternative CWIS technologies, please see comment #316bEFR.005.020.

RFC: Regulating limited capacity facilities

CZM believes that flow reductions at facilities with limited capacity utilization should be addressed during periods when eggs or larval organisms are in the water in the vicinity of the CWIS. Flow reductions (and therefore entrainment reductions) should not be assumed to have occurred merely because a facility operates only 15% of the time on an annual basis. Biologically and ecologically what is most important is the frequency of the facility's open during the time period when spawning and early development is occurring. CZM is opposed to allowing facilities with limited capacity utilization to be categorically accepted as in compliance with the rule requiring 60-90% reduction in entrainment.

EPA Response

See response to comment 316b.EFR.330.032.

Comment ID 316bEFR.002.029

Subject Matter Code 17.01

RFC: Other proposed provisions

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

CZM opposes allowing facilities to request alternatives that are less stringent than those specified in the Proposed Rule, even if the facility believes compliance would result in significant adverse impacts on local energy markets. CZM believes that there are enough energy generating facilities in New England that significant adverse impacts would not occur to the local energy market as a result of compliance with the Proposed Rule (e.g., in Massachusetts alone there are several generating facilities that operate only during the highest peak generating times. In the summer of 2001 energy was limited more by transportation mechanisms than by generation).

EPA Response

Under this final rule, EPA has established national performance standards for the reduction of impingement mortality and, when appropriate, entrainment (see § 125.94). The performance standards consist of ranges of reductions in impingement mortality and/or entrainment (e.g., reduce impingement mortality by 80 to 95 percent and/or entrainment by 60 to 90 percent). These performance standards reflect the best technology available for minimizing adverse environmental impacts determined on a national categorical basis. EPA believes that a national standard will result in the most effective reduction in impingement and entrainment. Recognizing that site-specific conditions can influence the choice of technologies to meet the performance standards, EPA has also codified several alternatives for complying with the rule's requirements.

Today's rule also preserves each State's right to adopt or enforce more stringent requirements.

Subject Matter Code 18.03.02

Sample site-specific rule

Author Name Thomas W. Skinner

Organization Office Environmental Affairs; Office of Coastal Zone Management

As stated previously, CZM feels it is premature to allow energy-generating facilities to mitigate adverse environmental impacts with fish stocking or any other voluntary restoration measures until these measures can be proven to be effective at reconstructing the ecological networks (e.g., trophic webs, energy webs) that were disrupted by the facilities. Evaluation of these restoration measures should be conducted by an agency, university, or contractor that is independent of the facility.

One flaw with determining BTA on a site-specific basis is that the biological "baseline" that will be determined as part of this demonstration will by definition not be a baseline of the biological or ecological integrity of the receiving water without the plant in operation. Any baseline data collected will have inherent in it the effects of the operation of the plant. While these data may be useful to future decisions about the operation of the plant, they will not allow a determination of full magnitude of the plant's effect on the receiving waters and the biota therein.

EPA Response

For information on the role of restoration, please refer to sections VII and VIII in the preamble to the final rule.

For a discussion of the calculation baseline, please refer to the preamble to today's rule.

RFC: Should EPA include impingement trading?

CZM is strongly opposed to establishing a trading program for entrainment reduction credits. Our chief concern arises from the spatial heterogeneity of watersheds and the risk of allowing continued impacts in areas of a watershed that are the most sensitive to CWIS impacts. CZM believes that a trading program is a disincentive for facilities with CWIS to achieve maximum reduction in entrainment required under the Proposed Rule. Further, allowing facilities to trade across waterbodies that share similar ecological characteristics, regardless of the relative geographic proximity of the facilities to each other (as on p.224) would allow for consolidation of high impact areas, most likely in lower socioeconomic areas. Such a strategy not only ignores the ecological importance of young life stages across all waterbodies, but also raises environmental justice issues.

EPA Response

Please see response to comment 316bEFR.034.027 regarding the role of trading in today's final rule, comment 316bEFR.077.051 regarding the spatial scale of trading and comment 316bEFR.077.052 regarding the appropriate units of trading.

Subject Matter Code 3.05

Facilities not covered by today's proposal

Author Name David E. Tomlinson

Organization Bethlehem Steel Corporation

Four conditions, all of which must apply, define a "Phase II Existing Facility" subject to proposed Subpart J. Condition 2 is that the facility "both generates and transmits electric power, or generates electric power but sells it to another entity for transmission." [Subpart J, §125.91, page 17220] A strict and literal reading of this condition could draw Bethlehem's power generating units operating as an integral part of iron and steel manufacturing sites into the Phase II requirements. At both of Bethlehem's integrated steel plants, the power generating units are used primarily to generate electricity for on-site consumption. The energy transmitted to another entity is de minimis compared to that generated. At one plant, because of contractual arrangements, some power is exported to the local utility, but the total annual integrated demand (purchased electricity plus internally generated electricity) greatly exceeds the amount of electricity that is fed back to the local public utility. At the other plant, power is "sold" into the grid but a greater amount is purchased back at lower rates, the site is a net consumer of electricity, not a net producer.

Power generating units operating as an integral part of iron and steelmaking (SIC 3312/NAICS 3311 and 3312) facilities should be administratively removed from the Phase II rule because the agency clearly intended that iron and steel facilities will be covered in Phase III. This was discussed at various points in the preamble.

Among these, EPA has established effluent limitations guidelines that apply to most of the industry categories that use cooling water intake structures (e.g., steam electric power generation, iron and steel manufacturing, pulp and paper manufacturing, petroleum refining, chemical manufacturing. [preamble Section I.C.1, page 17125]

Existing facilities with design flows below the 50 MGD threshold, as well as certain existing manufacturing facilities, and offshore and coastal oil and gas extraction facilities, would not be subject to this proposed rule, but will be addressed in Phase III. [preamble Section 11, page 17128]

Existing power generating facilities with design flows below this threshold [50 MGD], as well as certain existing manufacturing facilities, and offshore and coastal oil and gas extraction facilities, would not be subject to the proposed rule, but will be addressed under the Phase III rule. [preamble Section II.E, page 17130]

Five questionnaires were distributed to different industrial groups. They were: (1) Detailed Industry Questionnaire: Phase II Cooling Water Intake Structures – Traditional Steam Electric Utilities, (2) Short Technical Industry Questionnaire: Phase II Cooling Water Intake Structures – Traditional Steam Electric Utilities, (3) Detailed Industry Questionnaire: Phase II Cooling Water Intake Structures – Steam Electric Nonutility Power Producers, (4) Detailed Industry Questionnaire: Phase II Cooling Water Intake Structures – Manufacturers, (5) Watershed Case Study Short Questionnaire. [preamble, Section III.B., page 17134]

All of the above citations from the preamble to the proposed rules clearly show that the agency does not intend to have the Phase II regulations apply to the iron and steel industry. In addition, the data collection questionnaires sent by the agency prior to the rule proposal emphasized the distinction that was made between non-utilities and manufacturers such as the iron and steel industry, which is one of the four major industrial categories considered.

Having the power generation units located on a steel plant site subject to Phase II regulations and the other, traditional iron and steelmaking operations subject to the future Phase III regulations would result in a regulatory morass. At both of the integrated steelmaking facilities operated by Bethlehem, the power generation and steelmaking units share a common intake. To the extent that the Phase III requirements are different from Phase II, it will be difficult for permit writers to equitably apply a set of permit requirements.

Bethlehem's concern could easily be resolved if proposed §125.91 is amended to read:

(a)This subpart applies to an existing facility, as defined in §125.93, if it:

(1)Is a point source that uses or proposes to use a cooling water intake structure;

(2)Both generated and transmits electric power, or generates electric power but sells it to another entity for transmission (except for large industrial complexes whose total integrated demand exceeds the amount of electricity fed back to the local utility on an annual basis or exceeds the capability of its generating units) [new language is underlined]

(3)…

Proposed standards for FW rivers and streams

IMC questions the need for intake protection in excess of traveling screens along the lower Mississippi River.

Based on site-specific experience, IMC questions the need for biota protections (in excess of those provided by existing traveling screens) for cooling water intakes along the lower Mississippi River.

IMC's traveling screens have been cleared twice per day essentially every day for the past 35 years. Interviews with employees involved with screen cleaning activities reveal that there is very rarely evidence of fish, shellfish or other biota in the screens. For example, one of our operators responsible for this activity does not recall having seen evidence of any fish, shellfish or other biota in the screens for at least the past year. In discussions with our other operators, they report (for the period of record) a total of no more than 20 incidences per year of finding a fish or shellfish in the traveling screen.

Additionally, IMC has strainers (5/16" x 5/16" openings) in service inside the operating units on this water system. These strainers are back-washed as needed several times per week. Evidence of biota on these strainers also indicates no marine life forms are entering the water supply, passing through the traveling screens.

EPA Response

EPA disagrees that all intakes in the lower Mississippi River should not be subject to additional requirements. Facilities withdrawing greater than 5% of the mean annual flow from freshwater rivers and streams (and having a capacity utilization rate greater than 15%) are required to meet both impingement and entrainment requirements. The withdrawal threshold is based on the concept that absent any other controls, withdrawal of a unit volume of water from a waterbody will result in the entrainment of an equivalent unit of aquatic life (such as eggs and larval organisms) suspended in that volume of the water column. EPA discussed these concepts in more detail and invited comment on the use of this threshold and supporting documents in its NODA for the New Facility Rule (66 FR 28863). EPA believes that a 5% mean annual flow requirement for freshwater rivers and streams achieves an acceptable level of protection for the source water while remaining economically and practicably reasonable for existing facilities.

EPA notes that a facility on the Mississippi River is unlikely to withdraw more than 5% of the mean annual flow. Therefore, the facility would be likely be subject to impingement requirements only. Such a facility could elect to demonstrate that the current intake configuration meets the applicable performance standards, as described under § 125.94(a)(2) or could opt to seek a site-specific determination of best technology available, as described under § 125.94(a)(5).

Subject Matter Code 10.01.02.01

EPA methods: age 1 equiv, yield, prod foregone

IMC respectfully suggests that the data collected from the Ohio River (from which Mississippi River effects were projected) may not have been fully applicable to the Mississippi River. In reviewing data presented in section IX.E.2 of the proposed rule, it appears that the study assumes that more than 97% of the fish and shellfish killed in cooling water intakes would eventually be caught by commercial fishing, thus relating directly to that much "lost fishery yield". IMC respectfully suggests that this is not the case for the small amount of biota entrapped in our screens. First, the biota are almost always species which are not fished commercially, but are instead forage creatures which are fed upon by larger biota. We respectfully suggest that essentially all of the small number of biota entrapped and killed in IMC's traveling screens are promptly consumed by other biota in the river. In other words, these creatures become part of the food chain just as they would if they had not become entrapped in the screens.

Second, even if the entrapped biota are species which are fished commercially, it is extremely unlikely that more than 97% of those individuals would be netted by commercial fishermen. It would seem more likely that the vast majority would be consumed by other biota and/or would live their life cycle without being caught by commercial fishermen.

For these reasons, IMC respectfully suggests that the projected current impact of traveling screens on fishery yields along the lower Mississippi River is exaggerated in the proposed regulation, and consequently the projected positive impacts of additional controls are similarly exaggerated. To address these concerns, IMC proposes the following:

-If a relatively large number of facilities affected by these proposed regulations are located on the lower Mississippi River, IMC proposes that EPA conduct a supplemental study specifically to project effects of the cooling water intakes present along the lower Mississippi River. IMC is confident that such a study will conclude that traveling screen technology of the type in use at IMC is sufficient to protect biota along this stretch of the Mississippi River.

-If the number of affected facilities on the lower Mississippi River is relatively small, we request that the final rule allow for individual facilities such as ours to provide site-specific data to the regulatory agencies quantifying fish, shellfish and other biota trapped in our traveling screens over the course of a year (or over some other significant time period). Based on that data, site-specific water intake provisions could be written into NPDES permits, if appropriate, to protect biota from the specific intake structures.

EPA Response

EPA's analysis did not assume that "97% of the fish and shellfish killed in cooling water intakes would eventually be caught by commercial fishing, thus relating directly to that much 'lost fishery yield'." EPA's yield calculations take into account rates of fishing mortality, which are typically 20% or less. The commenter is referred to Chapter A5 of Part A of the Phase II Regional Study Document.

EPA recognizes that Mississippi River I&E rates may not be identical to Ohio River rates. However, the intention of EPA's analysis was not to develop facility- or river-specific estimates of I&E, but rather to develop an estimate of the relative magnitude of I&E for the entire Inland region.

For a national estimate, similarities include the fact that both are large river systems, have large human populations residing near them, who have multiple uses for the river.

Facilities will have the opportunity to present relevant site-specific information during the permitting process.

Organization IMC Phosphates Company

Subject Matter Code 7.01.03

Option 3--Site-specific determination

IMC requests maximum flexibility in the regulations.

As currently written, the proposed regulations are quite flexible in most areas. This is good, because the regulations are proposing to address intakes associated with a great many types of water bodies in a great many geographic regions. IMC requests that all existing flexibility in the regulations be maintained, and that supplemental flexibility be added, wherever possible. In particular, we request that the administrative authority which issues NPDES permits be given full authority to determine Best Available Control Technology for facilities under its jurisdiction based on cost/benefit analyses and site-specific information such as the data presented earlier in this document.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

General Statement of Opposition

Author Name Robert N. Stavins

Organization John F.Kennedy School of Government, Harvard University

In numerous important respects, the economic analysis offered by EPA in support of the rule is severely flawed, biased, and misleading. Indeed, some of the methodologies employed are neither recommended nor endorsed by EPA's own Guidelines for Preparing Economic Analyses or by the U.S. Office of Management and Budget's guidelines under Executive Order 12866. <FN 2>

In the late 1990s, a dedicated team of EPA economists, economic analysts, and others produced EPA's revised Guidelines for Preparing Economic Analyses, published in September of 2000. <FN 3> But the economic analysis that EPA has prepared to support the proposed rule under Section 316(b) is — in very important dimensions — inconsistent with those Guidelines. In my view, the serious problems I identify could not have occurred had the proposed rule and its economic analysis been subjected to wide internal review by EPA's economics staff. This is particularly striking because EPA's leadership recognizes the importance of having at their disposal the best scientific and economic analysis for this and all other rules. <FN 4> In this spirit, I sincerely hope my comments will help foster the execution of a sound economic analysis and the development of an environmentally and economically sensible rule for implementation of Section 316(b) of the Clean Water Act.

Footnotes

2 U.S. Environmental Protection Agency. Guidelines for Preparing Economic Analyses. Office of the Administrator, EPA 240-R-00-003. Washington, D.C., September 2000. U.S. Office of Management and Budget. Economic Analysis of Federal Regulations Under Executive Order 12866. Washington, D.C., January 1996.

3 In its review of EPA's Guidelines for Preparing Economic Analyses, the Science Advisory Board summarized its findings as follows: "... the Committee's general conclusion is that the Guidelines succeed in reflecting methods and practices that enjoy widespread acceptance in the environmental economics profession. Although some concerns remain about particular parts of the Guidelines, our overall assessment is that the Guidelines are excellent. It is our hope that the Guidelines demonstrate EPA's commitment to credible and consistent economic analyses in support of the policy process" (U.S. Environmental Protection Agency 2000, Appendix A, page 1, Letter to Administrator Carol Browner, signed by Dr. Joan Daisey, Chair, Science Advisory Board, and Dr. Robert N. Stavins, Chair, Environmental Economics Advisory Committee).

4 On July 12, 2002, EPA Administrator Christine Todd Whitman sent a memorandum to all EPA employees on the subject of "Strengthening Economic Analysis at the Environmental Protection Agency." In the memorandum, the Administrator announced that the Associate Administrator of the Office of Policy, Economics, and Innovation [OPEI] will henceforth serve as EPA's Economics Advisor to "help strengthen the analytic foundation of the Agency's decision making process." The second in a list of specific directives in the Administrator's memorandum is the establishment of "a system through which OPEI economists will review program office analyses to ensure compliance with EPA's Guidelines for Preparing Economic Analyses."

Mkt-level impacts/Reliability/EO 13211: Energy Effects

Before turning to my comments, I wish to emphasize the great importance of the proposed 316(b) rule and the analysis used by EPA to support it. According to EPA's calculations, 550 facilities nation-wide will be subject to the Phase II rule, representing 13 percent of the total number of facilities generating electricity for the market (Economic Analysis, page A2-3). This statistic greatly understates, however, the significance of the proposed rule's impact, because this same set of facilities provides fully 48 percent of nation-wide electric generating capacity and 56% of net generation (Economic Analysis, page A2-3). Hence, the impacts of the proposed rule will be widespread and exceptionally important. Given the prominence of the proposed rule, the analytical methods employed in its support are especially critical. Generic methodologies employed in support of the proposed rule, such as those used for estimating benefits and costs, may well be employed for other rules in the future. EPA should take the time to do it right in this important rule.

EPA Response

EPA acknowledges the importance that the facilities subject to the Phase II rule have in the electricity market. As documented in the preamble and the supporting documents, EPA modified a number of assumptions and methodologies in response to comments submitted on the proposed rule and the Notice of Data Availability. Many of the models and methodologies used by EPA are widely accepted and have been peer-reviewed and OMB-approved. EPA therefore asserts that it "did it right."

Benefit Estimation Methodology

In this introductory overview, I highlight the major issues that arise in EPA's proposed rule and the economic analysis which stands behind it. The most egregious errors in the analysis occur in the use of an avoided-cost method to calculate major elements of the rule's "benefits," including indirect and non-use values. Pleading constraints of time and money, EPA did not employ well-accepted and appropriate economic methods. Instead it developed and applied a completely illegitimate method of analysis, a so-called "habitat replacement cost" (HRC) method, which estimates the costs of an alternative approach — and a very costly alternative — for achieving the same functions as targeted by the proposed regulation. EPA then uses those avoided costs as a "substitute" for a calculation of the real benefits of the rule.

This is not merely a flawed approach to estimating benefits; it is not a benefit-estimation method at all. Such "avoided-cost methods of benefit estimation" have long been recognized as essentially oxymoronic and completely invalid. Applying these methods will mean that any proposed project (whether the project is good or bad for the environment) will appear to be desirable. By taking the next most costly approach of achieving an objective and calling that the project's benefits, one will always find that "benefits" — so measured — exceed costs. This completely faulty reasoning will come back to haunt EPA when others use it to push for actions the Agency opposes.

EPA Response

The HRC method is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the HRC method, please see response to comment # 316bEFR.005.035.

In the analyses for the NODA and the final rule, EPA no longer uses hatchery costs to estimate impacts on forage species. Instead EPA translates foregone production among forage species into foregone production among harvested species that are impinged and entrained using an assumed trophic transfer ratio, and then translates foregone production among these harvested species to foregone yield. Further information on the methods EPA used to estimate forage losses is provided in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003). See Chapter A5: Methods Used to Evaluate I&E.

Subject Matter Code 10.02.03

Use of Replacement Costs (HRC and hatchery-based)

Author Name Robert N. Stavins

Organization John F.Kennedy School of Government, Harvard University

While mitigation, restocking, and/or habitat restoration may be acceptable approaches as alternatives to the installation of specific technologies in order to offset I&E losses, the cost of such alternatives is not a reasonable proxy for the value (that is, the benefits) of reducing I&E.

EPA Response

In the analyses for the NODA and the final rule, EPA no longer uses hatchery costs to estimate impacts on forage species. Instead EPA translates foregone production among forage species into foregone production among harvested species that are impinged and entrained using an assumed trophic transfer ratio, and then translates foregone production among these harvested species to foregone yield. Further information on the methods EPA used to estimate forage losses is provided in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003). See Chapter A5: Methods Used to Evaluate I&E.

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule. Please see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method. Please also see EPA's response to comment #316bEFR.005.035.

Benefit Estimation Methodology

Author Name Robert N. Stavins

Organization John F.Kennedy School of Government, Harvard University

EPA needs to use an appropriate methodology for calculating the rule's benefits before it can compare those benefits with the costs of the proposed regulation. To the extent that EPA believes that non-use and other values exist which are not adequately captured by the standard and well-accepted valuation methods, it should postpone finalization of this regulation and go back to the drawing board. My comments on the HRC method are presented in detail in section III.D, below.

EPA Response

EPA agrees that they must use appropriate methodologies for calculating benefits. EPA's approach to benefit cost analysis of the final Section 316(b) Phase II rule is consistent with principles outlined in the EPA's Guidelines for Preparing Economic Analyses, United States EPA (EPA 240-R-00-003).

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, did explore several alternative non-use valuation methods to appreciate the potential magnitude of non-use values. These methods include meta-analysis of surface water valuation studies and a benefit transfer method. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Use of Replacement Costs (HRC and hatchery-based)

Related to EPA’s proposed habitat replacement cost method is another proposed valuation method, which EPA characterizes as “societal revealed preference.” Like the HRC method, this approach has no foundation in economic theory, is not accepted by economists as a legitimate empirical method of valuation, and is no more than a method of cost analysis mistakenly applied to the benefit-side of the ledger. It takes the historical cost to restore particular species under various government mandates as an indication of benefits (despite the fact that those mandates — in most cases — were developed without any systematic evaluation of their benefits and costs). The very purpose of a benefit-cost analysis is to assess policies by contrasting their benefits and their costs. EPA’s methodology completely reverses this, and takes the fact that a policy exists as evidence that its benefits exceed its costs (and therefore that its benefits can be proxied by its costs, at a minimum). This makes a complete sham of the very process in which the proposed 316(b) rule is being considered. My comments on this point are presented in section III.E, below.

EPA Response

EPA does not use the Societal Revealed Preference (SRP) method in the cost benefit analysis for the final Section 316(b) Phase II rule. Even though the SRP approach is no longer applied to the 316b benefits assessment, EPA believes that the method does have some merit and applicability under suitable conditions.

Dr. Stavins argues that EPA’s method for valuing threatened and endangered species in California, referred to as "societal revealed preference," is not truly a revealed-preference method and has no foundation in economic theory. Dr. Stavins, and some other commenters, base this assertion on the fact that the approach relies on estimates of restoration program "costs" and that these costs should not be confused with "value." They further argue that this approach would simply take the cost of any program or regulation and infer that it has a value equal to its cost.

The Agency agrees with many comments received that, in general, "costs" should not be confused for "values." However, EPA also notes that there are many instances in which cost-based information can provide useful insights to policy makers, and that under suitable circumstances, costs can be used as a proxy for (i.e., in lieu of) more desirable but less accessible "value" information.

There are many instances under which it would be wholly inappropriate to take the costs of some program or activity and assume that the "value" of that activity or program can be inferred from the cost. EPA clearly recognizes that there are specific circumstances and conditions that must apply in order for costs to suitably be interpreted as a reflection of societal (or individual) value. These conditions apply for the SRP.

For example, cost-based data may be viewed as an indication of "value" where the costs are borne voluntarily by the individuals involved, or in cases where public policies reflect a broad consensus based on continuous and extensive input from the general public and the broad array of interested parties. This would be especially true where an adaptive management approach enables adjustments over time in what actions are taken and what costs are incurred. This is the case for the restoration elements of the Cal-Fed program that serve as the basis for the Agency's initial application of the SRP. The SRP analysis was based on a public policy program involving extensive stakeholder input, in a consensus-oriented decision-making context, applying adaptive management. Under such conditions, the outcomes can be conceived as reflecting a real "social choice," and hence the resulting real costs currently borne by the public do provide a valid indication of potential value. Both individual and social choices are important and should be valued, and this approach provides a useful tool for examining social choices, under suitable conditions.

Also note that within the economics profession there are differences of opinion about social preferences. Please refer to comments submitted by Frank Ackerman (316bEFR.014.001 through 316bEFR.014.012). See especially comment #316bEFR.014.009.

RFC: Test: benefits should justify the costs

Author Name Robert N. Stavins

Organization John F.Kennedy School of Government, Harvard University

In an important part of the Proposed Rule, EPA solicits comments on four alternative decision criteria for comparing the benefits and costs of alternative CWIS technologies: (1) the wholly disproportionate cost test, whereby the alternative which exhibits the greatest environmental gain without bringing about costs which are "wholly disproportionate" to the benefits is preferred; (2) a modified wholly disproportionate cost test; (3) a significantly greater cost to benefit test; and (4) a benefits should justify the costs test, whereby the alternative which exhibits the greatest net benefits without bringing about negative net benefits is preferred. Only one of these alternative criteria will lead consistently to decisions that are in the general social interest: only criterion (4) — the benefits should justify the costs test — whereby the alternative which exhibits the greatest net benefits without bringing about negative net benefits is preferred. <FN 5> My comments on this are presented in detail in section I, below.

Footnotes

5 It is important to keep in mind that the correct economic concept of social benefits is by no means limited to financial or commercial benefits. Rather, social benefits is a measure of the net utility that all relevant members of society receive. In the present context, this would include benefits associated with commercial and recreational fishing, as well as any relevant non-use value (that is, the utility that individuals receive simply from knowledge of an amenity's existence).

EPA Response

Please refer to the response to comment 316bEFR.005.020 for a discussion of the application of the cost-benefit test to assessing the value of alternative approaches.

Facility & firm-level costs/Econ. Practicability

Closely related to the issue of alternative decision criteria is EPA's attempt to assess "economic practicability" or "affordability." In this context, EPA argues that the rule will not be damaging to firms (and individuals) which bear its costs, basing this claim upon an examination of the ratio of the annual costs of the rule to the annual revenues of the companies affected. The comparison is utterly irrelevant! It tells us nothing about whether a technology helps to achieve specific objectives, whether it does so at minimum cost (cost effectiveness), or whether an alternative investment would provide greater net benefits to the company, the environment, or society as a whole. The identification of any particular ratio as a criterion for "economic practicability" or "affordability" would be arbitrary and unsupported by sound economics.

The appropriate way, in economic terms, of evaluating society-wide "affordability" is to use a social net present value criterion, in which it is considered to be in society's interest that a technology be adopted by a firm if the present discounted value of anticipated net benefits is greater than the present discounted value of anticipated net benefits from alternatives. Note that although such a socially efficient technology maximizes net benefits to society, it may yield higher costs than benefits to an affected company. My comments on this point are presented in detail in section II, below.

Fish Population Modeling

A large and important part of EPA's overall analysis is its attempt to estimate the potential benefits of the proposed rule in reducing losses from impingement and entrainment (I&E) and any resulting increases in fish stocks and landings. <FN 6> In addition to the severe problems associated with EPA's fatally flawed HRC and related methods, there are significant flaws with its estimates of commercial fishery impacts, including the relationships between impacts on forage species and harvested species.

Changes in fish stocks and related catch levels are best analyzed with an appropriate bioeconomic "stock-recruitment model" that captures these complex relationships over time. EPA indicates that because of "uncertainties" involved in the data and the scientific relationships, and because "many fish stocks are at risk," it has chosen instead to adopt a "precautionary approach to environmental decision-making." This confuses the analysis by introducing what is — if anything — an alternative decision criterion (and one without sound foundation in the economics literature) into the estimation of benefits, rather than treating it as an explicit normative view of how decisions should be reached. Embedding a policy choice in a technical analysis intended to justify a regulatory decision would seem to contradict EPA's agency-wide standard that risk assessment should be kept separate from risk management.

Footnotes

6 I focused on economic aspects of the various analyses, and did not review for accuracy EPA's estimates of I&E losses.

EPA Response

This comment is in response to material on fish population modeling that was presented by EPA at proposal in Chapter A6 of Part A of the Phase II Case Study Document (DCN #4-0003). The commenter is incorrect to interpret the discussion in Chapter A6 to mean that EPA had embedded a policy choice in its technical analysis. Rather, the material in Chapter A6 was presented to provide the scientific basis for EPA's decision not to use dynamic fish population models for its benefits analysis. Because of the misunderstanding of some commenters about the intent of this material, EPA has withdrawn this chapter from its final analysis.

In place of the fish population modeling chapter, EPA provides its rationale for selecting the methods it used to evaluate I&E in Chapter A5 of the final Phase II Regional Analysis Document (DCN #6-0003). For harvested species, which represent less than 2 percent of total I&E losses, EPA used a simple, static model of foregone harvest that assumes that I&E losses of harvested species result in a reduction in the number of harvestable adults in years after the time that individual fish are killed by I&E and that future reductions in I&E will lead to future increases in fish harvest. The approach does not require knowledge of population size or the total yield of the fishery; it only estimates the incremental yield that is foregone because of the number of deaths due to I&E.

EPA believes that this approach provides reasonable estimate of foregone harvest projected directly within a cohort. EPA recognizes that the assumption that the key parameters in its yield model are static is an important one that is not met in reality. However, by focusing on a simple interpretation of each individual I&E death in terms of foregone yield, EPA concentrated on the simplest, most direct assessment of the potential economic value of eliminating that death.

Although EPA's approach to modeling yield requires estimates of a large number of stage-specific growth and mortality rates, the use of more complex fish population models would rely on an even larger set of significant data uncertainties and would require numerous additional and stronger assumptions about the nature of stock dynamics that would be difficult to defend with available data. Additional data uncertainties of population dynamics models include the relationship between stock size and recruitment, and how growth and mortality rates may change as a function of stock size and other factors. Obtaining this information for even one fish stock is difficult and time-consuming; obtaining this information for the many species subject to impingement and entrainment nation-wide was not possible for EPA's national benefits analysis, particularly given the lack of relevant data for the 98% of impinged and entrained species that are forage species.

In addition to a lack of data, there are numerous issues and difficulties with defining the size and spatial extent of fish stocks. As a result, it is often unclear how I&E losses at particular cooling water intake structures can be related to specific stocks. For example, a recent study of Atlantic menhaden (Brevoortia tryannus), one of the major fish species subject to impingement and entrainment along the Atlantic Coast of the U.S., indicated that juveniles in Delaware Bay result from both local and long distance recruitment (Light and Able, 2003, DCN #6-1484). Thus, accounting only for influences on local recruitment would be insufficient for understanding the relationship between recruitment and menhaden stock size. Geographic stock delineation is a significant, ongoing problem in fisheries management.

Another difficulty in developing more complex models of fish species subject to impingement and entrainment is that it is fundamentally difficult to demonstrate that any particular kind of stress causes a reduction in fish population size. All fish populations are under a variety of stresses that are difficult to quantify and that may interact. Fish populations are perpetually in flux for numerous reasons, so determining a baseline population size, then detecting a trend, and then determining if a trend is a significant deviation from an existing baseline or is simply an expected fluctuation around a stable equilibrium is problematic and often not possible with available data. Fish recruitment is a multidimensional process, and identifying and distinguishing the causes of variance in fish recruitment remains a fundamental problem in fisheries science, stock management, and impact assessment. This issue was beyond the scope and objectives of EPA's section 316(b) benefits analysis.

In light of the fact that the availability of current records of I&E loss rates is very limited, that I&E assessment is inherently complex, and that well-established methods for assessment of I&E on a national scale do not exist, EPA chose to use a static yield model to avoid additional uncertainties, and concomitant controversies about results.

For a discussion of the term "precautionary approach," please see EPA's response to Comment 316bEFR.005.026.

Use of Replacement Costs (HRC and hatchery-based)

EPA attempts to value impacts on forage species outside of a stock-recruitment model, by examining hatchery costs instead. This is not a valuation method at all, but a method of examining alternative costs. This is another example of the fatal error of confusing benefits and costs. My comments on this point are presented in section III.A, below.

EPA Response

In the analyses for the NODA and the final rule, EPA no longer uses hatchery costs to estimate impacts on forage species. Instead EPA translates foregone production among forage species into foregone production among harvested species that are impinged and entrained using an assumed trophic transfer ratio, and then translates foregone production among these harvested species to foregone yield. Further information on the methods EPA used to estimate forage losses is provided in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003). See Chapter A5: Methods Used to Evaluate I&E.

Subject Matter Code 10.02.02

Commercial Fishing Benefits

Another problem with EPA's approach to valuing commercial fisheries impacts is its unfortunate adoption of a rule-of-thumb by which it multiplies commercial valuations in a misguided effort to identify broader economic effects. This is arbitrary and not founded upon economic theory or empirical realities. This, like all of the problems I note, imparts a bias in EPA's analysis toward inflating estimated benefits of the proposed regulation relative to its costs. My comments on this are presented in section III.A, below.

EPA Response

Please see EPA's comments on stock-recruitment modeling in response to Comment 316bEFR.005.009.

For a discussion of the term "precautionary approach," please see response to Comment 316bEFR.005.026.

For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits please see the response to comment 316bEFR.005.029.

In the benefits analysis for the final rule, EPA did not use hatchery replacement costs or the 50% rule-of-thumb to estimate non-use benefits, as discussed in response to Comment 31bEFR.005.034.

Comment ID 316bEFR.005.012

Recreational Fishing Benefits

EPA's analysis of recreational fishery benefits is likewise flawed. The analyses in the various case studies rely — wholly or in part — on empirical results that were not derived from analyses of the cases in question. Instead, EPA uses a benefits transfer approach, in which results of previous studies of other recreational fishery resources are employed. This approach has considerable advantages — since it avoids the expense of carrying out original studies — but it needs to follow well-accepted steps, as documented in EPA's Guidelines for Preparing Economic Analyses. Otherwise, serious errors can occur. My comments on this point are presented in section III.B, below.

EPA Response

The commenter states that EPA's analysis of recreational fishing benefits presented at proposal is flawed because the Agency did not follow steps for developing a benefit transfer approach outlined in EPA's Guidelines for Preparing Economic Analyses. For EPA's response to comments on the benefits transfer approach used at proposal, see response to comment #316bEFR.075.504.

For the final Phase II 316b analysis, EPA has reduced its reliance on benefit transfer to estimate recreational fishing benefits. In addition, EPA no longer uses case studies of individual facilities. Instead, EPA has estimated regional models. For the recreational fishing analysis, benefit transfer is used for the Inland region, and benefit function transfer is used for the North Atlantic region. EPA has estimated RUM models for all other coastal regions (Mid-Atlantic, South Atlantic, Gulf of Mexico, and California), and for the Great Lakes region. Where the benefits transfer approach was applied (including proposed rule analysis), EPA generally followed its Guidelines for Preparing Economic Analyses for benefits transfer (BT) and has carefully applied benefit transfer methods. The following steps were followed as recommended in the Guidelines when using BT:

1. describe the policy case;
2. identify existing, relevant studies;
3. review available studies for quality and applicability;
4. transfer the benefit estimates; and
5. address uncertainty.

All of these steps were followed in the Phase II benefits analysis for the final rule.

Valuing Forage Species (incl non-use and non-landed)

EPA notes the potential importance of non-use value, for which the only available methods of estimation are stated preference surveys. But EPA did not carry out any original stated preference surveys of non-use value. Instead, it employs two surrogate approaches, and in doing so, it sacrifices accuracy and reliability in estimating benefits. First, EPA uses a rule-of-thumb in which non-use values are assumed to be equal to 50 percent of use values. There is no basis in economic theory for such an approach, and it is not supported by EPA's Guidelines for Preparing Economic Analyses. Second, EPA seeks to estimate non-use value by substituting "restoration-based costs as a proxy for the value of the change in stocks." As emphasized above, this habitat replacement cost approach is completely invalid, without foundation in economics, and likely to lead to highly biased and misleading results. My comments on this are presented in section III.C, below.

EPA Response

In this comment and others Dr. Stavins suggests that EPA has not followed EPA's Guidelines for Preparing Economic Analyses (EPA 240-R-00-003) on matters related to non-use values. On the contrary, EPA believes it correctly followed the guidelines when preparing the cost-benefit analyses for the proposed 316(b) Phase II rule.

Dr. Stavins states that the method used in the case study analyses to value non-use benefits (e.g.., existence and bequest values) is not recommended in the Guidelines. The Guidelines recommend using stated preference methods (e.g., contingent valuation, conjoint analysis, contingent ranking) and applying willingness-to-pay (WTP) values for non-use changes. However, due to time and budget constraints we applied a '50% rule of thumb,' which is based on the Fisher and Raucher (1984 -- DCN #1-3018-BE) study which found that nonuse benefits typically comprise approximately half of recreational use benefits. This method has been applied in many previous EPA cost-benefit analyses (e.g., the recent Economic, Environmental, and Benefits Analysis for the Proposed Metal Products & Machinery Rule, EPA #: 821-B-00-008).

Dr. Stavins states there is no justification for EPA's claim that its 50% rule-of-thumb provides "conservative" estimates. However, we note that Carson and Mitchell (1993, DCN - #4-1401) found a ratio of nonuse to use value ranging from one-fourth to two-thirds, and the 50% assumption falls in the middle of this range. The 50% rule is also conservative because it reflects only the nonuse component of total value to recreational users; it does not reflect any nonuse benefits to recreational nonusers. In addition, the 50% rule does not capture impacts on threatened and endangered species.

Despite EPA's belief that the methods used a proposal are in keeping with the guidelines, EPA made changes to the methodology used in the analysis for the final rule.

In the analyses for the NODA and for the final Section 316(b) Phase II rule, EPA did not use the 50%

rule-of-thumb to estimate non-use benefits.

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule.

Please see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method. Please also see EPA's response to comment #316bEFR.005.035.

Comment ID 316bEFR.005.014

Subject Matter Code 10.02
Benefit Estimation Methodology

Author Name Robert N. Stavins
Organization John F.Kennedy School of Government, Harvard University

Using flawed methodologies for estimating commercial and recreational values, including the wholly invalid habitat replacement cost method, EPA comes up with estimates that are not just highly biased upward, but are in some cases absurd. As I illustrate in detail in my comments, below, this is certainly true in the case of the Brayton Point Station case study, where the total benefit numbers reported by EPA as its estimate of the minimum value of losses are more than 100% greater than what EPA's own analysis would produce if incorrect elements of its analysis were eliminated, and approximately 21,000% (twenty-one thousand percent) greater than the acceptable elements of EPA's analysis would produce for its high case (EPA's "high" case employs its invalid HRC cost proxies instead of real value/benefit estimates). My comments on this are presented in detail in section IV.A, below.

EPA Response

The comment, referring to the proposed rule analysis, states that EPA's methodologies are flawed. While EPA has improved its methodologies for the final rule analysis, the Agency does not agree that the methods are flawed and result in overstatement of benefits by 100 percent.

For EPA's response to comments on commercial fishing methodology used at proposal, please see the response to comment 316bEFR.323.016.

For EPA's response to comments on recreational fishing methodology used at proposal, please see the responses to comments 316bEFR.041.452, 316bEFR306.320, and 316bEFR337.010.

For the final Phase II 316b analysis, EPA has reduced its reliance on benefit transfer to estimate recreational fishing benefits. In addition, EPA no longer uses case studies of individual facilities. Instead, EPA has estimated regional models. For the recreational fishing analysis, benefit transfer is used for the Inland region, and benefit function transfer is used for the North Atlantic region. EPA has estimated RUM models for all other coastal regions (Mid-Atlantic, South Atlantic, Gulf of Mexico, and California), and for the Great Lakes region. Where the benefits transfer approach was applied (including proposed rule analysis), EPA generally followed its Guidelines for Preparing Economic Analyses for benefits transfer (BT) and has carefully applied benefit transfer methods. The following steps were followed as recommended in the Guidelines when using BT:

1. describe the policy case;
2. identify existing, relevant studies;
3. review available studies for quality and applicability;
4. transfer the benefit estimates; and
5. address uncertainty.

All of these steps were followed in the Phase II benefits analysis for the final rule analysis.

The HRC method is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. While the Agency agrees that the HRC and hatchery costs are costs of replacement and not benefits, the Agency believes that understanding what it would cost residents in an area to replace CWIS losses is a very useful tool in the regulatory process and also informs decisions on the use of restoration. The HRC ,like the HEA, is a process that requires the analyst to systematically evaluate the losses caused by a CWIS, quantify them, and then consider the steps that would be necessary to replace these individuals and species. The species by species consideration of losses, even if not monetized, is a useful tool in considering the environmental effect of CWIS losses. For more detail on EPA's response to comments on the HRC method, please see the response to comment # 316bEFR.005.035.

Subject Matter Code 6.0

Environmental Impacts

In its various case studies, EPA identifies many causes of ecosystem stress, in addition to I&E associated with power plants, but it makes no effort to include these other stressors in its analyses. For example, EPA identifies a list of "major environmental stressors" of Mount Hope Bay, the body of water that may be affected by the Brayton Point Station facility, including: habitat alteration, dredging, coastal development, over-fishing, industrial pollution, nutrient pollution, wastewater runoff, climate change, and cooling water intake structure (CWIS) surface water withdrawals. No attempt is made in the analysis to attribute quantitatively any of the claimed degradation of the commercial and recreational fisheries to any of the aforementioned factors, with the exception of the Brayton Point Station's CWIS.

EPA Response

Please see comment response 316bEFR.025.018 for the discussion regarding the environmental impacts of cooling water intake structures.

National Benefits

Author Name Robert N. Stavins

Organization John F.Kennedy School of Government, Harvard University

EPA extrapolates from the case studies, many of which use flawed methodologies, to national-level "benefit" estimates. For its national-level calculations, EPA uses as "best estimates of baselines [economic] losses" due to I&E "mid-points" of its ranges (that is, means of the minimum and maximum values). In the case of the Brayton Point Station, for example, this "best estimate" of losses is claimed by EPA to be $14,711,000. But this "mid-point" is the average of the "reasonable" benefit estimate using "appropriate" benefit-estimation procedures (which carries a 100% upward bias) and the completely invalid "high" estimate from the HRC method (which carries a 21,000% upward bias).

To put this in perspective, if we draw upon EPA's own empirical estimates for Brayton Point, remove the most questionable elements — as identified above and below in my comments — from EPA's calculations, but include EPA's 50% rule-of-thumb for non-use value, then EPA's "best estimate of baseline losses" for annual I&E losses at Brayton Point (summing mid-points from appropriately specified ranges) would be $123,000. Thus, EPA's reported "best estimate" for I&E baseline losses (and hence, benefits) — which is almost completely driven by the invalid HRC results — is seen to carry an upward bias of approximately 12,000%!

The Brayton Point Station benefit estimates are part of the national totals, but are not used in the extrapolation to other facilities, despite the fact that EPA's purpose in carrying out the case studies was to develop a basis for extrapolation. No explanation is provided for this decision. Perhaps EPA recognized the absurdity of the Brayton Point results (due to the invalid HRC method), and so decided not to use these numbers as the basis for any part of the national extrapolations. Nevertheless, given the severe problems with the methodologies employed by EPA in this and the other case studies, the national-level estimates of "benefits" are themselves terribly biased, since those national-level estimates are based exclusively on the case study analyses. My comments on this are presented in detail in section IV.B, below.

Overall, while EPA repeatedly asserts in the proposed regulation that its analysis underestimates the true benefits of the regulation, the reality, in fact, is the opposite. Due to the numerous and important errors that are made by EPA in its flawed analysis, EPA has produced benefit estimates that are grossly overestimated, highly misleading, and should not be used as part of the basis for this rulemaking.

EPA Response

EPA disagrees with this conclusion and believes that the methods it used are not biased.

However, in response to this comment and others like it, EPA has reviewed and revised the case study approach to estimating national benefits. For the final section 316(b) Phase II benefits cost-benefit analysis EPA examined impingement and entrainment (I&E) losses, and the economic benefits of reducing these losses, at the regional level. All extrapolation is based on losses per unit of average annual operational flow. The extrapolation takes into account waterbody type and facility characteristics such as equipment in place.

The estimated benefits were then aggregated across all regions to yield a national benefit estimate. The primary objective of the regional approach is to refine the scale of resolution of the benefits case studies conducted for proposal, so that extrapolations were within regions rather than nation-wide. (Please refer to the EBA chapter C1 for a discussion of the regional approach - DCN #6-0002.)

In addition to extrapolating at a regional level only, EPA also collected and analyzed data for a greater number of facilities.

Thus, for the analysis for the final rule, extrapolation was needed for a smaller number of facilities, was based on a broader range of analyzed facilities, and was performed between facilities in the same region and on similar kinds of water bodies.

Regarding the use of Brayton Point results in the extrapolation, in the analysis for the final rule, the results from Brayton Point were used in the extrapolation of benefits for the North Atlantic region.

In addition, for the final analysis, EPA did not include results based on the HRC method; and EPA only extrapolated losses and benefits for recreational and commercial impacts. For these categories, only a single point estimate was reported, so no midpoint was calculated. For EPA's response to comments on the HRC methods please refer to the response to comment #316bEFR.005.035.

Best Technology Available (BTA)

Site-Specific Determination of Best Technology Available (§ 125.94(c), Proposed Rule, pages 17165-17166)

EPA has invited public comment (page 17166) on the criterion that will be employed by the U.S. Environmental Protection Agency in its site-specific determinations of the best available technological alternatives to be implemented by specific facilities, including the appropriate role for considering benefits and costs. The proposed rule recommends on page 17149 that "rigorous environmental and economic analysis should be performed," and with this I heartily concur.

Four possible criteria for identifying the "best technology" are considered by EPA in the proposed rule:

(1) the wholly disproportionate cost test, whereby the alternative which exhibits the greatest environmental gain without bringing about costs which are "wholly disproportionate" to the benefits (of the environmental gains) is preferred (p.17165)

(2) a modified wholly disproportionate cost test, proposed by Public Service Electricity and Gas Company (PSEG), whereby the alternative which exhibits the greatest net benefits (difference between benefits an costs) without bringing about costs which are "wholly disproportionate" to the benefits is preferred (p. 17166);

(3) a significantly greater cost to benefit test, whereby the alternative which exhibits the greatest environmental gain without bringing about costs which are "significantly greater" than the benefits is preferred (p. 17166); and

(4) a benefits should justify the costs test, proposed by the Utility Water Act Group (UWAG), whereby the alternative which exhibits the greatest net benefits without bringing about negative net benefits is preferred (p. 17165). <FN 8>

Mainstream economic thinking — as it is taught in any university from Maine to San Diego, from Miami to Seattle — points to one and only one of these alternative criteria as able to lead consistently to decisions that are in the general social interest: alternative (4), which is the so-called "efficiency condition" in economics. Under this standard criterion of economic analysis, universally accepted in economics and routinely practiced by private and public sector entities around the world, those options which exhibit benefits greater than costs are considered to merit further analysis, and of those, the option with the greatest (positive) difference between benefits and costs (positive net benefits) is the best option. <FN 9>

This is the "Kaldor-Hicks test," which is the basis of benefit-cost analysis, and which is the prescribed method in EPA's Guidelines for Preparing Economic Analyses. As the Proposed Rule indicates (page 17166), this criterion also is used in a wide variety of legal and regulatory contexts, including the guidelines which govern Regulatory Impact Analyses (Executive Order 12866, Section 1(b)(6)), as well as a number of statutes, such as the Safe Drinking Water Act.

Footnotes

8 The Proposed Rule's description of the UWAG recommendation incorrectly refers to the ranking as one characterized by "cost-effectiveness," whereas the ranking is actually according to efficiency (page 17165). This mistake is particularly unfortunate, because the distinction between efficiency (choosing a level of environmental protection which maximizes the difference between the benefits of protection and its costs) and cost-effectiveness (choosing the least costly means of achieving some given level of environmental protection, which may or may not be an efficient level) is crucial in later parts of the Proposed Rule.

9 For brief explications of the efficiency condition and its potential use in environmental policy analysis, see: Arrow, Kenneth J., Maureen L. Cropper, George C. Eads, Robert W. Hahn, Lester B. Lave, Roger G. Noll, Paul R. Portney, Milton Russell, Richard Schmalensee, V. Kerry Smith, and Robert N. Stavins. RFC: Appropriateness of "wholly disproportionate"

Before turning to a more detailed consideration of the merits of this criterion, I will comment briefly on the three other alternatives. Beginning with the first criterion, the wholly disproportionate cost test, it should be noted that whenever the benefits of a proposed action are less than its costs, the world is made worse off as a result of the action. Put simply, more is given up than is gained. The wholly disproportionate cost test thus goes considerably beyond what would already be economically irrational by suggesting that technologies which exhibit costs which are anywhere from one to perhaps ten times (or more) the magnitudes of their benefits ought to be pursued. There is no sound argument in economics in favor of such a decision criterion. This criterion virtually guarantees that social decisions will not be welfare-improving, indeed it guarantees that selected actions will make the world considerably worse off.

The second proposed criterion, the modified wholly disproportionate cost test, will also lead to decisions which make the world considerably worse off. Although this criterion has the admirable feature that the alternative with the greatest net benefits is to be selected, the criterion also allows for any alternative for which the costs are not wholly disproportionate to the benefits to be considered. Hence, this will often lead to the identification of a set of alternatives, all of which have benefits less than costs, with the one with the largest net benefits (but still negative) being selected.

EPA Response

EPA has not adopted the wholly disproportionate or modified wholly disproportionate standard in the final rule. See response to 316bEFR.006.003.

Comment ID 316bEFR.005.019

Author Name Robert N. Stavins
Organization John F.Kennedy School of Government, Harvard University

Subject Matter Code 10.07.02

RFC: Appropriateness of "significantly greater"

The third criterion, the significantly greater cost to benefit test, makes no more sense than the modified wholly disproportionate cost test. While EPA says that such a test would not be as conservative as a wholly disproportionate cost test, that assurance does nothing to make it economically reasonable. With this criterion, the alternative that provides the greatest environmental gain is preferred from the set of alternatives for which the costs are not significantly greater than the benefits. Hence, the set of alternatives to be considered could all exhibit negative net benefits (benefits less than costs), that is, all alternatives would make the world worse off.

EPA Response

Subject Matter Code 10.07.03

RFC: Test: benefits should justify the costs

Only the fourth proposed criterion, that the benefits should justify the costs, in the particular manner described in the Proposed Rule, will — by definition — lead consistently to decisions which make the world better off, and will identify the alternative that does so in the greatest magnitude, that is, with the largest net benefits. This is the social net present value criterion. It is in society's interest that a technology be adopted by a company if the present discounted value of anticipated net benefits to society (benefits minus costs, where benefits include environmental benefits) is greater than the anticipated net benefits of alternatives, including the status quo.

In economic terms, cost refers to the real opportunity cost <FN 10> of providing the given level of environmental protection, which may exceed — possibly by a significant amount — the out-of-pocket or accounting costs. The anticipated benefits of environmental protection are equivalent, by definition, to the value of the improvements that are brought about through the protection efforts.

Both benefits and costs typically increase with more ambitious levels of action. When the difference between benefits and costs is maximized, this is the point where society as a whole — including in the case of the 316(b) rule, commercial and recreational fishermen, electricity consumers, individuals owning shares in the company or mutual funds holding company stock, and everyone who benefits from healthy ecosystems — is made best off. This is the efficient level of environmental action that is identified by criterion (4).

Applying these concepts to the choice among alternative cooling water intake structure (CWIS) technologies <FN 11>, it becomes necessary to contrast the benefits of alternative technologies with the respective costs of alternative technologies. The best alternative CWIS technology in economic terms, from a social perspective, is the one which protects the target resources (for example, fisheries) up to the point where the incremental benefit from increased protection just equals the incremental cost of increased protection. Technologies that provide less protection are socially inefficient, because the benefits from additional protection would exceed the cost. Conversely, technologies that provide more protection are socially inefficient, because the cost associated with the increased protection would outweigh the benefits.

In sum, the best practice in economics is to assess the value of alternative technologies based on the difference between their social benefits and social costs. The best technology is the one with the highest net benefits to society. This is the technology that will be identified by the specific form presented in the Proposed Rule of criterion (4) — the benefits should justify the costs test — whereby the alternative which exhibits the greatest net benefits without bringing about negative net benefits is preferred (p. 17165). EPA should reject the other three criteria.

Footnotes

10 Opportunity cost is an indication of what must be sacrificed in order to obtain something. In the environmental context, it is a measure of the value of whatever must be sacrificed to prevent or reduce the probability of an environmental impact. These costs typically do not coincide with monetary outlays, the accountant's measure of costs. This may be because out-of-pocket costs fail to capture all of the explicit and implicit costs that are incurred, or it may be because the prices of the

resources required to produce environmental quality may themselves provide inaccurate indications of the opportunity costs of those resources.

11 Section 316(b) of the Clean Water Act directs EPA to identify "cooling water intake structures" that "reflect the best technology available for minimizing adverse environmental impact." Although some of the alternatives considered in the draft 316(b) rule for achieving flow reductions (that is, decreasing withdrawals of water for cooling purposes at power plants) involve intake structures and others do not, I employ the statute's designation of cooling water intake structures (CWIS) throughout my comments, except when it is necessary to do otherwise.

EPA Response

The comment suggests that the best way to evaluate the regulation is to use the maximum net benefit criterion. The Agency disagrees, because this could imply consideration only of quantifiable benefits. Cost benefit analysis provides a discussion of the costs and benefits of a regulation or other action, but does not specify any decision criteria or how the benefits and costs are weighted. EPA believes that is should fully consider benefits, even when the benefits are presented only as a qualitative discussion. For detail, see EPA's Guidelines for Preparing Economic Analyses (EPA 240-R-00-003).

A major problem common to the net benefits test, social net present value test, the benefits greater than costs test, the significantly greater than costs tests, the benefits equals cost test, and the greatest net benefits test is that all of these tests require that both costs and benefits be monetized because the results are reduced to a number. The tests, when defined or applied as a ratio, do not allow the consideration of unmonetized and unquantified benefits in any systematic way.

The traditional approach to quantifying environmental benefits of proposed regulations has focused on active use values, particularly direct use values such as recreational or commercial fishing because these categories of benefits are relatively easy to estimate (i.e. there are standard methods available to evaluate them and some available data to carry out the analysis) in comparison to other categories of benefits. Nonconsumptive uses (such as the importance of fish for aquatic food webs), and passive use or non-use values (including the value of protecting a resource for its own sake), are seldom considered because they are difficult to monetize with available economic methods.

For the 316(b) Phase II regulation, the Agency was not able to monetize benefits for 98.2% of the age 1 equivalent losses of all commercial, recreational, and forage species. (The percentages by region are as follows: California 95.2%, North Atlantic 99.0%, Mid Atlantic 98.4%, South Atlantic 98.1%, Gulf of Mexico 95.8%, Great Lakes 99.8%, and Inland 99.9%.) This means that the benefit analysis represents the benefits associated with less than 2% of the total age 1 equivalents lost due to impingement and entrainment by cooling water intake structures (CWISs)."

The regulation is expected to provide many benefits that were not accounted for in the benefits analysis by reducing impingement and entrainment (I&E) losses of fish, shellfish, and other aquatic organisms and, as a result, increase the numbers of individuals present, increase local and regional fishery populations (a subset of which was accounted for in the benefits analysis), and ultimately contribute to the enhanced environmental functioning of affected waterbodies (rivers, lakes, estuaries, and oceans) and associated ecosystems. The economic welfare of human populations is expected to increase as a consequence of the improvements in fisheries and associated aquatic ecosystem functioning.

Other commenters (e.g. : 316bEFR.206.047) have pointed out that the cost-benefit analysis is designed to weigh the relevant costs of a proposal against the corresponding benefits, and that this process cannot yield a meaningful result unless the calculations of costs and benefits are both complete. In the private sector, a balance sheet that weighs all of a company's income against some of its expenditures does not provide a useful picture of the company's true financial condition. The commenters also state that a comparison of complete costs and incomplete benefits does not provide an accurate picture of net benefits to society. These commenters go on to say that EPA has produced a comparison of complete costs and incomplete benefits in this case. Given that EPA wasn't able to estimate nonuse values for the majority of losses due to cooling water intake structures, the Agency believes that it is appropriate to consider both the qualitative and quantitative benefits associated with the regulation; that a test that simply compares the monetized numbers would underrepresent the true benefits. See also responses to comment #316bEFR.206.047 regarding limitations in EPA's benefits analysis .

Facility & firm-level costs/Econ. Practicability

Concept and Measure of Economic Practicability (Proposed Rule, pages 17144-17145)

The Proposed Rule contains a brief discussion of what is characterized as the rule's "economic practicability," a phrase which has no particular definition in economics (pages 17144-17145). EPA has referred to the same issue in other contexts as one of "affordability." EPA appears to be arguing that the rule will not be damaging to the firms (and individuals) which must bear its costs. EPA bases this claim upon empirical examination of the ratio of the annual costs of the rule to the annual revenues of the affected companies. The comparison is utterly irrelevant! <FN 12> It tells us nothing of value for judging this rule, either at the facility or the firm level. Even if the rule's compliance costs were a very small (whatever that might mean) percentage of annual sales, those compliance costs could cause some firms' otherwise profitable business to lose money on an ongoing basis. But by EPA's measure, this would be "economically practicable."

Although neither "economic practicability" nor "affordability" have technical definitions in economics, the criteria discussed by EPA (such as the ratio described above) are clearly intended to be economic in nature. <FN 13> Hence it is relevant and important to ask what these phrases may mean from the perspective of economics. At first blush, the issue would appear to be whether or not a particular technology is "affordable" to the firm.

Firms operating in competitive markets, such as that of electricity generation, are under considerable pressure to maximize their profits. Those which fail to earn maximum profits on their investments are unable to compete; they lose market share and may eventually close down, although before this happens they may be bought out by other firms, which recognize that the target firms are achieving subnormal returns on their investments. Hence, from the perspective of private firms, the question of whether a particular investment is "affordable" is equivalent to the question of whether that investment is consistent with a normal strategy of profit maximization. Therefore, a proper economic analysis (on the part of or on behalf of a firm) of a potential intake technology — or of any investment project, for that matter — will compare the technology's anticipated economic benefits (revenues, as well as cost savings) with its anticipated costs throughout the lifetime of the proposed project, and contrast the project's anticipated net benefits (benefits minus costs) with the anticipated net benefits of other potential projects.

The economically appropriate analysis comparing the timing of the benefits and costs of alternative investment projects is carried out by calculating the net present value (NPV) of each project. The NPV is the value of the benefits of a project, net of all costs, including opportunity costs, expressed in current dollars. This approach discounts benefits and costs that occur in the future, relative to those that occur in the present, and provides the value of the project to the business today. Projects may be considered admissible (that is, meriting further consideration) if their respective NPV exceeds zero (that is, if the present value of benefits exceeds the present value of costs). <FN 14> When comparing alternative projects, a company should invest in the one that has the greatest NPV.

Thus, the economic interpretation of "affordability" in the context of the Proposed Rule yields a decision criterion whereby the NPV of alternative intake technologies are compared, using a discount rate that reflects the individual company's cost of capital for each project under consideration. If one or more of the technologies are profitable (that is, have positive NPV), then considerations of affordability indicate that the company should install the technology with the highest NPV. <FN 15> If none of the projects is profitable, the company should not install any of the technologies, unless it is basing its decision on factors other than what is affordable.

Footnotes

12 For this reason, I have not sought to confirm the costs or revenues used by EPA.

13 A generic and pervasive problem with EPA's analysis of the proposed rule arises here and elsewhere in the relevant documents, namely EPA's tendency to place equal weight on each of a variety of studies cited, despite the tremendous variance in the quality of these underlying studies. When economic theories are being offered, empirical economic research methods described, and/or economic arguments made, it is important that literature cited ought to have — at a minimum — economists as authors and/or economists as editors of respective periodicals.

14 An equivalent way of characterizing a project with positive NPV is that the project's internal rate of return (IRR) exceeds the company's discount rate. The internal rate of return is defined as the discount rate for which the project's NPV is zero. When comparing alternative projects, however, the use of NPV analysis is preferred to a comparison of IRRs, as it provides a more reliable assessment of the impact of alternative projects on the company's profits. See Richard A. Brealey and Stewart C. Myers, Principles of Corporate Finance (4th edition), New York: McGraw-Hill, Inc., 1991, chapter 5 for a detailed discussion of the benefits of using NPV as the investment decision criterion.

15 The appropriate economic analysis would consider all costs and all benefits to the company, including the effect of the technology on the company's tax liabilities and non-monetary costs and benefits, if they can be reliably quantified.

EPA Response

The commenter asserts that EPA bases the claim of the rule's economic practicability upon empirical examination of the ratio of the annual costs of the rule to the annual revenues of the affected companies, a comparison which is "utterly irrelevant."

EPA disagrees with this comment. The cost-to-revenue ratio is only one of several measures used. It is not the main measure used to assess economic practicability of the rule. EPA's main assessment of economic practicability to facilities subject to the rule is the IPM analysis which evaluates facility-level changes in dispatch, operating costs, and revenues in the context of the entire electricity market. As supplements to the IPM analysis, EPA uses other measures, including the cost-to-revenue ratio, to assess the magnitude of likely compliance costs. The limited use of the cost-to-revenue ratio was explicitly described in the beginning of Chapter B2 of the EBA. (EPA provided further clarification in the preamble (section VII) and the supporting documentation of this final rule that the economic practicability of Phase II regulation is based on the electricity market model analyses using the IPM, not the cost-to-revenue ratio.)

The commenter specifically cites the FR section on economic practicability of the rule (67 FR 17144-17145). It should be noted that this section discusses the cost-to-revenue ratio at the facility and firm level and "additional impacts," including "potential effects of the proposed rule on installed electric generation capacity, electrical production, production costs, and electricity prices." The reader is referred to Sections VIII and X.J for more information on these analyses. The economic practicability section concludes with the following statement: "After considering all of these factors, EPA concludes that the costs of the proposed rule are economically practicable." The commenter's claim that EPA based its economic practicability determination only on the cost-to-revenue ratio is therefore incorrect.

The commenter further states that the correct approach to determining “affordability” entails that facilities install the compliance technology with the highest NPV to each facility, and only if the net present value exceeds zero. EPA disagrees with this comment. The suggested approach is correct in the context of voluntary investment decisions but is irrelevant in the context of regulatory requirements.

Facility & firm-level costs/Econ. Practicability

EPA may intend to ask a broader question: namely, whether a particular technology is "affordable" for society as a whole. Here the question is whether society can afford the action under consideration, that is, are its anticipated social benefits greater than its anticipated social costs. This leads directly to the criterion of "efficiency," where the efficient set of practices refers to that specific set of technologies and management practices that yields the greatest difference between total social benefits and total social costs, that is, that provides maximum net social benefits. So, economics provides a clear and consistent criterion for comparing benefits and costs in order to determine what is socially affordable: choose that level of effort that maximizes net social benefits. This is the same social net present value criterion (4) discussed above. Although such a socially efficient technology maximizes net benefits to society, it may yield higher costs than benefits to an affected company.

EPA Response

The commenter states that EPA may have intended to evaluate affordability for society as a whole. In this case the technology with the highest positive social NPV should be installed, even if the NPV to an affected facility would be negative. EPA disagrees with this comment. EPA evaluated "affordability to society as a whole" in its benefit-cost analysis. The analysis discussed here evaluated the economic effects on facilities, firms, and the industry. This analysis reflects the affordability concept as conventionally understood and analyzed for OW rulemaking, which is different from an analysis of social costs and benefits.

Subject Matter Code 9.01

Facility & firm-level costs/Econ. Practicability

Finally, a question might be posed from an accounting perspective: will a company continue to earn a profit after the action in question is taken, such as adopting some specific technology? From economics, we know that the analysis must be carried out on the margin (that is, focusing on incremental or marginal benefits and costs) to be meaningful. Hence, one could ask whether marginal profits are positive, that is, are marginal benefits to the company greater than marginal costs? This returns us to the NPV criterion developed above. Or, if we are to take a broader, social view of "affordability," then we could ask whether social NPV is positive, and we are returned to the social NPV criterion developed above.

It is also important to examine the actual impacts of increasing costs and reducing profits, that is, the real economic incidence of such effects. First, a reduction in a company's profits would result in a decline in the share price of its parent company. Note, however, that all shares in any company are ultimately owned by individual persons, although some shares may be held by intermediaries. For example, about half of all outstanding shares in electricity generators in the United States are held by individuals, as distinct from institutions. More importantly, institutions — largely mutual funds, pension funds, and retirement accounts — are themselves owned by individuals. In addition to effects on share prices, reduced profits may lead to reduced or eliminated dividend payments, upon which many shareholders rely. Utility stocks have traditionally been held by investors looking for a steady stream of income.

Creditors would also feel the effects of decreased profits First, the market value of an affected company's debt would decline as projected earnings fell. Second, that company's ability to make its interest payments becomes less certain if energy prices fall or costs increase. As with shareholders, creditors ultimately are individuals, either holding corporate bonds directly, or through mutual funds, pension plans, and other investment accounts. Those people who depend on the income stream from interest payments would be harmed.

To the extent that defining electricity generators' "affordability" for a technology does not explicitly protect the financial health of the generator, employees would also be harmed. Direct employee compensation and employee benefits generally are related to the employer's financial health. Moreover, if the profitability of firms is jeopardized, they may have difficulty attracting new employees, and employees' jobs may ultimately become less secure.

Finally, electricity consumers may also be harmed by increased generation costs. As costs of production are increased (for example, due to compliance activities), some of those costs may be reflected in increased product prices. <FN 16> An increase in electricity rates, and a possible decrease in electricity supply, would affect very large populations.

In conclusion, finding that a particular intake technology — or any investment — is or is not "economically practicable" or "affordable" based on its costs relative to the firm's or facility's revenues could not be based upon a decision criterion with any normative standing in economics.

Such an approach would tell us nothing about whether the technology helps to achieve specific objectives, whether it does so at minimum cost, or whether an alternative investment would provide greater net benefits to the company, the environment, or society as a whole.

Footnotes

16 The share of the cost burden that is absorbed by firms in terms of reduced profits, versus the share that is passed on to consumers through increased prices, is determined by the competitiveness of the specific market (and, of course, any relevant regulatory constraints).

EPA Response

The commenter makes three points:

1. From an accounting perspective, a technology should only be installed if the marginal profits are positive. Therefore, the compliance technology with the highest positive NPV should be installed. EPA RESPONSE: The suggested approach is correct in the context of voluntary investment decisions but is incorrect in the context of regulatory requirements. If “positive” is removed from the second sentence of the comment, then the comment would be applicable to the choice among potential compliance alternatives, including shutdown instead of compliance. This, in fact, is the framework that EPA applies in its conventional analyses of likely firm/facility response to regulatory requirements.

2. It is also important to examine the “real economic incidence” of increased costs and reduced profits, including reduced or eliminated dividend or interest payments, reduced market value of the company’s debt, effects on affected facilities’ existing employees, and facilities’ ability to attract new employees. EPA RESPONSE: The requested level of examination far exceeds analyses needed for OW rulemakings. Any impacts in the categories of concern cited by the commenter must start from the finding of a material impact on the business performance of the regulated establishment. The more practical and meaningful focus of the economic impact analysis is thus on the regulated facility and its owning firm.

3. It is important to analyze impacts on electricity consumers due to increases in electricity rates and possible decreases in electricity supply. EPA RESPONSE: The comment is generally valid. However, the commenter apparently overlooked the fact that EPA’s IPM analyses explicitly considered the cited potential effects at proposal, for the NODA, and the final rule.

Benefit Estimation Methodology

Methodology of Benefit Analysis (Proposed Rule, page 17191; Case Study Analysis, Chapters A5, A6, A9, A10, A11)

As an essential part of the policy analysis that constitutes the justification for the proposed rule, it is necessary to value economically the changes in environmental quality that may be brought about by the proposed regulation. EPA begins its analysis by noting that changes in the design and/or operation of cooling water intake structures (CWIS) may reduce rates of impingement and entrainment (I&E) of aquatic species, thereby enabling fish and other aquatic organisms to avoid premature mortality. The result, according to EPA, may be an increase in fish stocks, as well as "enhanced environmental functioning of affected waterbodies and associated ecosystems." The crucial posited linkage for economic benefit analysis is a final one, namely that "the economic welfare of human populations is expected to increase as a consequence of the improvements in fisheries and associated aquatic ecosystem functioning" (Case Study Analysis, page A9-1). My comments on the methodologies of benefit analysis are focused on this final linkage.

The Case Study Analysis lays out the crucial foundation for EPA's benefit analysis as follows (page A9-2): "Conceptually, the monetary [economic] value of benefits is the sum of the predicted changes in 'consumer and producer surplus.' These surplus measures are standard and widely accepted terms of applied welfare economics, and reflect the degree of well-being derived by economic agents (e.g., people or firms), given different levels of goods and services, including those associated with environmental quality." Unfortunately, EPA departs from this conceptual foundation in several crucial ways, and that is where my criticisms are focused.

My review of EPA's methodologies for benefit analysis, <FN 17> described below in detail, comes to the following conclusions, among others: (1) EPA's estimates of commercial fishery impacts are severely flawed, due in part to a lack of reliance on standard and accepted bioeconomic models, and adoption of approaches which lack foundation in the scientific literature; (2) EPA's analysis of recreational fishery benefits is likewise flawed, because of reliance on problematic applications of benefits transfer methods, and the use of an arbitrary rule-of-thumb for estimating non-use values as a fixed fraction of use values; (3) EPA's habitat replacement cost (HRC) method represents one of the gravest of errors in economics, actually confusing benefits and costs, and — as such — this method is a completely invalid approach to identifying benefits; and (4) EPA's proposed "societal revealed preference" approach has no foundation in economic theory, is not accepted by economists as a legitimate empirical method of valuation, and — like the HRC method — is no more than a method of cost analysis mistakenly applied to the benefit-side of the ledger.

Footnotes

17 EPA identifies four categories of benefits: (1) market benefits (commercial fisheries); (2) non-market direct uses (recreational fisheries); (3) non-market indirect use (forage species); and (4) non-market non-use (sometimes characterized as existence or passive-use value). I examine all four of these categories of benefits in these comments, but I divide my comments on EPA's benefit assessment methodology into five different sections: methodology for valuing commercial fishing impacts (EPA's category 1); methodology for valuing recreational fishing impacts (EPA's category 2); concept and

methodology for valuing non-use value (EPA's category 4); EPA's proposed additional methodology for "valuing benefits" by assessing the costs of habitat replacement; and EPA's proposed methodology for "valuing benefits" by assessing the historical costs of government-mandated species restoration. I include consideration of EPA's category 3 (forage species) within my examinations of commercial and recreational fishing impacts.

EPA Response

The commenter states that EPA's analyses of commercial fishery impacts, recreational fishery benefits, and non-use benefits presented at proposal are severely flawed.

For EPA's Response to comments on the methods used to estimate commercial fishing losses and benefits please see the response to comment #316EFR.005.029.

For EPA's Response to comments on the methods used to estimate recreational fishing benefits please see the response to comment #316EFR.075.504.

As stated in the NODA, the rule-of-thumb approach to estimating non-use is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, did explore several alternative non-use valuation methods to appreciate the potential magnitude of non-use values, including meta-analysis and the benefit transfer method. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

The HRC method is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the HRC method, please see comment #316bEFR.005.035.

The SRP method is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the SRP method, please see comment #316bEFR.005.006.

Commercial Fishing Benefits

Methodology for Valuing Commercial Fishing Impacts (Proposed Rule, page 17191; Case Study Analysis, Chapter A5, A6, A9)

In Chapter A9 — “Economic Benefit Categories and Valuation Methods” — of its Case Study Analysis, EPA lays out its methodology for valuing the impacts of impingement and entrainment (I&E) on commercial fish stocks and landings. It notes that the first step of the analysis involves an assessment of the I&E-related changes in commercial landings. A fundamental aspect of the analysis of economic benefits is this first step of analyzing the effects of reductions of impingement and entrainment losses on stock levels of harvested species (and, as explained below, forage species) and the subsequent interactions of these stocks levels with one another and with catch levels over time.

Changes in fish stocks and related catch levels are best analyzed with an appropriate bioeconomic “stock-recruitment model” that captures these complex relationships over time, <FN 18> but EPA chose methods for quantifying the effects of impingement and entrainment on commercial harvests that overestimate actual increases in harvests that could occur if I&E were reduced. I believe that EPA recognizes that a properly-specified stock-recruitment model would be the appropriate method for analyzing these relationships, because it says as much in Chapter A6 of the Case Study Analysis, “Fish Population Modeling the Section 316(b) Benefits Case Studies,” where it devotes six of the chapter’s seven pages to an explication of stock-recruitment models (including the Beverton-Holt and Ricker stock-recruitment relationships).

Ecological Risk Assessment

At the end of Chapter A6, after having provided a description of the stock-recruitment models and their use in fisheries management, EPA departs from this accepted scientific approach, and introduces a discussion of what it labels a "precautionary approach." EPA indicates that because of the "uncertainties" involved in the data and the scientific relationships, and because "many fish stocks are at risk," it has chosen to adopt "a precautionary approach to environmental decision-making."

This approach subverts the analysis by introducing what is — if anything — an alternative decision criterion into the estimation of benefits, rather than treating it honestly as an explicit view of how decisions should be reached (in the manner of the four decision criteria discussed in the first section of these comments). In other words, the "precautionary approach" used by EPA to justify the use of conservative models is an approach to public-policy making, not an approach to economic valuation. Embedding a policy choice in a technical analysis intended to justify a regulatory decision would seem to contradict EPA's agency-wide standard that risk assessment should be kept separate from risk management.

EPA Response

EPA agrees that risk assessment should be kept separate from risk management, and did not intend to confuse the two by its unfortunate use of the term "precautionary approach" in the discussion referred to by the commenter. The purpose of EPA's discussion in this section was to note its concern that many fish stocks are at risk from multiple stressors, including cooling water intake structures, and to note that such risks can be difficult to adequately assess and mitigate because of data uncertainties, heightening concerns of resource managers. However, this discussion is not included in EPA's final analysis for the 316b Phase 2 rule. EPA has not applied the precautionary approach in the 316b benefits analysis.

Valuing Forage Species (incl non-use and non-landed)

An important element of the relationship between changes in impingement and entrainment and changes in commercial (and for that matter, recreational) landings is the impact of reductions in I&E on forage species. In the Proposed Rule (page 17191), EPA states that in the case of forage species, it can be difficult to estimate values because — by definition — the species are not targeted directly by commercial (or recreational) anglers, and direct use values are not revealed by market activity as they are in the case of commercial species or by market behavior from which recreational values can be inferred through reliable revealed-preference analytic methods. EPA posits two approaches to value I&E impacts on forage species.

One approach to valuing such impacts on forage species, which makes sense in theory and can provide very good estimates if properly applied with a sufficiently refined model, is to examine the biological consequences of changes in forage species stocks on stock levels of commercial and recreational species. EPA refers to this as the "production forgone approach." It "assigns a value to reduced forage species losses based on their indirect contribution to higher commercial and recreational fishery values." <FN 19>

So, the correct approach is to develop a theoretically sound and empirically valid model of the impacts of alternative CWIS technologies on affected species, including commercial, recreational, and forage species. The biological modeling and the subsequent bioeconomic modeling should then estimate how all of the stocks evolve through time, including the effects of changes in forage stocks on commercial (and recreational) stocks, which are then valued through appropriate market-based methods. Sound biological and bioeconomic models will include forage species and will fully provide for food web effects on commercially and recreationally harvested species. That is the correct way to account for the value of effects on forage species.

Footnotes

19 If there are other values of forage species — not associated with commercial or recreational impacts — then such values are presumably non-use values, the proper estimation of which I consider below in section III.C.

EPA Response

EPA agrees that valuing impacts on forage species is best accomplished by examining the impacts of forage species on commercial and recreational species. In the analyses for the NODA and the final rule, EPA translates foregone production among forage species into foregone production among harvested species that are impinged and entrained using an assumed trophic transfer ratio, and then translates foregone production among these harvested species to foregone yield. Further information on the methods EPA used to estimate forage losses is provided in the regional study document prepared for the analysis for the final Phase II rule. See Chapter A5: Methods Used to Evaluate I&E (DCN #6-0003)

Use of Replacement Costs (HRC and hatchery-based)

EPA's other proposed approach for valuing forage species — inference from hatchery costs — is not a valuation method at all, and should be deleted from the analysis. The benefits of increasing the stocks of forage species cannot be estimated in economic terms by observing the costs of developing and introducing hatchery fish into wild populations. In economic terms, the benefits of some action are equivalent to the aggregate of the willingness to pay (WTP) by the affected human populations for that action or outcome. In the case of the benefits of an increase in the stocks of forage species, a reasonable approximation of this WTP can be estimated by examining the biological impacts of the forage species stock increase on the stocks of commercial (and recreational) species, and then using a theoretically correct and empirically reliable method to estimate the WTP for the commercial (or recreational) species. This is essentially EPA's first approach, described above. But an attempt to short-circuit such an approach by examining the costs of re-stocking forage species incorrectly substitutes costs for benefits in a completely illegitimate manner. <FN 20>

This critical error of confusing benefits and costs by attempting to substitute some estimate of "avoided cost" for a valid measure of real benefits inevitably biases the benefit estimates upward. This same error also occurs with EPA's proposed "habitat replacement cost" (HRC) method, which plays an even more important role quantitatively in the overall analysis (in the Brayton Point Station case study). Hence, I defer further discussion of this extremely important error (of confusing benefits and costs) until section III.D, below.

Footnotes

20 The two methods proposed for valuing impacts on forage species are also discussed in the Case Study Analysis. The generic discussion is on pages A5-7 through A5-9.

EPA Response

In the cost-benefit analyses for the NODA and the final rule, EPA no longer uses hatchery costs to estimate impacts on forage species. Instead EPA translates foregone production among forage species into foregone production among harvested species that are impinged and entrained using an assumed trophic transfer ratio, and then translates foregone production among these harvested species to foregone yield. Further information on the methods EPA used to estimate forage losses is provided in the regional study document prepared for the analysis for the final Phase II rule. See Chapter A5: Methods Used to Evaluate I&E (DCN #6-0003).

EPA agrees that there are differences between costs and benefits but maintains that understanding and considering the replacement costs is an important tool in the regulatory process.

Commercial Fishing Benefits

Once the effects of reductions in impingement and entrainment on commercial landings have been correctly identified (which, as I've emphasized above, EPA has not done), the next step in the economic benefits analysis is to assign an appropriate market value to the changes in landings. This is relatively straightforward, as long as reasonable estimates of future market values are employed.

EPA next seeks to convert the dockside market value of changes in commercial landings into a measure of the economic surplus that constitutes social benefits. In principle, this is not unreasonable, but EPA notes (on page A9-5 of the Case Study Analysis) that "to do this with primary analysis would be an extremely complex process..." A sensible approach instead might simply be to use the valuation of landings, recognizing that this provides an upper bound estimate of respective producers surplus, since some part of this revenue covers associated costs. <FN 21>

But EPA chooses to adopt a set of rules-of-thumb that cannot be said to have any basis in economic theory and which are based — at best — upon a very limited set of empirical examples. Using these rules of thumb, EPA proceeds to multiply commercial valuations by a minimum of 1.8 and a maximum of 3.2 to establish its estimated range of social benefits from commercial fisheries impacts. In some situations, it can be desirable to examine general equilibrium (or at least, multi-market) rather than partial equilibrium impacts, <FN 22> but there are four significant problems with EPA's approach.

First, as suggested above, it is arbitrary and not founded upon economic theory nor upon a broad survey of empirical research.

Second, it is not clear what is the nature of the secondary economic benefits that EPA wishes to estimate. In the context of 316(b), the correct measure of the commercial value is the in situ (in place) value of an increase in catch due to reduced I&E losses. The commercial value to seafood processors or retailers are not appropriate measures, since those values include value added from use of labor, capital, and other inputs to process, preserve, and transport fish, once caught. The appropriate value is the in situ value of an increase in catch, reflecting willingness to pay for the additional harvest, measured by the landed price, assuming that there is no significant change in fishing effort. <FN 23>

Third, in order for there to be significant changes in consumers surplus associated with changes in commercial fishery landings, there would have to be induced changes in retail prices, which would only occur if there were significant aggregate supply effects <FN 24> for individual species. EPA has not presented evidence that the very small anticipated changes in landings would result in anything other than trivial changes in market prices.

Fourth, if an appropriate multi-market or general equilibrium analysis of the benefit side were carried out, then the same reasoning about multi-market, general equilibrium effects should be estimated on the cost side, which is not done in current analysis. <FN 25> Hence, this, like all the problems I note, imparts a bias in EPA's analysis toward inflating estimated benefits of the proposed regulation relative to its costs.

Footnotes

21 That would represent a true upper bound. In fact, the one empirical study cited by EPA that examines an Atlantic coast fishery (Norton et al. 1983) found that producers surplus was approximately 15% of dockside revenues, not the 40-70% assumed by EPA. Furthermore, the open-access conditions which characterize most fisheries indicate that in the long term, new entry will dissipate much of any producers surplus. On the first point, see: Norton, V., T. Smith, and I Strand, eds. Stripers: The Economic Value of the Atlantic Coast Commercial and Recreational Striped Bass Fisheries. Maryland Sea Grant, UM-SG-TS-83-12. 1983.

22 Economists frequently analyze policies with a partial equilibrium approach, where only a part of the economy (such as a single product market or a single industrial sector) is examined, using the simplifying assumption that conditions in the rest of the economy are unchanged or trivial. More difficult — both conceptually and empirically — is general equilibrium analysis, in which an entire economic system is modeled, allowing for simultaneous determination of prices and quantities of all goods and services in the economy.

23 A conceptually correct and empirically feasible approach would be to employ general equilibrium derived-demand functions, as suggested by: Thurman, Walter N. and J. E. Easley, Jr. "Valuing Changes in Commercial Fishery Harvests: A General Equilibrium Derived Demand Analysis." Journal of Environmental Economics and Management 22(1992):226-240. In the present context, the welfare impacts that would thereby be derived may be approximated by the product of the landed price and the harvest rate. See: Just, Richard E. and Darrel L. Hueth. "Welfare Measures in a Multimarket Framework." American Economic Review 69(1979):947-954.

24 For the various affected species, the relevant markets are not local, but regional, national, or international.

25 In addition to the imbalance that is imparted by accounting for multi-market effects on the benefit side, but not the cost side, there is considerable opportunity for double-counting of benefits if the analysis is not carried out correctly. In this regard, EPA's own description of "secondary benefits" is cause for concern (Proposed Rule, page 17192). For example, EPA lists "property values" as an important category of secondary benefits. But property values capitalize amenity values, such as proximity to improved fishing opportunities. For this reason, one category of benefit estimation methods (econometric "hedonic property value methods") assesses the value of local environmental improvements by observing the variance in property values among areas with various levels of the environmental amenity in question. Thus, if EPA were to value improvements in recreational fishing through a RUM or benefit-transfer analysis, for example, and then add to it related increases in property values, at least some of the same values would likely be counted twice.

EPA Response

This comment questions many of the methods used by EPA in estimating commercial fishing benefits. Other commenters raised many of the same points. The key topics in these comments are addressed below. Further detail on the methods EPA used to estimate commercial fishing losses and benefits in the analysis for the final rule is provided in the regional study document prepared for the analysis for the final Section 316(b) Phase II rule (DCN #6-0003). For response to comments regarding methods used to translate impingement and entrainment data into measures of fish used to estimate benefits, see EPA's response to comments #316bEFR.005.009, #316bEFR.025.015, #316bEFR.029.105, #316bEFR.206.065, #316bEFR.305.003, and #316bEFR.306.506.

1) Rule-of-Thumb Approach to Estimating Economic Surplus Lost

Dr. Stavins notes that for the proposed rule EPA estimated total current losses in the commercial fishing sector by multiplying the estimated loss of gross commercial fishing revenues by a minimum of 1.8 and a maximum of 3.2. EPA developed these estimates in two steps. First, EPA estimated lost producer surplus by multiplying gross revenues lost by a minimum of 0.4 and a maximum of 0.7, based on evidence from the empirical literature indicating that producer surplus ranges from 40% to

70% of gross revenues in the commercial fishing industry. Second, also based on evidence from the literature, EPA assumed that producer surplus accounted for 22% of total economic surplus. Thus, EPA multiplied the estimated producer surplus lost by 1/0.22, or 4.55, to estimate total economic surplus. Applying this value to the 40% to 70% range results in a range of 1.8 (0.4 x 4.55) to 3.2 (0.7 x 4.55).

Dr. Stavins and other commenters felt that this method over-stated current losses of economic surplus in the commercial fisheries. Based on these comments, EPA reviewed and ultimately updated many of the empirical relationships used to estimate lost economic surplus due to impacts on commercial fisheries. The revised methods are described below in sections 2 through 4.

2) Producer Surplus

Based on a more thorough review of the empirical literature, EPA updated the assumptions used to estimate producer surplus lost due to impingement and entrainment. EPA still applies a benefits transfer-based rule-of-thumb method to estimate producer surplus as a range of percentages of gross revenues lost. However, based on a more comprehensive review of the empirical literature, EPA now assumes a ratio of 0% to 40% of gross revenues rather than the ratio of 40% to 70% applied at proposal.

2) Consumer Surplus

Changes in consumer surplus will arise if the change in commercial landings affects retail market prices for the impacted fish. After reviewing the estimated losses in landings due to impingement and entrainment at baseline -- and their expected reduction under the rule -- EPA does not expect the magnitude of changes in the commercial catch to be large enough to significantly affect prices for commercially caught fish. Without a change in prices, there is no change in consumer surplus as a result of this rule. Thus, in the analysis for the final Section 316(b) Phase II rule EPA estimates the change in lost consumer surplus to be zero.

3) Surplus in Secondary Markets

In the analysis of benefits for the proposed rule, EPA assumed that producer surplus in the commercial fishing sector accounted for 22% of the total economic surplus. This estimate included economic surplus that accrued to secondary consumers such as seafood processors and retailers. Without a change in prices, these secondary benefits will not be realized. Thus, in the analysis for the final Section 316(b) Phase II rule EPA estimates the change in economic surplus in secondary markets to be zero.

4) Short-run vs. Long-run

Many commenters suggested that benefits of reduced impingement and entrainment only accrue to the commercial fishing sector in the short run. These commenters note that in the long run in an unregulated fishery the potential to realize economic rents will attract additional fishing effort (e.g., via new boats added to the fleet or increased efforts by existing boats) until rents are reduced to zero. Thus, these commenters felt that long-term economic rents are only sustainable in a fishery where increased effort is restricted.

Since this is a national rule, it will affect both regulated and unregulated fisheries. The revised range that EPA uses to estimate producer surplus effectively captures both cases. The lower bound assumption that producer surplus is 0% of gross revenues reflects the case of zero long run benefits in an unregulated fishery. The upper bound assumption of 40% indicates that losses of producer surplus may be reduced by up to 40% of the reduction in gross revenues lost.

The 0% lower bound also captures the case of a fishery in which quantity is limited by demand rather than supply. If there is no demand for the additional catch resulting from reductions in impingement and entrainment, then the quantity supplied to the market will not change and the change in producer surplus will be zero.

It should also be noted that Office of Management and Budget guidance for conducting economic analysis in support of executive order 12866 recommends that sensitivity analysis be performed around the baseline assumption of the world as it is today. It can be argued that fisheries management agencies (e.g., regional fisheries management councils) have been tasked with designing strategies to improve efficient use of our fishery resources, and that benefits associated with this final rule could be affected by those fishery management decisions as they affect open access.

5) Discounting

Though it is not addressed directly in this comment by Dr. Stavins, his other comments on the analysis for the proposed rule indicate the need to discount benefits and costs. Other commenters also suggested that benefits estimates should be discounted because the benefits and costs of the rule will, in some instances, occur in different years. Specifically, these commenters noted that the costs of installing new technologies to reduce impingement and entrainment will be incurred before the benefits are realized in the form of increased commercial or recreational landings.

For the section 316(b) Phase II rule, the need to discount arises from two sources. First, at many facilities there will be a delay between the time the rule is enacted and the time facilities attain compliance and begin to reduce impingement and entrainment impacts. EPA addressed the need for this type of discounting in the analysis for the final rule - it is assumed that there will be a one year lag from the time that costs are incurred to the time that benefits begin to be realized. Second, some fish saved today will require one or more years to grow to a size at which anglers will harvest them. EPA also addressed the need for this type of discounting in the analysis for the NODA as well as in the analysis for the final rule. The estimated time it is assumed that it will take to reach a beneficial age is a function of biological factors and varies by fish species.

Further detail on the discounting methods used by EPA is provided in the regional study document prepared for the analysis for the final Phase II rule. See Chapter A14: Discounting Benefits (DCN #6-0003).

Recreational Fishing Benefits

Methodology for Valuing Recreational Fishing Impacts (Case Study Analysis, Chapters A9, A10, A11)

There is a long-standing and extensive literature in environmental economics on the valuation of recreational activities, including those associated with fisheries. These valuation methods have the same objective as any and all valuation methods in economics, namely to provide unbiased and precise (low-variance) estimates of people's true willingness to pay for particular recreational experiences. The methods fall into two categories.

First, there are revealed preference methods, in which people reveal (unintentionally) their demand (willingness to pay) for non-marketed goods and services through observable behavior in other markets. These methods are well-regarded in economics, and tend to be econometric (that is, statistical) in nature. When the most sophisticated of these methods are appropriately applied, the results are thought to be quite reliable. Examples of revealed-preference methods in environmental economics include the hedonic property method, hedonic wage method, the so-called (but inappropriately named) travel cost method, and the random utility model. <FN 26> The last two have been applied frequently to value recreational fisheries, and — when correctly applied — these approaches can provide relatively reliable estimates.

The travel cost model may be thought of as examining the demand for the services of a site over some period of time, whereas the random utility model may be thought of as examining how individuals choose among a group of possible recreational sites each time a choice is made. Neither of these models is preferable in all situations; rather, there is a set of characteristics of the recreational fishery (or fisheries) in question that will determine which approach is likely to be better. <FN 27> Problems exist with both models, <FN 28> but it can fairly be said that the random utility model is the current state of the art for many applications.

Footnotes

26 One other revealed-preference approach is under development for valuing recreational fisheries. With this new approach, the demand for freely-available public goods, such as a recreational fishing experience, is estimated through analyzing the demand for a privately-traded option (that is, a fishing license) to use that public good. See: Stavins, Robert N. "Private Options to Use Public Goods: The Demand for Fishing Licenses and The Benefits of Recreational Fishing." Paper presented at the Allied Social Science Associations meetings, New Orleans, January 1997.

27 The gain with the random utility model in the ability to explain choices among sites as a function of the characteristics of available sites comes at the expense of an inability to explain the total demand for a recreational activity, such as the number of activity days in a season. See: Freeman, A. Myrick. The Measurement of Environmental and Resource Values: Theory and Methods. Washington, D.C.: Resources for the Future, 1993.

28 See the early discussion by: Bockstael, N.E., K. E. McConnell, and I. E. Strand. "Recreation." Measuring the Demand for Environmental Quality, eds. J. B. Braden and C. D. Kolstad. Amsterdam: North Holland, 1991.

EPA Response

EPA agrees that the random utility model (RUM) is the current state of the art for recreational fishing valuation, and that it can provide reliable estimates of recreational benefits. For the final Phase II 316b analysis, EPA has increased its reliance on RUMs to estimate recreational fishing benefits. EPA has estimated RUM models for all other coastal regions (Mid-Atlantic, South Atlantic, Gulf of Mexico, and California), and for the Great Lakes region. In addition, benefit function transfer based on a revealed preference study is used for the North Atlantic region. For detail, see Chapter A11, Estimating Benefits with a Random Utility Model, and Chapter 4, RUM Analysis, in Parts B through H of the final Phase II Regional Studies document (DCN #6-0003).

Stated preference (Contingent Valuation)

The other category of methods used to estimate peoples' willingness to pay for recreational experiences (and other environmental amenities) is known generally as stated preference methods, in which people are asked through surveys to state their willingness to pay for particular amenities, such as access to recreational fisheries with particular attributes. The first thing to be said about stated preference or survey methods — which often go under the label of "contingent valuation" — is that they are not universally accepted by economists. Indeed, it is fair to say that these methods are controversial within the economics community. <FN 29>

There is a consensus view in economics that when an appropriate and reliable revealed-preference approach is available for valuing a particular environmental amenity, then that approach should be used, rather than resorting to a stated preference approach, such as contingent valuation. On the other hand, it should also be acknowledged that for one class of environmental values — so-called non-use value — revealed preference methods are not available, and stated preference methods are the only possible alternative. I return to this in section III.C, below, on valuation methods for non-use value.

Footnotes

29 See, for example: Hausman, Jerry A., ed. Contingent Valuation: A Critical Assessment. Amsterdam: North-Holland, 1993. The authors of critiques in this volume include a remarkable set of leading economists, two of whom are Nobel laureates. For a more recent (and more balanced) view of the debates still raging among economists, see the following three articles: Portney, Paul R. "The Contingent Valuation Debate: Why Economists Should Care." Journal of Economic Perspectives 8(1994):3-17; Hanemann, W. Michael. "Valuing the Environment through Contingent Valuation." Journal of Economic Perspectives 8(1994):19-43; and Diamond, Peter A. and Jerry A. Hausman. "Contingent Valuation: Is Some Number Better than No Number?" Journal of Economic Perspectives 8(1994):45-64. All three articles are reproduced in: Stavins, Robert N. Economics of the Environment. Fourth Edition. New York: W. W. Norton & Company, 2000.

EPA Response

EPA agrees with Dr. Stavins, that revealed preference approaches should be used when available, and that stated preference methods (or benefit transfer based on stated preference methods) are the only alternative for valuing non-use values. For the final Phase II 316b analysis, EPA has increased its reliance on revealed preference methods to estimate recreational fishing benefits. EPA has estimated RUM models for four coastal regions (Mid-Atlantic, South Atlantic, Gulf of Mexico, and California), and for the Great Lakes region. In addition, benefit function transfer based on a revealed preference study is used for the North Atlantic region. For detail on recreational fishing benefits analysis, see Chapter A11, Estimating Benefits with a Random Utility Model, and Chapter 4, RUM Analysis, in Parts B through H in the Regional Case Study report (DCN #6-0003).

Random Utility Model (RUM)

In the case studies that comprise EPA's empirical analysis of the recreational benefits of the proposed rule, the Agency uses random utility models for part of its analysis for three cases: Delaware Estuary Watershed, Tampa Bay Watershed, and Ohio River Watershed. But in none of these cases are the results of the original RUM analyses employed in EPA's ultimate benefit calculations. In four other cases (Brayton Point Station Facility, Pilgrim Facility, J. R. Whiting Facility, and Monroe Facility), EPA relies partly on an approach which is not a benefit-assessment method at all, which is without conceptual foundation, and which is empirically biased. This is the so-called Habitat Replacement Cost Analysis (HRC) method, which I discuss in section III.D, below.

EPA Response

For the final Phase II 316(b) analysis, EPA has increased its reliance on revealed preference methods to estimate recreational fishing benefits. EPA has estimated RUM models for all other coastal regions (Mid-Atlantic, South Atlantic, Gulf of Mexico, and California), and for the Great Lakes region. In addition, benefit function transfer based on a revealed preference study is used for the North Atlantic region. Values from these analyses are included in the final benefit calculations. For detail on recreational fishing benefits analysis, see Chapter A11, Estimating Benefits with a Random Utility Model, and Chapter 4, RUM Analysis, in Parts B through H in the Regional Case Study report (DCN #6-0003).

The HRC method is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the HRC method, please see comment # 316bEFR.005.035."

General/Benefit Transfer

Furthermore, for each and every one of the case studies, EPA relies — wholly or in part — on empirical results that were not derived from actual analyses of the cases in question. Instead EPA uses a benefits transfer approach, which simply means drawing upon results of previous studies of recreational fishery benefits for other fisheries in other locations. It is important to recognize that there are several careful steps that must be taken to develop reliable benefit transfer results, as documented in EPA's Guidelines for Preparing Economic Analyses.

First, the results of the benefit transfer approach can only be as reliable (at best) as the results of the underlying studies, which in the case of the 316(b) proposed rule are a combination of contingent valuation, travel cost, and random utility modeling. Second, if the original studies involve different resources in different locations, as is the case in many of the 316(b) benefit transfers, then the values themselves are problematic for transfer, even if the numbers were valid for the original applications. <FN 30>

In developing its benefit transfer values, EPA uses several studies to develop a range of results. But developing a range of values through benefit transfers, as EPA does, can be highly misleading because a range of results implies to most readers a uniform distribution of uncertainty across the entire range. It is much more likely that the relevant probability distribution is not uniform and quite possibly not symmetric. Furthermore, ranges developed from methods and studies of highly varying quality are particularly misleading, since equal weight is given to all methods and studies, regardless of their relative soundness and reliability.

Moreover, as noted in EPA's Guidelines for Preparing Economic Analyses, four alternatives benefit transfer methods are available: point estimate, benefit function, meta-analysis, and Bayesian (page 87). The simplest approach, point estimate, is — according to the EPA Guidelines -- "not generally recommended," but this is essentially the approach that EPA employs in the 316(b) economic analysis. Thus, EPA's implementation of the benefit transfer method appears suspect, both with regard to the analysis of individual studies and with regard to the specific method employed.

In the documentation supporting its proposed rule, EPA refers to a category labeled "Indirect Use Benefits" (Case Study Analysis, page A9-9), which are primarily benefits related to impacts on forage species. As with the case of commercial valuation, so too with recreational valuation, EPA proposes (page 17191) to use a highly problematic method for valuing forage species. EPA posits two approaches to value impacts on forage species. One approach, which makes sense in theory and can provide reasonable estimates if properly applied with a sufficiently refined model, is to examine the biological consequences of changes in forage species stocks on stock levels of recreational species. EPA refers to this as the "production forgone approach." <FN 31>

So, the correct approach is to develop a theoretically sound and empirically valid model of the impacts of alternative CWIS technologies on affected species, including forage species. The biological modeling and the subsequent bioeconomic modeling should then estimate how all of the stocks evolve through time, including the effects of changes in forage stocks on recreational stocks, which are then valued through appropriate revealed-preference methods, as discussed above.

EPA's other proposed approach for valuing forage species — inference from hatchery costs — is not a valuation method. The benefits of increasing the stocks of forage species cannot be estimated in economic terms by observing the costs of developing and introducing hatchery fish into wild populations. As explained previously, employing the costs of re-stocking forage species incorrectly substitutes costs for benefits. The approach is both theoretically unsound and likely to lead to upward biased benefit estimates.

Footnotes

30 These two key conditions for a reliable benefit transfer have been characterized, respectively, as "soundness" and "similarity." For a detailed investigation of benefit transfer methods, see the following study, cited in EPA's Guidelines for Preparing Economic Analyses: Desvousges, William H., F. Reed Johnson, and H. Spencer Banzhaf. Environmental Policy Analysis with Limited Information: Principles and Applications for the Transfer Method. Northampton, Massachusetts: Edward Elgar, 1998. The criterion of "similarity" is particularly challenging in the context of natural resource impacts, such as in the 316(b) context. This is because the value of goods and services associated with natural resources are inherently dependent upon their location.

31 A comment I made earlier in the context of commercial species also applies here. If there are values of forage species not associated with recreational (or commercial) impacts, then such values would be non-use values. The proper estimation of these is discussed below in section III.C of these comments.

EPA Response

The commenter states that in estimating recreational fishing benefits at proposal EPA relied on the simplest benefit transfer approach that is "not generally recommended" by the EPA Guidelines. Thus, EPA's benefits transfer method "appears suspect". For detail on the benefits transfer approach used at proposal, see response to comment #316bEFR.075.504.

For the final Phase II 316b analysis, EPA has reduced its reliance on benefit transfer to estimate recreational fishing benefits. In addition, EPA no longer uses case studies of individual facilities. Instead, EPA has estimated regional models. For the recreational fishing analysis, benefit transfer is used for the inland region, and benefit function transfer is used for the North Atlantic region. EPA has estimated RUM models for all other coastal regions (Mid-Atlantic, South Atlantic, Gulf of Mexico, and California), and for the Great Lakes region. Where benefit transfer is used, EPA has followed generally accepted procedures, and has carefully applied benefit transfer methods.

For the North Atlantic region, EPA's benefit transfer uses the benefit function from the Hicks, et al., study recommended by several of those who commented as the most appropriate study for benefit transfer for the North Atlantic region. By using benefit function transfer, EPA was able to make appropriate adjustments to Hicks' model to estimate values for relevant changes in catch rates. This benefit function transfer follows accepted methods and was performed carefully to provide the best available estimates of values for changes in catch rates for the North Atlantic region.

For the Inland region, EPA did a benefit transfer using values from several studies. EPA generally followed its Guidelines for Preparing Economic Analyses for benefits transfer (BT) in developing a benefits transfer approach for the Inland region. The steps were followed as recommended in the Guidelines when using BT: (1) describe the policy case; (2) identify existing, relevant studies; (3) review available studies for quality and applicability; (4) transfer the benefit estimates; and (5) address uncertainty. Further information on the methods EPA used to estimate recreational fishing benefits is provided in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003). See Chapter H4: Recreational Fishing.

The commenter further states that the Agency used "highly problematic" methods for valuing forage species, including production foregone and inference from hatchery costs.

EPA provides its rationale for selecting the methods it used to evaluate I&E in Chapter A5 of the final Phase II Regional Study Document (DCN #6-0003). For harvested species, which represent less than 2 percent of total I&E losses, EPA used a simple, static model of foregone harvest that assumes that I&E losses of harvested species result in a reduction in the number of harvestable adults in years after the time that individual fish are killed by I&E and that future reductions in I&E will lead to future increases in fish harvest. The approach does not require knowledge of population size or the total yield of the fishery; it only estimates the incremental yield that is foregone because of the number of deaths due to I&E.

EPA recognizes that the assumption that the key parameters in its yield model are static is an important one that is not met in reality. However, by focusing on a simple interpretation of each individual I&E death in terms of foregone yield, EPA concentrated on the simplest, most direct assessment of the potential economic value of eliminating that death.
Although EPA's approach to modeling yield requires estimates of a large number of stage-specific growth and mortality parameters, the use of more complex fish population models would rely on an even larger set of significant data uncertainties and would require numerous additional and stronger assumptions about the nature of stock dynamics that would be difficult to defend with available data. Additional data uncertainties of population dynamics models include the relationship between stock size and recruitment, and how growth and mortality rates may change as a function of stock size and other factors. Obtaining this information for even one fish stock is time-consuming and resource intensive; obtaining this information for the many species subject to impingement and entrainment nation-wide was not possible for EPA's national benefits analysis.

In addition to a lack of data, there are numerous issues and difficulties with defining the size and spatial extent of fish stocks. As a result, it is often unclear how I&E losses at particular cooling water intake structures can be related to specific stocks. For example, a recent study of Atlantic menhaden (Brevoortia tryannus), one of the major fish species subject to impingement and entrainment along the Atlantic Coast of the U.S., indicated that juveniles in Delaware Bay result from both local and long distance recruitment (Light and Able, 2003). Thus, accounting only for influences on local recruitment would be insufficient for understanding the relationship between recruitment and menhaden stock size. Geographic stock delineation is a significant, ongoing problem in fisheries management.

Another difficulty in developing more complex models of harvested species is that it is fundamentally difficult to demonstrate that any particular kind of stress causes a reduction in fish population size. All fish populations are under a variety of stresses that are difficult to quantify and that may interact. Fish populations are perpetually in flux for numerous reasons, so determining a baseline population size, then detecting a trend, and then determining if a trend is a significant deviation from an existing baseline or is simply an expected fluctuation around a stable equilibrium is problematic. Fish recruitment is a multidimensional process, and identifying and distinguishing the causes of variance in fish recruitment remains a fundamental problem in fisheries science, stock management, and impact assessment (Hilborn and Walters, 1992 (DCN #2-019A-R11); Quinn and Deriso, 1999(DCN #2-019A-R45); Boreman, 2000 DCN #2-018A)). This issue was beyond the scope and objectives of EPA's § 316(b) benefits analysis.

In the analyses for the NODA and the final rule, EPA no longer uses hatchery costs to estimate impacts on forage species. Instead EPA translates foregone production among forage species into foregone production among harvested species that are impinged and entrained using an assumed trophic transfer ratio, and then translates foregone production among these harvested species to foregone yield. Further information on the methods EPA used to estimate forage losses is provided in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003). See Chapter A5: Methods Used to Evaluate I&E.

Valuing Forage Species (incl non-use and non-landed)

Methodology for Estimating Non-Use Value (Proposed Rule, page 17193; Case Study Analysis, Chapter A9)

In its analysis of the proposed rule, EPA notes the potential importance of the category of non-use (or passive use) value, which refers to the aggregate of individuals' willingness to pay for an environmental amenity, apart from its direct or indirect use, because individuals derive utility (welfare) simply from knowledge of the amenity's existence. Such non-use value is controversial in economics <FN 32> and notoriously difficult to estimate. The only available methods for estimating non-use value are the stated preference methods, which — as emphasized above — are themselves controversial, not particularly reliable, and potentially biased. With these methods, people are asked through surveys to state their willingness to pay for particular amenities, such as access to recreational fisheries with particular attributes.

EPA maintains that due to budget and other constraints, it was unable to carry out any original stated preference surveys of non-use value. <FN 33> Instead, EPA proposes two surrogate approaches, and in doing so, it sacrifices any semblance of accuracy and reliability in estimating "benefits." First, EPA uses a rule-of-thumb in which non-use values are assumed to be equal to 50 percent of use values. There is no direct basis in economic theory for such an approach, and it is not supported by EPA's Guidelines for Preparing Economic Analyses. Nonetheless, EPA has used such metrics in other analyses, and similar approaches were employed in early studies two decades ago by some environmental economists. <FN 34>

It is now widely recognized by environmental economists that this so-called "50%-rule" is not a sound basis for benefit estimation, a fact which EPA appreciates. On page A9-10 of the Case Study Analysis, EPA recognizes three significant concerns with regard to this approach: (1) the very dated nature of the literature on which the ratio is based; (2) key differences among the underlying studies (and the current application); and (3) problems of applying the results in a consistent manner. EPA correctly identifies these significant problems with using this simple ratio technique, and notes that it intends in the future to revisit the literature and explore how best to apply benefit transfer methods for non-use value. This is commendable, but EPA proceeds to apply the "50% rule" in its current analysis of the proposed regulation.

Use of the 50% rule-of-thumb is particularly problematic in the present context, because the "rule" is based largely upon a literature review (carried out nearly twenty years ago by Fisher and Raucher, 1984) which did not include any studies which addressed the circumstances relevant for the proposed rule, namely non-use values linked with I&E impacts and/or CWIS impacts. Furthermore, it is very doubtful that non-use values in the I&E/CWIS context could be significant. The reason is that the anticipated I&E impacts of changes in CWIS technology cannot reasonably be characterized as affecting the existence of unique resources with high public awareness levels. <FN 35> There is surely no justification whatsoever for EPA's claim that its 50% rule-of-thumb provides "conservative" estimates (Proposed Rule, page 17193).

The other alternative approach EPA proposes for estimating non-use value is one of employing "restoration-based costs as a proxy for the value of the change in stocks." EPA uses this habitat restoration cost approach in several of its case studies. As mentioned above and as explored in detail in the next section of my comments, such an approach is completely invalid, without any foundation in economics, and likely to lead to highly biased and misleading results. This approach makes one of the gravest of errors in economics, confusing benefits and costs. Because of the importance of this error, I dedicate a complete section of comments to it, and turn now to consideration of EPA's claimed new method for valuing "benefits" — habitat replacement cost analysis. <FN 36>

Footnotes

32 See, for example: Hausman, Jerry A., ed. Contingent Valuation: A Critical Assessment. Amsterdam: North-Holland, 1993. Although the title of the volume refers to the empirical method for attempting to estimate non-use value, a number of the essays in the volume actually critique the underlying theoretical construct.

33 On page A9-10 (section A9-5 on "Nonuse Benefits") of the Case Study Analysis, EPA states: "In the case of the §316(b) proposed existing facilities rule, no primary research was feasible within the budgeting, scheduling, and the other constraints faced by the Agency."

34 Early studies by environmental economists developed and employed such rule-of-thumb ratios to estimate non-use values, including: Fisher, Ann and Robert Raucher. "Intrinsic Benefits of Improved Water Quality: Conceptual and Empirical Perspectives." Advances in Applied Microeconomics, Kerry Smith and Ann Dryden White, eds. Greenwich, Connecticut: JAI Press, 1984.

35 Contrast the anticipated marginal changes in fish stocks due to implementation of new CWIS technologies with, for example, the uniqueness and the high public awareness of the Grand Canyon or, for that matter, a built resource such as the Statue of Liberty, classic examples of resources for which non-use value is assumed to be a significant component of total value.

36 A third alternative noted by EPA (Case Study Analysis, page A9-11) for estimating non-use values in the absence of original empirical research is another benefit transfer approach, in which willingness-to-pay estimates for non-use value per household are employed. An early study which employed such an approach was: Stavins, Robert N. The Tuolumne River: Preservation or Development? Berkeley, California: Environmental Defense Fund, October 1983. Two major problems with this approach are: (1) identifying the appropriate willingness-to-pay measure per household for non-use (knowledge of existence, for example) value for the specific fishery and/or other ecological impacts of concern; and (2) identifying the appropriate number of households to which the benefit-transfer number should be applied. EPA takes note of the second problem, and consequently does not employ this approach.

EPA Response

In the cost-benefit analyses for the NODA and for the final Section 316(b) Phase II rule, EPA did not use the 50% rule-of-thumb to estimate non-use benefits. As stated in the NODA, EPA agrees with the commenters that the 50% rule relies on outdated studies. For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. See Chapters A12, Non-use Meta-analysis Methodology, and A9, Economic Benefit Categories and Valuation Methods of the final Phase II Regional Studies Document (DCN #6-0003). Please see Chapter D1 of the final Phase II EBA document regarding break-even analysis (DCN #4-0003).

Please also refer to EPA's response to comments on the HRC methods (316bEFR.005.035) and the SRP methods (316bEFR.005.006); the document entitled "Habitat-based Replacement Cost Method"

(DCN #6-1003); and to EPA's Guidelines for Preparing Economic Analyses.

Use of Replacement Costs (HRC and hatchery-based)

Proposed Methodology for "Valuing Benefits": Habitat-Based Replacement Cost Analysis (Case Study Analysis, Chapter A11)

EPA notes that there may be willingness to pay for preservation of forage species because of their impacts on harvested commercial and recreational species. As explained above, the proper way to account for this is through an appropriate stock-recruitment model that correctly accounts for food web effects. Likewise, EPA notes that willingness to pay may exist among some individuals in society for I&E impacts not valued through the use value associated with commercial or recreational fisheries. Putting aside the serious concerns that exist regarding the concept of non-use value (see above), and putting aside as well the considerable controversy that exists regarding empirical (stated preference) methods for estimating non-use value, the fact remains that the only feasible means to attempt to estimate such non-use values is through one of the stated-preference methods, such as contingent valuation or conjoint analysis.

Unfortunately, in some of its case studies, EPA turns away from both of these approaches and employs instead a completely illegitimate method of analysis, which it claims is an alternative method for valuing benefits, but is actually nothing of the kind. EPA's "Habitat-Based Replacement Cost (HRC) Method" is — pure and simple — a measure of costs, not benefits. The habitat replacement costs are the design, implementation, administration, maintenance, and monitoring costs of various identified means of restoring under-water habitats in the hopes of producing the same in situ services and service flows that are associated with the various technological alternatives under consideration (Case Study Analysis, page A11-7). In other words, these are the costs of another alternative — and a very costly alternative — for achieving the same functions as targeted by the proposed regulation. While mitigation, restocking, and/or habitat restoration may be acceptable approaches as alternatives to the installation of specific technologies in order to offset I&E losses, the cost of such alternatives is in no sense whatsoever a reasonable proxy for the value (that is, the benefit) of reducing I&E.

It is very important that the approach taken by EPA with its completely invalid HRC method not be confused with legitimate applications of "defensive expenditure" or "averting behavior" methods of estimating benefits. Those methods are based upon observed actions, that is, individual behavior. In particular, a necessary condition for using defensive expenditures or averting behavior for purposes of benefit estimation is that the researcher observes people revealing their preferences by actually (and voluntarily) incurring costs to avert (or tolerate) the environmental disruption in question. <FN 37> This is obviously not the case with the hypothetical habitat replacement activities that EPA uses to develop its cost estimates. Indeed, EPA makes no claims that such activities have actually and voluntarily been carried out by individuals.

So, this method yields, at best, the cost of yet another alternative, not the benefit of the original alternative(s). EPA acknowledges this: "In other words, the HRC valuation estimate reflects the cost now for increasing the production of I&E species at an average annual level that would offset the losses in the current year and all future years, all else being equal" (Case Study Analysis, page A11-

8). On the same page, the document notes that the motivation for employing this new analytical method is “the explicit recognition that I&E losses [may] have impacts on the aquatic ecosystem and the public’s use and enjoyment of that ecosystem beyond that estimated by reduced commercial and recreational catches.” As emphasized above, I have no quarrel with the notion that if there are other use-values, they should be estimated with theoretically sound and empirically valid revealed-preference methods. Likewise, if there are legitimate “non-use values,” they should be estimated with original applications of the best stated-preference methods (or failing that, EPA could employ benefit-transfer methods, if appropriate studies are available for transfer purposes, as discussed above). But in neither case does the possible existence of excluded use values or unassessed non-use values justify the employment of this invalid approach, which is not a method of benefit estimation in any legitimate sense whatsoever.

In the Case Study Analysis (page A11-1), it is claimed that “the HRC method can be used to value a broad range of ecological and human service losses...” False. It is also asserted that “it can be used as an alternative to conventional valuation approaches that are based on recreational and commercial fishing impacts.” False. And it is stated that “in addition, HRC can supplement conventional valuation results...” False.

EPA has severely undermined proper economic analysis by examining the cost of habitat restoration and calling that cost a “benefit.” <FN 38> This sort of “avoided-cost method of benefit estimation” has long been recognized as fatally flawed. Applying it would mean that any proposed project (whether the project is good or bad for the environment) will appear to be desirable. By taking the next most costly approach of achieving an objective and calling that the project’s benefits, one will always find that “benefits” — so measured — exceed costs. This completely flawed reasoning will come back to haunt EPA when others use it to push for actions the Agency opposes. <FN 39>

Let us be clear. What EPA is proposing is not just an inferior method of benefit estimation (valuation); it is not a method of benefit estimation at all. All that can be demonstrated with this approach is that other approaches for reducing I&E, such as closed cycle cooling, are less costly or more costly than habitat restoration, not that the benefits of closed cycle cooling are greater than its costs. <FN 40> Note that the lengthy discussion of the Habitat-Based Replacement Cost Method in Chapter A11 of the Case Study Analysis, in particular the text on page A11-2, is not about the method at all, but about the concept of non-use value. There is a list of 28 references on this page, which might lead the unsuspecting reader to believe that there is a scholarly basis for the avoided-cost method of “benefit” estimation. In fact, every one of those references — some solid, some not — is on a different topic, non-use value; none consider, let alone validate EPA’s proposed methodology.

It is very disappointing to see this in the 316(b) analysis. Needless to say, such an approach is not supported by EPA’s Guidelines for Preparing Economic Analyses, nor by any sound guide to benefit-cost analysis or environmental economics, more broadly. <FN 41>

EPA Response

EPA does not use the HRC approach as part of its benefit cost analysis for the final rule. More information can be found in Chapter A11 from the Case Study Analysis at proposal, that can be found in the docket (DCN #4-0003).

For the 316(b) Phase II regulation, the Agency was not able to monetize direct use benefits for 98.2% of the age 1 equivalent losses (the percentages by region are: California 95.2%, North Atlantic 99%, Mid Atlantic 98.4%, South Atlantic 98.1%, Gulf of Mexico 95.8%, Great Lakes 99.8% and Inland 99.9%). This is because the vast majority of I&E losses are of forage species that are not fully accounted for by the Agency's commercial and recreational fishing analyses.

To address this difficulty, the HRC results presented at proposal were intended to provide a way to quantify all I&E losses and provide an estimate of the cost to offset these losses through habitat restoration. Dr. Stavins rightly points out the HRC approach is not a benefits "valuation" estimation method or a proper measure of the proposed rule's economic benefits. EPA agrees, and to avoid any misunderstanding on this point, EPA has not included HRC results in its final analysis for the Phase II rule. Nonetheless, the Agency notes that an HRC analysis is a way to evaluate impingement and entrainment losses by considering the cost to offset these losses through habitat production.

HRC is related to approaches such as Habitat Equivalency Analysis (HEA) used by federal and state agencies to monetize damages in cases where physical impacts are otherwise difficult to value. As such, it provides useful information for the 316(b) rulemaking and related permitting activities.

HRC information can be properly used within the policy context for which it is well suited and originally intended -- as a useful mechanism for understanding the physical and monetary magnitude of the physical injury caused by impingement and entrainment. Indeed, EPA Region 1 has used this correct perspective and context for HRC as part of the permit for the Brayton Point facility.

Note that replacement costs based on fish stocking are used routinely to monetize the damages associated with fish kills, including fish losses resulting from impingement and entrainment (e.g., by the Maryland Power Plant Program). While all parties acknowledge that these hatchery-based replacement "costs" are not true "benefits values" per se, in the absence of information on public values, these are accepted and used as the only available alternative for monetizing damages. In fact, in its publication presenting estimates of fish replacement costs, the American Fisheries Society (1993 - DCN #4-1302) states that such costs can be considered a "proxy for value."

HRC is an alternative to this stocking-based estimate of replacement cost. It is based on the premise that stocked fish are not an exact replacement of fish lost from natural habitats. The HRC approach estimates replacement costs based on the production of wild fish as opposed to the artificial propagation of fish in hatcheries.

As both Dr. Stavins and EPA's Guidelines indicate, there are certain conditions under which replacement or avoidance costs can be appropriately used as a lower bound measure of value, such as when actions are undertaken voluntarily. In fact, many of the restoration options identified by local experts in the HRC analyses presented at proposal are voluntary actions and therefore, according to Dr. Stavins's own criteria, indicate "value."

While the Agency agrees that the HRC and hatchery costs are costs of replacement and not benefits, the Agency believes that understanding what it would cost residents in an area to replace CWIS losses is a very useful tool in the regulatory process and also informs decisions on the use of restoration. The HRC, like HEA, is a process that requires the analyst to quantify all losses of organisms caused by a CWIS and then consider the steps that would be necessary to offset these losses by means of habitat restoration. This is a useful tool in considering the environmental effect of CWIS losses.

Additional discussion of the HRC method and its uses is provided in the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003).

Revealed preference

Proposed Methodology for "Valuing Benefits": Cost of Threatened and Endangered Species Restoration (Case Study Analysis, Chapter A12)

Related to but distinct from EPA's proposed Habitat Replacement Cost method is a proposed approach for valuing threatened and endangered (T&E) species (see Case Study Analysis, Chapter A12). EPA characterizes this approach as "societal revealed preference." The proposed method is not a revealed-preference method, has no foundation whatsoever in economic theory, is not accepted by economists as a legitimate empirical method of valuation, and is — like the HRC method — no more or less than a method of cost analysis mistakenly applied to the benefit-side of the ledger.

In its discussion of economic valuation methods for threatened and endangered species, EPA correctly indicates that "the only available way to directly estimate non-use values for special status species is through applying stated preference methods, such as the contingent valuation method (CVM)" (Case Study Analysis, page A12-13). EPA states, however, that it "cannot apply this approach to the 316(b) rulemaking because [of] the time and cost associated" with such methods. EPA then turns to an explication of the use of benefits transfer approaches (which I have discussed, in general, above). Despite the problems with such benefit transfer approaches, if properly done they would constitute a second-best alternative to original CVM studies in the current context.

It is very troubling, however, that EPA then indicates that "for the case study analysis, EPA pursued an innovative alternative to infer societal WTP [willingness-to-pay] to preserve T&E species" (Case Study Analysis, page A12-18). This "innovative alternative," like the HRC approach, is a totally invalid, non-economic approach for "benefit" estimation. It takes the historical cost to restore particular species under various government mandates (which were themselves adopted without any systematic benefit/cost analysis) as "an indication of societal revealed preference to preserve and protect these species" (page A12-18), thus using program costs as a measure of benefits.

This is a complete corruption of the notion of a revealed-preference method, an essential characteristic of which is that the benefits — the willingness to pay — is revealed by those individuals who are doing the paying, not by the judgement of others (in this case, legislatures, executive departments and agencies, and/or courts). There is no sound logic behind taking the costs that are incurred in achieving various government programs and policies as being indicative of the true benefits of those programs and policies.

The very purpose of a benefit-cost analysis is to assess projects, programs, and policies by comparing their benefits and their costs. The proposed methodology completely reverses this, and takes the fact that a project, program, or policy exists as evidence that its benefits exceed its costs (and therefore that its benefits can be proxied by its costs, at a minimum).

Use of this approach would imply that any project, program, or policy that is approved by a legislature, executive agency, or court has true benefits at least equal to its costs, and — presumably

— that failure of the government to carry out any project, program, or policy indicates that its social benefits are less than its costs. This makes a complete sham of the very process in which the proposed 316(b) rule is being considered. <FN 42> It also would render meaningless requirements for benefit/cost analysis, such as those imposed under Executive Order 12866.

Footnotes

42 This method of “valuation” is employed by EPA in its case study of the San Francisco Bay/Delta Estuary.

EPA Response

EPA does not use the Societal Revealed Preference (SRP) method in the cost benefit analysis for the final Section 316(b) Phase II rule.

For EPA’s response to comments on the SRP, please see the response to comment #316bEFR.005.006

For EPA's response to comments on the limited feasibility of doing original Stated Preference work, please see the response to comment ##316bEFR.306.105.

Brayton Point

The Brayton Point Station Case Study Analysis (Proposed Rule, pages 17193-17200; Case Study Analysis, Chapter F1, F2, F3, F4, F5, F6, F7; Economic Analysis, Chapter C1, C2)

My comments in this section are based largely upon my review of "Part F: Brayton Point Station Case Study," pages F1-1 through F7-1 of the Case Study Analysis document. As I emphasized at the very beginning of these comments, the fact that I do not comment on any specific aspect of the various documents should not be taken as indicating that I find the methodologies or empirical applications therein to be valid. Thus, I focus my commentary on Part F on specific elements of the analysis, without thereby suggesting that areas on which I do not comment meet with my acceptance.

First of all, it is interesting that the case study identifies a considerable list of "major environmental stressors" of Mount Hope Bay, the body of water that may be affected by the Brayton Point facility, including: habitat alteration, dredging, coastal development, over-fishing, industrial pollution, nutrient pollution, wastewater runoff, climate change, and cooling water intake structure (CWIS) surface water withdrawals. It is striking that no attempt is made in the analysis to attribute quantitatively any of the claimed degradation of the commercial and recreational fisheries to any of the aforementioned factors, with the exception of Brayton Point Station's CWIS.

In part, EPA estimates the economic value of forage species impacts by estimating the replacement cost of these fish if they were restocked from hatcheries. As previously explained, this is inappropriate; it provides an estimate of costs, not of economic damages or economic benefits. This critical mistake of substituting some estimate of "avoided cost" for a valid measure of real benefits also occurs with EPA's proposed "habitat restoration cost analysis" (HRC), which plays an even more important role quantitatively in the Brayton Point analysis.

Once the effects of reductions in impingement and entrainment on commercial landings have been correctly identified — which EPA has not done — the next step is to assign an appropriate market value to the changes in landings. This is relatively straightforward, as long as reasonable estimates of future market values are employed. But EPA next seeks to convert the dockside market value of changes in commercial landings into estimates of the economic surplus that constitute social benefits. As EPA notes (on page A9-5 of the Case Study Analysis), "to do this with primary analysis would be an extremely complex process..." EPA's flawed substitute approach is to adopt a set of rules-of-thumb that have no basis in economic theory and which are based — at best — upon a very limited set of empirical examples.

Using such rules of thumb, EPA proceeds to multiply the commercial valuations by a minimum of 1.8 and a maximum of 3.2 to establish its estimated range of social benefits from commercial fisheries impacts. First, this approach is arbitrary and not founded upon economic theory nor upon a broad survey of empirical research; second, the appropriate measure is the in situ value of the induced increase in catch; third, there is no reason to anticipate that price changes would be induced by the relatively trivial quantity impacts of commercial landings in Mount Hope Bay; and fourth, if the benefit side of the analysis is to be treated in this fashion, then the same reasoning about multi-market, general equilibrium effects should be estimated on the cost side.

For purposes of valuing impacts on recreational fishing in the Brayton Point Station case study, EPA relies upon the benefits transfer approach, drawing upon results of previous studies of recreational benefits for other fisheries in other locations, where the methodologies employed were simple travel cost models and contingent valuation. <FN 44> Chapter F4 describes EPA's valuation of I&E impacts using benefit transfer methods. As I noted previously, obtaining reasonably reliable results using such benefit transfer techniques creates a number of challenges, which EPA has not met. In the Brayton Point Station case study, EPA transferred results from previous studies of other areas in which the methodologies employed included a simple travel cost model and contingent valuation. Since the original studies were of different resources, the values themselves are, at best, problematic for transfer, even if the numbers were valid for the original applications.

This is particularly striking because EPA could have drawn upon a much more appropriate source for its recreational benefit transfer method, namely a recent National Oceanographic and Atmospheric Administration (NOAA) study conducted by Hicks, et al. (1999) of the National Marine Fisheries Service (NMFS). <FN 45> The Hicks, et. al. (1999) study is the most appropriate source for benefit transfers of recreational fishing values for this work since it provides estimates of the value of a marginal increase in catch for relevant species groups for the affected geographic area. The methodology employed in that study was a random utility model.

The Brayton Point Case Study also includes an estimate of "non-use value." EPA did not carry out a stated-preference survey for the Brayton Point impacts. Instead it used a rule-of-thumb in which non-use values are assumed to be equal to 50 percent of use values. As I discussed above, there is no basis in economic theory for such an approach, and it is not supported by EPA's Guidelines for Preparing Economic Analyses. Furthermore, there is no justification for EPA's claim that its 50% rule-of-thumb provides "conservative" estimates (Proposed Rule, page 17193).

At this stage of the analysis, EPA estimates — using the methods identified above — that the annualized economic value of the losses due to I&E at the Brayton Point facility ranges from \$169,899 to \$308,257. If the most questionable elements — as identified above — are removed from the calculations, the range becomes \$95,731 to \$112,565, for a midpoint (mean) value that is less than half of the EPA midpoint. If EPA's 50% rule-of-thumb for non-use value is employed, then the range becomes \$107,579 to \$133,371. <FN 46>

Apparently not satisfied with these results, EPA employs its completely illegitimate method of analysis. The "Habitat-Based Replacement Cost (HRC) Method" — applied to the Brayton Point case in Chapter F5 (pages F5-1 through F5-39) — is a measure of costs, not of benefits. The habitat replacement costs are the costs of what is essentially another alternative — and a very costly alternative — for achieving the same functions as targeted by the proposed regulation.

The Brayton Point Station case study reveals the absurdity of this approach, which violates the most basic principles of economics. The document states (on page F5-1): "The HRC method is a supply-side approach for valuing I&E losses in contrast to the more typically used demand-side valuation approaches." Economic benefits, by definition, are measured as the area under a demand curve; economic costs, by definition, are measured as the area under a supply curve. This claimed method of benefit estimation is without foundation, is misleading, and imparts a horrendous bias to the results, as I document below. <FN 47> The so-called HRC valuation method should be removed from the regulation, and the “values” thereby calculated should be subtracted from all benefit estimates, including those carried out for the Brayton Point facility.

For the most part, I will not comment on the development of the empirical estimates of habitat-replacement costs — restoring submerged aquatic vegetation, restoring tidal wetlands, creating artificial reefs, improving anadromous fish passages, further improvements in water quality, and reducing fishing pressures (pages F5-2 through F5-34) — because those calculations are completely irrelevant and inappropriate for the purpose for which they are used in the Case Study, that is, for estimating benefits. <FN 48>

Table F5-39 (Case Study Analysis, page F5-35) sums up the total habitat replacement costs that would — according to EPA — be required to replace the species affected by entrainment and impingement due to cooling water withdrawals at the Brayton Point facility. The total is over $1 billion annually. <FN 49> EPA may have recognized the absurdity of these calculations. It proceeds to eliminate the largest component (artificial reef creation), leaving $28 million of costs annually. <FN 50> Not only is this a biased estimate of the costs of habitat replacement to achieve the specified purposes, but it is completely irrelevant to the calculation of the benefits of the technologies specified in the rule for achieving reductions in I&E at the Brayton Point facility. If EPA demonstrates anything with this calculation it is simply that various technological approaches under consideration — such as closed cycle cooling, which EPA characterizes as a CWIS technology — are less costly than various forms of habitat restoration, not that the benefits of such closed cycle cooling are greater than its costs.

In the penultimate chapter of the Brayton Point Station Case Study (Part F of the Case Study Analysis), EPA summarizes the results of its so-called “benefits analysis.” As should be clear by this point, the results reported in Table F6-1 (page F6-1) are biased and less than useless; they are misleading. In this table, EPA takes the midpoint <FN 51> of the standard estimates of benefits from Chapter F4's benefits transfer analysis <FN 52> (drawing upon previous revealed-preference and stated-preference analyses of benefits from other cases), and labels these as the minima of ranges of impingement and entrainment benefits. Then it takes the annualized HRC estimates from Chapter F5, and labels these as the maxima of ranges of impingement and entrainment benefits. This makes no sense. The “minima” of the ranges of “benefits” are the mid-points of EPA’s benefit estimates, and the “maxima” of the ranges are EPA’s cost estimates (for the most costly alternative method of achieving the rule’s objectives)!

Using EPA’s own calculations of benefits (from Chapter F4), without the invalid HRC estimates, the final row in Table F6-1 (“Total Baseline Economic Loss from I&E, 2000$, Annually”) should read as follows:

	Impingement	Entrainment
Range	$6,591 to $11,637	$163,362 - $296,620

If we remove the most questionable elements — as identified previously — from EPA’s calculations in Chapter F4, the final row in Table F6-1 would read as follows:

Impingement Entrainment
Range $3,769 to $4,450 $91,962 - $108,115

If we remove the most questionable elements but include EPA's 50% rule-of-thumb for non-use value, then the final row in Table F6-1 would read:

Impingement Entrainment
Range $4,297 to $5,319 $103,282 - $128,052

Importantly, the misleading results reported by EPA in Table F6-1 in the Case Study Analysis are carried over (apparently with adjustments for year 2001 dollars) into the Proposed Rule, Exhibit 19, on page 17199 of the Federal Register. There EPA reports annual average baseline losses (for Brayton Point) due to impingement of $9,000 to $890,000, and $200,000 to $28.3 million due to entrainment! These terribly biased and misleading results should read as follows, if the corrected range above were employed, updated to year 2001 dollars, <FN 53> and approximated by rounding as in EPA's reported figures in the Federal Register: $4,000 to $5,000 for impingement, and $105,000 to $131,000 for entrainment.

Returning to the Brayton Point analysis reported in Chapter F6 of Part F of the Case Study Analysis, we find that the results reported in Tables F6-2 and F6-3 are misleading, because EPA has again taken the midpoints from the standard estimates <FN 54> of benefits from Chapter F4's benefits transfer analysis, and labels these as the minima ("low") of ranges of impingement and entrainment benefits. Then it takes the annualized HRC cost estimates from Chapter F5, and labels these as the maxima ("high") of ranges impingement and entrainment benefits. This is mixing legitimate benefit estimates with cost estimates (of an exceptionally costly alternative method of achieving the rule's objectives) and falsely labeling those as "benefits."

A pictorial representation of a set of analytic procedures can be useful, and in the case of Figure F6-1 on page F6-3 of the Case Study Analysis, EPA provides an image of both the valid and the invalid methods it has applied to the Brayton Point Facility Case Study analysis. If this figure is intended to represent the calculation of the true economic values associated with impingement and entrainment at the Brayton Point Station, as the figure's title claims, then —at a minimum — the dollar amounts (of benefits) in the boxes labeled 4, 5, 6, and 7 need to be corrected as indicated above, and box 8 needs to be eliminated altogether. For similar reasons, the graphics and text in Figures B6-2 (a typographical error presumably, it should read F6-2) and F6-3 are misleading. These two figures should be eliminated.

In Table F6-4, EPA provides what it characterizes as a summary of omissions, biases, and uncertainties. EPA claims— quite incredibly — that every simplifying assumption and omission has led to understatement of benefits (or to unresolvable uncertainty), suggesting in the accompanying text here and elsewhere that the overall results provide an underestimate of the true benefits. This is patently false. To the contrary, note that the upward biases involved in EPA's reported estimates of the annual economic values of losses caused by impingement and entrainment at Brayton Point Station (and thus the benefits of reducing those losses) are absolutely massive. Referring to the results discussed above that are reported in Exhibit 19, on page 17199 of the Federal Register (and the more precise estimates on page 17204, Exhibit 26), we find that the total loss numbers (combining impingement and entrainment) reported by EPA for its "low" case are more than 100% greater than what EPA's own analysis would produce if incorrect elements of its analysis were eliminated, <FN 55> and approximately 21,000% (that is not a typographical error on my part, twenty-one thousand percent) greater than the correct elements of EPA's analysis would produce for its "high" case (EPA's "high" case employs its bogus HRC cost proxies instead of real value/benefit estimates). <FN 56>

Finally, in Chapter F7, EPA provides a brief summary of the conclusions it wishes to draw from the Brayton Point Facility Case Study. Given that the summary statistics provided are extracted from the calculations in the previous chapters of this case study, it goes without saying — based upon my comments above — that this brief chapter of conclusions is incorrect and misleading. As I have explained, EPA's benefit estimates (values of I&E losses) overstate what EPA could claim to be a reasonable estimate <FN 57> by up to 21,000% (twenty-one thousand percent). <FN 58>

Footnotes

44 The two key conditions, described previously, for a reliable benefit transfer are "soundness" (of the original study) and "similarity" (of the original study's target benefits and the actual application's apparent benefits). As explained above, EPA's benefit transfer in the Brayton Point case study fails on both criteria.

44 Hicks, Robert, Scott Steinback, Amy Gautam, Eric Thunberg, 1999. "Volume II: The Economic Value of New England and Mid-Atlantuc Sportfishing in 1994." U.S. Dept. of Commerce, National Oceanographic and Atmospheric Administration, National Marine Fisheries Service, NOAA Technical Memorandum NMFS-F/SPO-38 (August).

46 Sources for the numbers are as follows: value of commercial loss for entrainment (page F4-6 of the Case Study Analysis) and impingement (page F4-5); value of recreational loss for entrainment (page F4-5) and impingement (page F4-4); and non-use value for entrainment (page F4-9) and impingement (page F4-9).

47 The only situations in which such an estimate could be interpreted as providing benefit information would be one in which the aggregate of affected parties had revealed through their own market behavior that they were willing to pay this amount for the services (or knowledge) in question. This is obviously not the case here.

48 It should nevertheless be noted that these estimated costs of habitat restoration are wholly and grossly disproportionate to the real benefits as estimated by EPA. So, according to EPA's analysis, habitat restoration is not a viable alternative. There are numerous ways in which EPA has clearly over-estimated habitat restoration costs, as others will no doubt comment. Hence, from the existing analysis, it cannot be concluded that (some degree of) habitat restoration is an inappropriate approach to achieving the objectives of Section 316(b) in the case of the Brayton Point facility.

49 The exact amount is $1,045,218,361, which is an annualized amount, not a present value!

50 The exact amount is $28,306,491 per year.

51 EPA mis-calculated at least one of the "midpoints." Its benefit transfer mid-point for impingement is $9,114, not $9,077, as indicated in Table F6-1.

52 Although these estimates reflect, in part, theoretically sound benefit concepts and standard methods of estimating such benefits, there are also considerable problems with elements of EPA's calculations, as I indicated in my commentary on Chapter F4, and as I summarize below.

53 Adjustment from year 2000 to year 2001 dollars is carried out with EPA's inflation rate of 2%.

54 As I explained above, these estimates reflect, in part, sound benefit concepts and standard methods of estimating such benefits, but there are significant problems with elements of EPA's calculations, as summarized in my previous comments. These two tables exhibit another problem with EPA's benefit estimation procedures. Note that the results presented in Tables F6-2 and F6-3 are based on simple, linear proportionality, as if a given percentage reduction in flows would necessarily result in the same percentage change in benefits. On the contrary, it is necessary to estimate the impacts of any change in flows on actual entrainment and impingement, estimate the effects of such entrainment and impingement on mortality, estimate the effects of mortality of target and forage species on available catch through an appropriate stock-

recruitment model, and then estimate the real benefits of respective changes in commercial and recreational fishing opportunities, plus any appropriate changes in non-use values.

55 Compare $109,731 (from the final table in my comments above, allowing for EPA's 50%-rule estimate of non-use value and adjusting from year 2000 to year 2001 dollars at EPA's 2% inflation rate) with EPA's estimate of $244,000 (Proposed Rule, page 17204, Exhibit 26). EPA's estimate represents an upward bias of 122%.

56 Compare $136,038 (from the final table in my comments above, allowing for EPA's 50%-rule estimate of non-use value and adjusting from year 2000 to year 2001 dollars at EPA's 2% inflation rate) with EPA's estimate of $29,178,000 (Proposed Rule, page 17204, Exhibit 26). EPA's estimate represents an upward bias of 21,348%.

57 Employing EPA's own analysis, but with the invalid elements removed, in particular the attempt to employ an estimate of the cost of a more expensive way of accomplishing the rule's objectives as a measure of the "benefits."

58 Incredibly, the final paragraph of this concluding chapter of the Brayton Point Facility Case Study states that "EPA believes that the estimates developed here underestimate the total economic benefits of reducing I&E at Brayton Point."

EPA Response

This comment refers to the Brayton Point Case Study presented at proposal. Many of the analyses discussed by the commenter have been modified or eliminated for the benefits analysis for the final 316b Phase 2 rule, as discussed below.

First, EPA notes that the general information on the ecology of Mt. Bay referred to by the commenter was presented as background information only to provide a context for EPA's analysis. It was not EPA's intent to evaluate the relative importance of all environmental stressors affecting aquatic resources in Mt. Hope Bay.

Secondly, EPA notes that it did not use hatchery- or habitat-based replacement costs in its final analysis. For further detail, please refer to the response to comment 316bEFR.005.053 and the document entitled "Habitat-based Replacement Cost Method" (Docket #6-1003). This information addresses the commenter's concerns about the appropriate use of replacement costs.

For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits please see the response to comment 316bEFR.005.029.

To estimate recreational fishing benefits for the North Atlantic region for the final rule, EPA applied a benefit-function transfer using a fishing site choice model developed by Robert Hicks from the National Marine Fisheries Service (NMFS), Office of Science and Technology (Hicks, et al., 1999). This study was recommended by the commenter.

EPA's final analysis did not use the 50% rule-of-thumb to estimate non-use benefits, as explained in response to Comment 316bEFR.005.034. For additional discussion of nonuse benefits, please see response to Comment 316bEFR.206.047.

Finally, EPA has not claimed, as the commenter asserts, that all omissions, biases, and uncertainties lead to an underestimate of true benefits. For additional discussion of uncertainty in the context of EPA's analysis, please see Chapter A6 of the Regional Analysis Document (DCN # 6-0003).

National Benefits

Extrapolation to National Benefits (Proposed Rule, pages 17203-17208; Economic Analysis, Chapter C3, C4, D1)

In Part C of the Economic Analysis, EPA summarizes the results of its eight case study analyses, and explains how the results from some of these case studies were extrapolated to the more than 500 facilities that are within the scope of the proposed rule. Given the severe problems with the methodologies employed by EPA in the case studies, as I have described above in generic terms in section III and as I have described in specific terms in regard to the Brayton Point Facility Case Study in section IV.A, I do not provide extensive comments here on EPA's attempt to extrapolate such highly biased case study results to the national level.

The summaries of the individual case studies — including but not limited to Brayton Point — provided in the text and tables in Chapters C1 and C2 and the extrapolations of some of those results to aggregates of particular regions and ecologies in Chapter C3 are highly biased and hence misleading in their current form. For example, in the case of the Brayton Point facility, Table C2-5 repeats the same mistakes made in Exhibit 19 and elsewhere, as I discussed in detail above. Chapter C3 adopts midpoints from its case study analyses for purposes of extrapolation and aggregation to national estimates.

Thus, the annual impingement and entrainment "best estimates of baselines losses" in the case of Brayton Point, for example, are claimed by EPA to be $450,000 and $14,261,000, respectively. But these "mid-points" of baseline losses (benefits of eliminating losses) are each calculated as the averages of the somewhat "reasonable" benefit estimates using "appropriate" benefit-estimation procedures (which I noted above, themselves carry a 100% upward bias) and the completely invalid "high" estimates in which EPA used an alternative, high-cost approach of achieving the rule's objectives as a false measure of losses and benefits (which I noted above, carry a 21,000% upward bias).

If, more appropriately, we draw upon EPA's own empirical estimates for Brayton Point, remove the most questionable elements — as identified previously — from EPA's calculations in chapter F4, but employ EPA's 50% rule-of-thumb for non-use value, then EPA's "best estimates of baseline losses" for impingement and entrainment at Brayton Point (mid-points from appropriately specified ranges) are $4,800 and $116,000, respectively. Inflating to year 2000 dollars, as EPA has done, this yields best estimates of $4,900 and $118,000, respectively, indicating that EPA's "best estimates" carry upward biases of 9,084% and 11,986%, respectively, for impingement and entrainment losses. To simplify matters, EPA's total "best estimate" (I&E combined) is reported as $14,711,000 (Proposed Rule, page 17204, Exhibit 26), which contrasts with a sensible estimate, based upon EPA's own numbers, of $123,000, thus indicating an overall upward bias in EPA's final results of 11,860%!

The highly biased Brayton Point numbers become part of the national totals, but are not used by EPA for purposes of extrapolation to other facilities. Considering the fact that EPA's purpose in carrying out the case studies was to develop a set of bases for extrapolation, it is interesting that the Brayton Point results are not used. No satisfactory explanation is provided in any of the documentation for this decision. Perhaps EPA recognized the absurdity of the Brayton Point results (due to the use of the invalid HRC method), and hence decided not to use these fundamentally flawed and highly misleading numbers as the basis for part of the national extrapolations.

In Chapter C4, EPA provides national-level estimates of the “benefits” associated with various regulatory options. The driving numbers behind these estimates are in all cases the national-level estimates of I&E losses, which as I have just explained, are highly biased, since those are based in turn on the case study analyses. Therefore, the results provided on overall regulatory benefits are exceptionally misleading. <FN 59>

For this and other reasons, the comparisons of “benefits” and costs carried out in Chapter D1 of the Economic Analysis — which EPA uses to support the proposed rule — are likewise misleading. All of the biased results from the Economic Analysis are carried over into the Proposed Rule as described in the Federal Register. For example, for the reasons I have explained here — in reference to the Economic Analysis — the results provided in Exhibits 24 (page 17203), 25 (17203-17204), 26 (17204), 27 (17205), 28 (17205-17206), 29 (17206), 30, 31, 32, 33 (17207), and 34 (17207-17208) are unreliable and highly biased, and as such, should not be the basis for this rule-making.

Footnotes

59 Furthermore, simple extrapolation and aggregation of a set of localized analyses is itself highly problematic. For example, even if partial equilibrium estimates of costs are acceptable for facility-level analyses, simple aggregation of such costs is bound to underestimate aggregate costs, because of the significant quantity-induced electricity price effects that would be induced.

EPA Response

In response to this comment and others like it, EPA has reviewed and revised the case study approach to estimating national benefits. The approach described in the comment pertains to the approach applied by EPA at proposal, and is no longer used. As described in the NODA, for the section 316(b) Phase II benefits analysis, EPA examined impingement and entrainment (I&E) losses, and the economic benefits of reducing these losses, at the regional level. All extrapolation is now based on losses per unit of average annual operational flow on a region-specific basis.

The estimated benefits were then aggregated across all regions to yield a national benefit estimate. The primary objective of the regional approach is to refine the scale of resolution of the benefits case studies conducted for proposal, so that extrapolations were within regions rather than nation-wide.

In addition to extrapolating at a regional level only, EPA also collected and analyzed data for a much greater number of facilities for the final rule.

Thus, for the analysis for the final rule, extrapolation was needed for a smaller number of facilities, was based on a broader range of analyzed facilities, and was performed between facilities in the same region and waterbody type.

In regard to the upward bias of results, the commenter's figures have been developed by eliminating methods that the commenter feels are invalid. The most significant of these is the HRC methodology used by EPA to measure the non-use value of fish lost to I&E. Please refer to EPA's response to comments on the HRC methods (316bEFR.005.035).

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. See Chapters A12, Non-use Meta-analysis Methodology, and A9, Economic Benefit Categories and Valuation Methods of the final Phase II Regional Studies Document (DCN #6-0003). Please see Chapter D1 of the final Phase II EBA document regarding break-even analysis (DCN #6-0002).

Role of Trading

Proposed Trading Program (Proposed Rule, pages 17170-17173)

In Section VI.E.2 of the Proposed Rule (pages 17170 to 17173), EPA outlines briefly the possibility of establishing an "entrainment trading program" among Phase II existing facilities for the purpose of achieving overall (aggregate) standards of performance at lower cost. <FN 60> EPA is to be commended for having taken note of the potential of market-based instruments for achieving resource protection, and for having begun the process of thinking carefully about how such an initiative could be incorporated within an existing regulatory program.

Before I turn to the text of EPA's proposal and before I provide responses to some of the questions EPA has posed, I wish to express two general concerns regarding the proposed trading program. My first concern might be said to refer not to the proposal for the trading program itself, but to the broader context in which it arises. Although I have devoted a great deal of time over the past decade and a half to studying and working to implement market-based approaches for environmental protection, <FN 61> I believe it is important to keep in mind that improving the cost-effectiveness of regulations can take us only so far, particularly in the current context of the proposed regulation implementing section 316(b) of the Clean Water Act. Let me explain.

It is important to consider cost-effective means to achieve existing goals, and tradeable permit systems are good candidates for supplying those means. But when the ends — the goals or targets — are themselves highly flawed, we have to beware of "designing fast trains to the wrong station." I am referring to the tremendous inefficiencies that exist in regard to the targets that are established in the proposed rule, as I have discussed in great detail above. In Section 316(b), the environmental concern is the potential for damages due to impingement and entrainment of small fish, larvae, and eggs at water intake structures at power plants. That is a legitimate concern, of course, and common sense — as well as best-practice environmental economics — would tell us to employ technologies or other methods to reduce environmental damages up to the point where we have maximized the difference between legitimate benefits and legitimate costs.

Clearly, this means that the benefits of the technology chosen ought to be (at an absolute minimum) greater than the costs; otherwise we are actually making the world worse off, rather than better off. Under previous implementation of Section 316(b), EPA's approach to identifying the best technology has been to insist that firms undertake increasingly ambitious and expensive solutions until the "costs are wholly disproportionate to the benefits." <FN 62> Furthermore, as I have documented carefully in these comments, EPA's analysis of the benefits of the proposed rule is exceptionally biased.

Thus, in the present context, identifying a cost-effective approach — such as through tradeable permits — for achieving an irrational goal would indeed qualify as "designing a fast train to the wrong station."

RFC: Harmonize of permit reissuance with trading

My second general concern can be characterized as a caution: with tradeable-permit systems, as with any regulatory approach, the devil tends to be in the details. Perhaps some reviewers of EPA's proposed rule will be interested in modifying EPA's tradeable-permit proposal in ways that would appear to lead to greater environmental achievements. There are good ways and bad ways of doing that, and a prominent example of the latter is the "20% rule" which became part of EPA's criteria air pollutant emissions trading program in the 1970's.

In response to the wishes expressed by some reviewers of that proposed tradeable permit mechanism, EPA modified the program so that each time a permit was exchanged, its quantitative value (expressed in tons) would decrease by 20%. The result, of course, was a strong disincentive for trading, and so there was much less trading than there otherwise would have been, and aggregate compliance costs were much greater than they needed to be (and there was little improvement in environmental quality, since the only way it would take place was when there was a trade).

The alternative and vastly preferable approach is to avoid any such "taxes" or ratios on trading. If it is desired to reduce aggregate pollution levels simultaneously with the instigation of a tradeable permit program, then the cost-effective way to do so is with a system of permits that themselves decrease in magnitude over time (in the case of a cap-and-trade program). In this way, the desired environmental improvement is actually achieved (unlike in the ratio approach, which discourages trading and hence discourages improvements) and it is accomplished cost effectively, since a high level of trading is not discouraged.

EPA Response

Role of Trading

Having expressed these two caveats and concerns, I wish to note that a well-designed trading program could provide greater flexibility to permitees and so facilitate the achievement of reasonable targets (not those contained in the current rule, in my judgment) at substantial cost savings by providing greater incentives for voluntary reductions, technology innovation, and diffusion. <FN 63> Experiences with trading programs, both in the United States and elsewhere, have confirmed our theoretical expectations that aggregate targets can be achieved cost-effectively if clear legal authority for trading is provided (well-developed property rights), well-defined fungible units of trade are established, transaction costs are minimized by avoiding requirements for prior government approval of trades, <FN 64> clear protocols established to quantify units to be traded, and reasonable mechanisms for compliance are established. <FN 65>

So, although the proposal for entrainment trading is new in some ways, the degree of its innovation should not be exaggerated, lest we fail to learn from previous experience. For example, EPA indicates on page 17170 that the trading program "differs from previous trading strategies implemented by EPA because it involves trading living resources rather than pollutant loads." This may be true (and EPA is to be commended), but we should not lose sight of the fact that tradeable permit programs have a very long history of use in the natural resources realm in tradeable development rights (TDRs), wetland mitigation banking, and individual transferable quotas (ITQs) for fisheries, many of which programs predate more recent applications of trading mechanisms to reducing pollutant emissions.

RFC: Should EPA include impingement trading?

Turning to some of the specific issues that EPA raises, it asks whether the trading program should be expanded to include impingement (as well as entrainment) of aquatic organisms. My answer is yes, because numerous technological and process alternatives affect both entrainment and impingement.

EPA Response

Spatial scale for entrainment trading

What should be the spatial scale for trading? EPA considers various alternatives: limiting trading to specific waterbodies, specific watershed, or general waterbody types. There are arguments in favor of each approach, but the rebuttable presumption in my view ought to be to establish the largest geographic limits feasible in order to provide maximum flexibility (and thus greater cost-effectiveness). Concerns about localized impacts can then be addressed in a manner parallel to the approach taken in the sulfur-dioxide allowance trading program under the 1990 Clean Air Amendments wherein only those trades are allowed that do not violate emission rate limits found in individual plant permits (included in corresponding State Implementation Plans, which are designed to achieve and maintain ambient air standards).

EPA Response

Please see response to comment 316bEFR.077.051 for the discussion on the appropriate spatial scale for trading.

RFC: Potential trading units/ credits

What should be the unit for regulation? This question arises with any environmental regulation, not just with trading. At the extreme, risks associated with environmental end-points might seem to be the appropriate units for regulation and thus for trading with any environmental problem. But this is virtually never done, because the implementation costs are excessive to the point of infeasibility. In the pollution context, one step down is exposure, and another step down is ambient concentration, then emissions, and then inputs (such as the lead content of gasoline). A level for trading should be chosen not because it is closest to what might seem to be the theoretical ideal of the environmental end-point, but because that level of trading will result in achieving given targets at the lowest cost over time, taking into account not only technological costs of meeting the program requirements but also monitoring and enforcement costs.

EPA Response

Please see response to comment 316bEFR.077.052 for the discussion on the appropriate unit for trading. EPA cannot see how trading risk, exposure, ambient concentration, emissions or inputs in the context of section 316(b) could possibly be implemented. The author of this comment has not provided adequate information for EPA to consider these units of trading. However, the decision whether to approve a trading program under § 125.90(c) will be made on a case-by-case basis.

RFC: Include Phase I facilities in trading program

What about new facilities? This is another question that arises with virtually any environmental regulatory program, including trading programs. New facilities should be allowed to engage in trade for precisely the reason that EPA notes, the greater scope for trading (thicker market) will have the effect of lowering compliance costs, which will make it easier for sources to meet performance requirements.

EPA Response

The section 316(b) Phase I New Facility Rule did not authorize trading. EPA has elected not to make any amendments to the New Facility Rule to allow for trading. Thus, the Phase I rule does not authorize new facilities to trade with each other to comply with the underlying technology-based standards.

Comment ID 316bEFR.005.046

Subject Matter Code 20.0

Role of Trading

Author Name Robert N. Stavins

Organization John F.Kennedy School of Government, Harvard University

Finally, it should be recalled that EPA identifies (in the Brayton Point and other case studies) a considerable list of "major environmental stressors" of the waterbodies in question, including: habitat alteration, dredging, coastal development, over-fishing, industrial pollution, nutrient pollution, wastewater runoff, climate change, and cooling water intake structure surface water withdrawals. If the desire is to achieve real environmental improvements while keeping costs down, then surely greater cost-effectiveness could be achieved by expanding trading beyond power plants to include potential offsets from other sources of the major environmental stressors.

EPA Response

Please see response to comment 316bEFR.034.027 for the role of trading in today's final rule. Section 316(b) of the Clean Water Act intends to minimize the adverse environmental impact associated with cooling water intake structures. In order to qualify as an alternative regulatory requirement under § 125.90(c), a State's voluntary trading program would need to result in environmental performance within a watershed that is comparable to the reductions of impingement and entrainment that would otherwise be achieved under the requirements established at § 125.94. A trading program that includes other stressors such as habitat alteration, dredging, coastal development, overfishing, industrial pollution, nutrient pollution, wastewater runoff, and climate change might not satisfy the requirements of § 125.90(c) because these types of trades could introduce comparability and implementation challenges that would be difficult to overcome. EPA also questions whether such a program would be consistent with the recent Water Quality Trading Policy. Thus, it is doubtful whether such a program would not meet the requirements for approval.

RFC: Test: benefits should justify the costs

First, in regard to EPA's discussion of alternative decision criteria, all of the alternatives would assess the value of CWIS technologies based on their benefits and costs. The best technology, from an economic perspective, is the one with the highest net benefits (positive difference between benefits and costs) to society. This is the technology that will be identified by the specific form presented in the Proposed Rule of criterion (4) — the benefits should justify the costs test — whereby the alternative which exhibits the greatest net benefits without bringing about negative net benefits is preferred.

EPA Response

See the preamble for a discussion of the site-specific compliance alternative.

For EPA's response to comments on application of the cost-benefit test to assessing the value of alternative CWIS technologies, please see comment #316bEFR.005.020.

For EPA's response to comments on application of the "significantly greater then" test to assessing the value of alternative CWIS technologies, please see comment #316bEFR.006.003.

Facility & firm-level costs/Econ. Practicability

Second, I examined EPA's consideration of "economic practicability" and "affordability," and identified how these concepts can be interpreted to yield economically sensible and operational decision criteria. For the firm this led to the standard net present value (NPV) criterion, in which the firm should adopt a technology if the present discounted value of the anticipated net returns from that technology is greater than the present discounted value of anticipated net returns from alternatives, including the status quo. For a society-wide perspective, the result was the social net present value criterion, in which it is in society's interest that a technology be adopted by the firm if the present discounted value of anticipated net social benefits (including environmental benefits) is greater than the present discounted value of anticipated net social benefits from alternatives, again including the status quo. In comparison, EPA's apparent definition of "economically practicable" or "affordable" — based on a technology's costs relative to a firm's or facility's revenues — could not be based upon a decision criterion with any normative standing in economics. Such an approach would tell us nothing about whether the technology helps to achieve specific objectives, whether it does so at minimum cost, or whether an alternative investment would provide greater net benefits to the company, the environment, or society as a whole.

EPA Response

Commercial Fishing Benefits

In the third section of my comments, I examined EPA's methodology for evaluating the benefits of the proposed 316(b) regulation. First, I examined EPA's methodology for valuing commercial fishing impacts. Such changes in fish stocks and related catch levels are best analyzed with an appropriate bioeconomic "stock-recruitment model" that captures these complex relationships over time, but EPA departs from this in ways that impart a significant bias to its results. One is the so-called precautionary approach described by EPA, and another is the attempt to value impacts on forage species outside of a properly specified stock-recruitment model, such as by examining hatchery costs. Another problem with EPA's approach to valuing commercial fisheries impacts is its unfortunate adoption a rule-of-thumb by which it multiplies commercial valuations in a misguided effort to identify general equilibrium effects. This, like all of the problems I noted, imparts a bias in EPA's analysis toward inflating estimated benefits of the proposed regulation relative to its costs.

EPA Response

In the cost-benefit analyses for the NODA and for the final Section 316(b) Phase II rule, EPA did not use hatchery replacement costs or the 50% rule-of-thumb to estimate non-use benefits. For a discussion of fish population modeling in the context of EPA's 316(b) analysis, please see response to Comment 316bEFR.005.009. For a discussion of the term "precautionary approach," please see response to Comment 316bEFR.005.026.

Comment ID 316bEFR.005.051

Subject Matter Code 10.02.01

Recreational Fishing Benefits

I also considered EPA's methodology for valuing recreational fishing impacts, where I noted that there is a long-standing and extensive literature in environmental economics on the valuation of recreational activities, including those associated with fisheries. EPA relies — wholly or in part — on empirical results that were not derived from actual analyses of the cases in question, drawing upon results of previous revealed-preference and stated-preference studies of recreational fishery benefits for other locations. In my comments, I reviewed the problems with using such benefit transfer techniques.

EPA Response

For detail on the benefits transfer approach used at proposal, see response to comment #316bEFR.075.504.

For the final Phase II 316b analysis, EPA has reduced its reliance on benefit transfer to estimate recreational fishing benefits. In addition, EPA no longer uses case studies of individual facilities. Instead, EPA has estimated regional models. For the recreational fishing analysis, benefit transfer is used for the inland region, and benefit function transfer is used for the North Atlantic region. EPA has estimated RUM models for all other coastal regions (Mid-Atlantic, South Atlantic, Gulf of Mexico, and California), and for the Great Lakes region. Where benefit transfer is used, EPA has followed generally accepted procedures, and has carefully applied benefit transfer methods.

For the North Atlantic region, EPA's benefit transfer uses the benefit function from the Hicks, et al., study recommended by several of those who commented as the most appropriate study for benefit transfer for the North Atlantic region. By using benefit function transfer, EPA was able to make appropriate adjustments to Hicks' model, to estimate values for relevant changes in catch rates. This benefit function transfer follows accepted methods and was performed carefully to provide the best available estimates of values for changes in catch rates for the North Atlantic region.

For the Inland region, EPA did a benefit transfer using values from several studies. EPA generally followed its Guidelines for Preparing Economic Analyses for benefits transfer (BT) in developing a benefits transfer approach for the Inland region. The steps were followed as recommended in the Guidelines when using BT: (1) describe the policy case; (2) identify existing, relevant studies; (3) review available studies for quality and applicability; (4) transfer the benefit estimates; and (5) address uncertainty. Further information on the methods EPA used to estimate recreational fishing benefits for the Inland region is provided in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003). See Chapter H4: Recreational Fishing.

Valuing Forage Species (incl non-use and non-landed)

EPA notes the potential importance of non-use value, which is controversial in economics and notoriously difficult to estimate. EPA did not carry out any original surveys of non-use value, but employed two alternatives in the 316(b) analysis. First, EPA used a rule-of-thumb in which non-use values are assumed to be equal to 50 percent of use values. There is no basis in economic theory for such an approach, and there is no justification for EPA's claim that its 50% rule-of-thumb provides "conservative" estimates.

EPA Response

For EPA's response to comments on the use of the 50% rule-of-thumb to estimate non-use benefits, please refer to EPA's response to comment #316bEFR.005.034.

Please also refer to EPA's response to comments on the HRC methods (316bEFR.005.035) and the SRP methods (316bEFR.005.006); the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003); and to EPA's Guidelines for Preparing Economic Analyses (EPA 240-R-00-003).

Organization John F.Kennedy School of Government, Harvard University

Subject Matter Code 10.02.03

Use of Replacement Costs (HRC and hatchery-based)

Despite the significance of these problems and outright errors, those mistakes pale by comparison with EPA's attempt to introduce what it characterizes as an alternative method of valuation and benefit estimation, namely the "Habitat-Based Replacement Cost (HRC) Method," which is not a method of valuation or benefit estimation at all, but a method of assessing costs. This method estimates the costs of another alternative — and a very costly alternative — for achieving the same functions as targeted by the proposed regulation. If there are omitted use-values, they should be estimated with theoretically sound and empirically valid revealed-preference methods. If there are legitimate "non-use values," they should be estimated with original applications of the best stated-preference methods. But in neither case, does the possible existence of excluded use values or unassessed non-use values justify the employment of this wholly invalid approach, which is not a method of benefit estimation in any legitimate sense.

EPA Response

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule. Please see EPA's response to comment #316bEFR.005.035. Please also see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method.

For the cost-benefit analysis for the final rule, the angling index was not used. Thus, all extrapolations were done based on flow. (Please refer to EPA's response to comment #316bEFR.041.037 for details on the use of flow as a basis for extrapolation.) In addition, for the final analysis, EPA only extrapolated losses and benefits for recreational and commercial impacts. For these categories, only a single point estimate was reported, so no midpoint was calculated.

Subject Matter Code 10.03.05

Brayton Point

Author Name Robert N. Stavins

Organization John F.Kennedy School of Government, Harvard University

In the fourth major section of my comments, I reviewed EPA's application of its "benefit assessment" methods for the analysis of case studies, which form the sole basis of its national-level benefit estimates. My comments focused on the Brayton Point Station Facility Case Study. Using flawed methodologies for estimating commercial and recreational values, combined with the wholly invalid HRC method of using the cost of a very expensive alternative means of achieving the rule's objectives as an increment to benefits, EPA comes up with estimates that are not just highly biased upward, but truly absurd. The total loss numbers (combining impingement and entrainment) reported by EPA for its "low" case are more than 100% greater than what EPA's own analysis would produce if incorrect elements of its analysis were eliminated, and approximately 21,000% (twenty-one thousand percent) greater than the correct elements of EPA's analysis would produce for its "high" case (EPA's "high" case employs its invalid HRC cost proxies instead of real value/benefit estimates). EPA's "best estimate" of baseline I&E losses (and hence, benefits) at the Brayton Point Station facility carries an upward bias of approximately 12,000%!

EPA Response

The results of the HRC analysis referred to by the commenter are not included in EPA's analysis for the final 316b Phase 2 rule. For additional discussion of HRC, please refer to the document entitled "Habitat Based Replacement Cost Method" (DCN # 6-1003) and response to Comment 316bEFR.005.035.

Subject Matter Code OPP

General Statement of Opposition

In summary, the comparisons of "benefits" and costs carried out in the Economic Analysis and the Case Study Analysis — which EPA uses to support the Proposed Rule in the Federal Register — are biased and misleading. The analysis is extremely flawed, and biased toward greatly exaggerating the rule's implementation benefits relative to its costs. EPA claims that its various assumptions and omissions lead to significant underestimates of true benefits, but there is no basis for this claim. On the contrary, through mistakes and outright faulty analysis, EPA has produced estimates of benefits that are highly upward biased, and should therefore not be used as part of the basis for this rule-making.

It was clearly challenging for EPA to carry out this large-scale and detailed analysis. But it is very disappointing to see flawed reasoning, confused concepts, and fundamentally invalid research methods in what is purported to be a reasonable and unbiased analysis. Needless to say, such approaches are not supported by EPA's Guidelines for Preparing Economic Analyses, OMB's Guidelines, nor any other sound guide to benefit-cost analysis or to environmental economics more broadly. Good analysis is good analysis, and bad analysis — by any other name — is just that.

I close these comments on a personal note. I have invested a considerable amount of time and effort over the past decade working with EPA to help its dedicated and talented staff of economists and policy analysts use correct conceptual frameworks for economic analysis and the best empirical methods for developing unbiased estimates of benefits and costs. For this reason, it has been disappointing, troubling, and ultimately painful to review this analysis and provide these comments.

I believe that the numerous, serious problems I have identified would not have occurred had the proposed rule and its economic analysis been subjected to wide internal review by EPA's economics staff. As I said at the outset, I believe that EPA's leadership recognizes the importance of using the best scientific and economic analysis for this and all other rules. It is my hope that the comments I have offered will help foster the execution of a sound economic analysis of the proposed rule and the development of an environmentally and economically sensible rule for implementation of Section 316(b) of the Clean Water Act.

EPA Response

Author Name Paul E. Reynolds

Organization Hoosier Energy Rural Elect. Co-op

Subject Matter Code 3.03

Definition: Waters of the U.S.

Cooling Lakes and Ponds Hoosier

Energy built a cooling lake (Turtle Creek Reservoir) expressly for the purpose of complying with restrictions on heat rejection rates. EPA should consider this lake a treatment system and not “Waters of the United States” thereby exempting this facility from the 316(b) regulations. Even if EPA decides not to designate this lake a treatment system, EPA should determine that this cooling system constitutes a “closed cycle recirculating system” and is, therefore, in compliance with the 316(b) rules.

EPA Response

See section II.C. of the preamble to the final rule. As noted in that section, the determination of whether a particular cooling pond is or is not “waters of the United States” is to be made by the permit writer on a case-by-case basis. Such an approach is most appropriate given the many criteria and site-specific factors that must be considered and assessed when applying the relevant definitions and regulations to specific existing facilities. Similarly, whether use of a specific pond or reservoir meets the definition of a closed-cycle, recirculating system, as well as whether a specific cooling pond is considered a waste treatment system, also will be determined on a case-by-case basis.

RFC: Cost: benefit ratio for site-specific BTA?

Cost - Benefit Test

The cost-benefit test is the key to the successful implementation or failure of this rule. If EPA adopts their framework as proposed, it is essential that this test be included in the final rule and given the same significance it has in the proposed rule.

EPA Response

EPA has included a site-specific compliance option based on cost-benefit considerations.

RFC: Appropriateness of "significantly greater"

Author Name Paul E. Reynolds

Organization Hoosier Energy Rural Elect. Co-op

"Significantly Greater"

The proposal provides for a site-specific determination of the "best technology available" if the costs of compliance at a site would be "significantly greater" than either the benefits of meeting the performance standards or the cost of what the agency considered. EPA must provide a clear definition of what is meant by "significantly greater." To maximize net benefits to society, economic theory would dictate that this should be interpreted to mean any cost benefit ratio greater that 1:1. This reflects the most cost-effective, performance-based outcome.

EPA Response

Under § 125.94(a)(5), a Phase II existing facility may seek a site-specific determination of best technology available if the Director determines, based on the facility's demonstration, that its compliance costs would be significantly greater than the costs determined by the Administrator in establishing the final rule performance standards, or if its costs of compliance are significantly greater than the benefits of complying with the performance standards at the facility. As discussed in the proposed rule at 67 FR 17145 - 17146 (April 9, 2002), EPA has adopted the significantly greater cost-cost standard, rather the wholly disproportionate standard used in the Phase I rule, based on the fact that new facilities, regulated under Phase I, have greater flexibility than existing facilities, regulated under Phase II, in selecting the location of their intakes and technologies for minimizing adverse environmental impact so as to avoid potentially high costs, and it is therefore appropriate to push such facilities through use of a more stringent economic standard. In contrast, Phase II existing facilities encounter more substantial retrofit challenges (e.g., retrofitting an existing facility requires special consideration of various factors, including but not limited to the adequacy of space to accommodate a technology, approval and special conditions to locate such technology, potential redesign of intake, piping and cooling system components, often unique construction concerns, and secondary effects) and associated costs, and thus warrant somewhat broader flexibility. In addition, in contrast to the Phase I rule, the Phase II rule affects a significant portion of existing electric generating capacity. Thus, EPA believes it is appropriate to set a lower cost threshold in this rule to avoid economically impracticable impacts on energy prices, production costs, and energy production that might otherwise occur.

EPA has not expressly defined the term "significantly greater" in this rule. The Agency believes that a general standard, to be applied by the Director on case-by-case basis, is more appropriate for application in this rule since such a standard preserves reasonable discretion for the Director to compare assessments of costs and/or benefits, and make determinations that ensure that the costs of the rule are economically practicable or that there is a reasonable relationship between the costs of cooling water intake technology and the environmental benefits associated with its use. Numerous factors are considered in assessing costs and benefits, and use of a general standard allows an appropriate consideration of the totality of these factors under the rule. EPA notes that the "wholly disproportionate" standard applied historically, and as used in the Phase I rule, are not explicitly defined. The former has proven workable and, although it is too early to assess, the latter appears equally useful.

RFC: Use of previous demonstration studies

Author Name Paul E. Reynolds

Organization Hoosier Energy Rural Elect. Co-op

Application to Existing Facilities

The proposal should include a process for approving existing intake technologies as “best available” if it can be shown that the facility is not causing adverse environmental impact or the technologies have been deemed “best available” by the state. Such a process is reasonable since Section 316(b) has been in effect since 1972 and has been implemented case-by-case at many sites. There are many electric generating facilities for which there is already a high degree of confidence that the facility is not causing adverse environmental impact or that it has already installed the best technology available. In addition, if the facility has data indicating that the amount of entrainment and impingement is so small that there is no significant harm to the aquatic community or the environmental impact is of so little economic and environmental significance that the costs of a comprehensive 316(b) study would be significantly greater than its benefits, then there should be no need for either further studies or for additional intake technology.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today’s final rule, however existing data that is reflective of current conditions may be used to support application studies. Please see response to comment 316bEFR.040.001 for details.

Additionally, under compliance alternative 2 (see 125.94(a)(2)), a facility may demonstrate that it already meets rule requirements if its existing design and construction technologies, operational measures, and/or restoration measures meet the performance standards at 125.94(b) and/or the restoration requirements in 125.94(c).

Comment ID 316bEFR.006.005

Subject Matter Code 7.02
Performance standards

Author Name Paul E. Reynolds
Organization Hoosier Energy Rural Elect. Co-op

Compliance Assessment

Since there is such variability in biological systems, it is not practical to require the permittee to meet a specific numerical reduction in affected organisms. The proposed performance criteria should not be directly implemented as enforceable permit limitations. Rather, when the existing technology is not the ‘best available,‘ the permit should require the installation of technology identified collaboratively by the permittee and the state. Then compliance with the permit would be based on installation, operation and maintenance of the selected technology.

EPA Response

EPA has attempted, in a variety of ways, to account for the variability of aquatic environments and the various performance factors that can influence the overall success of a design and construction technology, operation measure, and or restoration measure option. Today's final rule allows a facility to demonstrate its existing technology or operation meets the performance standards with respect to impingement mortality and entrainment reduction. First, EPA has expressed the performance standards in terms of ranges. Second, EPA authorizes the use of several different compliance alternatives. Third, EPA authorizes the use of a Technology Installation and Operation Plan. If the existing technology or operational measures does not meet the performance standards, the facility must select one of the other compliance alternatives authorized in today's rule. Adaptive management is also part of this rule.

Tampa Bay

Author Name Ernst Peebles

Organization College of Marine Science, University of South Florida

The last sentence on page D3-25 of the Case Study Analysis states

"To a lesser extent, the concurrence between the two sets of results also supports the use of records from Big Bend as a basis for extrapolation of entrainment rates to other facilities in Tampa Bay, and the use of larval densities to estimate potential entrainment at facilities that have not conducted monitoring studies, including new facilities."

However, the presence of distinct spawning grounds within Tampa Bay creates spatial gradients in the egg and larval densities of many species, including spotted seatrout (McMichael and Peters 1989), red drum (Peters and McMichael 1987), bay anchovy (Peebles et al. 1996, Peebles 2002) and others (Peebles, unpublished data). These gradients cause densities to vary substantially within short distances (several km). Therefore, extrapolation of entrainment rates from one monitored site to other locations may produce highly inaccurate results. In the case study (section DC-10, pages D3-24 and D3-25), the two data sets were similar only because the second set intentionally bracketed the geographic location of the first. From a logical perspective, observed similarity within a specific region of Tampa Bay does not support extrapolation of larval densities to other (unmonitored) regions.

The case study could be interpreted as support for using unrealistic data extrapolations during implementation of the rule.

EPA Response

The purpose of this analysis was to examine the potential relationship between ambient larval densities and entrainment rates. The analysis was not used in any way in EPA's section 316(b) benefits analysis and was not included with EPA's materials in support of the final Phase II rule.

EPA's legal authority to:

EPA Lacks Authority to Apply 316(b) to Facilities Subject Only to a NPDES Storm Water Permit

EPA is proposing to apply section 316(b) to all facilities that are covered by NPDES permits, including those subject only to NPDES storm water permits. The Federal Water Pollution Control Act Amendments Section 316 Thermal Discharges paragraph (b) states the following:

Any standard established pursuant to section 301 or section 306 of this Act and applicable to a point source shall require that the location, design, construction, and capacity of cooling water intake structure reflect the best technology available for minimizing adverse environmental impact.

Section 301 establishes the requirement for adoption of effluents limitations for all point sources. Section 306 establishes requirements for best demonstrated control technology and a list of source categories that must comply with standards of performance for new sources within the category. Those standards were subsequently adopted and implemented as the Steam Electric Point Source Effluent Guidelines in 40 CFR Part 423.

Thus, the 316(b) requirements apply to only to those facilities that are subject to sections 301 and 306 and not to facilities that are required to have storm water permits under section 402.

Furthermore, Otter Tail does not believe that EPA has the authority under section 402 to issue a general NPDES permit that would include section 316(b) requirements. Nor does it have the authority to amend existing individual or general storm water permits to include section 316(b) requirements without amending the storm water rules and corresponding permit requirements.

EPA Response

Option: Reduce capacity comm. with closed-cycle

EPA's Operational Performance Standards Penalize Certain Geographical Regions

EPA is proposing to establish performance standards in section 125.94(b) that would offer facility owners several options for compliance including the option to reduce "intake capacity to a level commensurate with the use of closed-cycle, recirculating cooling system;?"

Otter Tail is concerned that the existing performance standard does not offer sufficient latitude to accommodate all closed-cycle, recirculating facilities in all geographical regions. Some facilities that are located in more arid regions have on-site cooling ponds and pumping facilities that are designed to appropriate large amounts of water from waters of the U. S. over a limited time period during, for example, spring run-off. Such facilities have a higher pumping capacity, but the pumps would operate for only a portion of any calendar year. States have considered and mitigated possible impacts by limiting pumping based on site-specific permit conditions.

It is unreasonable for EPA to establish performance standards based strictly on an intake capacity comparison with closed-cycle, recirculating cooling systems while ignoring the annual amount of water pumped.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161). Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to section VII.E of the preamble for more information on why EPA rejected this alternative.

Option: Site-specific determination of BTA

Author Name Terry Graumann

Organization Otter Tail Power Company

EPA's Attempt to Cover All Situations with a One-Size Fits All is Costly

In EPA's attempt to cover all situations regarding cooling water intake structures (CWIS) with a broad sweeping, one-size fits all rule, the result will be a more complicated and costly program to State agencies, utilities, and their customers. Just as there are many types of aquatic ecosystems in the U.S. waters, so are there different CWIS. One-size definitely does not fit all.

A structured, site-specific approach is the only way to accurately choose the best technology for each CWIS. Many states have existing programs, which should be utilized by EPA to provide the greatest amount of protection, while implementing the best technology for each site. EPA should not try to rewrite what the States have already accomplished. Rather, they should codify that expertise into a flexible system that will meet all needs. Revamping the entire program would be very costly to State agencies.

Sound science is also necessary for complete evaluation of each site. Not all sites have the same potential for impact on aquatic life. This is yet another reason why a site-specific approach is the best approach.

EPA Response

EPA disagrees that the final rule is insufficiently flexible. EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

The final rule provides for EPA approval of alternative State program requirements where such State NPDES requirements will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment that would otherwise be achieved under § 125.94. (see § 125.90(c)).

Option: Site-specific based 1977 Draft Guidance

The 1977 Draft Guidance for Evaluating the Adverse Impact of Cooling Water Intake Structures on the Aquatic Environment: Section 316 b) P.L. 92-500 (U.S. EPA, 1977) states that the best technology available for intake design, location, construction, and capacity must be made on a case-by-case basis. [This is stated in the proposed rule's Preamble.] This Draft Guidance should be the basis for the 316(b) Phase II requirements. Since each state may have very different water issues based on climate and other water uses, the States have more knowledge of what is needed to protect the aquatic environment in their particular region.

One-size-fits-all may be the easy fix, but the costs will most likely not justify the benefits to the environment.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

General statement of support

On April 9, 2002, the U.S. Environmental Protection Agency (EPA) proposed regulations (68 FR 17122) that would establish requirements for cooling water intake structures (CWIS) at existing power producing facilities (known as the Phase II rule). These regulations, when adopted, will implement Section 316(b) of the Clean Water Act (CWA). The U.S. Department of Energy (DOE) commends the EPA for developing and proposing regulatory approaches which will achieve the CWA's environmental protection objectives while minimizing the economic and energy impacts of mitigation measures. We believe that EPA has correctly dismissed dry cooling towers as a retrofit option as this agrees with the results of the enclosed DOE report. We also agree with EPA's proposal not to require wet cooling towers due to the high costs and energy impacts. In addition, the current proposal includes limited flexibility for States to comply with the proposed regulations with comparable existing 316(b) programs. DOE recommends that the final rule expand this flexibility in order to be consistent with the general policy statements of the CWA.

EPA Response

No response necessary.

Comment ID 316bEFR.010.002

Author Name Carl Michael Smith

Organization Dept of Energy

Subject Matter Code 7.01.03

Option 3--Site-specific determination

DOE believes that all 316(b) determinations should be made on a site-specific basis. A site-specific approach is most consistent with the CWA, as well as current EPA regulatory policy, and we believe is the least costly way to provide the required environmental protection. We also support inclusion in the site-specific "Sample Rule" of an appropriate definition of adverse environmental impact such as the preamble's "Alternative Definition" focused on population effects.

EPA Response

No response is required for this comment as DOE is a Federal partner in the rulemaking.

Comment ID 316bEFR.010.004

Organization Dept of Energy

Subject Matter Code 17.06

Option: Site-specific determination of BTA

A site-specific regulatory approach is most consistent with the Clean Water Act's mandate for "best technology available for minimizing adverse environmental impacts" and economic achievability requirements set forth in the legislative history and cited in previous EPA rule makings. DOE believes that a site-specific approach is the least costly and most cost-effective way to accomplish the Act's goals under Section 316(b). Moreover, conversion of a cooling system to a wet cooling tower should only be required if that is the conclusion of a site-specific analysis.

EPA Response

Implement a site-specific alternative

Site-Specific Approach is Required - Section 316(b) of the Clean Water Act (CWA) requires, in standards established under sections 301 and 306 of the CWA, that "the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact" (33 U.S.C. 1326(b)). To implement this mandate, EPA has proposed impingement mortality and entrainment performance standards, based on generalized determinations of adverse environmental impact (AEI), that would apply to all in-scope existing facilities, subject only to limited cost-based variances. EPA does not propose to mandate the use of any specific technology for minimizing AEI. As stated on page 17124, the proposed performance standards constitute a departure from the approach EPA adopted in its 1977 draft guidance which was based on the judgment that "[t]he decision as to best technology available for intake design, location, construction, and capacity must be made on a case-by-case basis." As a matter of both law and policy, DOE believes that the only viable approach to implementing section 316(b) is a site-specific approach. Consequently, DOE urges EPA to adopt such a site-specific approach rather than the across-the-board performance standards and generalized determination of "adverse environmental impact" suggested in the notice of proposed rule making.

EPA Response

No response is required for this comment as DOE is a Federal partner in the rulemaking.

Author Name Carl Michael Smith

Organization Dept of Energy

Subject Matter Code 18.03

Process for determining site-specific BTA

In our view, EPA's proposed performance standard approach lacks the precision needed to satisfy the statute's command that cooling water intake structures (CWIS) reflect the best technology available for minimizing AEI. EPA states (at page 17141) that it –

"is proposing to set performance standards for minimizing adverse environmental impact based on a relatively easy to measure and certain metric – reduction of impingement mortality and entrainment. EPA is choosing this approach to provide certainty about permitting requirements and to streamline and speed the issuance of permits."

Although we appreciate EPA's desire to streamline the permitting process, we firmly believe that as a matter of both fact and statutory mandate, determinations of the best technology available for minimizing AEI must be based on an assessment of the full range of environmental impacts related to particular CWIS. As the preamble to the Phase I regulations states, "it is reasonable to interpret the phrase adverse environmental impacts as including a range of impacts, including impingement and entrainment, diminishment of compensatory reserve, stresses to the population or ecosystem, harm to threatened or endangered species, impairment of state water quality standards. . ." (66 FR 65314). Our comments on the definition of "adverse environmental impact" also identify non-aquatic impacts that are encompassed by the term (see Comment 16 below). EPA's proposed reliance on generalized determinations based on anecdotal nationwide or water body type information is not consistent with the determination contemplated by section 316(b); that is, a determination of best technology available for minimizing AEI based on an assessment of all environmental impacts at a particular facility in light of the unique environmental situation at that facility.

EPA Response

No response is required for this comment as DOE is a Federal partner in the rulemaking.

Comment ID 316bEFR.010.012

Author Name Carl Michael Smith

Organization Dept of Energy

Subject Matter Code 2.04.03

Define BTA as anything less than closed cycle

Our view that "best technology available for minimizing adverse environmental impact" must be determined on a site-specific basis is bolstered by the provision for variances from thermal discharge effluent limitations in section 316(a). It is highly unlikely that Congress, having provided for variances from thermal effluent limitations on a showing that alternate limitations would "assure the protection and propagation of a balanced, indigenous population of shellfish, fish, and wildlife in and on the body of water," intended that EPA impose CWIS requirements that do not include a site-specific assessment. Under EPA's proposed performance standard approach, an existing facility that has been granted a variance under section 316(a), based on the "balanced, indigenous population" test, might be required to install expensive equipment to satisfy the proposed performance standards. Such a result would be inconsistent with the text and intent of section 316.

Further, we believe legislative history indicating Congress intended "best technology available" to be interpreted to mean the best technology available commercially at an economically practicable cost (referenced in the preamble to the 1976 final rule, 41 FR 17388) points to a site-specific assessment. What is economically practicable depends on highly site-specific factors, such as the existing CWIS features and location, as well as a localized evaluation of the precise adverse environmental impact to be avoided.

EPA Response

No response is required for this comment as DOE is a Federal partner in the rulemaking.

Comment ID 316bEFR.010.013

Author Name Carl Michael Smith
Organization Dept of Energy

Subject Matter Code 17.06
Option: Site-specific determination of BTA

Also from a policy standpoint, DOE believes the site-specific approach is superior, and DOE's specific comments which follow identify problems with the proposed performance standards that would be avoided by using a site-specific approach. More generally, DOE believes that a site-specific rule is both the least expensive and most cost effective approach. Only by evaluating the specific attributes of a regulated source, and its receiving water body, can the most economical method to achieve environmental objectives be determined. Other regulatory approaches being considered by EPA contain elements of site-specific analysis, but only a rule that is completely site-specific can take full advantage of the additional information generated in assessing both the CWIS and the water body.

EPA Response

No response is required for this comment as DOE is a Federal partner in the rulemaking.

Comment ID 316bEFR.010.014

Author Name Carl Michael Smith

Organization Dept of Energy

Subject Matter Code 17.06

Option: Site-specific determination of BTA

Finally, beginning on page 17159 of the proposal, EPA considers several versions of site-specific approaches as alternative regulatory options, but does not propose these as its preferred option. DOE continues to believe it is critical for the final rule to embody a site-specific approach. This will allow regulators to equitably tailor the degree of changes to the level of AEI caused by the intakes. The preamble describes four different site-specific approaches – a Sample Rule, an approach based on EPA's 1977 guidance, the Utility Water Act Group (UWAG) approach, and the Public Service Electricity and Gas Company (PSEG) approach. Each of these centers on site-specific evaluations, but includes different methodologies. DOE is generally supportive of all four approaches but notes that the details of implementation are most clearly spelled out for the Sample Rule approach. Regardless which site-specific approach is adopted, it should contain a definition of AEI. As EPA notes, the preamble's Sample Rule does not provide a definition of AEI. We address this critical feature of a site-specific rule in specific comments that follow, particularly Comment 16.

EPA Response

Option: Site-specific determination of BTA

Author Name Carl Michael Smith

Organization Dept of Energy

Performance Ranges Are Problematic - EPA proposes performance standards for reduction of impingement mortality and, in some water body types, reduction of entrainment. As noted in Comment 1 above, DOE believes that a site-specific approach is required under Section 316(b). However, if EPA decides to adopt its current proposal or some other regulatory strategy that incorporates impingement and entrainment (I&E) performance standards, we believe that those standards should be expressed as single-number limits and not as ranges.

EPA Response

Performance standards

Author Name Carl Michael Smith

Organization Dept of Energy

DOE recommends against the use of performance ranges for several reasons. First, not all locations within a water body type have the same potential for impingement and entrainment harm. Further, the level of performance of fish protection technologies varies with the type of water body and the aquatic organisms that are present at each specific location. The use of a constant performance standard across all estuaries, tidal rivers, Great Lakes, and oceans ignores the fact that some locations in those types of water bodies contain large concentrations of organisms that might be impinged or entrained, while other locations have relatively few organisms that might be affected.

Option: Site-specific determination of BTA

Author Name Carl Michael Smith

Organization Dept of Energy

We reiterate our premise that the appropriate means of implementing Section 316(b) is through a site-specific determination of whether adverse environmental impact is occurring and the best technology available for minimizing such impact, taking into account features of the CWIS and the cost and efficacy of additional technologies.

EPA Response

No response is required for this comment as DOE is a Federal partner in the rulemaking.

Performance standards

Second, we do not believe that EPA has provided any rationale for selecting the numerical values that are included in the proposed performance ranges. Why is the impingement range set at 80-95 percent instead of 75 percent or 90 percent? Any performance range or single-number performance limit would need to be based on the performance needed to minimize adverse environmental impact. EPA has not documented that AEI occurs at all facilities operating outside of the performance ranges proposed. The type of AEI being addressed by the proposed rule does not lend itself to a performance-based approach because of the wide diversity of the biological systems at the specific locations affected by the proposed rule.

A third reason for not employing a performance range is that this would be inconsistent with other enforcement approaches imposed in National Pollutant Discharge Elimination System (NPDES) permitting. It is not clear if EPA intends for NPDES permits to include an enforceable performance range. If so, this would be the only example, outside of a pH range, of which DOE is aware, in which range-type limits are imposed in NPDES permitting. The use of pH ranges is different in that either too-high or too-low pH is undesirable. Other than that exception, the use of any numerical limit that is not clearly defined as a single-limit minimum presents compliance and enforcement concerns. On the other hand, if EPA envisions that the permit writer will choose a single value from within the promulgated range, then EPA would need to provide guidance on how the permit writer could justify anything higher than the minimum value. We do not see this type of guidance referenced in the preamble.

The proposed rule (page 17141) states that " EPA is proposing performance ranges rather than a single performance benchmark because of the uncertainty inherent in predicting the efficacy of a technology on a site specific basis." DOE agrees that the efficacy is definitely a site-specific issue. However, DOE continues to feel strongly that the ranges will only create more uncertainty for the State permit writer and the permittee. The preamble then goes on to state that "the lower end of the range is being proposed as the percent reduction that EPA, based on the available efficacy data, has determined that all facilities could achieve if they were to implement available technologies and operational measures on which the performance standards are based." DOE believes that if a single limit must be set at all, it should be set at a value no higher than what facilities can actually do (i.e.; no higher than the lower end of the range). However, while possible from an engineering perspective, that approach would not be consistent with the focus on AEI in section 316(b) of the Clean Water Act, which requires that "cooling water intake structures reflect the best technology available for minimizing adverse environmental impact."

RFC: Req. greatest possible reduction within range?

We believe that most companies will probably implement control measures that will be more stringent than the minimum limit. This is done as a matter of engineering practice so that they have a cushion between the limit and the actual performance and therefore do not risk compliance problems. There is no value to adding an upper end to the range; it will only create uncertainty.

Director's role in determining requirements

Author Name Carl Michael Smith

Organization Dept of Energy

On page 17142, EPA requests comments on whether decisions about appropriate performance levels should be left to the discretion of a State Director. We believe that this is the correct approach. EPA does not need to adopt strict overarching national regulations, but rather should set up a regulatory framework that allows flexibility and judgment by the agencies issuing NPDES permits. These agencies will be knowledgeable about the site-specific issues that should dictate performance levels.

Performance standards

Proposal Relies Too Heavily on Extrapolation of Performance - For the proposed rule, EPA established a baseline level of performance as a shoreline intake with no impingement or entrainment controls installed. The performance standards are expected to be measured as reductions compared to the baseline. DOE believes that EPA chose a reasonable baseline. However, many existing facilities have already installed some degree of improvement beyond baseline (e.g., intake canal, traveling screens, fish return troughs, etc.). In order to determine the baseline level of performance, the facility must project or extrapolate backwards to estimate how much more impingement and entrainment would be occurring under a baseline configuration at the plant as compared to the current configuration. Facilities must then extrapolate forward to estimate the percentage reduction that a proposed suite of controls would yield over the baseline configuration. DOE agrees that these extrapolations should be the responsibility of the facility.

Both of these steps will involve making some assumptions and probably running some fisheries models. By having to model/project impacts in both directions, the potential for inaccuracy is compounded. Even under the best of assumptions and models, the ability to get within 10-20 percent of real-world performance would be quite fortunate. This degree of uncertainty could present real compliance issues. If a facility runs a legitimate fisheries model and installs and operates technologies properly but still misses the performance target by 20 percent or more, it could be out of compliance. These forecasting uncertainties need to be recognized.

Determination of compliance

On page 17143, EPA discusses the situation under which a facility designs, installs, operates, and maintains intake technologies or restoration measures properly yet still is unable to achieve the performance standards outlined in the permit. Is that facility out of compliance? EPA solicits comments on an approach that would consider properly designed, installed, operated, and maintained facilities to be in compliance until the permit is reissued. DOE supports this approach as offering a solution to the uncertainty described above. If the permitting agency concurs that a suite of controls included in a permit should achieve the target and the facility has made a good faith effort to meet the performance standards then the facility should be considered in compliance for the permit term. If EPA adopts the proposed regulatory approach using performance standards, we believe that this type of compliance interpretation and protection is essential.

RFC: Performance/effectiveness of restoration

When examining biological systems, it is important to note that populations fluctuate naturally from season to season and from year to year. These fluctuations can be substantial. To the extent that restoration measures are made part of a facility's compliance strategy, there is additional concern over how and when to measure the effectiveness of the restoration. Many types of restoration measures take years to reach their full benefit potential. After two years of monitoring, they may not show the full level of performance that they will achieve after 5 or 10 years. If EPA elects to adopt a performance-standard regulatory approach, these types of temporal variation must be somehow considered by the rule. By adopting a site-specific option for the final rule, EPA would be better able to take these temporal variations into account and also avoid the problems associated with extrapolation discussed above.

RFC: Appropriateness of and tests for variance

Variances Must Be Viable - DOE is generally supportive of the variance provisions that EPA has included in the proposed rule or lead option, although we firmly believe the site-specific approach is the most appropriate way to implement section 316(b). If EPA elects to adopt the lead option approach in the final rule, the variance provisions would provide a necessary measure of flexibility and allow for consideration of site-specific factors. DOE supports the concept of the cost-to-cost and cost-to-benefit variances. However, DOE recommends that provisions be included in the final rule to make variances more realistically obtainable. In other words, the variances must truly be a viable mechanism. DOE notes that several other types of CWA variances have been very difficult for applicants to obtain even though the CWA allows their use. For example, a 1994 article (Veil, J.A., "Using Clean Water Act Variances as Economic Incentives," Journal of Environmental Regulation, Spring 1994, pp. 281-291) indicates that through 1993, EPA had approved only 7 of 249 “fundamentally different factor” variance requests, 19 of 64 301(g) variance requests, and 51 of 111 301(h) variance requests that had been submitted to EPA. We want to ensure that the cost-to-cost and cost-to-benefit variances can be obtained in a reasonable amount of time and that State or regional permit writers, who can appreciate the site-specific nature of any AEI, will have the final say on variances rather than having the decision-making reside with the Federal government.

RFC: Appropriateness of "significantly greater"

Significantly Greater Than - Pages 17145 and 17166. DOE welcomes the shift in decision-making criteria from "wholly out of proportion," as used in the new facilities rule, to "significantly greater than," in the proposed cost-to-cost and cost-to-benefit variances. This should provide a greater opportunity for affected facilities to demonstrate that the proposed I&E reductions are not appropriate. Yet we note the proposed rule does not define or expand upon the meaning of "significantly greater than." We want to make sure that the term is interpreted and implemented in such a way that the cost variance is truly a viable mechanism for plants with a legitimate case. Therefore, DOE recommends that the interpretation of "significantly greater than" be left to the State permit writer, who is in a better position to make variance decisions.

Dry Cooling

Dry Cooling Is Not Best Technology Available - On page 17168, EPA states that it does not consider dry cooling a reasonable option for best technology available on a national basis for existing facilities. This determination is based on the high cost of dry cooling and the energy penalty impacts of using a less efficient form of cooling. We strongly support this position, and further add that dry cooling towers would probably be infeasible in certain locations. For instance, the turbine back pressure could increase beyond recommended manufacturer specifications for a number of existing units and would require severe curtailment of normal operations, or a redesign of the circulating water system and associated equipment. From a technical and economic perspective, such attempts to force a dry cooling tower system into typical power plants would result in an inability to continue operations. ASPEN modeling done by DOE/NETL shows that during hot weather the dry cooling tower would not be able to safely (due to the operation of the existing turbines above back pressure design limits) supply sufficient cooling at a significant number of existing power plants .

Even if a company were able to use dry cooling as a retrofit option, the land area footprint would be very large and create other land use, construction issues, and other environmental issues of concern, such as noise and increased air emissions. For instance, a representative dry cooling tower installation at an existing power plant located in the Eastern United States would have a footprint area that is 50 percent to 100 percent the size of a typical power plant footprint. For a number of existing power plant facilities, this amount of additional space is simply not available.

DOE, NETL, and ANL have analyzed the energy penalties and air emissions resulting from retrofitting a power plant with once-through cooling to both wet and indirect-dry cooling towers ("Energy Penalty Analysis of Possible Cooling Water Intake Structure Requirements on Existing Coal-Fired Power Plants" June 14, 2002). A copy of this report is enclosed and the issues above are analyzed in detail. The report concludes, based on a wide range of assumptions, that dry cooling towers are not a viable option to be used as retrofits for once-through cooled plants. The primary reasons for such a stark assessment of this technology option are as follows: at the peak time of summer electricity demand many of the existing power plants' turbines could not perform safely; energy penalties associated with a dry cooling tower retrofit could range from 9 to 16 percent at times of peak electricity demand; the dry cooling tower system may require significant plant modifications to retain the integrity of power plant operations; secondary impacts of increased air emissions are significant (could be as great as 4 to 8 percent higher) for a dry cooling tower system; and, retrofit difficulty in a number of plant locations would be too great to warrant continued operations of the power plant.

Subject Matter Code 17.03.02
RFC: EPA rationale to not require closed-cycle

Wet Cooling Towers Should Not Be Required Except on a Case-by-Case Basis - Although EPA's proposed rule does not directly require any facilities to convert their cooling systems to wet cooling towers, some of the alternative options presented do require wet towers or their flow-based equivalents at some subset of facilities. DOE does not believe that the Phase II rule should require any particular class of facilities to convert to wet towers. We acknowledge that some existing, once-through cooled plants are causing AEI and will need to make some changes to their current operations. These changes could involve a combination of new intake technologies, or voluntary operational changes, and restoration measures. Some companies may elect to install wet cooling towers in order to minimize AEI. We believe that these cases will be infrequent, however.

In most cases, the costs to retrofit wet cooling towers will far exceed the costs to employ other remedies. We are pleased that EPA states on page 17155 that it did not select wet cooling towers as the best technology available for existing facilities because of the high costs of the retrofits and the potential for energy shortfalls related to concurrent retrofits at multiple plants. Even though we agree with EPA's decision, we feel that for several reasons the EPA projections of the costs and energy impacts of retrofit to wet towers have been underestimated. EPA presents their estimate of the cooling system conversion capital costs to be $53 per kW (moderate) to $62 per kW (high)--(Appendix C, Phase II Technical Development Document (TDD), page C-5). In comparison NETL has developed retrofit cost estimates through a draft study by its contractor, Parsons Infrastructure and Technology Group. That draft report (forthcoming), entitled "An Investigation of Site-Specific Factors for Retrofitting Recirculating Cooling Towers at Existing Power Plants," estimates wet cooling tower retrofit costs at four sites. The site-specific nature of wet cooling system retrofits at existing facilities is further underscored by the wide range of the cost estimates for the four sites in that draft study which are $66 per kW to $128 per kW. These estimates are on a similar basis as the EPA estimates.

Neither the EPA nor the NETL cost estimates take into account certain site specific factors such as plume abatement. DOE feels that the Agency should have made some assumptions in their cost estimates for a range of site-specific factors affecting the costs of retrofits at existing facilities. These factors include, but are not limited to, the necessity for plume abatement and/or drift control for facilities located in urban areas or in close proximity to highways or airports, and the location of existing underground utilities that may have to be re-routed to accommodate the recirculating system's piping lay-out. For one of the sites in the NETL draft study, the capital cost of the cooling tower alone would double should the local permitting authority require the use of plume abatement. This was not included in the costs presented in the study. However if 1 out of 4 sites studied may have needed plume abatement, we believe EPA should have assumed that a certain number of facilities in their national cost estimate included site-specific retrofit costs such as plume abatement (see Comment 26).

Costs

Further, conversions from once-through cooling to wet towers imposes an energy penalty, albeit not as large as the energy penalty associated with dry cooling. In the enclosed DOE study, the annual average energy penalty associated with conversion of a once-through cooling system to a wet cooling tower varied between 1.1 percent and 2.1 percent of the power plant output and the peak summer energy penalties were estimated to be 2.4 percent to 4.0 percent of the power plant output. EPA, on the other hand, estimates the annual average energy penalty associated with conversion of a once-through cooling system to a wet cooling tower between 1.5 to 1.8 percent with corresponding peak penalties ranging from 1.4 to 2.0 percent. DOE's annual average energy penalties are similar to those calculated by EPA, but the EPA estimates of peak summer energy penalties are considerably lower than DOE's estimate. The reasons for this discrepancy are detailed at Comment 38 below. However, we are pleased that the Agency reports (page 5-35, Phase II, TDD) that it "... views the DOE estimates to be reasonable for a variety of retrofit scenarios at existing facilities and will reconsider this subject in the analysis of regulatory options for the final rule."

The costs and other types of environmental impacts associated with cooling towers must be carefully considered on a site-by-site basis before a regulatory agency requires facilities to retrofit wet cooling towers. We strongly believe that EPA's national Phase II regulation should not include any requirement that has the effect of forcing any class of facilities to install wet cooling towers.

EPA Response

No response is required for this comment as DOE is a Federal partner in the rulemaking.

Cooling system costs (e.g., dry, wet, recirculating)

Cost Uncertainty May Lead to Plant Shut-Downs - A significant degree of uncertainty surrounds multiple aspects of EPA's cost estimation, including estimates of administrative costs, capital costs, and economic impacts and a complete lack of any assumptions for site-specific retrofit factors. (Please see specific Comments 23-37 below for detailed discussion of DOE's concerns with EPA methods). First, EPA's presentation of "maximum" NPDES permit and re-permit application costs optimistically refers to certain costs as "one-time" with minor follow-up costs only to be incurred every five years. There is no apparent allowance for costs that would arise in the event of disputes between facility operators and regulatory authorities and environmental interest groups. Second, although capital costs reflect the largest single cost element in facility compliance strategies (Table B1-7), EPA does not report confidence levels for the estimates. Consequently, DOE has no basis other than EPA's assertions to judge whether compliance with the proposed rule will involve plant closures over and beyond those that would have occurred in the absence of the rule(see Comment 27.) EPA should develop a full market analysis using their modeling tools of the proposed rule.

Performance standards

Impingement and Entrainment Benefit Estimation is Flawed - An examination of the case studies underlying the benefits estimates of the EPA's proposed 316(b) rule reveals at least two issues of concern. The first concern addresses arbitrary application of ecology-based models instead of economic models in certain water body types without any rational documented explanation. Use of ecology-based models increases benefits estimates by over 27 percent. The second concern addresses apparent major differences in EPA's various estimates of the efficacy of the non-dry cooling tower technologies in reducing I&E. The lack of clarity in the methodology stymies attempts to analyze the proposed rule across facilities. DOE has had limited time to review and discuss the apparent discrepancies with EPA. In the proposal at page 17141, EPA states that all facilities could use the technologies being considered for the proposed rule to meet at least the bottom of the performance ranges. However the efficacy estimates or "performance targets" for both the proposed rule, option (3), and the "all plants retrofit to wet towers"option (4) do not imply that even the bottom of the range for impingement of 80 percent could be achieved in most water body types. Similar problems exist in the entrainment estimates. This apparent inconsistency needs explanation. The two issues are discussed further below.

Random Utility Model (RUM)

The EPA case studies attempt to apply economic models to assign values to certain levels of recreational fish and consequently to benefits to anglers. The EPA states that these models, among them the "Random Utility Model" (RUM), are well-accepted in the "recreation demand" literature. <FN 1> The underlying premise of the RUM model is that if more fish exist, more fish can be caught; if more are caught, anglers are happier and, would therefore take more fishing trips. The discussion of the model in Chapter C2 (of the economic study) explains that EPA attempted to estimate demand curves for recreational fishing. Changes in I&E affect the parameters that identify the location of an angling demand curve. I&E reduction thus leads to increases in consumer welfare (greater angler happiness). In its comments, the industry implicitly accepts the model per se, focusing criticism on faulty or thin data used by EPA modelers. <FN 2> For its part, EPA considers RUM estimates "conservative" because, for instance, some of the fish-level data used is from a period (the1970's) when water quality was relatively poor. <FN 3> Depleted fish stocks do not show as big a response to I&E reduction as otherwise would happen had 1) the preceding centuries of American economic development not taken place (lumped together as "other stressors"), or 2) more modern data reflective of water quality improvements been available.

Subject Matter Code 10.02.03
Use of Replacement Costs (HRC and hatchery-based)

In certain cases, however, EPA dispenses with RUM (or other economic models') estimates of baseline losses from I&E (or benefits from no I&E) without any rationale for doing so. EPA uses the alternative, ecology-based "habitat restoration cost" (HRC) models to obtain value for I&E reductions by centering on the cost of the actions required to provide an offsetting increase in the existing populations of those species in their natural environment.

The HRC model's standard is the one presumed to exist if no impingement and entrainment occur. EPA states that HRC models represent "supply-side," rather than demand-side, methods of valuing I&E losses. <FN 4> However, EPA does not attempt to find any point where supply (of I&E reduction) meets demand; instead, estimates of losses derived from HRC models – the sum of the costs across the categories of preferred habitat restoration alternatives at each facility – are simply added to the benefits-transfer model estimates. <FN 5> EPA only says that HRC is used to provide "more comprehensive" estimates of losses, but doesn't distinguish when such a need arises.

To determine the effect of using HRC estimates, one must examine how EPA constructs its extrapolation of losses. EPA divides the power plant industry by water body: Estuary – Non-Gulf, Estuary – Gulf Coast, Freshwater, Great Lake, and Ocean. Estimates of losses from plant(s) in each area are used to extrapolate to all plants within such categories. Section C3-2 of Chapter 3 presents tables detailing national estimates of baseline losses that vary depending upon extrapolation method. In three of the areas, Estuaries-Gulf, Estuaries – non-Gulf, and Freshwater, benefits-transfer model estimates (impact on fishing) are used. Results are presented using lower bound, mean, and upper bound estimates. For the remaining water body types, Great Lakes and Oceans, the midpoint of the angling-based model is used as the lower bound, whereas the lower and upper bounds of the HRC estimates are presented as the mid-point and upper-bound estimates of losses. For "best estimates" of losses, EPA presents mid-points for estuaries and freshwater, but high-end estimates of HRC for Great Lakes and Oceans. EPA provides no explanation for this apparent arbitrary use of the HRC estimates in certain water body types. The increase in loss estimates due to using high-end HRC estimates in two categories, rather than benefit-transfer midpoints in all categories, can be deduced simply:

Benefits Estimates:
[see hard copy for table]

EPA's use of HRC, in two categories, augments total impingement losses nearly 39 percent and total entrainment losses over 26 percent compared to using economic loss models (overall losses increase over 27 percent). Note that the inflation occurs at a facility level and then is extrapolated to the water body category, before being summed nationally.

Subject Matter Code 7.02
Performance standards

Reduction targets in EPA's proposed rule and current technological performance do not appear consistent. It is unclear to DOE what these targets represent and how they may be utilized. We hope it is just a problem that is unclear to us due to the lack of documentation and explanation. The proposed rule states that facilities must reduce impingement losses by 80 percent to 95 percent of their baseline calculation, and entrainment losses by 60-90 percent. However, the estimated reductions shown in tables in Chapter C4 are often out of those ranges. Consider option 3 (the proposed rule or lead option), option 4 (all wet cooling towers), and option 5 (dry cooling towers):

Impingement	Option 3	Option 4	Option 5
Estuary - Non Gulf	33.2%	41.4%	97.5%
Estuary -Gulf	27.1%	45.3%	96.7%
Freshwater Systems	47.2%	58.9%	98.0%
Great Lake	80.0%	88.6%	96.3%
Ocean	50.1%	58.9%	87.6%

Entrainment	Option 3	Option 4	Option 5
Estuary - Non Gulf	48.5%	79.4%	97.5%
estuary -Gulf	47.2%	79.3%	96.7%
Freshwater Systems	12.4%	72.8%	98.0%
Great Lake	57.8%	88.6%	96.3%
Ocean	44.1%	72.8%	87.6%

Source: Tables C4-1 and C4-3

Under option 3, in which EPA surmises that most facilities will not adopt wet cooling towers, only Great Lake facilities seem close to the ranges in the proposed rule, probably because the baseline losses are relatively small to begin with. <FN 6> The low impingement reduction estimates for wet cooling towers, option 4, seem to imply that more impingement controls would be necessary. Only option 5, dry cooling towers, reduces impingement to levels associated with the proposed rule's performance ranges.

Attempts to resolve the apparent inconsistency have not been successful. In conversation, EPA staff has implied that if facilities have some controls in place, then installation of more controls will not reduce I&E to the same extent as would have occurred in the absence of controls. This presumably means that the number of facilities at which no action will be undertaken affects the results, in the opposite direction of the adoption of more stringent controls (i.e.; the type of controls adopted directly affect the estimated reductions above). Calculations demonstrating these effects have not been published. Efforts to reconcile estimated reductions under the proposed rule with the distribution of proposed controls across facilities have been unsuccessful. The following table reports the distribution of controls, by water body type, both as presented in Table A1-1 of EPA's Economic and Benefits Report (EBA) and as gleaned from Appendix A to the TDD. The appendix lists the technology modifications, by facility, that EPA projects will be adopted under option 3.

Facility Distribution of Projected Controls, Proposed Rule

Water body Type	EBA Table A1-1 (option 3)	TTD Appendix A	Difference
Cooling tower (i.e. recirculating systems, no action)			
Freshwater Lakes	Unknown	29	
Freshwater Rivers/Streams	Unknown	41	
Total	69	70	+1
Impingement only (fish handling/return)			
< 15% capacity	53	Unknown	
Freshwater Lakes	94	74	
Freshwater Rivers/Streams	94	64	
Great Lakes	0	3	
Estuaries/Oceans	0	14	
Total	241	155	-86
Impingement & entrainment (both fine mesh+fish handling and fine mesh traveling screen only)			
Freshwater Lakes	0	0	
Freshwater Rivers/Streams	107	86	
Great Lakes	13	13	
Estuaries/Oceans	109	90	
Total	229	189	-50
No modifications necessary, non-recirculating systems			
Freshwater Lakes	0	31	
Freshwater Rivers/Streams	0	69	
Great Lakes	0	0	
Estuaries/Oceans	0	25	
Total	0	125	+125

Source: Table A1-1, p.A1-9, and TDD, Appendix A (Author counts)

Merely counting facilities by proposed technology modification yields the result that 125 more facilities do nothing, as compared to totals presented in the economic study. Whether the model results in Appendix A of the technical document bear any relation to the distribution in the economic study seems questionable. It would be of great benefit to resolve these inconsistencies. Analysis of the proposed rule across facilities can not proceed without more straightforward documentation.

Without a clear understanding of how EPA arrived at the technological performance estimates detailed above, it is unclear how the non cooling-tower I&E technologies could meet the performance ranges in the proposed rule. If option 3 is the preferred option, then the threshold of success should be lowered (with lowered ranges, or no ranges but site-specific solutions).

Special definitions

Minimize - Page 17130. EPA defines minimize as "to reduce to the smallest amount, extent, or degree reasonably possible." EPA offers further explanation on page 17168 as follows: "EPA interprets the use of the word 'minimize' in section 316(b) in a manner that allows EPA the discretion to consider technologies that very effectively reduce, but do not completely eliminate, impingement and entrainment and therefore meet the requirements of section 316(b)." DOE supports that interpretation. We believe that there are a variety of highly effective control mechanisms that can reduce impingement and entrainment to a very low level but that do not completely eliminate them. This interpretation allows use of such mechanisms.

RFC: Entrainment vs. entrainment mortality

Entrainment Mortality - Page 17136. EPA notes on this page that the mortality of entrained organisms varies from 2 to 97 percent. The existing scientific evidence, although not extensive, clearly shows that not all entrained organisms are killed. Yet on page 17149, EPA notes that it has based its proposal on reducing entrainment rather than on reducing entrainment mortality. DOE does not see any justification for this and we find that it runs counter to the intent of the Clean Water Act that "cooling water intake structures reflect the best technology available for minimizing adverse environmental impact." The focus should be on the adverse environmental impact that is being caused (i.e.; mortality) and not on a more easily determined, but less relevant, parameters such as entrainment. We recognize that the studies needed to demonstrate entrainment mortality at a facility could be complicated and expensive. We believe that each permitted facility should be given the opportunity to evaluate entrainment mortality or, if the effort and cost are considered excessive, to assume that there is 100 percent mortality. As proposed, companies would not have that opportunity.

We further note that the site-specific Sample Rule on page 17160 (preferred by DOE) would allow consideration of entrainment mortality [125.94 (c)(2)].

Proposed standards for tidal rivers and estuaries

Estuaries and Tidal Rivers Are More Sensitive - Page 17140. The proposed rule states that "estuaries and tidal rivers have a higher potential for adverse impact because they contain essential habitat and nursery areas for the vast majority of commercial and recreational important species of shell and fin fish, including many species that are subject to intensive fishing pressure. Therefore, these areas require a higher level of control that includes both impingement and entrainment controls." We agree that, taken as a whole, estuaries and tidal rivers are very productive water bodies and contain much useful habitat. We strongly disagree with EPA's presumption that a facility located on any portion of any estuary or tidal river will have high potential for causing adverse impact. In our view, the science does not bear this out. Just as people are not uniformly distributed across all square miles of our country, fish and other aquatic species are not uniformly distributed across estuaries and tidal rivers. Fisheries managers can provide indications on the locations of fish populations and the highest concentration of eggs and larvae at different times of the year. It is not unreasonable to believe that power companies can find locations in estuaries and tidal rivers at which intakes will affect far fewer organisms than at others. We oppose any regulatory scheme that assumes that all facilities located on certain bodies of water will be harmful and must summarily be forced to apply very costly remedies. We request that EPA either provide scientific justification for these important assumptions or revise the proposal to remove them.

RFC: 5% threshold and supporting documents

5 Percent Flow Threshold - Page 17151. EPA states that if a facility withdraws 5 percent of annual stream flow, the facility will entrain 5 percent of the entrainable organisms within the zone of hydraulic influence of the intake. EPA does not believe that an intake should impact more than 5 percent of the organisms within the zone of hydraulic influence of the intake and therefore imposes entrainment controls on those facilities that withdraw more than 5 percent of the mean annual flow.

DOE believes that the science does not support this interpretation. The population of concern to the ecosystem is not necessarily those organisms that fall within the zone of hydraulic influence. For many species, the population of concern occupies an entire watershed or a stream segment. A facility's intake may have been intentionally located at a position and depth that would entrain fewer than the average density of organisms. Yet under EPA's arbitrary 5 percent threshold, this is not taken into account.

EPA provides no justification for why it sets the threshold at 5 percent rather than at a higher percent flow. The only accurate means to assess AEI is to use a site-specific approach to evaluate the effect of a CWIS on populations of concern in the water body from which cooling water is taken.

Role of States and Tribes (alt./equiv. programs)

State Program Equivalence - Page 17151. The proposed rule seeks comments on whether EPA should allow States to apply to EPA for approval of their existing section 316(b) programs, either as currently in effect or with minor revisions, as providing comparable reductions of impingement and entrainment to the new rules--on a watershed basis.

The Clean Water Act establishes a strong Congressional intent for States to carry the primary responsibility for managing the Nation's water resources and states:

It is the policy of the Congress to recognize, preserve, and protect the primary responsibilities and rights of States to prevent, reduce, and eliminate pollution, to plan the development and use (including restoration, preservation, and enhancement) of land and water resources, and to consult with the Administrator in the exercise of his authority under this chapter. It is the policy of Congress that the States manage the construction grant program under this chapter and implement the permit programs under sections 1342 and 1344 of this title. It is further the policy of the Congress to support and aid research relating to the prevention, reduction, and elimination of pollution and to provide Federal technical services and financial aid to State and interstate agencies and municipalities in connection with the prevention, reduction, and elimination of pollution.

DOE believes that such language creates an imperative for EPA to extend the maximum possible flexibility to States, as they implement Federal requirements under the Act.

DOE strongly recommends that EPA allow States to continue implementing their successful State programs, but does not understand why this must be done on a watershed basis. We believe that comparability may be demonstrated on a Statewide basis. We encourage EPA to show flexibility in determining comparability.

As a model for how this might work, we point out the paradigm for Underground Injection Control (UIC) Class II well programs. Section 1422 of the Safe Drinking Water Act allows EPA to delegate the UIC program to States in cases where States have developed regulations as strict as EPA's national regulations. Congress went out of its way to add a separate Section 1425 that applies to underground injection programs dealing with oil and gas fluids. Section 1425 allows States to receive program delegation by submitting programs that meet the general criteria of Section 1422 without having to incorporate all the elements of Section 1422. Most oil and gas producing States that have UIC delegation have obtained it through Section 1425. This approach allows the States greater flexibility and saves costs to the operators.

Burden on permitting agencies (general)

Costs to States May Be High - Page 17153 and 17167. EPA notes that a detailed site-specific evaluation process, such as required under a site-specific approach or under the cost-to-cost or cost-to-benefit variances in the proposed rule, may lead to time delays and extensive costs to State permitting authorities. DOE recognizes that a careful evaluation of data and studies will take time and resources, but it is not unreasonable to expect a permitting agency to devote significant analytical resources when the outcome of its decision may result in expenditures of millions to tens of millions of dollars for an existing facility employing technologies, operational changes, and restoration measures. Therefore in light of this and DOE's earlier comments on the need for the site-specific variances in the proposed rule, we feel strongly that the negative statements at the end of page 17152 (last 4 paragraphs) should be omitted from the final rule.

Process for determining site-specific BTA

Determination of AEI - Page 17164. EPA seeks comments on several possible approaches for determining AEI. We believe that the presence or absence of AEI and its magnitude can only be assessed through a site-specific evaluation. We do not disagree with the approaches summarized in (4) (d) and (e) on page 17164 (use of conservative decision criteria and structured AEI decision process, respectively). However, DOE prefers a slightly different approach that is described in a recent (attached) journal article [Veil, J.A., M.G. Puder. D.J. Littleton, and N. Johnson, A Holistic Look at Minimizing Adverse Environmental Impact under Section 316(b) of the Clean Water Act, The Scientific World Journal, 2002(2)]. The approach would consider all types of environmental impacts associated with the intake and any proposed controls. After balancing the impingement, entrainment, energy penalty, air emission, water consumption, and other impacts, the regulatory agency would determine which approach minimizes AEI.

EPA Response

No response is required for this comment as DOE is a Federal partner in the rulemaking.

RFC: Definition of "adverse environmental impact"

DOE does not support any approach that assumes that any degree of impingement or entrainment constitutes AEI. In past permitting decisions, EPA has applied the AEI standard in a way that would indicate damage to individuals is not the proper test, and in at least one case, a reviewing court has suggested that focus should be on whether a CWIS affects the ability of a species to propagate and survive. (See William A. Andersen & Eric P. Gotting, Taken In Over Intake Structures? Section 316(b) of the Clean Water Act, 26 Colum. J. Envtl. L. 1, 43-44 (2001).) An "any impingement or entrainment" or "one dead fish" approach would create needless tension with section 316(a), which provides for variance from thermal discharge effluent limitations if the owner or operator of a facility can demonstrate that such effluent limitation is more stringent than necessary to assure the protection and propagation of "a balanced, indigenous population of shellfish, fish, and wildlife" in or on the affected body of water (42 U.S.C. 1326(a)). The AEI standard in section 316(b) is broader than that in section 316(a), in that it allows for consideration of non-aquatic impacts. But with respect to aquatic impacts, interpreting AEI to refer to population-level impacts would be consistent with Congress' concern for populations in section 316(a).

EPA Response

RFC: Should EPA include impingement trading?

Trading - Pages 17170-17173. DOE is pleased to see that EPA has put so much effort into the trading concept. We believe that there is merit to raising trading issues to a national audience. Although we endorse the concept of trading as part of a 316(b) determination, we caution EPA to limit the number of rigid national conditions placed on trading. Trading of impingement or entrainment allowances has never been tried before. Companies are often reluctant to place their means of compliance in the hands of another entity because they lose control of their destiny. Trading must offer truly significant cost savings for companies to try it. We are concerned that national-level restrictions on a section 316(b) trading program could scare companies away from trying it.

Voluntary adoption of trading by States and Tribes

We support flexibility and recommend that decisions on how to set up and administer trading programs be left to State- or watershed-level decision makers. In particular, we do not think the national 316(b) rules should specify geographic limits on trading. This should be left to State or local discretion. We also do not believe that trading programs should be mandatory. The decision on whether to undertake trading programs should be left to States. We believe that if trading programs are authorized, they should include both entrainment and impingement trading as well as water quality improvements trading for I&E .

RFC: Include Phase I facilities in trading program

The proposed rule discusses the concept of extending the trading program to new facilities (page 17172). The proposed rule suggests that new facilities could implement controls beyond what is required in the Phase I, new facility rule. We believe that is not practical. Our understanding of Track I controls in the new facility rule is that facilities must implement closed-cycle cooling or equivalent flow reductions, reduce intake velocity, meet proportional flow requirements, and on top of these, undertake appropriate intake technologies. We do not see how there would be any room left for additional control measures that could provide a means for trading.

Non-aquatic impacts

Thermal Discharge Implications - Page 17193. EPA states that thermal impact reductions associated with conversions of once-through cooling systems to closed-cycle cooling systems will yield benefits. This is an argument that ignores the positive impacts of heated discharges in some ecosystems. For example, we cite the example described in a February 19, 2001 letter from the Marine Mammal Commission to EPA that deals with the dependence of manatees on heated discharges from several Florida power plants to survive winter cold spells. The letter states: "If one or two of those outfalls were eliminated, many manatees that have learned to rely on those power plant outfalls to survive cold winter periods would likely die of cold stress before they could find an alternative warm-water source. If all of those outfalls [at 10 power plants] were eliminated, it is possible that the Florida manatee population would undergo an initial precipitous decline in numbers followed by a substantial long-term decline."

Industry Sectors Descriptions - Section A3, Page1.1. The 1st paragraph of the section, Industry Sectors, is confusing, with corrections needed. Fuel cells and geothermal power generation are left out entirely. DOE suggests EPA consider the following rewrite:

"The generation sector includes power plants that produce or "generate" the electricity.2 Electric power is usually produced by a mechanically driven rotary generator. Generator drives, also called prime movers, may be internal combustion machines such as gas turbines or diesels or turbines that extract mechanical energy from a stream of moving fluid such as wind, water from a hydroelectric dam, or steam from a boiler. Most power boilers are heated by direct combustion of fossil or biomass-derived fuels, or waste heat from the exhaust of a gas turbine or diesel engine, but heat from nuclear, solar and geothermal sources is also used. Electric power may also be produced without a generator by using electrochemical, thermoelectric, or photovoltaic technologies."

System Descriptions - Section A3, Page1.2. The system descriptions in the section, Prime Movers, also need corrections. DOE suggests that EPA consider the following rewrite:

“Steam Turbine: Steam turbine or “steam electric” units are driven by steam produced in a boiler. A boiler is a heat exchanger in which water is heated to generate steam, using hot gases from combustion of some type of fossil or biomass-derived fuel, hot coolant from a nuclear reactor, waste heat from another power system or an industrial process, solar energy or geothermal heat. Individual steam electric units range in size from 30 to 1500 megawatts and are generally baseload units that are run continuously to serve the minimum load required by the system. Steam electric units provide the majority of the electric power generated in the U. S.

Simple-Cycle Gas Turbine: A gas turbine, also called a combustion turbine, is an internal combustion machine wherein a compressor supplies air to a combustion chamber where fuel is burned to produce hot, high-pressure gases, which are expanded through a turbine to produce mechanical energy. The turbine produces enough power to drive both the compressor and a mechanical load, in this case an electric generator. Simple-cycle gas turbine power plants, which consist of a single gas turbine and generator, range in size from 5 to 330 megawatts, have efficiencies ranging from 28 to 42 percent on a Lower Heating Value (LHV) basis, and are generally used for peak load operation serving the highest daily, weekly, or seasonal loads. The LHV is the standard practice for reporting efficiencies of gas turbines. (Using the LHV the efficiency is defined as the amount of energy produced divided by the amount of energy consumed, based on the energy’s lower heating value.) Gas turbines usually operate on distillate oil or natural gas fuel, but can also burn crude oil, residual oil, and synthetic fuels produced from coal or biomass.

Gas Turbine Combined-Cycle: Combined-cycle units utilize both steam and gas turbines to generate power while achieving high plant efficiency. Hot exhaust gases from the gas turbine are directed to a heat recovery boiler, also called a heat recovery steam generator (HRSG). The steam produced in the HRSG generates additional power when it is expanded through a steam turbine. A combined cycle system achieves higher efficiency than is possible with a gas turbine alone by producing additional power from heat that would otherwise be released to the atmosphere. The HRSG may be fired or unfired. In an unfired system, the boiler produces steam solely through the recovery of gas turbine exhaust heat. In a fired system, additional fuel is burned upstream of the HRSG to increase the temperature of the exhaust gas and thus augment its steam generating capacity. Combined-cycle plants are usually configured in a “single shaft” arrangement with a single gas turbine, a single HRSG, and a single steam turbine, with the steam turbine and gas turbine driving opposite ends of a single generator. Larger plants can be configured with multiple gas turbines; each equipped with its own HRSG, where all the HRSGs feed into a single large steam turbine. Combined plants range in size from 7 to 400 megawatts for systems with a single gas turbine and from 28 to 800 megawatts for systems having 2 or 3 gas turbines. Combined-cycle plants range in efficiency from 38 to 60 percent (LHV basis), and are mainly used for intermediate loads.

Reciprocating Engines: This type of internal combustion machine utilizes multiple cylinders and is usually fired on natural gas or distillate oil, but can also burn crude oil, residual oil, and synthetic fuels produced from coal or biomass. Reciprocating engines may be naturally aspirated or turbocharged, and utilize spark or compression ignition. These units are generally less than 20 megawatts in size, and are capable of rapid installation and startup. Like simple-cycle gas turbines, reciprocating engines are generally used only for peak loads.

Hydraulic Turbine: These units extract power from a stream of moving water, usually generated by a hydroelectric dam. Individual units vary in size from a few kilowatts to several hundred megawatts. Hydroelectric systems are used for all types of loads.

Alternative Systems: These systems utilize unconventional prime movers, such as windmills or biomass-fired steam or internal combustion systems, or no prime mover at all as in direct conversion systems utilizing electrochemical, thermoelectric, or photovoltaic technologies. Alternative systems currently represent only a tiny percentage of U.S. generating capacity, but their role may expand in the future because recent legislation includes incentives to encourage their use."

Costs

Industry Sectors Descriptions - Section B1, Page B1-5. Condenser costs are estimated as the "depreciated" costs of replacing a condenser with the useful remaining life given as a measure of premature replacement. This approach reduces the capital cost of the retrofit. Although this approach has some merit, it is not consistently applied to other cost areas. The concept of replacement cost for a depreciated asset is reasonable but must be used consistently. For instance, the cooling water pump is a depreciated asset. As stated on page B1-5, under Intake Pumping Costs, "The Agency estimated, based on a set of example cases, that existing intake structures could be reused for the circulating cooling systems and that a portion of the existing pumping system would be reused." If any credit is taken for the pump, then this credit must properly account for its depreciated value.

Private Sector Compliance Costs - Section B1, Page B1-16. EPA estimates private sector post-tax compliance costs as the pre-tax compliance cost less the tax savings that would result from these compliance costs. EPA calculates tax savings as the annualized compliance cost multiplied by the total tax rate. Using this methodology, the post-tax compliance cost is less than two-thirds of the pre-tax compliance cost. It is unclear, however; if EPA has taken into account the corporate tax structure in developing "post-tax" compliance liability for each facility. DOE would argue that compliance costs proportionally reduced by the tax rate is a simplification that may understate the "post-tax" compliance costs. For example, EPA uses the wholesale price of electricity to estimate energy costs associated with compliance for long-term "energy penalty" costs. This cost estimation procedure is a good example of how the "post-tax" compliance cost would be underestimated. In essence, the wholesale price of electricity should already have built-in post-tax costs and this "compliance cost" is further reduced in EPA's post-tax compliance methodology. It should be noted that EPA believes that the post-tax compliance costs are probably overestimated (see footnote 6 on page B1-16). DOE prefers that the pre-tax compliance cost and post-tax compliance cost be provided together so that the magnitude of the assumptions made by EPA is more transparent. DOE disagrees with EPA’s assumptions in estimating post-tax compliance costs.

Comprehensive demonstration study (7 parts)

Administrative Costs - Section B1, Page B1-9. EPA estimates administrative costs for post-promulgation NPDES permit application. A list of activities and associated costs are identified. Some of these activities are considered one-time efforts while other activities recur for each NPDES permit renewal. The Agency's cost estimate seems to imply that impingement and entrainment (I&E) characterization studies are a one-time cost. As such, DOE interprets this as meaning that no additional I&E characterization studies would be required under the rule making after an initial I&E study is carried out by a power plant operator. EPA should clarify its estimate for administrative costs. This cost is a significant burden to the industry even as a one time cost and we are concerned that the subsequent repermit cost estimates for I&E studies is far too low (Table B1-3 at p.B1-12).

Costs

Compliance Cost Estimate - Section B1, Page B1-17. EPA identifies uncertainties and limitations to their compliance cost estimate. However, EPA does not identify uncertainty in their cost estimating procedure. For instance, what is the level of uncertainty in the capital cost estimate? This is the largest cost element provided in Table B1-7, yet there is no mention of the level of accuracy for such an estimate. The reader is unclear whether this is based on conceptual, preliminary, or detailed engineering studies for all potentially affected facilities. The level of accuracy expected from EPA's cost estimation methodology should be discussed. Moreover, EPA's cost analysis for wet cooling tower retrofits neglects to make any allowance for site-specific requirements which may be mandated by State and local ordinances for plume cooling tower installation.

Through a web search on plume abated cooling towers, DOE was able to identify the following URL's describing either new facilities that will employ wet cooling tower technology, or existing facilities that are retrofitting with wet cooling towers. DOE offers the following websites for EPA's consideration:

AES Granite Ridge, Londonderry, NH: http://www.aesc.com/londonderry/aesl_qna.html

NIST nuclear plant: http://www.ncnr.nist.gov/AnnualReport/FY2000/operations.pdf and http://www.frm2.tu-muenchen.de/igorr/igorr-nl13/ig-nl13-11.html

FPL Sacramento Power LLC: http://www.energy.ca.gov/sitingcases/riolinda/documents/applicants_files/2001-08-22_PROP_REVISION.PDF

Blythe Energy LLC: http://www.energy.ca.gov/sitingcases/blythe/documents/2001-03-06_APPLICANTCOMMENT.PDF

New York Power Authority, Astoria Plant, Queens, NY, new 500 MW CC: http://www.nypa.gov/ccf/NYPA%20Article%20X/text/Section%202.0%20Public%20Involvement%20(final).pdf

Badger Generating Co. LLC, Kenosha County, WI , new 1050 MW CC:
http://www.psc.state.wi.us/cases/badger/exec_sum.htm

Customer list – Plume Abatement Cooling Towers – Emcotek:
http://www.emcotek.com/references.htm

Duke Energy Morrow Bay Power Plant, conversion of 1058 MW gas-fired steam plant from once-through saline water cooling to cooling towers (saline water): http://www.morro-bay.ca.us/rwqcbsup.pdf

FPL Energy Elverta Power Project, Rio Linda, CA: http://obri.net/stop/fplcpac.html

Athens Generating Company, Athens, Greene County, NY, 1080 MW CC:
http://www.stoptheplant.org/parks_and_recreation_brief.htm

From this list, it appears as though plume abatement features are commonly employed in new and retrofit wet cooling towers thereby further supporting DOE's position.

As can be seen by visiting the URL's identified on the list, plume abatement is not required by EPA rules, but by local permitting regulations. These regulations generally require that "visual impacts" of any proposed new installation be minimized. This usually means eliminating any visible vapor plume from a cooling tower. If there is an airport anywhere in the vicinity, the FAA will also have to evaluate any potential visibility or icing impacts from a cooling tower vapor plume.

After reviewing this information, it seems obvious that by neglecting plume abatement entirely in their cost analysis, EPA is considerably underestimating the cost of compliance with the proposed Phase II regulations for options 1 and 4, given that plume abatement approximately doubles the cost of the cooling tower (by EPA's own cost estimate).

Additional costs should also be included for materials that would appropriately handle brackish or saline water. As EPA has indicated in a fax sent to NETL (D. Nagle to E. Parsons, January 18, 2002), these additional costs should be valued at 25 percent of tower costs. DOE agrees that this is a reasonable factor for corrosion resistant materials and drift elimination technology.

Facility & firm-level costs/Econ. Practicability

Plant Closure and Other Economic Impacts - Section B2, Page B2-1. EPA concludes that compliance with this proposed rule (page B2-1) is economically feasible. However, EPA notes that this did not factor in plant closures or other types of economic impacts on facilities subject to the proposed Phase II rule (footnote 1 on page B2-1). EPA further states on page B2-3 that they estimate eleven facilities would be baseline closures (closures that would occur with or without the Phase II rule). Next, on page B8-13, additional closures above the baseline closures are estimated for the water body/capacity-based option (option 1) and the all cooling tower option (option 4). If such estimation can be made for the baseline and for these two options, why was an estimation of closures resulting from the Phase II rule not included? While EPA provides clarification on other aspects of their cost impact analysis, they are relatively silent on this issue.

Further information about possible closures under the proposed rule is available from a simple analysis of Appendix A to the technical document which suggests that most compliance costs are borne by relatively few facilities. Perhaps relatively few facilities need be “in-scope”(EPA’s definition).

	Total Sample	Positive Costs
Number of facilities	539	344
Total est. retrofit capital cost	$963,438,222	$963,438,222
Average	$1,787,455	$2,800,693
Median	$490,252	$1,427,204
Standard deviation	$3,585,858	$4,162,029
Costs over $10MM (number)	16	16
Costs over $10MM	$278,194,992	$278,194,992
% of total cost	28.9%	
% of facilities	3.0%	4.7%
Costs over $5MM (number)	51	51
Costs over $5MM	$517,286,308	$517,286,308
% of total cost	53.7%	
% of facilities	9.5%	14.8%

The table above shows that approximately 3 percent of in-scope facilities bear over a quarter of the costs of compliance; 10 percent bear over half of the costs. That the average compliance cost exceeds the median cost by a factor of 2 to 3 reflects the following skewed distribution:

Compliance Cost Range (million $)	$0 < $1	$1-$2	$2-$3	$3-$5	$5-$10	>$10
Number of Facilities	195	134 71	44	44	35	16

Focusing on the facilities which might bear over $10 million in (retrofit) capital costs constructs the following table of 16 facilities.

Plant Code	Water Body Type	Steam Plant Fuel Type	Compliance CWIS Technology Modification	Total Capital
170	Fresh Stream/Riv	Coal	Fine Mesh Trav w/ Fish Handling	$45,223,779
44	Estuary/Tidal Riv	Oil	Fine Mesh Trav w/ Fish Handling	$21,731,505
32	Ocean	Nuclear	Fine Mesh Trav w/ Fish Handling	$19,139,311
241	Estuary/Tidal Riv	Oil	Fine Mesh Traveling Screen	$18,748,809
28	Estuary/Tidal Riv	Nuclear	Fine Mesh Traveling Screen	$18,247,203
70	Ocean	Nuclear	Fine Mesh Traveling Screen	$18,025,893
510	Estuary/Tidal Riv	Nuclear	Fine Mesh Traveling Screen	$16,875,397
280	Estuary/Tidal Riv	Nuclear	Fine Mesh Traveling Screen	$16,834,637
268	Estuary/Tidal Riv	Coal	Fine Mesh Trav w/ Fish Handling	$15,282,924
395	Estuary/Tidal Riv	Other	Fine Mesh Traveling Screen	$14,707,137
415	Ocean	Oil	Fine Mesh Trav w/ Fish Handling	$14,339,794
413	Fresh Stream/Riv	Coal	Fine Mesh Trav w/ Fish Handling	$13,190,121
358	Estuary/Tidal Riv	Coal	Fine Mesh Trav w/ Fish Handling	$12,330,972
191	Fresh Stream/Riv	Coal	Fine Mesh Trav w/ Fish Handling	$12,311,066
442	Estuary/Tidal Riv	Nuclear	Fine Mesh Traveling Screen	$10,835,998
149	Great Lake	Coal	Fine Mesh Trav w/ Fish Handling	$10,370,446

Note that one coal-fired plant will incur a $45 million capital cost, nearly 5 percent of the national total. It would appear that further analysis may show that this plant would shut-down if it had to put these technologies in place and pay this cost. Since the cost seem to be on a very small number of plants a site-specific solution would better focus on those creating the AEI and the best technologies for minimizing AEI.

With regard to economic impact, one can not determine from available documentation which are the 11 facilities the EPA believes will shut down, irrespective of the proposed rule. One therefore is ignorant of whether any of those 11 form part of the 16 above. Of these 16 facilities, 6 are coal-fired, and 6 are nuclear. Most of these facilities supply baseload power to their regions. If the utilities are regulated, some of the compliance costs presumably could flow through to ratepayers; otherwise, some plants may shut down. For the coal-fired plants, large capital costs incurred to comply with 316(b), combined with regulatory uncertainty and the potential for additional costs to comply with air emissions regulations, may result in forced shut downs. DOE believes that an IPM analysis of these issues with the proposed rule must be performed.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

Market Model Analysis - Section B3, Page B3-12. EPA's use of the Integrated Planning Model (IPM) to estimate national compliance impacts for only four of the ten NERC power pool regions is of some concern to DOE. EPA was not able to perform a market model analysis that completely matches the proposed rule's specifications (Option 3). EPA cites that market model analysis for the proposed rule was not performed because of limited time available after final definition of the proposed rule. DOE believes that such an analysis is essential to understand the economic and energy impacts associated with the proposed rule. EPA obtained a complete IPM analysis for two options: (1) the water body/capacity-based option (Option 1) and (2) the all cooling tower option (Option 4). Both options are more stringent than the proposed rule's specification. EPA determined that the water body/capacity-based option, as analyzed in the IPM, matches the technology specifications of the proposed rule for four of the ten regions. EPA compared the four regions as analyzed by the IPM with the other six regions in terms of characteristics relative to the rule's impact. EPA concluded that the results for the four regions would be representative of the other six regions. However, the IPM analysis was not a fully "integrated" analysis for the proposed rule since electricity exchanged between the regions did not properly reflect specifications for the proposed rule. This could limit the findings because the four analyzed regions may have benefitted from the higher compliance costs of the other six regions analyzed with the IPM in the more stringent option 1. DOE feels that the model input assumptions do not reflect the final proposed rule and that the results are subject to interpretation of what "might" occur if the IPM model had used inputs that reflect the final proposed rule. DOE believes that an IPM run should be made that exactly matches the proposed rules specifications. The credibility of the economic and possible energy impacts of the proposed rule is suspect in the absence of a complete market model analysis.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

IPM Model Assumptions - Appendix to Chapter B8, Page B8-26. EPA ran two different electricity demand assumptions. One uses EPA's electricity demand assumption and the other uses the Annual Energy Outlook (AEO) electricity demand assumption. Under the EPA assumption, electricity demand is based on AEO 2001 forecasts with an adjustment to account for demand reductions resulting from implementation of the 1993 Climate Change Action Plan (CCAP).

It is unclear if targets for GHG have been modified in the IPM electricity demand model from the original intent of CCAP. However, the EPA assumption clearly reduces fossil fuel power generation capacity over the model time frame compared to the AEO projections and consequently influences the results of the market analysis. For example, in Table B8-A-13 on page B8-33, the compliance forced increase in capacity of non-dispatched units projected by IPM with the AEO assumptions is nearly four times higher than that obtained with the EPA assumptions for electricity demand. This result suggests that compliance facilities become less competitive and are dispatched less frequently when using a more realistic electricity demand scenario such as provided in the AEO assumptions.

EPA has performed additional market analysis with IPM using the unadjusted AEO projections as suggested by DOE. This same type of IPM analysis was not performed for the proposed rule. DOE believes that the market analysis is warranted to completely understand the economic impact of the proposed rule and should be conducted through a vehicle such as a Notice of Data Availability (NODA).

Compliance Costs - Section B7, Page B7-2. EPA considered a number of alternative regulatory options. A summary of estimated alternative compliance costs is listed in the following table.

Alternative Regulatory Options	Post-Tax Annual Compliance Cost, Million $
Option 1 - Retrofit wet cooling tower (estuaries, tidal rivers, and oceans)	595
Option 2 - Same as 1 except at a select number of facilities (33 vs. 54)	379
Option 3a - I&E control technology everywhere	195
Option 4 - All Phase II plants reduce intake velocity	2,316
Option 5 - Same as 1 except retrofit dry cooling tower	1,252
Option 3 - Proposed Rule	182

The difference in the proposed rule's compliance cost of $182 million/year and alternative compliance cost estimates for option 3a of $195 million/year may be based on the allowance for a habitat restoration option. This would appear to suggest that the habitat restoration candidates will have a significant cost reduction potential. However, as the estimated cost reduction potential is not clearly identified, we are only guessing. It is recommended that the cost estimate for habitat restoration and primary compliance options be separately identified for the proposed and alternative compliance option cost estimates.

Modeling of Regulatory Options - Section B8. IPM was used to model two of the six regulatory options: Option 1- wet cooling towers on units located on estuaries, tidal rivers, and oceans and Option 4 – all Phase II units reduce intake velocity (i.e.; install cooling towers). The IPM estimated a "pre-run" capacity that is defined as the current operating and planned/committed generating units. As such, the base case does not provide a useful measure of the magnitude of capacity affected by the alternative options. The marginal impacts of each alternative option should be clearly stated in light of this modeling approach.

Significant Energy Actions - Section B8, Page B8-4. For both alternatives considered by IPM, each option would be considered a significant energy action under Executive Order 13211. However, for other options considered such a statement is not made. A clear statement for each option considered, including the proposed option, should be made that indicates if a significant energy action is anticipated.

Amount of Cooling Water Needed - Page 2.19. The first sentence of the fourth paragraph of Section 2.2.1, Capital Costs of Wet Towers, reads:

"Recirculating the cooling water in a system vastly reduces the amount of cooling water needed."

DOE points out, and EPA acknowledges in later passages, that this is not true in that the condenser cooling flow is the same as in once-through system. What is reduced is the amount of water that must be withdrawn from the cooling-water source. DOE therefore suggests the following rewrite:

"Switching from once through cooling to recirculating the condenser cooling water greatly reduces the amount of water that must be withdrawn from the cooling-water source."

Power Plant Heat Losses - Page 2.21. Footnote 4 reads:

“4 With a 33 percent efficiency, one-third of the heat is converted to electric energy and two-thirds goes to waste heat in the cooling water.”

This is not accurate – for fossil fuel-fired power plants, heat rejected to the cooling water does not account for all power plant losses. DOE suggests footnote 4 be rewritten as follows:

“4 In a steam electric plant with 33 percent efficiency, one-third of the heat input is converted to net electric energy sent to the grid and two-thirds is rejected to the environment. The condenser cooling water typically represents 80 percent or more of this loss, with the remainder going to stack gases, frictional, thermal and auxiliary losses.”

Retrofit Factor - Pages 2.29 - 2.30. The text states that the “retrofit factor” is not considered a “contingency.” DOE believes that EPA is using the retrofit factor exactly the same way that a normal contingency allowance is used for estimation of construction projects. It is strongly recommended that the Agency use cost engineering terminology associated with recognized industry standards, such as the Association for the Advancement of Cost Engineering (AACE).

Moreover, DOE asserts through independent analysis that EPA’s contingency factor of 1.20 is too low and that a more appropriate contingency factor for a project such as a cooling tower retrofit would be 1.45, based on recognized industry standards compiled by AACE. DOE suggests that EPA refer to http://www.netl.doe.gov/publications/others/techrpts/parsons.pdf for a thorough discussion of these industry standards and their application to cost analysis.

For this case, where cost analysis is being done at a conceptual design phase of the project, the largest uncertainty is simply the incomplete state of the engineering design, which is 5 percent or less complete. To cover this uncertainty, AACE recommends a contingency allowance of 40 percent. The other major uncertainty is simply the technical risk inherent in the process technology being used. For this case, where standard commercial process technology is being applied in a retrofit situation, AACE recommends a minimum additional allowance of 5 percent, bringing the total allowance to 45 percent or a cost factor of 1.45.

Site Specific Nature of Cooling System Conversions - Chapter 4. DOE recognizes the value of the information presented in the chapter titled, “Cooling Systems Conversions at Existing Facilities.” Above all else, this chapter demonstrates the importance of all the site-specific analyses that must be conducted before consideration of a wet cooling tower retrofit. DOE will make the draft report, “An Investigation of Site-Specific Factors for Retrofitting Recirculating Cooling Towers at Existing Power Plants” available for review and consideration in the Fall 2002. The report, drafted by the Parsons Infrastructure and Technology Group, Inc., under DOE Contract Number DE-AM26-99FT40465, Task 50802, examines some of the issues (effect on turbine performance, increased plant parasitic power losses, land space consideration, tower size and type, permitting restrictions, tower plume and noise abatement, tower drift loss control) involved with a wet-cooling tower retrofit at four representative facilities. EPA may find the document useful for crafting a final 316(b) Phase II final rule.

Non-Viable Options - Chapter 5. DOE is pleased that the Agency has provided, with DOE input, an explanation into the differences between DOE's estimation of wet-cooling tower retrofit energy penalties and EPA's. (See Chapter 5: Energy Penalties of Cooling towers, 5.6.2). Both EPA's (1.1 percent) and DOE's (1.15percent, average excluding Yuma) estimate (for plants operating at 100 percent capacity) for the annual average energy penalties are similar (1.1 .vs. 1.15), but EPA estimates of peak summer energy penalties are considerably lower. EPA estimate ranges from 1.4 to 2.0 percent while the DOE estimate ranges from 2.4 to 4.0 percent. The reasons for this discrepancy (after discussions between EPA and DOE) probably include the following factors:

-EPA does not include all the pumping costs associated with a wet tower retrofit. The additional pumping costs could add approximately 0.2 to 0.7 percent to EPA's energy penalty estimates.

-EPA uses a range assumption at or near 20 degrees, which is higher than that used in most of the DOE model runs which were based on actual temperature data provide by EPA for each of the model locations (see descriptions in Chapter 7). If a 15-degree range were used, the energy penalty would increase by about 0.5 percent.

-EPA's analysis assumes that the condenser duty is the same when converting from once-through cooling to wet cooling towers. DOE estimates that this could result in a maximum additional penalty of 0.5 percent.

Adding these contributions from these three items yield a possible increase in the EPA peak energy penalty of 1.2 to 1.7 percent and a revised EPA peak energy penalty of about 2.9 to 3.5 percent for conversion to wet towers. These revisions to the EPA analysis to adjust to similar basis with the DOE study shows approximate agreement to the DOE results.

DOE also accepts EPA's position that a direct-dry cooling tower retrofit to existing steam condensing power generation facilities is a non-viable option. Neither should, as documented in Energy Penalty Analysis of Possible Cooling Water Intake Structure Requirements on Existing Coal-Fired Power Plants, an indirect-dry cooling tower retrofit be considered as a viable option for the Agency's proposed 316(b) Phase II rule.

EPA Response

No response is required for this comment as DOE is a Federal partner in the rulemaking.

Energy Penalty Analysis of Possible Cooling Water Intake Structure Requirements on Existing Coal-Fired Power Plants

US Department of Energy

Working Draft -- May 23, 2002

1.0 Executive Summary

Section 316(b) of the Clean Water Act requires that cooling water intake structures must reflect the best technology available for minimizing adverse environmental impact. Many existing power plants in the United States utilize once-through cooling systems to condense steam. Once-through systems withdraw large volumes (often hundreds of millions of gallons per day) of water from surface water bodies. As the water is withdrawn, fish and other aquatic organisms can be trapped against the screens or other parts of the intake structure (impingement) or if small enough, can pass through the intake structure and be transported through the cooling system to the condenser (entrainment). Both of these processes can injure or kill the organisms. EPA adopted 316(b) regulations for new facilities (Phase I) on December 18, 2001. Under the final rule, most new facilities could be expected to install recirculating cooling systems, primarily wet cooling towers. The EPA Administrator signed proposed 316(b) regulations for existing facilities (Phase II) on February 28, 2002. The lead option in this proposal would allow most existing facilities to achieve compliance without requiring them to convert once-through cooling systems to recirculating systems. However, one of the alternate options being proposed would require recirculating cooling in selected plants.

EPA is considering various options to determine best technology available. Among the options under consideration are wet-cooling towers and dry-cooling towers. Both types of towers are considered to be part of recirculating cooling systems, in which the cooling water is continuously recycled from the condenser, where it absorbs heat by cooling and condensing steam, to the tower, where it rejects heat to the atmosphere before returning to the condenser. Some water is lost to evaporation (wet tower only) and other water is removed from the recirculating system as a blow down stream to control the building up of suspended and dissolved solids. Makeup water is withdrawn, usually from surface water bodies, to replace the lost water. The volume of makeup water is many times smaller than the volume needed to operate a once-through system.

Although neither the final new facility rule nor the proposed existing facility rule require dry cooling towers as the national best technology available, the environmental community and several States have supported the use of dry-cooling technology as the appropriate technology for addressing adverse environmental impacts. It is possible that the requirements included in the new facility rule and the ongoing push for dry cooling systems by some stakeholders may have a role in shaping the rule for existing facilities. The temperature of the cooling water entering the condenser affects the performance of the turbine -- the cooler the temperature, the better the performance. This is because the cooling water temperature affects the level of vacuum at the discharge of the steam turbine. As cooling water temperatures decrease, a higher vacuum can be produced and additional energy can be extracted. On an annual average, oncethrough cooling water has a lower temperature than recirculated water from a cooling tower. By switching a once-through cooling system to a cooling tower, less energy can be generated by the power plant from the same amount of fuel. This reduction in energy output is known as the energy penalty. If a switch away from once-through cooling is broadly implemented through a final 316(b) rule or other regulatory initiatives, the energy penalty could result in adverse effects on energy supplies.

Therefore, in accordance with the recommendations of the Report of the National Energy Policy Development Group (better known as the May 2001 National Energy Policy), the U.S. Department of Energy (DOE), through its Office of Fossil Energy, National Energy Technology Laboratory (NETL), and Argonne National Laboratory (ANL), has studied the energy penalty resulting from converting plants with once-through cooling to wet towers or indirect-dry towers. Five locations – Delaware River Basin (Philadelphia), Michigan/Great Lakes (Detroit), Ohio River Valley (Indianapolis), South (Atlanta), and Southwest (Yuma) – were modeled using an ASPEN simulator model. The model evaluated the performance and energy penalty for hypothetical 400-MW coal-fired plants that were retrofitted from using once-through cooling systems to wet- and dry-recirculating systems. The modeling was initially done to simulate the hottest time of the year using temperature input values that are exceeded only 1 percent of the time between June through September at each modeled location. These are the same temperature inputs commonly used by cooling tower designers to ensure that towers perform properly under most climatic conditions. The high temperature inputs correspond to the time of year when the highest power demands are observed and the needs for generating capacity are most critical due to the very high cost of buying replacement power on the spot market. Later, modeling was completed to estimate the monthly energy penalties, which were arithmetically averaged to generate an estimate of annual average energy penalty.

The results of the one-percent-high temperature modeling show that conversion to a wet tower could cause energy penalties ranging from 2.4 percent to 4.0 percent. This means that the plant will produce 2.4 percent to 4.0 percent less electricity with a wet tower than it did with a oncethrough system while burning the same amount of coal. That lost electricity could be made up at this plant or at some other existing or new plant by burning additional fuel. These peak-summer penalties are somewhat higher than those estimated by EPA in the technical documentation published with its April 9, 2002 proposal for existing facilities. DOE believes that EPA did not include all the relevant costs and made some inappropriate assumptions; these are described at the end of Chapter 4. When more appropriate costs and assumptions are considered, EPA estimates compare favorably with those in this report.

Conversion to an indirect-dry tower, where possible, could cause energy penalties ranging from about 8.9 percent to 12.14 percent using 20 degrees F for the approach (the difference between the inlet air dry-bulb temperature and the desired cold water temperature), and 12.7 percent to almost 16 percent using an approach of 40 degrees F. The industry norm for indirect dry towers – a 40-degree approach -- was evaluated initially, but the resulting pressures for the steam turbines were found to result in unacceptable operating conditions during the one-percent highest temperature times of the year. The mostly likely way that a company could operate a retrofitted indirect-dry tower at a 40-degree approach would be to reduce the power output from the plant (load shedding) during the hottest times of the year – just when the power demand is the greatest.

This power output reduction imparts an immediate energy penalty. On completion of the analysis it was determined that even if load shedding was attempted on all the 40-degree approach cases it would still be technically infeasible to operate the turbines safely during the summer months. To provide more information on dry tower energy penalties, a more conservative approach of 20 degrees was subsequently modeled.

The results of the annual energy penalty modeling show that conversion to a wet tower could cause energy penalties ranging from 0.8 percent to 1.5 percent. Conversion to an indirect-dry tower could cause energy penalties ranging from about 4.2 percent to 5.2 percent using 20 degrees F for the approach, and 7.9 percent to almost 8.8 percent using an approach of 40 degrees F.

A review of the "Environmental Directory of US Powerplants" (EEI 1996) indicated that in 1996, there were 258,906 MW of electric generating capacity in the United States that consisted of steam electric power plants employing once-through cooling. The one-percent highest temperature analysis modeled plants in just five locations and under very warm temperature conditions, but the modeled facilities are believed to be representative of the climatic conditions found throughout those portions of the country where once-through cooling is prevalent. It is quite possible that much of the Nation could experience very high temperatures at the same time (e.g., week of August 6, 2001), leading to results even more extreme than those calculated here. Tables ES-1 and ES-2 demonstrate the effects on electric generating capacity during the onepercent highest temperature conditions if 10, 25, 50, or 100 percent of the existing once-through cooled power plants in the United States were required to convert to either wet or indirect-dry cooling towers. The example of a requirement for 100 percent of the plants to retrofit to either wet or dry towers is hypothetical since it would be technically infeasible to do either. The energy, time, and expense required to make up for these losses is significant and would not necessarily require building new plants. But for example in the "average" case, 19 additional 400-MW plants might have to be built to replace the generating capacity lost by replacing oncethrough cooling with wet cooling towers in 100 percent of existing steam plants. If some of those affected plants were required to retrofit an indirect-dry tower, the energy penalty impacts would be over three times higher. For example, the "average" case might require 66 new 400-MW plants to be built to replace the generating capacity lost by replacing once-through cooling with indirect dry cooling towers with a 20-degree air-side approach in 100 percent of existing steam plants. This example of new plants needed if 100 percent of existing plants were required to retrofit to dry towers is far too low since after thoroughly completing this analysis it has been determined that it would be impossible for most existing plants to be retrofitted to dry towers at many locations and therefore there would be a need for closures and far more new power plants than provided in the simple example above.

These new power plants may be needed to replace the energy lost as a result of the conversion from once-through to recirculating cooling, and do not reflect the need to build additional new generating capacity to meet the nation's growing demands for electricity. The U.S. Department of Energy's Annual Energy Outlook states that anticipated growth in electricity sales between 2000 and 2020 is about 1.8 percent per year (EIA 2001a). Alternatively, some of the existing plants that might have to retrofit to either wet or indirect-dry cooling systems may be able to just burn more fuel to replace the electricity lost due to the cooling system conversion. Either way, additional fuel will be burned and other adverse environmental impacts will be created such as increased emissions, land use, and noise pollution.

To more closely evaluate the impact of increased air emissions from burning additional fuel, several additional analyses were performed. Estimates of incremental air emissions were made using the average annual energy penalty results at the Delaware River Basin site and the South site. The results show that when once-through cooled plants are converted to wet cooling towers, the incremental air emissions are not large on a percentage basis (generally less than one percent), but the absolute increases in pounds or tons of key air pollutants (SO2, NOx, PM, mercury, and CO2) are large nonetheless. If once-through cooled plants are converted to indirect-dry towers, however, the incremental air emissions can be significant. For dry towers with a 20-degree approach, the percentage increase in air emissions can exceed 4 percent depending on how the power company makes up the lost energy. For dry towers with a 40- degree approach, the percentage increase in air emissions can approach 8 percent and the number of additional pounds or tons is quite large.

Incremental air emissions are of greatest concern in nonattainment areas. Nonattainment areas are identified for "criteria pollutants" established under the 1970 Amendments to the Clean Air Act that do not meet standards set by EPA. The term "criteria pollutants" derives from the requirement that EPA must describe the characteristics and potential health and welfare effects of these pollutants. It is on the basis of these criteria that standards are set or revised. Although a national impact analysis is not performed in the present study, a general conclusion is that incremental air emissions are counterproductive to achieving standards set by EPA for air quality. There are a number of nonattainment locations throughout the United States where incremental air emissions could occur from an energy penalty associated with a requirement to add a cooling tower to existing power plants.

One important finding of this report is that neither indirect-dry nor direct-dry towers are viable as a retrofit technology at most U.S. locations under the one-percent-highest temperature conditions. As previously noted, many of the model runs evaluating conversion to indirect-dry towers resulted in calculated turbine pressures that exceeded the upper limit for safe turbine operation. This was true of all of the model runs made using the 40-degree approach assumption and for one quarter of the runs made at 20 degrees. The point should be made that the practice of load shedding, a method of reducing the steam load through the turbine, thereby reducing the condenser heat duty by a proportional amount, would not effectively lower the turbine backpressure enough for safe operation under the runs modeled with a 40-degree approach assumption. Even for those 20-degree approach cases in which the turbine pressures were below the upper safe limit, an indirect-dry tower would occupy huge amounts of space, which may not be available in an existing plant originally built with once through cooling. The results of sizing calculations to determine the required footprint area for a representative case of retrofitting to indirect dry towers at a 20-degree approach are discussed in section 10.2. Direct-dry towers are not practical either. In an existing plant, there simply is no room for the large-diameter ductwork required to conduct -atmospheric steam from the turbine exhaust hood to a direct-dry cooling tower.

Dry towers have been used as part of newly constructed cooling systems. If the entire power generating system (boiler, turbine, condenser, and cooling) is designed with dry cooling in mind, dry cooling does have applications. For retrofitted dry towers, the issues of large footprint and high energy penalty are important.

3.0 Introduction

3.1 Legal Background for Cooling Water Intake Structure Requirements

Section 316(b) of the Clean Water Act, enacted by Congress in 1972, addresses withdrawal of cooling water from surface water bodies, as follows:

Any standard established pursuant to section 301 or section 306 of this Act and applicable to a point source shall require that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact.

In 1976, the U.S. Environmental Protection Agency (EPA) promulgated final §316(b) regulations (April 26, 1976; 41 FR 17387). However, those regulations were successfully challenged by a group of 58 utilities [Appalachian Power Co. v. Train, 10 ERC 1965 (4 th Cir. 1977)]. In 1979, EPA formally withdrew its §316(b) regulations (June 1979; 44 FR 32956). As a consequence of the vacuum created by the absence of Federal regulations, many States adopted their own cooling water intake regulations to implement the §316(b) requirements. The broad statutory language facilitated widely differing interpretations by the States. Some adopted comprehensive programs, others imposed less rigorous requirements, and still others never developed formal regulations.

In the mid-1990s, a coalition of environmental groups, headed by the Hudson Riverkeeper, filed suit against EPA over failure to repromulgate §316(b) regulations [Cronin, et al. v. Reilly, 93 Civ. 0314 (AGS)]. On October 10, 1995, the U.S. District Court, Southern District of New York, entered a Consent Decree between the parties, directing EPA to regulate cooling water intake structures within 7 years. Under the Consent Decree, EPA agreed to propose regulations by June 1999 and promulgate a final rule by 2001. The Consent Decree was modified on November 21, 2000 to: a) finalize new facility regulations by November 9, 2001; b) propose existing source large utility and non-utility power producer regulations by February 28, 2002 and issue final regulations by August 28, 2003; and c) propose regulations by June 15, 2003 and issue final regulations by December 15, 2004 for other existing facilities not covered in b) above.

3.2 Purpose of This Report

EPA adopted 316(b) regulations for new facilities on December 18, 2001 (66 FR 65256). Under the final rule, most new facilities could be expected to install recirculating cooling systems, primarily wet cooling towers. The EPA Adminstrator signed proposed 316(b) regulations for existing facilities on February 28, 2002. The lead option in this proposal would allow most existing facilities to achieve compliance without needing to convert once-through cooling systems to recirculating systems. However, one of the alternative options proposed requires recirculating cooling in selected plants.

Until this rule is finalized, retrofitting to recirculating cooling remains a regulatory option.

Although neither the final new facility rule nor the proposed existing facility rule require dry cooling towers as the national best technology available, the environmental community and several States have supported the use of dry-cooling technology as the appropriate technology for addressing adverse environmental impacts. It is possible that the requirements included in the new facility rule and the ongoing push for dry cooling systems by some stakeholders may have a role in shaping the rule for existing facilities. Recognizing that over 50 percent of the existing coal-fired power plants employ once-through cooling systems, a decision to require many or all of these plants to install dry- or wet-cooling tower systems could have impacts on electricity costs and availability as well as secondary environmental impacts.

The purpose of this report is to quantify the loss of net electric output from an existing coal-fired power plant that would result from the replacement of its once-through cooling system to either a wet- or a dry-cooling tower. The reduction in net electric output is known as the energy penalty and is discussed below. Modeling was done for five locations to simulate the hottest time of the year using temperature values that are exceeded only 1 percent of the time between June through September at each modeled location. This corresponds to the time of year when the highest power demands are observed. To give an idea of the energy penalty at times other than the hottest period of the year, additional modeling was conducted on a monthly basis. This technique allowed for the calculation of an annual average energy penalty value at each site.

In order to compensate for the electricity lost as a result of the energy penalty, utilities would need to produce more electricity through burning additional fuel, thereby generating additional air emissions. A second purpose of this report is to quantify the additional amount of air emissions that would result at existing coal-fired plants using wet or dry cooling systems. Estimates of incremental air emissions were made at the Delaware River Basin and the South sites.

4.0 Overview of Cooling Systems at Steam Electric Power Plants

4.1 Cooling Water Use

Water is used in many industrial applications to cool machinery or to condense steam. The largest industrial user of cooling water is the steam electric power industry. Data from a recent U.S. Geological Survey (USGS) report indicate that steam electric power generation uses approximately 190 billion gallons of water per day (USGS 1998). In 1999, more than 60 percent of the utility power generating capacity in the United States (382,270 MW) utilized the steam-electric process (EIA 2000). At nuclear and fossil-fuel power plants, electricity is produced by heating purified water to create high-pressure steam. The steam is expanded in turbines, which drive the generators that produce electricity. After leaving the turbines, the steam passes through a condenser that has multiple tubes and a large surface area. A large volume of cool water circulates through the tubes, absorbing heat from the steam. As the steam cools and condenses, the temperature of the cooling water rises.

4.2 Types of Cooling Systems at Steam Electric Power Plants

Most power plants use either once-through cooling or recirculating cooling. Once-through cooling systems withdraw large volumes of water -- typically in the range of tens of millions to billions of

gallons per day from a river, lake, estuary, or ocean. The water is pumped through the condenser and finally returned to the same or a nearby water body. Recirculating cooling systems receive their cooling water from and return it to a cooling tower and basin, cooling pond, or cooling lake. Because evaporation and planned cooling tower blowdown (periodic discharges of portions of the recirculating water to remove build up of solids and other undesirable constituents) removes cooling water from the evaporative system, regular additions of "makeup" cooling water are needed. Makeup volumes are much lower than daily once-through volumes,
and may range from hundreds of thousands to millions of gallons per day. The USGS estimates that about 2 percent of the water withdrawn for steam electric power generation was consumed as a result of once-through cooling, cooling towers, or pond cooling (USGS 1998).

This report considers two types of recirculating cooling systems – wet towers and indirect-dry towers. These are defined in Section 2 and described in Section 5.3.

4.3 How Cooling Water Affects Steam Power Plant Performance

High-pressure steam is generated in a boiler whose heat source is a high temperature atmospheric pressure furnace fired by some type of fossil fuel or a nuclear reactor. The high-pressure steam is expanded through a multistage turbine that turns a generator to produce electricity. Spent exhaust steam exiting the turbine is condensed and recycled to the boiler for steam production. During the condensation process, a large quantity of low-grade heat is absorbed by the condenser coolant, which is typically water.

The steam side of the condenser operates under vacuum conditions (i.e., a pressure below normal atmospheric pressure). The magnitude of the condenser vacuum depends chiefly upon the condenser design and the incoming temperature of the condenser coolant. Lower coolant temperatures will produce a larger vacuum in the condenser that, to a certain extent, has a favorable effect on performance. Likewise, higher condenser coolant temperatures are associated with a smaller vacuum, resulting in reduced energy output. These relationships are based on the laws of thermodynamics and hold true regardless of the type of cooling system used (once-through or recirculating).

4.4 The Energy Penalty

Steam condensers are designed to produce a vacuum at the outlet end of the turbine, thereby increasing the efficiency of the system. The temperature of the cooling water exiting the condenser affects the performance of the turbine -- the cooler the temperature, the better the performance. As cooling water temperatures decrease, a higher level of vacuum can be produced and additional energy can be extracted. On an annual average, once-through cooling water has a lower temperature than recirculated water from a cooling tower. Because most of the heat rejection in a wet cooling tower is due to evaporation, the temperature of the recirculated cooling water is limited by the ambient air wet-bulb temperature. It can never be lower than the wet-bulb temperature and generally is about 5 to 10 F higher. As a result of switching from a once-through cooling system to a cooling tower, less energy can be generated by the power plant from the same amount of fuel.

In a related manner, the performance of a dry cooling system is limited by the ambient air dry-bulb temperature because all of the heat rejection in a dry cooling system is attributable to sensible heating of the surrounding air. Since dry-bulb temperatures are higher than corresponding wet-bulb temperatures, the performance of dry cooling systems will be less than wet systems (either once-through or recirculating). In fact, a recent analysis of cooling system options for combined-cycle power plants found that at nearly all locations and under nearly all climatic conditions in the United States, the performance of a properly designed and operated recirculating cooling system would be superior to a comparable direct-dry cooling system (Burns and Micheletti 2000).2001). Therefore, switching a once-through cooling system to a dry cooling system would mean that the decline in power generation for a given amount of fuel would be even greater than for a once-through to a recirculating wet cooling system retrofit.

Veil et al. (1992) summarized literature values for the energy penalty associated with retrofitting once-through cooled plants with wet-cooling towers. The majority of the data points for the energy penalty for fossil-fueled plants were clustered in a band between 1.5 percent to 2.5 percent. Results for nuclear power plants show greater variability, ranging between 1 percent and 5.8 percent. The data points were not as clearly clustered in a narrow range as were the data points for the fossil plants. Veil et al. (1992) selected a range of 2 percent to 3 percent for the decrease in net electrical power that could be experienced if existing nuclear power plants retrofit from once-through to wet cooling.

In a more recent study, Burns and Micheletti (2000) estimate the maximum energy penalty values for a new generic 750-MW combined-cycle power plant using either a wet recirculating cooling system or a direct dry cooling system at sites in five different parts of the country. In this study, the energy penalty is defined as the loss of electricity generating capacity incurred when a cooling system is unable to perform at design efficiency. Then for both types of cooling systems, the maximum energy penalty occurs during the hottest times of the year when ambient wet-bulb and dry-bulb temperatures are greatest. This period normally is represented by 1 percent of the time during the four warmest months, which also happen to coincide with the times of national peak electricity demand. For recirculated wet cooling, the estimated maximum energy penalty was less than 1 percent for any of the five sites. For direct dry cooling, the estimated maximum penalty ranged from 11.6 percent to 18.1 percent, depending on site climatic conditions. Although the estimates prepared by Burns and Micheletti indicate a dramatic difference in the maximum energy penalties expected from using wet and dry cooling systems, the results are not directly comparable to this study for two reasons. First, the Burns and Micheletti estimates were based exclusively on new cooling systems for new plants and did not consider any of the retrofit complexities associated with an existing once-through cooling system at an existing plant. Second, the Burns and Micheletti estimates were based on a direct-dry cooling system, while an indirect dry cooling system would be a more suitable retrofit option for an existing once-through cooling system (see subsequent discussion in Section 5.3).

For its 316(b) regulation development, EPA researched and derived energy penalty estimates based on empirical data and proven theoretical concepts for a variety of conditions (EPA 2002). To estimate nationally representative energy penalties, EPA sought data to estimate representative regions. These four regions include Northeast (Boston, MA), Southeast (Jacksonville, FL), Midwest (Chicago, IL) and Northwest (Seattle, WA). The Agency calculated the turbine component of the energy penalty by examining the empirical effect on net plant heat rates resulting from changing turbine exhaust pressures for fossil-fueled, combined-cycle, and nuclear plants. The Agency related the turbine exhaust pressure to ambient conditions for the selected locations. Because the source water temperature for once-through cooling systems and the ambient wet bulb and dry bulb temperatures for cooling towers varies with location and time of year the Agency used empirical coastal water temperatures at the four selected locations.

For calculation of monthly average wet and dry bulb temperatures, EPA calculated time-weighted averages during the daytime period between 8 AM and 4 PM. Since the energy penalty will vary over time as ambient climatic and source water temperatures vary, the calculation of the total annual energy penalty for a chosen location integrated the results of individual calculations performed on a periodic, monthly basis. EPA used design temperatures to calculate peak-summer penalties for the selected locations based on the temperature that ambient conditions equaled or exceeded one percent of the time.

EPA derived the turbine exhaust pressure values for alternative cooling system scenarios in conjunction with the empirical temperature values. EPA used these turbine exhaust pressure values to estimate the associated change in turbine efficiency. EPA then calculated either the peak-summer (design) or the monthly energy penalty. Annual values were calculated by averaging the 12 monthly values. The annual average energy penalty values for fossil-fueled plants at the four regional sites ranged from 1.5 to 1.8 percent and the peak-summer energy penalties ranged from 1.4 to 2.0 percent.

It should be noted that EPA's annual average energy penalties were based on assuming that plants operate at just 67 percent of maximum load. The DOE does not agree with this assumption for base load plants and has brought this to EPA's attention. Subsequently, EPA estimated a 1.1% annual energy penalty based on assuming that plants operated at 100 percent of the maximum load.

The annual average penalties presented in Chapter 8 of this report are similar to those calculated by EPA, but the EPA estimates of peak summer energy penalties are considerably lower than those presented in Chapter 7 of this report. The reasons for this discrepancy are:

- EPA does not include all the pumping costs associated with a wet tower retrofit. The additional pumping costs could add approximately 0.2 to 0.7 percent to EPA's energy penalty estimates.
- EPA uses a range assumption at or near 20 degrees, which is higher than that used in most of the DOE model runs. Those runs were based on actual temperature data provided by EPA for each of the model locations (see descriptions in Chapter 7). If a 15-degree range were used, the energy penalty would increase by about 0.5 percent.
- EPA's analysis assumes that the condenser duty is the same when converting from once-through cooling to wet cooling towers. DOE estimates that this could result in a maximum additional penalty of 0.5 percent.

Adding the contributions from these three items yield a possible increase in the EPA peak energy penalty of 1.0 to 1.5 percent and a revised EPA peak energy penalty of 2.7 to 3.2 percent for conversion to wet towers. These revisions to the EPA analysis to adjust to similar basis with this study shows approximate agreement to the DOE results.

5.0 Description of Models and Modeling Efforts

5.1 - Background on ASPEN Model

ASPEN (Advanced Simulator for Process Engineering) PLUS is a simulator software package commercially available from Aspen Technology (the original development was co-sponsored by the DOE) that is used worldwide by companies and universities to examine both commercially available and conceptual processes. Examples of technologies for which ASPEN has been used as part of the development process include integrated gasification combined cycle (IGCC) power plants, pulverized-coal power plants, fuel cells, advanced gas turbine systems and Vision 21 systems (see the NETL web site at http://www.netl.doe.gov). The simulator includes a suite of built in physical property packages and engineering process models and an additional flexibility for adding user-generated models. The ASPEN model provides a steady state representation of the overall process units (or process sections) that includes sufficient detail to accurately predict the energy and mass balances.

5.2 Specific Model for Pulverized Coal Power Plant

An ASPEN PLUS 10.2 model developed for a pulverized coal power plant in an earlier study by NETL (Shah et al. 2001) was used as a starting point for this analysis. For this study, cooling-tower systems (i.e. “Wet” and “Indirect Dry”) were added as options to the original model’s “Once-Through” steam condenser cooling.

The ASPEN model used for this study was based on a detailed design by Buchanan et al. (1998) for a power plant feeding pulverized coal to a conventional steam boiler and steam turbine. The process design uses a single reheat steam power cycle to generate nominally 400 MW of power. The steam boiler can be viewed as containing two major heat-transfer sections, a radiant section and a convective section. The radiant section consists of a natural circulation, wall-fired, subcritical unit arranged with a water-cooled dry-bottom furnace. The convective section consists of a superheater, reheater, and economizer heat exchangers. An additional air heater is external to the steam boiler. The furnace burners were a low-NOx type. The flue gas was desulfurized by treating it with lime slurry.

In the design, air is preheated in the air heater by exchanging heat with the flue gas. Coal and hot air are fed to the boiler from the bottom. High-pressure steam is generated in the radiant section. Flue gas from the radiant section enters the convective section at 2,200 F. In the convective section, thermal energy from the flue gas is transferred to high-pressure steam (in the superheater heat exchanger), intermediate-pressure steam (in the reheat heat exchanger), and feed water (in the economizer heat exchanger). Flue gas leaves the convective section at 600 F and passes through the air heater to preheat combustion air. An ESP is used to remove particulates and the flue gas is then sent to a sulfur dioxide (SO2) scrubber with the aid of an induced draft fan. Lime slurry is employed to scrub SO2 from the flue gas. The treated flue gas leaves through stacks.

High-pressure steam is superheated in the convective section. Superheated steam at 2,415 psi and 1,000 F is expanded in the high-pressure turbine to an intermediate pressure of 604 psi. The intermediate-pressure steam is reheated in the convective section to 1,000 F and is then expanded in the intermediate-pressure steam turbine. Finally, the exhaust from the intermediate-pressure steam turbine is expanded in the low-pressure turbine to approximately 1 psia and is then sent to a condenser. The condensate water is sent to a series of low-pressure feed heaters. The heated water is sent to the deaerator to remove dissolved gases. De-aerated water is passed through high-pressure water heaters and is then fed to the economizer portion of the convective section. Water is further heated to close to its saturation temperature in the economizer and then sent to radiant section for boiling.

5.3 - Model Adaptation for Cooling Systems

The ASPEN model described above provides the heat duty (heat of condensation for the exhaust steam) for the steam-cycle condenser. For the purposes of this study the following options were added to the model described above:

−Once-Through Cooling - this modification considers that cooling water is used in a single open-loop pass in a shell-and-tube heat exchanger. The simulator estimates the cooling water requirements and associated circulating water-pump power.

−Wet Cooling Tower - a detailed model for a wet cooling tower (Enick et al. 1994) was added to the simulator. The cooling tower operates in a closed-loop with the steam condenser. The tower cools the hot cooling water from the steam condenser by both evaporation of some of the entering water and sensible heating of the ambient air entering the tower. Estimates for blowdown and drift losses were assumed. Makeup water is provided for these losses and for evaporative losses. The cooling tower air fans' power requirements were predicted based on induced-draft fan design.

−Indirect Dry Cooling Tower - a cooling tower in which a hot liquid such as condenser coolant rejects heat to the atmosphere without the evaporation of water. Heat from the water is transferred to the surrounding atmosphere in finned-tubes, which are cooled by large diameter fans blowing air over the finned surfaces. The cooling tower air fans' power requirements were predicted based on induced-draft fan design.

The hot cooling water from the steam condenser enters countercurrent to the entering ambient air. Since the dry tower uses only sensible heat transfer to cool the water, the required air-flow rate and fan power is considerably higher than for the wet-cooling tower.

For each of the above options, the steam turbine exhaust pressure to the steam condenser is dependent on the assumptions (such as cooling water range and approach temperatures) for a particular case.

A direct-dry cooling system was not considered for use with the ASPEN model because the focus is to provide a cooling system that can be retrofitted to existing plants. In an existing plant, there simply is no room for the large-diameter ductwork required to conduct sub-atmospheric steam from the turbine exhaust hood to a direct-dry cooling tower. Additionally, existing plants have steam turbine designs that result in only allowable maximum backpressures of approximately 5.5 inches of mercury.

This limit would probably be exceeded with the choice of a direct-dry cooling system when ambient temperatures are above 90 F.

5.4 Air Emissions Calculations

The process for estimating increased air emissions as a result of an energy penalty associated with conversion of a once-through cooling system to a cooling tower is focused on existing coal power plants. Calculation of air emission increases will depend on the extent and type (e.g., wet or dry cooling tower) of cooling system conversions. For illustrative purposes, this analysis assumes that all once-through cooling systems at existing coal power plants are converted to a recirculating cooling tower. The procedure to conduct this analysis is described in the following discussion.

The ASPEN Model was used to determine the peak and annual energy penalty estimates associated with replacing once-through cooling with cooling towers. The incremental air emissions resulting from combustion of additional fuel to make up for these energy penalties are estimated using the following process. First, the regional power system that is associated with the location of the model plant is defined (see Figure 1). The Delaware River Basin model plant is located in the Mid-Atlantic Area Council (MAAC) regional power pool. The MAAC Region, geographically the same as the PJM Interconnection (a company responsible for the operation and control of the bulk electric power system) control area, encompasses nearly 50,000 square miles. MAAC encompasses approximately 58,000 MW of installed generating capacity of which 20,000 MW is coal-fired capacity.

The South (Atlanta) model plant is located in the Southeastern Electric Reliability Council (SERC) regional power pool. The SERC Region covers an area of about 464,000 square miles and includes parts or all of 13 southeastern and south central States. The Region is divided geographically into four diverse Sub regions - Entergy (the geographical area of the Entergy Operating Companies and Associated Electric Cooperative, Inc.), Southern (the geographical area of the Southern electric system), TVA (the Tennessee Valley Authority area), and VACAR (the Virginia-Carolinas area).

The MAAC and SERC Regions have 332 coal-fired boiler generator sets connected to various cooling systems. The MAAC Region has 73 coal-fired boiler generator sets with about 46 percent of its capacity using cooling towers. The dominant type of cooling tower is natural draft (36 percent), followed by forced mechanical draft (8 percent). The natural draft towers will cost more but emit less pollutants. The least common type of cooling tower installed in the MAAC Region is the induced draft (2 percent) design. Similarly, the SERC Region has about 36 percent of its coal-fired capacity cooling system operating with cooling towers. The SERC Region has 259 coal-fired boiler generator sets and its coal-fired capacity is approximately four times larger than the MAAC Region capacity. The cooling tower type is dominated by the natural draft design (20 percent) followed by forced mechanical draft (10 percent) and then induced draft (5 percent).

Next, the total of all atmospheric emissions of concern associated with coal-fired power plants in this region are estimated for a baseline time period (1998). The basis for these estimates was taken from the NETL database for coal-fired power plant operations in 1998. The database contains power plant equipment details as well as an accounting of existing air emissions from these plants. The database was linked to results of ASPEN model simulations of energy penalties for model plants located in the power pool regions. The air emission model was comprised of the NETL database and logical code for translating energy penalty into increased air emissions. Also, the regional plant capacity and electricity generation are defined for the baseline time period in order to determine the amount of lost generation and lost plant capacity.

In the third step, the annual energy penalty estimates from the ASPEN simulations are used to develop estimates of plant-level emissions increase of sulfur dioxide (SO2), nitrogen oxides (NOx), particulate matter (PM), mercury (Hg), and carbon dioxide (CO2), under the assumption that all coal-fired plants currently employing once-through cooling systems will need to retrofit to either wet or dry cooling towers. The model considers three different scenarios for making up the energy lost to the energy penalty. Scenario 1 assumes that new coal-fired power plants will be built to replace lost power generation capacity. Scenario 2 assumes that the replacement capacity is provided by a new gas-fired combined-cycle unit. Scenario 3 assumes that no new plant construction is needed to replace the loss of generating capacity, but that existing units are able to supply the needed power through increased dispatching of these units. This scenario implies the availability of power outside each regional power pool or sufficient marginal capacity to achieve reliable operations while reducing reserve margins within that power pool. Power generation availability is a function of supply and demand. Forecasts for power generation availability in these regions indicate that supply will be able to meet demand over the next decade. However, these forecasts do not account for energy penalties associated with installations of cooling towers. As the energy penalty increases, the availability of power generation will likely diminish. For low energy penalties (e.g., wet cooling towers), there is less risk to realizing insufficient availability than for high energy penalties (e.g., dry cooling towers). An independent availability analysis was not performed for the present study.

The replacement options in scenarios 1 and 2 consider either an advanced design coal-fired power plant or an advanced design gas-fired combined cycle power plant that meets or exceeds the Clean Air Act's New Source Performance Standards (NSPS). These scenarios will result in less emissions since the newer plants have greater efficiency and, on average, have better pollution controls. Reference plant designs for each of these options are taken from DOE's Market-Based Advanced Coal Power Systems report (DOE 1999).

Pollution control equipment at existing coal-fired power plants is accounted for in the NETL database for coal-fired power generation. Pollution control equipment is comprised of particulate control devices, SO2 control equipment and NOx control devices.

For the MAAC region, particulate controls are predominantly cold-side electrostatic precipitators (ESPs) and represents about 94 percent of the capacity for power generation. Baghouses are used at about 5 percent of the power generation capacity with the remaining capacity equipped with mechanical devices. Most of the capacity (86 percent) in the MAAC region does not have flue gas desulfurization controls installed to reduce SO2 emissions. The balance of coal-fired power plant capacity (14 percent) has wet scrubbers to control SO2 emissions. NOx control equipment includes combustion controls (low NOx burners and/or overfire air) and post combustion controls (selective catalytic reduction [SCR] and selective noncatalytic combustion controls). Only 13 percent of the coal power plant capacity in the MAAC region do not have some form of combustion controls –this means that NOx emissions are higher. On the other hand, only 18 percent of the capacity are equipped with post combustion NOx controls (SCR). Therefore 82 percent, or a majority of systems in the MAAC region, are emitting high levels of NOx. This amounts to 2 to 4 times the emissions rate of the Advanced Coal-Fired replacement plants.

For the SERC region, particulate controls are predominantly cold-side ESPs (78 percent of capacity) with a lesser amount of hot-side ESPs (17 percent) and baghouses (4 percent). Mechanical devices to control particulates are installed at less than 1 percent of the capacity of coal power plants. Approximately 85 percent of the capacity in the SERC region does not have controls to reduce SO2 emissions. SO2 control is predominantly wet scrubbers (14 percent) with only 1 percent using spray dryer absorbers. Combustion controls to reduce NOx emissions are installed in nearly all coal-fired power plants located in the SERC region (94 percent of capacity). Less than 1 percent of the coal power plant capacity in the SERC region has post combustion NOx controls.

5.4.1 Advanced Coal-Fired Replacement Plant

The design of the replacement coal-fired power plant is based on a 400 MW supercritical steam cycle (3500 psig/1050 F/1050 F), which is a power generating facility configured to run under a Rankine cycle where the pressure and temperature of the steam inside the boiler exceed 3,200 psi and 1,100 o F respectively. The overall net plant efficiency is 39.9 percent, which exceeds the efficiency of the existing coal-fired plants (typically 34 to 38 percent). The maximum coal burn rate is 147 tons per hour with a design margin of 5 percent to get to a burn rate of 154 tons per hour.

The flue gas desulfurization (FGD) system for removing sulfur emissions is comprised of a limestone forced oxidation reactor designed to remove up to 96 percent of the sulfur dioxide in the flue gas. A single module reactor is configured with countercurrent flow of the flue gas and limestone slurry. Formic acid is used as a buffer to enhance the SO2 removal characteristics.

NOx control consists of a dual system, low NOx combustion and selective catalytic reduction (SCR). The low NOx combustion system is comprised of low NOx burners (LNB) and overfire air (OFA). The SCR system is designed to remove 63 percent of the incoming NOx. Particulate control is achieved with a pulse jet fabric filter capable of removing 99.9 percent of the particulates.

Design conditions for emission control equipment of major pollutants are given in Table 1. The design conditions include controls for SO2, NOx and particulate emissions. Emission control equipment for mercury and CO2 are not included for the advanced coal-fired replacement plant.

Table 1 - Design Emission Rate for Airborne Emissions (lb/MWh)
[see hard copy for table]

Mercury emissions are estimated from the mercury content in the coal and emission modification factors associated with the pollution control equipment for SO2, NOx, and particulates. An approximate control rate is taken as 90 percent removal of the oxidized mercury from coal combustion, based on preliminary field data taken from EPA's Mercury Information Collection Request (ICR) data (EPA 2000). Using these preliminary data, the oxidized fraction of mercury for bituminous and sub-bituminous coal is 70 percent and 35 percent. The estimated overall mercury removal is 31.5 percent and 63 percent for sub-bituminous and bituminous coal, respectively.

Average emission rates from existing coal-fired power generation is higher than for the advanced coal-fired replacement plant. The average SO2 emission rate for the MAAC and SERC Regions is 19.8 lb/MWh and 14.7 lb/MWh, respectively. This is more than ten times greater than the SO2 emission rate for the advanced coal power replacement plant. The average NOx emission rate for the MAAC and SERC Regions is 4.27 lb/MWh and 5.5 lb/MWh, respectively. The average NOx emission rate for existing coal-fired power plants is more than three times greater than that for the advanced coal-fired power replacement plant. PM emission rate for the existing coal-fired power plants is more than three times greater than for the advanced coal-fired power plant. CO2 emission rate is about 25 percent larger for the existing power plants than for the advanced coal-fired replacement plant. The difference in CO2 emission rate is predominately caused by the higher efficiency of the advanced power plant.

The cooling water system for the coal-fired replacement power plant consists of two 50-percent capacity vertical circulating pumps, a multi-cell mechanical draft evaporative cooling tower, and carbon steel cement-lined interconnect piping.

5.4.2 Advanced Natural Gas Combined Cycle (NGCC) Replacement Plant

The design of the replacement NGCC plant is based on a natural gas combustion turbine (CT) coupled with a heat recovery steam generator (HRSG). The reference plant design for the CT/HRSG technology is based on gas turbine characteristics that are similar to the Westinghouse 501G machine. The combined cycle net efficiency of the plant is 50.6-percent and is capable of producing a net output of 326 MWe. The configuration of the NGCC involves one gas turbine in conjunction with one 1650 psig/1000 F/1000 F steam turbine. The steam turbine is a single multi-stage machine exhausting steam to a single pressure condenser operating at 2 inches of mercury (absolute) when operating at 100 percent design load conditions.

The advanced NGCC system is expected to produce low levels of SO2 and particulate emissions. For the purposes of this study, the plant is considered to produce negligible SO2 and particulate emissions as well as no mercury emissions. Low levels of NOx production from the combustion turbine are achieved by zoning and staging of fuel combustion using dry Low-NOx can-annular combustion systems. Design conditions for emission control equipment of major pollutants are given in Table 1.

The cooling water system for the NGCC replacement power plant consists of two 50 percent capacity vertical circulating pumps, a multi-cell mechanical draft evaporative cooling tower, and carbon steel cement-lined interconnect piping.

6.0 Model Assumptions

This section of the report outlines the data that were used as inputs to the ASPEN model, where the data came from and why they were selected, any analyses that were made to convert sets of data into single model inputs, and the assumptions that were made. The same model was used for estimating both the peak and the annual energy penalties but some of the inputs varied as appropriate.

6.1 Size and Type of Plant

The objective of this study was not to simulate every possible size and type of steam power plant, but to be representative of a large class of existing plants. Approximately 52 percent of existing net generation in the United States during 2000 was coal-fired (EIA 2001b). Out of 829 existing coal-fired generating units in the United States with capacities greater than or equal to 100 MW, 43 percent fall in the size range of 200 to 600 MW. A 400 MW plant was selected as representative of this range. Because DOE had previous experience using the ASPEN model to simulate various aspects of a hypothetical 400 MW pulverized coal plant, the same model plant was used in this analysis.

6.2 Plant Location

DOE attempted to strike a balance between the number of modeled locations and the number of runs using alternate inputs at each location. Five locations were selected to represent a geographic cross-section of the existing fleet of coal-fired power plants using once-through cooling. Figure 2 plots data from the Edison Electric Institute's (EEI's) Power Statistics Data Base to show that nearly all of the coal-fired power plants with once-through cooling are located in the eastern United States, and particularly in the mid-Atlantic, Appalachian, and Great Lakes regions. Therefore, the first four sites are located in Philadelphia, Pennsylvania, Detroit, Michigan, Indianapolis, Indiana, and Atlanta, Georgia. The fifth site, Yuma, Arizona, is somewhat of an artifact because no once-through cooling plants exist in the southwestern United States except for several coastal California facilities. None of those California plants is coal-fired. Although the southwest Arizona leg of the Colorado River could theoretically support a once-through cooled power plant, this model case was run primarily to get a sense of the potential impact of a hot, dry climate on steam power plant efficiency. In addition, the southwestern site was included to give a projection of the energy penalty for converting from a wet tower to an indirect dry tower.

Site selection was also based on the availability of climatic information (e.g., wet-bulb and dry bulb temperatures, humidity, surface water temperatures) and State and Federal thermal discharge permit data used as input to the Aspen model. Table 2 shows the five site locations and a variety of information about each location for the 1 percent peak summer conditions. Table 3 includes the average monthly wet-bulb, dry-bulb, and surface water temperature for the four sites. The source of these data was the NOAA's 30-year normal temperature records.

The analysis to calculate the incremental air emissions was highly labor intensive and therefore was run for the Delaware River Basin and South sites only.

Table 2 - Locations for Model Runs
[see hard copy for table]

Table 3 – Monthly Average Temperatures
[see hard copy for table]

6.3 Discharge Temperatures and Range

EPA provided DOE with information on actual and permitted discharge temperatures from commercial coal- and oil-fired power plants in each of the locations selected for analysis (the actual power plants are not identified in the report). The information was compiled from the National Pollutant Discharge Elimination System (NPDES) permit records as found in EPA's Permit Compliance System (PCS) database (http://www.epa.gov/enviro/html/pcs/pcs_userguide.html).

Table 2 indicates that the ambient air and water temperatures are similar for several of the regions. Thus modeling would lead to a corresponding similar energy penalty if the same ranges (difference in temperature between the hot water entering and the cold water leaving the condenser; often referred to as “delta-T”) were used. To provide an indication of the energy penalty sensitivity, two or three different ranges were modeled at each location for the peak summer conditions. Additionally, the various condenser ranges were employed to reconcile the differences between permitted and actual discharge temperatures at some of the sites. The primary range case for peak summer conditions at each location is based on the lower of permitted or actual discharge temperatures provided by the EPA. Due to the amount of computer resources required (runs/time) only a single range (15-degrees) was considered for all sites in estimating the annual energy penalty (this was simply chosen as the middle of most of the range assumptions used for the sensitivities at the peak –summer modeling analysis). For some of the locations, surface water conditions in the winter would result in an unacceptably low turbine back pressure below 1 inch of mercury if the range of 15 degrees were used for the once-through cooling option. If this occurs, the range is allowed to increase until the turbine back pressure is approximately 1 inch of mercury. Note that all temperatures referenced in this report are expressed in Fahrenheit degrees. A brief description of the range assumptions derived for each location is provided below.

6.3.1 - Delaware River Basin

Actual summer average discharge water temperature for the modeled plant with once-through cooling is 96 degrees. As shown on Table 2, the water temperature is 76 degrees, so a 20-degree range was used as the base case. The Delaware River Basin Commission regulations require a five-degree maximum temperature increase at the limit of a mixing zone. This could require a smaller range depending on the design of the mixing zone. Consequently, cases were also analyzed for 10- and 15-degree ranges.

6.3.2 - Michigan/Great Lakes

The modeled plant uses once-through cooling. It operates with a typical 25-degree range that represents the base case for this location. Michigan’s regulations for Lake Erie require thermal discharges to the lake not to exceed an average of 80 degrees during summer months. This would require a seven-degree range during the summer season based on Table 2 water temperatures; therefore, that case was developed. An intermediate range of 15 degrees was also analyzed to define the sensitivity of temperature rise and energy loss.

6.3.3 - Ohio River Valley

Information from two plants was used to model this location. Both plants have permits restricting discharges to 90 degrees, thus making a 14-degree range the base case. Both of the plants appear to exceed the permitted temperatures regularly (perhaps due to variances) and therefore a case utilizing a 20-degree temperature increase was also developed. The annual energy penalty modeling was run for a 15-degree range case with the results compared to those that were obtained from a peak energy penalty that also employed a 15-degree range.

6.3.4 - South

The modeled plant discharges to the Chattahoochee River and its permit and operating data show a five-degree increase over receiving water temperature. A five-degree range is too small for a practical cooling system design. Therefore 10-degree and 15-degree range cases were analyzed.

6.3.5 - Southwest

As discussed previously, there are no once-through cooled coal-fired power plants in the southwestern United States. Using EPA's NPDES data, the model run was based on an allowable discharge temperature to the Colorado River in the Yuma area of 92 degrees. Therefore, a 10-degree range would be appropriate for a once-through plant. A 15-degree range case was also developed.

6.4 Approach

In a new installation using dry cooling, steam condensation would occur in a direct, air-cooled exchanger. The plant would be laid out to minimize distance from the steam turbine to the air cooler so that there would not be significant pressure drop between the turbine exhaust and the cooling tower. Direct, air-cooled heat exchangers occupy significant land space. The footprint for a direct, air-cooled condenser integrated with a 400-MW power plant of the type modeled herein would require additional land space on the order of several acres. Since the distance from the steam turbine to the dry tower could not be minimized, the diameter of the piping connecting the two units would be prohibitively large to accommodate minimal pressure losses. Therefore, in a retrofit situation, it is unlikely that a direct air-cooled condenser could be installed. For the purpose of this retrofit study, we have assumed that the existing water-cooled condenser will be retained and the water will be cooled by air in the dry-cooling tower; this is known as an indirect-dry tower.

Most dry-cooling towers existing at or being designed for utility steam power plants today are the direct, air-cooled condenser type and are designed for air-side approach temperatures of 40 degrees or greater. We therefore selected 40 degrees as our first case for dry cooling. This 40 degree air-side approach proved problematic for an indirect-dry system modeled under the one percent highest ambient air conditions because the resultant steam turbine back pressure, determined thermodynamically from the cooling tower approach, condenser range, and terminal temperature difference, was elevated to a level far in excess of the steam turbine's originally designed safe operating conditions based on once-through condenser cooling. Operation of a turbine so far above the design-point back pressure would not be viable without significant levels of modification. The energy penalties resulting from the assumption of a 40-degree air-side approach should be considered optimistic – the penalties actually realized for such a configuration would be higher than predicted here. To get a second, less extreme, set of model outputs, which would be more realistic for the case of an indirect-dry tower, we also evaluated a conservative air-side approach of 20 degrees. The rationale for this is discussed in more detail in Section 10.

For wet cooling towers, the typical commercial design is based on using an approach between the cooling water exiting and the wet-bulb temperature of the entering air of 8 degrees plus 1 to 3 degrees to account for possible plume recirculation. An approach of 10 degrees was used for the model runs used for estimating both the peak and annual energy penalties. For all cooling options (once-through, wet and dry), an 8-degrees approach was specified between the cooling water exiting and the steam entering the condenser. This approach is sometimes referred to as the terminal temperature difference.

6.5 Ambient Air Temperatures

Ambient air dry-bulb and wet-bulb temperatures for all five selected sites modeled under the one percent highest ambient air conditions are from the Marley Company's handbook (Marley 1970). Our estimate of the summer peak performance impact in going from wet to indirect-dry cooling towers was accomplished by evaluating the cooling scenarios at the maximum design point conditions. The industry accepted definition for maximum design point condition in the context of cooling towers is the dry-bulb (indirect-dry cooling towers) and wet-bulb (wet cooling towers) temperatures (o F) that are equaled or exceeded 1 percent of the time, on the average, during the warmest consecutive four months. This is also the period when the demand for electricity is at its peak. In the United States, these are the months of June through September, inclusive. By definition, the maximum design point wet-bulb temperature that would be used to design a wet cooling tower for a steam condensing power plant located in Philadelphia, Pennsylvania is 79 E because the ambient air wet-bulb temperature between the months of June through September (inclusive) for that city exceeds 79 E less than one percent of the time during that period (see Table 2).

The analysis of annual energy penalty is based on separate estimates made at monthly intervals. The monthly dry-bulb and wet-bulb temperatures are shown in Table 3.

6.6 Ambient Water Temperature

With the exception of the Michigan/Great Lakes site, the ambient water-surface temperatures required to evaluate once-through cooling were provided by the United States Geological Survey (USGS). However, because the USGS does not record water-surface temperatures for the southwest corner of Lake Erie, calendar year 1999 data supplied by the Fermi II nuclear power plant located on the lake's shore in the town of Newport, Michigan was used for peak summer conditions. For the Michigan/Great Lakes site, daily average surface-water temperature data for the years 1997- 2001 from the National Oceanographic and Atmospheric Administration (NOAA) was used in the annual energy penalty analysis. To remain consistent with the accepted definition of ambient-air maximum design point conditions, a mean water-surface temperature was developed by taking the arithmetic average of the 12:00 pm daily temperature recording at the specified sites over the months of June through September for the peak summer conditions. Water temperature decreases with depth in a water body. The ambient data are assumed to be values taken at the water surface. If a plant withdraws water from a deeper level, that incoming water may have lower temperature than the surface temperature used in the modeling. Monthly ambient water temperature data for each site are shown in Table 3. The site-specific data sources are described in greater detail below:

6.6.1 Delaware River Basin (Philadelphia, Pennsylvania):

USGS Water Resources Data – Pennsylvania, Water Year 2000, Volume 1, Delaware River Basin, Station Number 01474703, Delaware River at Fort Mifflin at Philadelphia, Pennsylvania.

6.6.2 Michigan/Great Lakes (Monroe, Michigan)

Fermi II Nuclear Power Plant
6400 N. Dixie Highway
Newport, Michigan 48166

EPA Response

No response is required for this comment as DOE is a Federal partner in the rulemaking.

[comment continued from 316bEFR.010.102]

7.0 Results of Peak Season Energy Penalty Analysis

7.1 Energy Penalties

The ASPEN model was run for five locations and either two or three ranges at each site for a total of twelve model runs. Each run calculated the energy penalty relative to once-through cooling for a wet tower, and indirect-dry towers at approaches of 20 degrees and 40 degrees. There may be cases in which plants already using wet towers may be asked to convert to indirect dry towers (e.g., plants in the Southwest, none of which use once-through cooling). Further calculations estimated the energy penalty that would be realized in going from a wet tower to an indirect-dry tower. These results are displayed in Table 4. The detailed model output charts are included in Appendix A.

For the purpose of this report, the peak and annual average energy penalties associated with a recirculating cooling system retrofit have been presented as the percent decrease in plant net power output, holding fuel consumption constant, compared to the same facility operating under a once-through cooling scenario. The reduction in plant net power output was determined by the summation of turbine performance loss due to increased steam backpressure and the increase in plant parasitic loads caused by the cooling tower's induced draft fans and head pressure losses. Energy penalties at the 1-percent highest temperature condition relative to once-through cooling systems ranged from 2.41 percent to 3.95 percent for wet towers, from 8.85 percent to 12.14 percent for indirect-dry towers at a 20-degree approach, and 12.67 percent to 15.9 percent for indirect-dry towers at a 40-degree approach. The larger energy penalties that were obtained from
the 40-degree approach model results versus the 20-degree approach model results would indicate that the reduction in plant net power was driven to a greater extent by the steam turbine's performance loss than could be overcome by the net gain in parasitic power loss (i.e., the 40-degree approach tower's fans would not consume as much power as those would on the 20-degree approach tower). A sensitivity analysis on condenser ranges, in the case of an indirect-wet cooling tower, shows that increasing the range by 5 degrees tends to decrease the energy penalty, on average, by 0.3 percent. For indirect-dry cooling towers with a 20-degree approach, increasing the condenser range by 5 degrees decreases the energy penalty, on average, by 0.9 percent. Five-degree increases for the condenser range of power plants modeled with 40- degree approach indirect-dry cooling towers decreased the energy penalties, on average, by 1 percent. This trend would seem to indicate that the parasitic power savings that can be had by reducing the cooling water flow rate through the condenser, effectively increasing the condenser range, more than makes up for the minor decrease in turbine performance due to the resultant higher backpressure. Note that the calculated energy penalties for the Southwest location have been omitted from these ranges because there is not likely to be a once-through system located in Yuma. Energy penalties associated with a retrofit from wet towers to indirect dry towers ranged from 6.1 percent to 10.9 percent at a 20-degree approach, and 10.0 percent to 15.2 percent for indirect dry towers at a 40-degree approach.

7.2 Turbine-Back Pressure

Because turbine-back pressure is an important consideration in plant performance, calculated back pressure values are presented in Table 5. The model runs using an approach of 20 degrees calculated a back pressure of the condensing steam between 4.18 and 8.35 inches of mercury and for 40 degrees calculated a back pressure between 7.03 and 13.37 inches of mercury. Steam turbines manufactured in the United States are designed to operate at back-pressures as high as 5.5 inches of mercury. Operation of a steam turbine at backpressures in excess of that recommended by the manufacturer will void the warranty and may cause significant damage to the machine because of adverse aerodynamic effects on the blades. Dry-cooling towers modeled with a 40-degree approach to ambient dry-bulb temperature yielded turbine back pressures that would require prohibitive levels of modification and re-tooling, resulting in even higher energy penalties than shown in this report by virtue of load shedding. For comparison, 6 out of 12 of the dry cooling tower model runs incorporating a 20-degree approach to ambient dry-bulb temperature produced steam-turbine-back pressures in an acceptable, albeit borderline, range.

Table 4 - Energy Penalty Results from ASPEN Model at One Percent Highest Temperature Conditions
[see hard copy for table]

Table 5 - Turbine-Back Pressure Results from ASPEN Model at One Percent Highest Temperature Conditions
[see hard copy for table]

8.0 Results of Annual Energy Penalty Modeling

8.1 Energy Penalties

The energy penalties were calculated on a monthly basis for each site. Monthly penalty values were arithmetically averaged to estimate the annual energy penalty. Note that this is not exact because the use of averaging conditions may underestimate penalties occurring during the very hot and very cold times of the year when electricity demand is greater than the periods with more moderate temperatures. Table 6 shows the estimated annual energy penalties for each site. The penalty associated with retrofitting wet towers ranges between 0.8 and 1.5 percent while retrofits to dry towers are considerably higher. For the sake of comparison, the one percent highest temperature energy penalties, assuming a 15-degree range, are shown in parentheses.

Table 6 – Estimated Annual Energy Penalty
[see hard copy for table]

8.2 Turbine Back Pressure

None of the monthly pressure values at any of the sites exceeds the critical threshold of 5.5 inches of mercury design point for the turbine’s safe operation for the once-through, wet cooling, or 20-degree approach dry cooling options. Some exceptions are present primarily for the 40-degree approach dry cooling option for the Southwest (Yuma) site. It should be noted that using temperature averaging misses the peak summer conditions when this threshold of 5.5 inches of mercury is often exceeded for the dry cooling options at both approach assumptions (see section 7.2).

9.0 Results of Air Emissions Modeling

Increased air emissions of SO2, NOx, PM, Hg, and CO2 have been estimated under three scenarios for two power pool regions. Air emissions increase as the energy penalty increases Increased air emissions are a function of baseline operating conditions and increased fuel consumption. Increased fuel consumption is a result of the energy penalty associated with conversion of an existing cooling system to a closed cycle cooling system employing a cooling tower. Baseline air emissions are contained in the NETL database for coal power plant operations.

For the three scenarios developed in this study, increasing fuel consumption at existing coal power plants yields the largest increase in air emissions because existing systems are both less efficient at producing power and therefore burn more coal and , on average, have less emissions control equipment. The higher the energy penalty, the larger the fuel consumption and increase in air emissions. In this study, the largest energy penalty is associated with conversion of a once-through cooling system to a dry tower.

The capacity of coal power plants in the MAAC region is about one quarter of that in the SERC region. Since the SERC region has a larger power generation capacity, the baseline air emissions are consistently higher than that for the MAAC region.

The emission rate, expressed in mass per unit of power generation, varies with the installed control equipment and coal properties (e.g., sulfur content). For the SERC region, the average SO2 emission rate (14.7 lb/MWh) is slightly lower than for the MAAC region (19.8 lb/MWh). Even though there are a similar percentage of SO2 controls in both regions, the SO2 emission rate is lower in the SERC region because a lower sulfur coal is used in that region. The average sulfur content of coal in the SERC region is 0.95 lb/MMBtu as compared to an average sulfur content of 1.22 lb/MMBtu for the MAAC region.

The NOx emission rate for the MAAC region (4.27 lb/MWh) is lower than for the SERC region (5.50 lb/MWh). One of the principal reasons for the lower emission rate in the MAAC region is the more frequent installation of post-combustion NOx controls.

The particulate emission rate for the MAAC and SERC region is similar, 0.29lb/MWh and 0.27 lb/MWh, respectively. The dominant particulate control device is cold-side ESPs for both regions.

The mercury emission rate for the MAAC region is 7.2 x 10 -5 lb/MWh and is more than 70 percent greater than in the SERC region 4.1 x 10 -5 lb/MWh. The dominant reason for the higher mercury emission rate in the MAAC region is the higher mercury content in the coal.

CO2 emissions are not controlled at existing coal power plants. Emission rates are primarily a function of the efficiency of power generation while fuel properties play a minor role. The CO2 emission rates are similar for the MAAC and SERC region, 2,190 lb/MWh and 2,200 lb/MWh, respectively. Increased CO2 emissions that yield no significant economic benefit to the gross domestic product will negatively affect this Administration's carbon intensity reduction goal to mitigate the threat of climate change associated with increased emissions of greenhouse gases. For a given amount of power generation, fuel consumption will increase proportionally with an increase in energy penalty. For the three scenarios developed in this study, the energy penalty and increased fuel consumption as a result of conversion of a power plant to a closed-cycle cooling system is lowest for a wet cooling tower and highest for conversion to a dry cooling tower with a high range.

Annual coal consumption for existing power plants in the MAAC and SERC region is 45 million tons and 201 million tons, respectively. For the scenario where existing coal power plants will makeup lost power generation by increasing coal feed rate, the increase in coal consumption is equal to the energy penalty multiplied by the baseline coal consumption for each affected facility.

If a replacement plant is used to make up lost power generation from an energy penalty, the replacement plant will use less fuel to produce an equivalent amount of power. This is because the replacement plants are designed to be more efficient than the existing plants. The NETL database contains fuel consumption and associated power generation for each coal power plant. It also contains power generation losses associated with each energy penalty scenario developed in the present study. Replacement plant fuel consumption is calculated from lost power generation from the existing plant and the efficiency of the replacement plant.

The baseline air emissions for the two regions modeled in this study are provided in Section 9.1 and 9.2.

9.1 – MAAC Region (Region for Delaware River Basin Site)

The baseline generating and emission conditions for the MAAC in 1998 are outlined in Table 7. The additional emissions associated with making up electricity lost to the energy penalty under three different generating scenarios are shown in Table 8.

Table 7 – Baseline Conditions for MAAC – 1998
[see hard copy for table]

Table 8 – Increased Annual Emissions for MAAC
[see hard copy for table]

9.2 – SERC Region (Region for Southern Site)

The baseline generating and emission conditions for the SERC in 1998 are outlined in Table 9. The additional emissions associated with making up electricity lost to the energy penalty are shown in Table 10.

Table 9 – Baseline Conditions for SERC – 1998
[see hard copy for table]

Table 10 – Increased Annual Emissions for SERC
[see hard copy for table]

As seen in Tables 8 and 10, the largest increase in annual emissions is for CO2. There are no controls for carbon dioxide at power plants so emissions increase proportionally with increased fuel consumption. If increased coal consumption is used to compensate for lost power production associated with an energy penalty, SO_2 and NOx emission will increase. Both of these pollutants have adverse health and welfare impacts. These pollutants contribute to acid rain formation that causes acidification of lakes and streams and can damage trees at high elevations. Based on health concerns, SO_2 and NOx have historically been regulated under the Clean Air Act. These pollutants interact with the atmosphere to form fine sulfate and nitrate particles. Scientific studies have identified a relationship between elevated levels of fine particles and increased illness and premature death from heart and lung disorders, such as asthma and bronchitis.

The range of results for increased air emissions from the three scenarios indicates that widespread installation of wet cooling towers on coal power plants would likely stress the power industry's ability to meet demand and regulatory requirements but would likely not impact the ability for the electric generation sector to meet more stringent air emission caps, such as limits for NOx emissions under the NOx State Implementation Plan (SIP) Call or for limits of SO_2 and NOx emissions under the Acid Rain Program (Title IV of the Clean Air Act Amendments of 1990). A likely scenario for mitigation of increased emissions (with the exception of CO_2 emissions) would be installation of environmental control equipment at existing plants. The extent to which controls would be added to offset increased emissions has not been investigated in this report.

10.0 Discussion

10.1 Energy Penalties

10.1.1 One Percent Highest Temperature Conditions

The one-percent highest temperature energy penalties estimated in this study are significant in light of the large number of coal-fired and other-fueled plants that currently operate under once-through cooling systems. If new regulations for existing facilities cause more than a few such plants to retrofit wet- or dry-cooling towers, the loss of available energy to the nation as a whole or to certain regions of the country where once-through cooling is widely used could be very important to utilities' ability to supply abundant and affordable electricity.

For the sake of discussion, consider that in 1996, 258,906 MW of electric generating capacity consisted of plants employing once-through cooling systems (EEI 1996). Assume that 10 percent, 25 percent, 50 percent, or 100 percent of the once-through plants producing that power may be required to retrofit to wet cooling towers. Using the low (2.4 percent), arithmetic average (3.0 percent) and the high (4.0 percent) energy penalties generated by the ASPEN model, the resulting loss in power generating capacity would be significant and is illustrated below (Table 11). Keep in mind that these energy penalties were generated in five different locations during the peak energy demand period of the summer months. Many of the locations are in the Eastern half of the country (see Figure 2) and heat waves could affect the entire area where the once-through cooled plants are concentrated. Note that in developing these tables, we have extrapolated these energy penalties to the whole United States at the same time of peak demand.

The energy, time, and expense required to make up for these losses is significant. The energy lost to the energy penalty could range from 621 MW to more than 10,000 MW. This represents from 0.24 to 4 percent of the quantity of power currently generated by once-through cooled plants. For example in the "average" case, 19 additional 400-MW plants would have to be built to replace the generating capacity lost by replacing once-through cooling with wet cooling towers in 100 percent of existing steam plants. The amount of additional fuel that would be required to generate the lost power is huge.

The second reason involves whether the existing turbines in place at most U.S. once-through cooled power plants could operate at such high levels of back pressure. The results of the modeling suggest that, under the climatic inputs assumed, dry cooling will not be a feasible option as a retrofit during peak summer conditions for many plants originally designed to operate with once-through cooling.

Table 11 - Wet Cooling Tower Energy Penalties and Impact at One Percent Highest
[see hard copy for table]

A similar analysis was performed for those plants that might be required to retrofit their once-through cooling systems to indirect-dry towers using the conservative 20-degee approach; the resulting energy penalty impacts would be over three times higher (see Table 12), ranging from more than 2,000 MW to over 33,000 MW. This represents from 0.9 to more than 13 percent of the quantity of power currently generated by once-through cooled plants. There are two contributors to the increased impacts. First of all, the magnitude of the energy penalties for indirect-dry towers is several times higher than the penalty for wet towers due to much higher turbine back pressures associated with dry towers. To accommodate the energy lost to the energy penalty, the “average” case would require 66 new 400-MW plants to be built to replace the generating capacity lost by replacing once-through cooling with indirect dry cooling towers with a 20-degree air-side approach in 100 percent of existing steam plants. If the 40-degree approach had been analyzed here, the results would have been significantly higher.

Table 12 - Indirect-Dry Cooling Tower Energy Penalties and Impact at One Percent Highest Temperature Conditions
[see hard copy for table]

As noted earlier, 6 of the 12 model runs using a 20-degree approach resulted in pressures that exceeded the 5.5 inches of mercury threshold. For situations in which the turbine backpressure falls within 1 to 1.5 inches of mercury of that threshold, it would be theoretically possible to reduce the back pressure to safe levels through load shedding. This possibility may be applicable for 3 of the 6 model runs that exceeded the pressure threshold. The load shedding would be accomplished through a reduction in the temperature range of the condenser cooling water, which is directly proportional to plant output. For example, if the condenser cooling water temperature range were 20 degrees at full load, reducing the plant output by 50 percent would reduce the condensing temperature by 10 degrees. This would provide about 1.2 inches of mercury reduction in turbine back pressure. However, the severity of the energy penalty (in terms of reduced power output) associated with this small amount of back pressure relief makes it an unattractive option that would only be selected in an emergency situation for a short time. Peer review comments received on this report indicated that a 20-degree approach was too conservative and cooling systems designed on that basis would not function properly. Even if a retrofitted dry tower with a 20-degree approach is hypothetically assumed, it cannot operate safely under the peak temperature conditions at most U.S. locations.

Many plants would face costly modifications to enable existing steam turbines to operate safely at back pressures so far removed from their original design point. The standard steam turbine in most water-cooled plants is designed for optimal operation at 1.5 inches of mercury back pressure. These units are designed to normally operate between 1.0 and 6.5 inches of mercury without significant loss of turbine performance. At extreme off-design operation, pressures significantly above 6.5 inches of mercury, standard turbines will experience degraded turbine performance, and physical damage to the turbines is possible.

All of the model runs using an approach of 40 degrees calculated a back pressure of the condensing steam of between 7.03 and 13.37 inches of mercury. This range of turbine back pressures would not allow for safe operation of the system. In order to operate above 5.5 inches of mercury, existing standard steam turbines would either have to be replaced by new turbines with different designs, or at the very least, would need to be significantly modified by removal of stages (this means that the last few stages of the turbine would actually be removed, causing even greater losses in efficiency). Therefore, the turbines would not be fully operational at the assumed approach of 40 degrees and the estimated energy penalties would likely be greater than forecasted in this study. We concluded that the cost of such modification would be unacceptable. Retrofit of once-through cooled plants to dry cooling using a 40-degree approach (the current industry norm) is not a practical or acceptable option for peak season conditions.

It is interesting to note that attempts to retrofit a dry tower at the Southwest location, using either a 20-degree or a 40-degree approach, would exceed the 5.5 inches of mercury threshold. According to the model results, dry towers could not be retrofit onto once-through plants in the Southwest. Two points can be made on this issue. First, since few if any plants in the Southwest are likely to use once-through cooling, the case is purely hypothetical. On the other hand, the calculations point out that dry cooling combined with traditional boilers and turbines will not be an effective cooling remedy in very warm climates. If dry cooling is to be used in hot climates, the entire power generating system – boiler, turbine, condenser, and cooling – must be built to a different set of specifications in a coordinated fashion.

The cost to convert/retrofit an existing plant to operate using a dry tower would be very high and could cause utilities to evaluate various options. The requirement and design details would be site specific and we have not analyzed this option. In one example reported in the literature (http://www.glencanyon.net/navajo.htm), the Navajo power plant would have to reduce its output by 30 percent to utilize dry cooling.

10.1.2 Annual Average Temperature Conditions

The annual average energy penalties are lower than those calculated for the one-percent highest temperature conditions and the impacts to national and regional energy supply are consequently less extreme. Nevertheless, in parts of the country with many once-through cooled plants, even the annual energy penalty can have a significant impact. Using an average of the annual average energy penalties from the four sites excluding the Southwest site (1.15 percent) and following the same types of calculations outlined in Tables 11 and 12, requirements to retrofit wet cooling towers at 100 percent of once-through cooled plants would result in 2,984 MW of lost energy. Requirements to retrofit indirect-dry towers with a 20-degree approach at 100 percent of once-through cooled plants would result in 12,375 MW of lost energy. These composite losses are not huge, but they could have an undesirable affect on some regions of the country.

Apparently, the issue of excessive turbine backpressure for dry tower retrofits does not apply during most temperature conditions. Nevertheless, the periods of highest electricity demand typically occur during those one-percent highest temperature conditions, such that dry cooling is most likely not a retrofit option.

10.2 Dry Cooling Tower Footprint Area

Another significant issue limiting the viability of a potential retrofit of an indirect dry tower to an existing plant is the amount of land area required by the cooling tower. A commonly used measure of plant equipment land use is called the battery limit footprint area, which is defined as the amount of land area “inside the fence” occupied by the actual equipment, plus any additional space needed for maintenance access. For power plants, the footprint area is usually expressed in square feet of land needed per megawatt of generating capacity.

To determine what the footprint area would be for indirect dry cooling towers, a representative site was selected (Delaware River Basin) and the indirect dry towers that would be needed for those design conditions were sized. This involved: performing design calculations for the actual heat exchanger modules that would be needed at that site to accomplish the degree of cooling required; calculating the amount of space these units would occupy; and then adding an allowance for the additional space that would be needed for maintenance access determined the footprint area.

An indirect dry cooling tower is simply a heat exchanger in which hot water rejects heat to the atmosphere by conduction and convection. The hot water flows inside a series of tubes that are cooled by ambient air. To enhance the heat transfer efficiency of the tubes, helical fins are attached to the outside of the tubes to provide additional surface area on the air side. As is typical of other large heat exchangers, these finned tubes are arranged in large factory-assembled modules that can be trucked to the plant site and connected together to complete the cooling tower assembly.

The most critical parameter in sizing an indirect dry cooling tower is the total surface area required for the heat exchanger, which may be readily determined from simple engineering relationships, depending upon the hot water flow rate and temperature, the ambient dry-bulb temperature and the desired approach temperature. The most important of these is the desired approach temperature. As the approach temperature is reduced, the cooling tower is forced to operate closer to the thermodynamic limits on how much heat can be theoretically transferred from the water to the air and the surface area increases significantly.

Once the total surface area is determined, it is a straightforward matter for the designer to select a tube configuration, module layout and then calculate the number of tubes and modules required to complete the cooling tower heat transfer array.

The heat exchanger sizing calculations for this example were based on the following design parameters:

- 1-inch diameter finned tubes made of hot-dipped galvanized steel,
- 50 feet long tubes,
- 0.375-inch high helical fins,
- 10 fins per inch,
- spaced at 2.2-inch pitch laterally and longitudinally, and

- an optimized tube array configured in an A-frame overall arrangement.

The calculated battery limit footprint for the indirect dry tower for the 40-degree approach Delaware Valley case was 186 square feet per megawatt of generating capacity. This is nearly equal to the footprint typical of an entire coal-fired power plant with once-through cooling (200 square feet per megawatt). Retrofitting such a cooling tower to an existing plant would mean nearly doubling the battery limit footprint area.

The indirect dry tower footprint for the 20-degree case approach was 57 percent larger than the 40-degree approach case, 292 square feet per megawatt. Retrofitting that tower to an existing plant would entail about a 150 percent increase in the plant footprint area.

To observe a visual example of the large battery footprint of a dry cooling system for a new facility, readers are directed to a website describing a direct-dry tower system at a 40-MW geothermal power plant operated by Steamboat Geothermal near Reno, Nevada. The plant employs 240 fans covering a significant area of land relative to the overall size of the plant. Photographs of that facility are available at http://home.nvbell.net/sbgeo/steamboat.html. Note that these towers are direct-dry towers that were built as part of the original construction. Also note the large surface area of fans for just 40-MW of generating capacity.

10.3 Incremental Air Emissions

The incremental air emissions associated with the annual average energy penalty are proportional to the energy penalty. For each increase in energy penalty, the air emissions will increase at a constant rate. When once-through cooled plants are converted to wet cooling towers, the incremental air emissions are not large on a percentage basis (generally less than one percent), but the absolute increase in pounds or tons of air pollutants is large nonetheless. If once-through cooled plants are converted to dry towers, however, the incremental air emissions can be significant. For dry towers with a 20-degree approach, the percentage increase in air emissions can exceed 4 percent depending on how the power company makes up the lost energy. For dry towers with a 40-degree approach, the percentage increase in air emissions can approach 8 percent and the number of additional pounds or tons is quite large.

It is logical to assume that numerous power plants are located in highly populated areas. By virtue of their high populations, many of those same areas are likely to experience less than ideal air quality. If some or many of the power plants in areas with diminished air quality must modify their cooling systems, thereby imposing an energy penalty, they will need to generate additional power. Assuming that plants in the same highly populated areas generate the additional power, air quality will be further diminished by virtue of the additional air emissions resulting from burning additional fuel. Of the five air pollutants evaluated in this report, three (SO2, NOx, and PM) are of national concern to human health and welfare. EPA’s National Ambient Air Quality Standards (NAAQS) set concentration limits for those pollutants to maintain suitable air quality. NOx also contributes to the formation of ozone, which is yet another criteria pollutant having standards set under NAAQS. Mercury is an air toxic and can bioaccumulate into the food chain. Carbon dioxide (CO2) is a greenhouse gas and is the largest contributor to global warming potential.

EPA refers to those parts of the country where air pollution levels consistently exceed the NAAQS as nonattainment areas. As of January 2002, the EPA website for listing nonattainment areas, http://www.epa.gov/air/oaqps/greenbk/index.html, has identified a significant number of nonattainment areas in the MAAC and SERC power pools. The MAAC region is in nonattainment for ozone in 18 counties located in New Jersey, 36 counties in Pennsylvania, and 14 counties in Maryland. A smaller area is in nonattainment for SO2 and PM. The SERC region is in nonattainment for ozone in 13 counties located in Georgia, and 2 counties in Alabama.

Increased emissions of NOx, SO2, and PM will stress areas that are currently in nonattainment. Although the impact of increased emissions on air quality is not part of this study, it should be a consideration for at least nonattainment areas. Increased air emissions associated with increased fuel usage required to offset the energy penalty from a cooling tower is of special concern in Class I areas. The Clean Air Act defines mandatory Class I federal areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence as of August 1977. These sensitive areas have undergone significant change in air quality. For example, without the effects of pollution, a natural visual range is approximately 140 miles in the West and 90 miles in the East. When considering our current air quality, in the West, the range is 33-90 miles, and in the East, the range is only 14-24 miles.

Through the 1977 amendments to the Clean Air Act, Congress set a national goal for visibility as "the prevention of any future, and the remedying of any existing impairment of visibility in mandatory Class I Federal areas which impairment results from manmade air pollution." The amendments required EPA to issue regulations to assure "reasonable progress " toward meeting the national goal. Furthermore, the Clean Air Act requires all states to develop and implement an operating permit program that meets minimum Federal requirements. The operating permit program covers a variety of significant operations, including sources required to have pre-construction or new source permits under New Source Review or Prevention of Significant Deterioration (PSD) requirements. Although the calculated increase in emissions is relatively small, for plants located near a national park, even a small increase in emissions would not be allowed under the Clean Air Act's PSD requirements. Increased air emissions associated with the installation of cooling towers may not be permitted under PSD requirements if these emissions were shown to affect the quality of air in Class I areas.

There is one Class I area in the MAAC power pool and fifteen Class I areas in the SERC power pool. This represents about 10 percent of the 163 federally mandated Class I areas designated in the United States. Special analyses are required when a proposed new emissions source may impact any of the Class I areas. The Class I areas in the SERC regional power pool include the Shenandoah and Great Smokey Mountain National Parks, both of which have seen a statistically significant upward trend in ozone concentration from 1990 to 1999.

All increased emissions presented in this study are estimated on an annual basis. However, air quality can be sensitive to climatic conditions that are seasonal in nature. For instance, Nox emissions (a precursor to ozone formation) can be especially damaging to air quality during hot summer days. This period of time encompasses the period in which electricity frequently peaks to its greatest demand. Peak energy penalties for the MAAC and SERC regions can be 2.6 to 2.9 times greater than for annual energy penalties based on model plant estimates for conversion of a once-through cooling system to a wet cooling tower (see Table 6). The increase in air emissions during peak temperatures (1 percent highest temperature condition) would be 2.6 to 2.9 times greater than the annual average increase in air emissions.

RFC: States to demonstrate comparable env. perf.?

As your agency formulates a final rule for Phase II facilities under Section 316(b) of the Clean Water Act (CWA), we urge you to design a rule that allows the states maximum flexibility to implement programs that have been developed by us over the past 25 years. During those 25 years we have applied Section 316(b) on a site-by-site basis, examining the impacts of existing cooling water intakes in relation to the specific biological community. Further, the Phase II rule should not overturn existing state 316(b) decisions at existing facilities.

EPA Response

EPA believes today's final rule allows ample flexibility with section 316(b) determinations. In addition to five means with which to comply with the applicable performance standards, the rule allows States and Tribes to demonstrate alternative regulatory requirements (§ 125.90(c)) that will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment in the performance standards. Additionally, § 125.90(d) states that nothing in today's rule precludes a State or Interstate Agency from adopting or enforcing any requirement that is not less stringent than those required by Federal law. As with any new rule, existing State section 316(b) determinations must be revisited to determine compliance with today's final rule and may need to be changed.

General statement of support

Generally, we believe the new regulations will provide consistency and an improved understanding of the requirements for all parties involved since the proposal establishes national technology-based performance standards on the location, design, construction, and capacity of cooling water intake structures. This will assist the regulated community and the permitting and enforcement authorities in minimizing adverse environmental impacts associated with the cooling water structures at these facilities.

EPA Response

EPA notes the comment. No response necessary.

Comment ID 316bEFR.011.003

Subject Matter Code 15.02

RFC: States to demonstrate comparable env. perf.?

Author Name Christine Martin

Organization PA Dept of Environmental Protection

We would, however, emphasize that the resulting regulations and program guidance must not be overly prescriptive, but allow for continued sufficient flexibility to address case-specific concerns when necessary. For instance, we generally support technologies such as closed cycle cooling that conserve water, and view these technologies as a way to better manage our limited water resources while protecting aquatic life. However, we feel it is unnecessary for the EPA to prescribe any single technology (i.e., closed cycle recirculating system) by imposing specific, strict performance criteria. The Department encourages EPA to develop cooperative, common sense approaches that promote program flexibility while maintaining water quality protection to meet the unique needs and conditions being faced by the States/Tribes and the regulated community. Using a technology-neutral approach to decisions will allow Pennsylvania and other states to achieve the most environmentally effective and cost-effective reduction in adverse environmental impact.

EPA Response

EPA believes today's final rule allows ample flexibility with section 316(b) determinations. The rule contains five means with which to comply with the applicable performance standards. These performance standards do not prescribe any single technology but rather allow the best technology available to achieve the performance standard to be chosen for each facility. Also, the rule allows States and Tribes to demonstrate alternative regulatory requirements (§ 125.90(c)) that will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment in the performance standards. Additionally, § 125.90(d) states that nothing in today's rule precludes a State or Interstate Agency from adopting or enforcing any requirement that is not less stringent than those required by Federal law.

RFC: Definition of "adverse environmental impact"

[A] definition of "adverse environmental impact" (AEI) focused on overall environmental protection is necessary to provide the flexibility needed to achieve the best environmental outcome in individual cases. PA DEP generally supports using biological assessment approaches to determining the ecological and/or community or populational impacts that may be related to adverse environmental impacts which are associated with the impingement and/or entrainment by a cooling water intake structure. This follows the approach PA DEP uses in assessing environmental impacts of thermal discharges under Section 316(a) of the CWA. The Section 316(a) provisions are intended to "assure the protection and propagation of a balanced indigenous population of shellfish, fish, and wildlife in and on that body of water;" and would be workable and consistent with federal and state goals of ensuring adequate protection to aquatic resources. PA DEP, however, fully recognizes that determining the potential AEI that may be attributed to the cooling water intake structure is difficult, especially in complex situations where multiple stressors may compound the observed impacts. Therefore, PA DEP would request that we remain party to EPA's on-going considerations of the definition and related methods that will identify what is considered as AEI under this rule.

EPA Response

In today's final rule, EPA has elected not to define adverse environmental impact. Consistent with the Phase I New Facility Rule, EPA believes that it is reasonable to interpret the minimization of adverse environmental impact as minimizing the loss of aquatic organisms due to impingement and entrainment. The Agency has long maintained that adverse environmental impact from cooling water intake structures must be minimized to the fullest extent practicable. The objective of section 316(b) includes population effects but is not limited to those effects. EPA has considered the consequences associated with the loss of large numbers of aquatic organisms, including impacts on the stocks of various species, loss of compensatory reserve due to the deaths of these organisms and the overall health of ecosystems. Given all of these considerations, EPA determined that there are multiple types of undesirable and unacceptable adverse environmental impacts which result from impingement and entrainment and which must be minimized. EPA has rejected all proposed alternative definitions of adverse environmental impact because they are too broad and dependent on proven damage on the community and population levels before controls on cooling water intake structures could be put in place as the best technology available. EPA does not view adverse environmental impact as limited to demonstrated community or population level effects. Damage on the community or population level is extremely difficult to quantify and attribute to a particular cooling water intake structure given the vast number of environmental factors and anthropogenic factors which work concurrently on fisheries at that organizational level. It is difficult to isolate the effect of a single factor. Many cooling water intake structures have been in operation for decades. During these years, fish populations have been affected by other factors such as overfishing, habitat alteration and water quality changes. Because of these simultaneously-occurring factors, the determination of a change in a population that is directly attributable to the operation of a cooling water intake structure may prove to be very difficult.

Thus as in the Phase I rule, EPA continues to interpret adverse environmental impact to include impingement and entrainment; reductions of threatened, endangered, or other protected species; diminishment of a population's potential compensatory reserve; damage to ecologically critical aquatic organisms, including important elements of the food chain; losses to populations, including reductions of indigenous species populations, commercial fishery stocks, and recreational fisheries; and stresses to overall communities or ecosystems as evidenced by reductions in diversity or other changes in system structure or function. EPA also continues to assert that for section 316(b), measuring environmental performance in terms of reduction of impingement and entrainment is appropriate because it has a higher degree of certainty than conducting population or ecosystem studies.

Subject Matter Code 18.01.04

RFC: Alternative definition of "AEI"

Moreover, while our primary objective is to assure that intake structures minimize possible adverse impacts from the entrainment and impingement of fish, the state should be able to consider local concerns and guard against undesirable environmental effects, such as water use, water quality, or transference of problems to other media such as air emissions or solid waste generation, that might occur from using certain technologies. A rule that adopts a holistic approach to evaluating adverse environmental impact is better. We strongly encourage EPA to define AEI in a way that is understandable, defensible and considers all types of adverse environmental impacts, including those involving possible transfer to other media (e.g., air emissions, noise, water usage).

EPA Response

EPA has elected not to define adverse environmental impact as part of this rulemaking. Please see response to comment 316bEFR.011.004. Today's final rule contains much flexibility which will allow States to consider local concerns. These include but are not limited to the provisions in § 125.90 which allow States to demonstrate alternative regulatory requirements which would result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment that would otherwise be achieved under § 125.94 and which allow States to adopt or enforce any requirement with respect to control or abatement of pollution that is more stringent than those required by Federal law. Since the final rule is not based on and does not require installation of cooling towers, non-aquatic impacts such as air emissions, water consumption and noise should not be a concern with regard to adverse environmental impacts.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

[T]he Section 316(b) rule for existing sources, while protecting our fisheries, should not unduly affect national or regional energy supply. A rule requiring an unnecessary or overly burdensome retrofit of cooling towers to generation plants will increase energy production costs, reduce output as a result of efficiency losses, and necessitate taking base load capacity out of production for significant periods of time. All of this has the potential for significant adverse impacts on energy supply that will vary regionally. If premature closure occurs, fuel diversity would be compromised.

EPA Response

The final Phase II rule does not contain requirements to retrofit cooling towers. In addition, EPA's analysis of the potential effects of the final rule on the electricity market showed no adverse energy supply effects (see results in EBA chapters B3 and B6, DCN 6-0002).

Comment period

Author Name Christine Martin
Organization PA Dept of Environmental Protection

We appreciate this opportunity to comment on EPA's proposals for guiding the implementation of Section 316(b) of the Clean Water Act. We would like to continue to work with you to formulate a sound program that builds on a history of partnership with the states, is effective in protecting our environment, and does not adversely affect national energy policy. It is important to balance the need for federal authority with a tailored regulatory program that will fit the unique aspects of our state waters. We must take into account the numerous biological, hydrological, and ecological factors that affect our waters. Because there is such an array of scientific, biological, engineering, economic, social and environmental concerns associated with this proposal, which will affect the management of state run NPDES programs and the welfare of our residents and the resources on which they derive benefit and recreation, we respectfully request that any additional comments we may choose to file after the current comment deadline be given due consideration.

EPA Response

EPA accepted and considered all comments. EPA considered those that were submitted after the official close of the comment period to the extent it was able. Those comments were included in the public rulemaking record.

Applicability to facilities subject to NPDES permit

New Mexico is an arid to semi-arid state, and semi-arid/arid conditions were not utilized by EPA in formulating the proposed Rule. None of the facilities modeled by EPA are located in this physiographic region of the US, so many of the environmental and water resource factors unique to or especially important to our facilities are simply not addressed at all in the rulemaking.

The major facility owned/operated by PNM likely to be affected by either the Phase II regulations (current rulemaking proposal) or the Phase III regulations (to be the subject of a future rulemaking) is the coal-fired San Juan Generating Station, located near Waterflow, New Mexico, in the Four Corners region of the US. This facility is currently the only facility operated by PNM that depends upon the use of surface water for cooling and other process water. (In New Mexico, much of the potable, municipal, agricultural, and industrial use water is from groundwater sources not directly regulated under the Clean Water Act, rather than from surface watercourses).

EPA Response

EPA disagrees. EPA notes that the comment does not indicate specifically the environmental and water resource factors unique to New Mexico that are not addressed in the final rule. Regardless, numerous aspects of this rule have considered the southwest region of the U.S., including New Mexico. Such aspects include EPA's profile of the electric power industry (New Mexico is part of the WSCC NERC region), assessment of rule costs and impacts by NERC region, assessment of the rule's power market impacts (New Mexico and Arizona are one of 26 regions modeled in the IPM), and regional approach to assessing benefits (e.g., see NODA, 68 FR 13543). In fact, the benefits assessment was specifically expanded to address regional differences throughout the country.

Author Name Toni Ristau

Organization PNM Bulk Power Services

Subject Matter Code 3.04

Applicability to facilities subject to NPDES permit

Stormwater National Pollutant Discharge Elimination System (NPDES) Issues:

San Juan Generating Station (SJGS) currently holds two NPDES permits – one (NM 0028606) is a "zero discharge" permit for process/cooling wastewater, and the other (NM R05A433) is a stormwater NPDES permit for sporadic stormwater runoff discharges to intermittent/ephemeral watercourses; there is no direct discharge or outfall to the river (the San Juan River, a tributary to the Colorado River) of either process/cooling wastewater or stormwater runoff. The existing cooling/process water intake is situated on the San Juan River.

To the extent that stormwater NPDES alone would cause SJGS to be subject to the Phase II or Phase III regulations under 316(b), our preference would be that we would be provided the option of formulating a site-specific permit for the intake structure. Currently, EPA has compiled essentially no data on the appropriate requirements for a general permit for the arid/semi-arid regions of the west and southwest, and the "case studies" have identified requirements that may not be particularly appropriate for this environment and that, if imposed, may actually be counterproductive in terms of environmental protection or enhancement.

EPA Response

Either NPDES permit indicates the facility is a point source, potentially subject to this rule if other applicability requirements are satisfied. The specific approach to permitting is to be determined by the Director (in this case the EPA Regional Administrator) based on applicable regulations and facts. EPA notes that the case study data referenced in the comment was expanded to encompass a regional approach to assessing benefits, as described in the NODA (see, 68 FR 13543). Also see response to 316bEFR.013.001.

Organization PNM Bulk Power Services

Subject Matter Code 6.05

Impacts to T&E species

Endangered Species Act (ESA) Coordination Issues:

SJGS's intake structure is located within a reach of the San Juan River that is designated critical habitat for an endangered fish species (the Colorado Pike Minnow), and several state and Federal entities (including the U.S. Fish and Wildlife Service, which is charged with assuring ESA compliance and recovery efforts for endangered species) have had ongoing studies and species recovery efforts for several years.

PNM is concerned that the prescriptive technology requirements (see Section VI, Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities) may be in conflict with mandates under the ESA, including endangered species recovery plans, and directives of other agencies.

For example, the San Juan River Basin Recovery Implementation Program (effective November 1, 1992) provides guidelines for structures and intakes in the river (as well as for other management efforts) with which SJGS has been cooperating and complying for almost 10 years. Nine years of research have been conducted to determine what is needed for the endangered fish recovery, including the total eradication of non-native fish and elimination of any sport fishing. Despite several years of studies, the USFWS has yet to identify specific technologies for water intake structures which would enhance the recovery efforts. The USFWS has made a preliminary determination that employing fish screens, as is suggested in EPA's Best Available Technology requirements, would only work for sub-adults (greater than 300 mm total length) and adult fish of this endangered fish species; they are not effective for larval/juvenile stages, which are the developmental stages which are in need of the greatest protection to ensure recovery of the endangered fish.

Also, research has indicated that the San Juan River is "biomass limited" (i.e., there is only so much food available, and it must support the entire food chain, from insects to top predators). Thus, changes in the distribution and numbers of various populations may change, but the total biomass within the river cannot change. If screens at the current intake structure were upgraded to keep out the fry of the endangered fish species, this could cause a shift in population densities for other species but have no positive effect on the endangered species, due to the total biomass limitation.

In addition, EPA's own guidance indicates that fine-mesh screens, traveling screens, etc. may not be feasible in streams/rivers with a high silt burden (as is the case in the San Juan River). Any techniques employed that would impede the downstream flow of silt or diminish the amount of silt in the river could adversely affect endangered fish viability, as these species are adapted to and dependent upon the naturally occurring silt loads in these streams.

Thus, for these reasons, PNM would prefer that, if SJGS is subject to the Phase II or Phase III regulations under 316(b), we would be provided the option of formulating a site-specific permit for the intake structure, rather than being subject to the prescriptive technology requirements currently proposed by EPA, so that we could take into consideration the research and directives under the mandates of the ESA.

EPA Response

Today's final rule allows for site specific determinations of best technology available. In addition, the provisions in this rule should not be construed to preclude or deny the right of any State or Interstate agency to set or enforce any requirement to protect species under the Endangered Species Act.

Organization PNM Bulk Power Services

Subject Matter Code 2.04.01

Require closed cycle cooling

Water Rights Issues:

SJGS currently has a right to 16,200 acre-feet/year of the flow of the San Juan River based on a prior contract with the U.S. Bureau of Reclamation. In the western US, in states that are appropriation states, water rights are property rights, and the possession and maintenance of water rights is an important economic, as well as physical, asset for any facility that uses water in its processes.

Water rights simply have not been analyzed as an issue at all in EPA's economic analyses. Any rulemaking proposal that either proposes measures that would increase the amount of water that must be taken by the facility to maintain operations or that would prevent that facility from applying its existing water rights to beneficial use would have an impact not only on that facility but on the region in which the facility is located. Forcing changes to an operating facility that would limit flows and thus limit the amount of water that could be applied to beneficial use could cause an impairment of existing water rights, potentially constituting a taking.

EPA Response

Subject Matter Code 3.03

Definition: Waters of the U.S.

Cooling Ponds/Lakes Issues:

In addition, clarification is needed regarding whether cooling ponds [or lakes] are considered "waters of the U.S." if they meet the criteria of the 40 C.F.R. § 122.2 definition. SJGS is a facility that "stores" water withdrawn from the river in a raw water reservoir temporarily, then withdraws water from the reservoir to use for steam, cooling, and other processes at the plant. The raw water reservoir does not receive any discharges from plant operations, and is not open to the public for recreational or other uses. Thus, PNM is concerned that any intake structures, etc. associated with the raw water reservoir would not also be subject to the prescriptive technology requirements contained in the proposed rule. PNM would urge the EPA to instead clarify the definition of such facilities as parts of a process/treatment facility rather than as "waters of the United States", so that such facilities are not subject to the 316(b) intake requirements.

EPA Response

Option: Site-specific determination of BTA

SUMMARY:

In summary, PNM supports the comments by EEI and UWAG on general issues, and strongly supports the application of site specific permitting processes (or other mechanisms allowing for permitting flexibility) in view of the lack of analysis by EPA in identifying appropriate BTA for the environment in which we operate.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA does not intend to specify technologies for individual facilities. The final rule offers facilities flexible alternatives for compliance.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Benefit Estimation Methodology

Briefly stated, EPA's analysis of the benefits of reduced cooling water intake is seriously incomplete, and should be considered as no more than an extreme lower bound on the complete benefits. A simple quantitative adjustment, filling in just two of the many gaps in EPA's estimate of benefits and drawing on more recent economic literature than EPA has used, results in substantially greater benefits for every option EPA is considering, and show that EPA's proposed option does not maximize net social benefits. To be sure, my adjustments remain incomplete; they do not come close to capturing all of the benefits of regulating cooling water intake structures. Nevertheless, my estimates are sufficient to demonstrate that policy options involving greater reduction in water intake create greater net benefits than the proposed option.

EPA Response

EPA agrees with the commenter that the proposed rule analysis does not include all possible benefits of CWIS, and that, therefore, the value of entrained and impinged fish to an ecosystem is likely to be underestimated. As stated in the NODA, EPA attempted to include non-use benefits categories for the final Section 316(b) Phase II rule analysis. For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN #6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN #6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

For EPA's response to comments that the Agency's benefit estimates are incomplete, please see response to comment #316bEFR.206.047.

Benefit Estimation Methodology

Author Name Frank Ackerman

Organization Global Development and Environmental Institute

These comments also examine the methodological problems of valuation of the environmental benefits involved in this case. Natural ecosystems, such as the aquatic ecosystems affected by cooling water intake, provide numerous interrelated services, some of which are clearly valuable but difficult to quantify. Assigning a zero value to these benefits would misstate society's preferences and values. Yet rigid insistence on applying a single, narrowly defined valuation methodology to every benefit would, in effect, dismiss (that is, value at zero) all hard-to-quantify environmental values. For this reason, EPA's analysts should be commended for exploring valuation methodologies such as habitat-based replacement cost (HRC) and societal revealed preferences, which have the potential to address the full range of ecosystem services. The problems with these alternative methodologies are that they do not go far enough, and cannot be consistently applied across the board.

EPA Response

EPA agrees that ecosystems provide many difficult-to-value services and that assigning zero values to this services would misstate society's values. As stated in the proposed rule analysis and in the NODA the Agency explored various alternatives to quantifying and monetizing non-use benefits. However, given the unavoidable uncertainties in estimating non-use benefits, the Agency presented a qualitative assessment of the non-use benefits of the environmental protections at issue in the final 316(b) benefit cost analysis. For the final regulation, EPA considered all benefits -- monetized, quantified but unmonetized, and qualitatively in the decision making process.

For EPA's response to comments that the Agency's benefit estimates are incomplete, please see response to comment #316bEFR.206.047.

The HRC method is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the HRC method, please see response to comment #316bEFR.005.035.

The SRP method is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the SRP method, please see response to comment #316bEFR.005.006.

Benefit Estimation Methodology

In addressing the methodological problems, I also respond to aspects of the comments on this rule by Dr. Robert Stavins. Commenting on behalf of PG&E National Energy Group, one of the major corporations that has a direct financial interest in the outcome of this rulemaking procedure, Dr. Stavins reaches conclusions opposite to mine, arguing that all methodological innovations in benefits valuation in this case are illegitimate and that many EPA benefit estimates are drastic overestimates. Throughout his comments, he inaccurately suggests that he speaks for all economists. However, he neglects to document the supposed unanimity of economists on these issues, repeatedly offering only his own personal authority as evidence for the views of the entire profession. In my comments I describe the ongoing differences among economists, including recent Nobel Prize winners, on the issues at stake in this case.

Here I will focus on three of the numerous points on which I disagree with Dr. Stavins: the treatment of non-use values, the basis for habitat replacement cost estimates, and the validity of societal revealed preferences. My conclusions on these issues, in short, are that

-Dr. Stavins ignores the extensive evidence that EPA's non-use values are conservative underestimates;

-Habitat replacement cost valuation is similar to standard approaches to asset valuation used through the economics literature, and provides a reasonable approach to valuation of large but uncertain ecosystem benefits; and

-Societal revealed preference is a reasonable approach to the problems of social choice, which are intrinsically different from the individual choice paradigm that is assumed in Dr. Stavins' preferred approach.

Finally, despite our differences, Dr. Stavins and I agree that there are enormous methodological difficulties in complete valuation of the benefits of reducing cooling water intake requirements, but we disagree about the implications of these challenges. Dr. Stavins urges EPA to wait to regulate until the valuation methodologies of economists catch up to the environmental aspirations of the Clean Water Act. I, in contrast, conclude that the difficulties in valuing environmental benefits illustrate the limits to the usefulness of cost-benefit analysis in the environmental setting. In contrast to the cost-benefit analysis EPA now appears to endorse, identification of the best available technology is a process in which costs are only one of many factors to be considered, and benefits need not be precisely quantified and monetized in order to be taken seriously. A recommendation based on the best available technology could be made, as has been done for numerous regulations in the past, without entangling the agency in the massive web of methodological, technical, and even philosophical challenges to cost-benefit calculations.

EPA Response

EPA agrees with the commenter that the proposed rule analysis does not include all possible benefits of CWIS, and that, therefore, the value of entrained and impinged fish to an ecosystem is likely to be underestimated. As stated in the NODA, EPA attempted to include non-use benefits categories for the final Section 316(b) Phase II rule analysis. However, given the unavoidable uncertainties in estimating non-use benefits for this rule, the Agency presented a qualitative assessment of the non-use benefits of the environmental protections at issue in the final 316(b) benefit cost analysis.

For EPA's response to comments that the Agency's benefit estimates are incomplete, please see response to comment #316bEFR.206.047.

The HRC method is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the HRC method, please see response to comment #316bEFR.005.035.

The SRP method is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the SRP method, please see response to comment #316bEFR.005.006.

Benefit Estimation Methodology

The incompleteness of EPA's benefit estimates

Cost-benefit analysis is designed to weigh the relevant costs of a proposal against the corresponding benefits. This process cannot yield a meaningful result unless the calculations of costs and benefits are equally complete. In the private sector, a balance sheet that weighs all of a company's income against some of its expenditures does not provide a useful picture of the company's true financial condition, as recent corporate scandals have reminded us. Likewise, in the public sector, a comparison of complete costs and incomplete benefits does not provide an accurate picture of net benefits to society.

Yet a comparison of complete costs and incomplete benefits is exactly what EPA has produced in this case. The costs of reducing the impacts of cooling water intake are monetary costs for marketed goods and services, such as production and installation of screens, cooling towers, and other equipment. Such costs are backed up by detailed engineering analyses, and often by recent experience in buying and installing similar equipment. There are no categories of costs which are intrinsically difficult to express in monetary terms.

Contrast this with the calculation of the benefits of reducing cooling water intake. In general terms, the benefits consist of reduced damage to aquatic ecosystems. But how should those benefits be measured and monetized? EPA's analysis focuses on a more restricted question, namely valuing the benefits of killing fewer fish; this is already a complex problem with no simple answers. Market prices are available only for a few commercially valuable fish species; even when available, commercial prices do not necessarily capture all the value of avoided fish mortality. And avoided fish kills are far from the only significant benefits of reduced ecosystem damages, since many other organisms and environmental services are also affected.

EPA's economic benefit analysis (EBA) explicitly describes the categories of benefits that have been omitted. EBA Chapter C1, particularly section C1-5, lists the following reasons why the environmental impacts of cooling water intake structures, and consequently the benefits of regulating them, are underestimated:

-Facility-provided monitoring data, the basis for EPA's analysis, typically focus on only a subset of the species impacted by impingement and entrainment (I&E), thus underestimating total losses.

-Monitoring data often pertain to conditions existing many years ago, before the Clean Water Act had improved aquatic conditions; if the numbers and diversity of fish were depressed by degraded water quality, estimates of I&E losses would be similarly low.

-Cumulative impacts of multiple facilities on the same fish population are often important, but have been considered only to a limited extent.

-Estimated recreational and commercial values include only the proportion of I&E losses that would have been caught, typically less than 20 percent of I&E mortality of recreationally and commercially valuable species.

-Secondary economic impacts such as effects on marinas, bait sales, and property values have not been included.

-Losses of invertebrate species such as lobsters, mussels, crabs, and shrimp were not included, even though these include commercially valuable species.

-Effects on fish-eating (piscivorous) birds were not included.

-Current fishing mortality rates often reflect already-depleted fisheries, as for example in the case of winter flounder near the Brayton Point facility, one of the EBA case studies.

-Forage species, accounting for the predominant share of I&E losses, are poorly documented, and their full ecological value to the food web is not considered.

-Non-use benefits are estimated only for recreational users, not for the population as a whole.

-Thermal impact reductions are not accounted for in some options, such as replacement of once-through cooling with cooling towers.

Another portion of the EBA, Case Study Chapter A11, re-examines the areas of incompleteness from a different perspective, focusing on the ecological services that are disrupted by I&E, but are not addressed by conventional valuation methods. Quoting directly from the EBA, those omitted or undervalued services include:

-decreased numbers of ecological keystone, rare, or sensitive species;
-decreased numbers of popular species that are not fished, perhaps because the fishery is closed;
-decreased numbers of special status (e.g., threatened or endangered) species;
-increased numbers of exotic or disruptive species that compete well in the absence of species lost to I&E;
-disruption of ecological niches and ecological strategies used by aquatic species;
-disruption of organic carbon and nutrient transfer through the food web;
-disruption of energy transfer through the food web;
-decreased local biodiversity;
-disruption of predator-prey relationships…
-disruption of age class structures of species;
-disruption of natural selection processes;
-disruption of public uses other than fishing, such as diving, boating, and birding; and
-disruption of public satisfaction with a healthy ecosystem.
(EBA Case Studies, p. A11-2.)

This second list is presented as part of the rationale for HRC valuation, a method that can encompass the full diversity of ecosystem values. My comments on HRC appear in section 5 below.

It would be impossible in practice to estimate all of these omitted values. However, benefit analyses for other proposed rules have estimated a broader set of values. For example, the economic and environmental benefits analysis for the metal products and machinery (MP&M) rule estimated separate recreational benefits for fishing, other boating, and wildlife viewing and near-water activities. Recreational fishing accounted for only one-fourth of all recreational benefits from reduced MP&M discharges. <FN 2> EPA has now issued a Notice of Data Availability for the MP&M rule; it suggests that the estimates of recreational benefits were increased in response to peer reviewers' comments. <FN 3> If similar relationships hold for the recreational benefits of reductions in cooling water intake, then EPA's estimates of recreational benefits in the 316(b) analysis should be multiplied by 4 or more. However, the data needed to determine the magnitude of other recreational benefits are not presented in the EBA. I recommend that EPA should explore the impacts of cooling water intake structures on the other recreational benefits considered in the MP&M analysis, and increase its estimates of recreational benefits of cooling water intake reduction whenever appropriate

The two lists of omissions and underestimates presented here – both taken directly from the EBA – are more than sufficient to demonstrate the incompleteness of the benefits analysis in this case. Complete costs are being compared to a restricted subset of benefits; the bottom line of such a lopsided comparison slants heavily in a predictable direction, toward "justifying" less regulation and weaker environmental protection than a complete analysis would support. All that can be concluded from this misleading, incomplete comparison is that true, complete benefits must be larger, and net social benefits larger as well, for each of the various options under consideration.

Footnotes

2 Economic, Environmental and Benefits Analysis for the Proposed Metal Products and Machinery Rule (EPA 821-B-00-0008, December 2000, available at www.epa.gov/waterscience/guide/mpm/rule.html), Chapter 15; the results in Table 15-13, p.15-17, show that recreational fishing accounts for 24% of the midpoint values for recreation benefits as a whole.

3 Federal Register, June 5, 2002, p. 38774.

EPA Response

The comment focuses on understatement of benefits. EPA agrees that comparison of complete costs to incomplete benefits is not appropriate. EPA agrees that ecosystems provide many difficult-to-value services and that assigning zero values to these services would misstate society's values. As stated in the proposed rule analysis and in the NODA the Agency explored various alternatives to quantifying and monetizing non-use benefits. However, given the unavoidable uncertainties in estimating non-use benefits for this rule, the Agency presented a qualitative assessment of the non-use benefits of the environmental protections at issue in the final 316(b) benefit cost analysis.

For EPA's response to comments that the Agency's benefit estimates are incomplete, please see response to comment #316bEFR.206.047.

For the final 316(b) rule analysis, the Agency explored non-use benefit valuation estimates, including the value of threatened and endangered species lost to impingement and entrainment where relevant, for all study regions, but did not maintain these estimates due to the uncertainty of the estimates. See the Regional Analysis Document for the Final Section 316(b) Phase II Existing Facilities Rule for details (DCN #6-0003).

Benefit Estimation Methodology

Summary account of adjustment of EPA benefit estimates

I have prepared an adjusted set of figures incorporating estimates of corrections to just two of EPA's omissions and underestimates. This section presents my calculations; the rationale for the first correction appears in section 4 below.

My first adjustment is for the underestimate of non-use benefits. As I discuss in section 4, a recent literature review finds that non-use benefits are on average 1.9 – 2.5 times all use values, rather than 0.5 times recreational benefits alone as EPA assumed. My reading of the recent literature suggests that 1.9 – 2.5 times use value is still a conservative estimate for existence values of many natural ecosystems. To correct for EPA's underestimate in this area, I have recalculated their estimates assuming that non-use values are 2 times estimated recreational, commercial, and forage values.

My second adjustment is for the unvalued fraction of the mortality of recreationally and commercially valuable species. EPA's methodology values only the fraction of those species that would have been caught in the absence of I&E mortality. That is, I&E mortality rates are adjusted downward in proportion to historical catch rates before any valuation occurs in the EBA. Only the fraction of the fish that would have been caught are assigned any value; the rest are ignored. The catch rate, or "landed fraction," is below 20% in every case, and below 10% in some cases. <FN 4> Thus the great majority of I&E mortality of the most valuable species is never valued.

The nonlanded fraction of these species – the ones that survive uncaught – have an obvious ecological value. If nothing else, their reproduction is the source of the catch in future years; that is, they are essential to the creation of future recreational and commercial values. A catch rate of 100%, if it occurs, can only occur once. The available data do not allow calculation of the present value of future reproduction of nonlanded fish; the calculation would be complex and would likely vary by species. It seems reasonable to assume that nonlanded fish have a value that is significantly greater than zero, but not more than the value of the landed (caught) fish of the same species. I have conservatively assumed that nonlanded fish have a value equal to 0.25 times the value of landed fish of the same species. That is, I have created a new category of inferred recreational and commercial value in the case studies, as follows:

Value of nonlanded recreational = and commercial fish	(Value of landed recreational and commercial fish) x (nonlanded fraction / landed fraction) x 0.25

To calculate the effects of these adjustments, it was first necessary to construct a spreadsheet system that reproduces EPA's estimates. This spreadsheet reproduces in detail the benefit categories for each of the EBA case studies, extrapolates to best estimates of national baseline losses using the relationships described in the EBA, and then adjusts for the percentage reduction in losses achieved by each EBA policy option. <FN 5> My spreadsheet calculates national baseline losses, and benefits of each policy option, replicating EPA's values when using EPA's assumptions.

I then recalculated the spreadsheet three times: in Scenario A, keeping all EPA assumptions and input data, except assuming that non-use value is 2 times recreational, commercial and forage value; in Scenario B, restoring EPA's non-use assumption but assuming that nonlanded recreational and commercial fish are valued according to the above equation; and in Scenario C, combining my two assumptions. The results, as shown in Table 1 (next page), are:

-Estimated benefits of each policy option are more than doubled in Scenario A, relative to the estimates in the EBA;
-Estimated benefits of each policy option are roughly doubled in Scenario B; and
-In Scenario C, combining my two adjustments, benefits of policy options are roughly 4-6 times the estimates in the EBA.

When compared to the costs of the policy options, as reported in the EBA, my three scenarios of course have much greater net social benefits. The order of policy options, ranked according to net social benefits, is changed: Option 5 – the dry cooling option – has the greatest net benefit in all three scenarios, as shown in Table 2. In Scenario C, combining the two adjustments, EPA's proposed option, i.e. EBA Option 3, is the one that fares worst. Options 1, 2, 3a, and 4 all have net benefits of $4.1 – $4.5 billion in Scenario C.

Because my rough estimates of these two changes have such a large effect on the outcome of the analysis, I recommend that EPA explore both issues in greater detail. Specifically,

1. EPA should develop approaches to non-use value more consistent with the recent economic literature, to replace the outmoded "50% rule" used in the EBA; and

2. EPA should develop plausible values for the nonlanded fraction of I&E fish mortality. The one thing we know for certain is that the current estimate of zero is not the correct value.

An enormous amount is at stake here: my two adjustments show that all options have large net benefits, and that EPA's incomplete valuation of benefits misleadingly favors the option that has the lowest net benefits on a corrected basis. Thus it is important that EPA explore these corrections in detail.

[see hard copy for tables]

Footnotes

4 Data on the landed fraction of commercially and recreationally valuable species can be found in the EBA for every case study except Ohio. EPA's answers to Riverkeeper questions, received very late in the process of my analysis, imply a landed fraction of about 1-2% for Ohio; this appeared remarkably out of line with other case studies. My calculations conservatively assume a landed fraction of 10% for the Ohio case study. Use of EPA's Ohio data would lead to higher estimates of benefits in my Scenarios B and C in Table 1, below.

5 An additional stage of adjustments would have been necessary to convert to the policy options as presented in the Federal Register. EPA's explanation of these adjustments, in response to my questions, was received late in the process of my analysis. Therefore I did not develop calculations to match the Federal Register categories. In several of the key cases, EPA's estimates of Federal Register options benefits are about 95% of corresponding EBA benefits, suggesting that my conclusions apply almost equally to Federal Register options. The difference between Federal Register and EBA benefits includes both the distinction between estimates for 539 vs. 550 plants, and differences in the treatment of taxes.

EPA Response

EPA agrees that ecosystems provide many difficult-to-value services and that assigning zero values to this services would misstate society's values. As stated in the NODA (Federal Register: 68 FR 13522-13587), the rule-of-thumb approach to estimating non-use is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. Instead, the Agency explored various alternatives to quantifying and monetizing non-use benefit (e.g., meta-analysis), including benefits from non-landed fish. However, given the unavoidable uncertainties in estimating non-use benefits for this rule, the Agency presented only a qualitative assessment of the non-use benefits of the environmental protections at issue in the final 316(b) benefit cost analysis. For EPA's response to comments that the Agency's benefit estimates are incomplete, please see response to comment #316bEFR.206.047.

For EPA's response to comments on non-landed fraction of commercial and recreational fish see comment # 316bEFR.336.009.

Benefit Estimation Methodology

General comments on Dr. Stavins' arguments

Dr. Stavins argues repeatedly that EPA's benefits analysis violates the canons of approved economic theory. As he says on page 1, "some of the methodologies employed are neither recommended nor endorsed by EPA's own Guidelines for Preparing Economic Analysis…" This is the first of at least 16 mentions of the Guidelines in his 43 pages of comments; it is by far his most frequent source, repeatedly cited as the final, definitive source on allowable methods.

However, when the Guidelines were first approved, Dr. Stavins had a more flexible view of the document. The Guidelines were reviewed by EPA's Science Advisory Board – Environmental Economics Advisory Committee (EEAC), chaired by Dr. Stavins. The EEAC review of the Guidelines said, in its Executive Summary,

Economics, like any scholarly discipline, is constantly changing. Environmental economics, a relatively young branch of the discipline, has experienced particularly rapid growth. New areas of the literature continue to emerge, and existing areas change and expand. Hence, despite the Committee's generally positive assessment of the revised Guidelines, we urge EPA to carry out new reviews every two to three years. <FN 6>

The cover letter signed by Dr. Stavins, transmitting the EEAC review of the Guidelines to Carol Browner, the EPA Administrator at the time, likewise said,

The best analytical tools of environmental economics are constantly changing, as experience with applications of existing tools and as new theoretical and empirical techniques appear in the scholarly literature. As a result, it is important that EPA carry out new reviews of the Guidelines every two to three years to reflect these developments in environmental economics. <FN 7>

Although the Guidelines were officially published in September 2000, the EEAC review occurred in 1998-99; the cover letter to Carol Browner is dated September 30, 1999. Thus it is now three years later, the time at which, according to the EEAC – and the Dr. Stavins of 1999 – a new review of the Guidelines would be called for. Dr. Stavins got it right the first time, in 1999: environmental economics is a fast-changing field, and it is important to take a fresh look at it, rather than being bound by scriptural references to a report from some years ago.

Looking more generally at the world of environmental economics and policy analysis, the choice of techniques for valuation of benefits, and the application of cost-benefit analysis to legal and regulatory issues, remain the subjects of active debate. Recent special issues of the Journal of Legal Studies and the University of Pennsylvania Law Review have highlighted the ongoing differences of perspective on these issues among legal scholars and economists. <FN 8>

The economics profession as a whole is exhibiting an increasing interest in alternative perspectives that question the conventional textbook wisdom. Two of the last four Nobel Prizes in economics have gone to scholars who are famous for their unorthodox views. Amartya Sen, the 1998 Nobel laureate, has raised fundamental questions about the nature of social choice, ethics, and equity in economics, including recent comments on cost-benefit analysis that I will discuss in section 6 below. The 2001 prize went to Joseph Stiglitz, George Akerlof, and Michael Spence, economists who have analyzed the problems of imperfect and asymmetric information – problems that require fundamental rethinking of the optimality of markets, and create a strong case for the benefits of regulation.

Several "heterodox" schools of economics have emerged in recent years, raising questions and developing methodologies that go beyond the conventional limits of economic theory. Ecological economics is one of the fastest-growing new perspectives, represented by the International Society for Ecological Economics and the journal Ecological Economics. Alternative approaches to ecosystem valuation, and studies of the role of "natural capital," are frequent topics that have received insightful analysis by ecological economists, with direct relevance to the issues raised in the current rulemaking procedure.

In short, it is increasingly inaccurate to say that there is a single, narrowly defined approach to economic theory, environmental economics, or the evaluation of ecological benefits. If EPA's past guidelines for economic analysis were as rigidly defined as Dr. Stavins now suggests, perhaps EPA should begin the next review of those guidelines with a broader representation of the full range of contemporary views on environmental economics. As Dr. Stavins anticipated in 1999, it is now time for a fresh look at the progress of the field.

7 Letter to Carol Browner from Joan Daisey and Robert Stavins, September 30, 1999, included in Appendix A of the Guidelines.

8 Journal of Legal Studies 29 no. 2, part 2, June 2000, and University of Pennsylvania Law Review 150 no. 5, May 2002, are both devoted to discussion of cost-benefit analysis. For my own views on the discussion see Frank Ackerman and Lisa Heinzerling, "Pricing the Priceless: Cost-Benefit Analysis of Environmental Protection," University of Pennsylvania Law Review 150 no. 5, 1553-1584.

EPA Response

Dr. Ackerman's main point is that EPA's Guidelines for Preparing Economic Analyses (DCN #6-1931) are in need of review, which is an issue that cannot be directly addressed in the 316(b) benefits analysis. The Agency, in preparing the 316(b) benefits analysis, interpreted the guidelines to be a general approach that "do not provide a rigid blueprint or a 'cook-book' for all policy assessments ... [and that t]he most productive and illuminating approaches for particular situations will depend on a variety of case-specific factors and will require professional judgment to apply." Id. at p. 2. The Guidelines also recognize that the choices made on how to approach the economic analysis issues in a given situation will necessarily be influenced by factors such as the nature of the issues present, the relevant statutory requirements, the availability of data, the cost and time needed to obtain data, and the need for expedition in taking regulatory actions. Id. at pp. 3, 5 (n. 2), 59, 64.

Therefore, EPA's Guidelines for Preparing Economic Analysis are not legally binding and, in fact, allow EPA to use the most up to date, state-of-the-art approaches to benefit estimation, if applicable.

Valuing Forage Species (incl non-use and non-landed)

Survey of non-use values and updated estimates of their magnitudes

EPA's approach to non-use values is one of the least defensible aspects of the EBA. Environmental economics increasingly recognizes the importance of non-use values: people place a substantial value on the mere existence of animals, ecosystems, wildernesses, and unique natural locations, quite apart from any past, present, or planned future use of those aspects of nature. It is frequently the case that existence values dwarf use values: in the Exxon Valdez oil spill, a court awarded compensatory damages – compensating for lost use values – of less than $300 million to those who lived and worked near Prince William Sound; economists using contingent valuation techniques estimated the existence value of the pristine environment of Prince William Sound at $9 billion, or 30 times use value.

The ratio of non-use value to use value is important here, because EPA uses an unfounded hypothesis about this ratio to estimate non-use value. Based on just a few, very dated citations, EPA suggests that non-use value can be estimated as 50% of the recreational component of use value. EPA notes that this is intended only as an estimate of non-use value to recreational users; there is no reason, however, to restrict the calculation of non-use value to this subset of the population. Here I am happy to agree with Dr. Stavins when he contends that the 50% rule is entirely inappropriate, since it fails to address any of the more recent literature on the subject. We differ, however, on the appropriate alternative.

A 1993 literature review by Thomas Brown – significantly newer and more comprehensive than the sources for the 50% rule – examines 31 contingent valuation studies published since 1980 that have estimated non-use values. <FN 9> Some of these studies contained multiple estimates, leading to 34 comparisons of non-use to use value for the same environmental benefit. The median ratio of non-use to use value was 1.92. After a thoughtful review of the varied methods used in the studies, Brown identifies 22 comparisons that appear to be more reliable than the others; these higher-quality comparisons have a median ratio of 2.56. It is on the basis of this study that I adopted the ratio of non-use to use value of 2 for the purpose of my recalculations presented in Tables 1 and 2 above. The Brown study contains a wealth of information about the effects of different methods of estimation on non-use value, and its relationship to use value, beyond the median ratio that I have used. I recommend that EPA explore additional uses of Brown's analysis, in devising more appropriate estimates of non-use value for the case studies.

Revised assumptions about non-use value have a large effect on net benefits. As shown in Table 1, moving from EBA estimates to my Scenario A, introducing the higher non-use value alone, adds $1 – 2 billion to the benefits of the various policy options. Billion-dollar existence values, and more, for nationwide benefits are relatively common in the environmental economics literature. <FN 10> Studies have repeatedly found very large non-use values; these values are best understood as a quantitative expression of widespread public concern about environmental resources – even in the absence of personal use.

One of the studies cited by Brown found a nationwide non-user willingness to pay of $111 per household for improving water quality in all U.S. rivers and lakes to a fishable level – implying a nationwide total value of more than $11 billion in 1981 dollars, or closer to $20 billion in today's dollars. <FN 11>   This remarkable figure emphasizes the great importance that people place on water quality, putting the benefit estimates for the current case in a broader perspective. Dr. Stavins' casual and undocumented suggestion that non-use values might be close to zero for this case appears to be quite at odds with the evidence of substantial non-user willingness to pay for improved water quality.

Other studies routinely find vast existence values for endangered species, for clean air in national parks, and other environmental resources and amenities. The surprising value, the figure that is out of line with the recent literature, is the very low estimate of non-use value found in the EBA. Revising this value up to a level more consistent with the literature, as shown in my Scenarios A and C, causes a fundamental change in the evaluation of the policy options considered by EPA.

Carson, "An Experiment in Determining Willingness to Pay for National Water Quality Improvements," preliminary draft of a report to EPA, Resources for the Future, 1981, as cited in Brown, supra note 9. My calculations in the text reflect the facts that there are more than 100 million households in the U.S. today, and average prices, as measured by the Consumer Price Index, have almost doubled since 1981.

EPA Response

EPA agrees that non-use benefits can be substantial and that the use of Brown's analysis would substantially increase the benefits estimates based on the rule-of-thumb approach. However, in the cost-benefit analyses for the NODA and for the final Section 316(b) Phase II rule, EPA did not use the rule-of-thumb approach to estimate non-use benefits.

For EPA's response to comments on the use of the 50% rule-of-thumb to estimate non-use benefits, please refer to EPA's response to comment #316bEFR.005.034.

Please also refer to EPA's response to comments on the HRC methods (316bEFR.005.035) and the SRP methods (316bEFR.005.006); the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003); and to EPA's Guidelines for Preparing Economic Analyses (EPA 240-R-00-003).

Use of Replacement Costs (HRC and hatchery-based)

Rationale for use of habitat replacement cost

In several of the case studies, the EBA uses calculations of habitat-based replacement cost (HRC) to value the damages due to impingement and entrainment. The rationale for this method is straightforward, although different from other approaches to valuation. Natural ecosystems produce numerous interrelated benefits, some of which are hard to quantify (see the lists of omitted benefit categories in section 2 above). Even if they all could be quantified, separate valuation of the entire list of ecosystem services is an impractical task. A simpler approach is to calculate the replacement cost of the ecosystem that provided the array of services.

Restoration cost is used as a measure of damages under CERCLA for Superfund sites, under the National Marine Sanctuaries Act, and under the oil spill provisions of the Clean Water Act. Use of restoration costs was explicitly upheld in the landmark Ohio vs. Interior court decision of 1989. I recommend that EPA revise and expand the EBA Case Studies Chapter A11, explaining and supporting HRC calculations, discussing the theoretical basis for HRC, and identifying categories of ecosystem value that are not measured by any other techniques.

Dr. Stavins finds HRC to be even more objectionable than other aspects of the EBA, describing it as “completely illegitimate” and “fatally flawed.” Yet again, we have only his word to go on, with little in the way of documentation. My reading of the literature is quite different; it appears to me that standard texts on environmental economics are not filled with warnings against the dire perils of the avoided cost method of benefits estimation.

Indeed, valuation of assets at replacement cost is a common practice in economics. In macroeconomics, depreciation is routinely valued at replacement cost; the difference between historical book value and market value (market value is current replacement cost, for a marketed asset) is essential in understanding investments. Any detailed analysis of capital costs focuses on “economic depreciation”, or the replacement cost of the capital that is consumed, and distinguishes it from accounting measures of depreciation based on book value or tax laws. <FN 12>

Insurance companies frequently value damages to property at estimated replacement cost. If any of us should experience a loss, our home insurance provider might pay us on the basis of “household replacement cost” – unless we have explained to them that the calculation is fatally flawed and insisted on using a much lower value, as Dr. Stavins proposes to do for ecosystems.

Another important disagreement lurks behind these comments. Are the natural resources that are affected by cooling water intake best thought of as long-lived capital goods – or are they more like consumer goods that people, or power plants, might choose to consume when they are hungry? If you eat the last cookie and then throw out the box, you may not have to pay the full “cookie replacement cost.” Perhaps you are getting tired of cookies and don’t plan to buy any more, so there is no need to worry about replacement cost. Something along these lines seems to be involved in the claim that

HRC overstates the value of environmental resources: if we are planning to consume the ecosystem without replacement, then HRC might overestimate the values at stake.

A cookie box is not an appropriate analogy for the environmental resources protected by the Clean Water Act. Rather, the aquatic ecosystems under discussion in this case are long-lived assets, comparable to capital goods, which provide a wide range of valuable services. Society values and plans to keep these assets for the long run, and expects to receive their services year after year. The view of nature as "natural capital" is one of the foundations of ecological economics; but more conventional environmental economists have also argued that natural resources should be analyzed as assets, i.e. comparable to capital rather than consumer goods. <FN 13>

HRC often looks more expensive than conventional approaches to valuation, as Dr. Stavins emphasizes. But this may simply reflect the incompleteness of conventional valuation, as discussed in section 2 above. Ecosystems provide numerous services simultaneously, using the same "capital equipment" to produce multiple benefits. Many of these benefits are not normally evaluated, but should be. As the list of separately evaluated benefits grows longer, the total benefit will of course increase. If we were able to achieve complete evaluation of ecosystem benefits, assuming that each benefit had to be produced and evaluated separately, we might well find that the totals exceeded HRC estimates. Nature has evolved efficient and parsimonious ways of producing many ecosystem services from limited resources; it would be surprising if artificial substitutes were routinely cheaper.

Although HRC is the only valuation method that even comes close to capturing the full range of ecosystem services, it, too, has shortcomings. In practical terms, it appears difficult and expensive to perform adequate HRC calculations; even more than with other valuation techniques, time and budget constraints may often limit the applications of HRC. Speaking more theoretically, HRC may at times be inappropriate because some ecosystems and natural services are not replaceable. If environmental damages involve risks of extinction of species, destruction of unique resources, or even disruption that allows unwanted invasive species to occupy vacated ecological niches, there may be no way to undo what has been done. Calculation of habitat replacement costs for regulatory purposes have often involved cost estimates for generic wetland restoration, an approach that captures only some of the ecosystem services that are at risk.

Despite these limitations, HRC remains a valuable contribution to the process of valuation whenever it can be used. I recommend that EPA explore HRC valuation of additional sites, to broaden the data and analysis used in the estimates of benefits in this case.

Revealed preference

Problems of social choice and the use of societal revealed preference

To value the effects of cooling water intake on threatened and endangered species, EPA employs an innovative method described as "societal revealed preference" in the case study of the San Francisco Bay estuary plants. Essentially, the method assigns values based on the amounts that society has been willing to pay for protection of similar threatened and endangered species in other contexts. Economists have frequently deduced individual "revealed preference" for environmental amenities from individual behavior in other markets; here EPA simply extends the same reasoning to social behavior and social choices. Dr. Stavins again displays his hostility to theoretical innovation, describing this procedure as having "no foundation whatsoever in economic theory"; it is in his view "totally invalid… a complete corruption of the notion of a revealed-preference method… a complete sham…"

The revealed preference procedure employed by EPA would be entirely orthodox and familiar, even qualifying for endorsement by Dr. Stavins and the Guidelines for Preparing Economic Analyses, if it referred to individual rather than social choice. Thus the question at issue can be restated: is it totally invalid and a complete sham to consider issues of social choice, separately from individual choice? Both economic theory and political reality show that there is an irreducible, independent role for social choice.

In economic theory, Kenneth Arrow's impossibility theorem proved long ago that there is no universal "social welfare function" – that is, no mathematical function of individual choices always produces meaningful social choices. <FN 14> Questions of public goods and public choice continue to challenge the standard model of individual choice; as textbooks often point out, there is no such thing as an individual demand curve for national defense. (Nor are there cost-benefit analyses to determine how much defense spending is "efficient" based on individual revealed preferences.) Any attempt to convert defense spending to a matter of individual purchases or private willingness to pay would be overwhelmed by the "free rider" problem: why pay for your individual share of defense, since your neighbors' contributions will defend you as much as them?

Exactly analogous questions arise in environmental economics. Nobel laureate Amartya Sen, in recent comments on cost-benefit analysis, points out that individual willingness to pay for major environmental initiatives is not always meaningful: if the amount you would contribute to cleaning up an Exxon Valdez-sized oil spill does not depend on whether anyone else contributes anything, then you have not understood the nature of the problem. On the other hand, if the question is how much would you contribute if everyone else contributes the same amount, we are no longer discussing individual willingness to pay. As Sen puts it:

The very idea that I treat the prevention of an environmental damage just like buying a private good is itself quite absurd. The amount I am ready to pay for my toothpaste is typically not affected by the amount you pay for yours. But it would be amazing if the payment I am ready to make to save nature is totally independent of what others are ready to pay for it, since it is specifically a social concern. <FN 15>

Dr. Stavins drifts out of economic theory and into political debate when he argues against societal revealed preference on the grounds that preferences must be "revealed by those individuals who are doing the paying, not by the judgment of others (in this case, legislatures, executive departments and agencies, and/or courts)." (Stavins comments, p. 27) Denouncing the supposed arbitrariness and unrepresentativeness of all government actions has become unfortunately fashionable; but in this case it is necessary to look beyond the rhetoric. Who exactly is paying for the actions of legislatures, executive agencies, and courts? Ultimately, the answer can only be the taxpayers, ratepayers (consumers), and shareholders – that is, society.

Do people feel that the decisions about environmental protection, made on their behalf by their elected representatives, are hopelessly inefficient and expensive? Is there a groundswell of popular demand to save money by eliminating the Clean Air Act, the Clean Water Act, protection for endangered species, and all the rest? Of course not. On the contrary, many successful politicians have figured out that people strongly prefer environmental protection, and are willing to have their money spent to back up that preference. That's how democracy is supposed to work, with or without the blessing of conventional economic doctrine. Social choice is alive and well in environmental policy, and cannot always be deduced from isolated individual behavior. Dr. Stavins is able to "prove" that individual preferences are necessarily more legitimate than social preferences only by assuming that answer to begin with.

There is one more piece to the case against inferring social values from past regulation, as seen in the "societal revealed preference" approach; this final argument is implicit rather than explicit in Dr. Stavins' comments. It is often said that past regulations, adopted without the benefit of careful economic analysis, have been disastrously expensive. Long lists of regulations, purporting to show wildly differing costs per life saved, are frequently cited as evidence of the need for cost-benefit analysis, rather than reliance on regulatory precedent. The lists, however, can almost always be traced back to just two original studies of the costs of regulation. Careful reading of those original studies reveals that they are routinely misquoted: they are studies of the costs of actual and proposed regulations, or in one case, actual, proposed, and other possible regulations that have never even been proposed by any agency. <FN 16> The ridiculously expensive regulations described in these studies are almost entirely the ones that were never adopted. In many cases, EPA and other agencies rejected the expensive proposed regulations, precisely because they were too expensive – evidence of the success, not failure, of past regulatory practice.

Since social choice cannot be reduced to individual choices, and past regulations are not nearly as expensive as is commonly believed, EPA's "societal revealed preference" method is a promising new innovation in the methods of valuation, one that deserves further development and discussion.

Footnotes

14 More precisely speaking, Arrow proved that there is in general no social welfare function that depends solely on individual preferences for relevant alternatives and avoids intransitivity, unless it is dictatorial (always agreeing with one individual no matter what others prefer).

Valuing Forage Species (incl non-use and non-landed)

Limitations of cost-benefit analysis and merits of the “best available technology” standard

To summarize briefly, I have demonstrated that EPA’s analysis of the benefits of reducing cooling water intake is incomplete, and underestimates true, complete benefits by an unknown but large amount. Just two corrections – accounting for the large “non-landed fraction” of I&E mortality of valuable species and increasing non-use values to levels more in line with the recent economics literature – add billions of dollars to the benefits of each regulatory option. These adjustments show that EPA’s proposed option does not maximize net social benefits. Dr. Stavins is not persuasive in his arguments for banning innovation in economics and lowering benefit estimates throughout the analysis. Two of the innovations adopted by EPA in this case, habitat-based replacement cost (HRC) and societal revealed preference, are useful contributions to the fast-changing field of environmental economics, and deserve to be analyzed in depth and applied more widely.

EPA Response

EPA agrees that focusing exclusively on direct use benefits from commercial and recreational fisheries will lead to an underestimate of total benefits from reduced I&E. The omission of nonuse values and other benefits associated with the relatively large unlanded fraction of I&E-impacted fish could also contribute to a significant underestimate of total benefits. Please see response to comment 316bEFR336.009 regarding a more in-depth discussion of the unlanded fraction and related valuation issues, and response to comment 316bEFR.005.029 for additional discussion of the limits and merits of the HRC approach.

Use cost-benefit tests

It is clear that there is no consensus on these issues. One of the few things that Dr. Stavins and I agree on is that EPA's published benefit estimates are an insufficient basis on which to make a decision in this case. The plain truth of the matter is that cost-benefit analysis has failed in its fundamental political ambition. Rather than providing an objective, transparent standard for cost-effective decision-making, cost-benefit analysis has become a partisan battleground where opposing parties fight over rival technical hypotheses about environmental valuation.

Fortunately, cost-benefit analysis is not required in this case. There is no reason to base the regulation of cooling water intake on an analysis that is neither required by law, nor close to complete representation of benefits, nor successful in achieving objectivity and transparency. My Scenario C (refer to Tables 1 and 2 above), combining my two revised estimates, makes it clear that every policy option under consideration has substantial net social benefits. Any choice of the "best available technology" from among these options will bring social benefits greater than its costs; options that achieve the greatest reduction in cooling water intake generally appear to have the greatest benefits.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Subject Matter Code 10.02.06.01

Stated preference (Contingent Valuation)

In the end, only one question of "willingness to pay" matters for the politics of regulatory policy. It is a much broader, less technical question than the ones raised in the EBA. Any regulation will impose some costs; power plant operators will undoubtedly pass those costs on to their customers. So the question that ultimately matters is, are ratepayers willing to pay the increased costs imposed by regulation? <FN 17> As Synapse Energy Economics has estimated in their comments on this rule, if all costs were passed on to the consumer, an all cooling tower rule would cost each ratepayer 28 cents per month on their electric bills. If the public was asked, "Are you willing to pay 28 cents more per month on your electric bill to avoid massive fish mortality and other underwater environmental damages caused by power plants?", I feel confident the answer would be "yes." And if people are willing to pay the costs of environmental protection, there is no way for experts to prove that they are wrong.

Footnotes

17 One could also examine the impact on the plant owners. EPA did in fact discuss comparison of the costs of the rule to the revenues of the affected companies. But Dr. Stavins, commenting on behalf of PG&E, says, "The comparison [of regulatory costs to company revenues] is utterly irrelevant!… Although such a socially efficient technology [one endorsed by Dr. Stavins' analysis] maximizes net benefits to society, it may yield higher costs than benefits to an affected company." (Stavins comments, pp. 11, 12)

EPA Response

EPA agrees that ultimately, the benefit-cost question is an empirical one of whether or not consumers are indeed willing to pay for the environmental improvement associated with the 316b rule. Unfortunately, without primary data collection through a stated preference survey, no one can effectively argue this point one way or the other; only the data would tell. Please see response to comment 316bEFR.306.105.

Please also refer to Chapter B2 of the EBA, section B2-2 on costs per household (DCN #6-0002).

Definition: Waters of the U.S.

Cooling Ponds and Reservoirs Designed and Constructed for Closed-Cycle Cooling Achieve the Requirements of Any Final Rule.

In identifying all cooling ponds as reasonably within the scope of § 316(b) EPA has neglected to consider unique circumstances associated with the design, operation, and ecosystems of cooling water ponds and reservoirs constructed for the purpose of providing closed-cycle cooling for electric generation. This is particularly important as those circumstances are related to ponds and reservoirs which were constructed in areas where, prior to the construction of the generation facility no "water of the United States" was present.

PNW facilities, which are located in the southwestern United States, have been designed to meet the challenges associated with the limited availability of surface waters that can be used for industrial purposes. All of PNW's facilities have been designed to implement closed-cycle, recirculating cooling systems; some of these designs include closed-cycle recirculating cooling water reservoirs. In all cases make-up water used to maintain these systems represents a very small fraction of the water required for plant operations.

The Four Corners Power Plant obtains make-up water for the cooling reservoir from the San Juan River in northwest New Mexico. The facility is a five unit, coal-fired facility with a generation capacity of approximately 2,000 megawatts. A small (less than 50 million gallon per day (mgd)) intake structure pumps make-up water uphill a distance of over three miles to the facility's cooling water reservoir. Intake structures for condenser cooling are located within the reservoir. Discharges from the reservoir represent a very small fraction of the intake water, and at times, discharges are not required. The cooling reservoir at this facility was not constructed in a water of the United States. EPA's rule should recognize that a facility of this size, which withdraws less than 50 mgd from a "water of the United States," has already been designed to minimize impacts on the aquatic environment, and that at such a facility the cooling reservoir is a recirculating closed-cycle cooling system, EPA's preferred alternative.

The Cholla Power Plant, a four unit, 950 megawatt coal-fire facility, operates a closed-cycle recirculating cooling water reservoir. The reservoir was constructed in an upland area previously used for dry land farming, and was not within a "water of the United States." The reservoir was filled and continues to receive make-up water exclusively from a large, deep groundwater well field owned and operated by the facility. Therefore, the reservoir is a groundwater surface impoundment and the present aquatic ecosystem entirely contrived, see Comment 3. The facility maintains a National Discharge Elimination System (NPDES) permit only as a result of recreational opportunities that have resulted from the development of the contrived ecosystem.

Further, management of both waterbodies by permitting recreational access provides a community benefit not otherwise available in the arid southwest. In the absence of sport fish stocking programs and recreational access, these reservoirs would likely not be required to maintain a NPDES permit, because under operating conditions more typical of the United States, these reservoirs would be defined as cooling “ponds” and be expressly “wastewater treatment systems” and not “waters of the United States.”

The proposed rule suggests that EPA has concluded that § 316(b) must be applied to all “waters of the United States” under EPA’s current definition. With this conclusion EPA has neglected to note that hydraulically isolated cooling water ponds and reservoirs do not need additional intake technology, because by design they already “minimize environmental impact” and meet EPA’s described preferred alternative for recirculating, closed-cycle cooling. Additionally, the proposed rule neglects the fact that some “waters of the United States” are impoundments of groundwater. EPA must recognize that § 316(b) was not intended to apply to groundwater impoundments.

EPA Response

Author Name Scott Davis
Organization Pinnacle West Capital Corp

Subject Matter Code 3.03
Definition: Waters of the U.S.

Because A Cooling Pond Or Reservoir Is Part Of A Plant's Treatment System, The Make-Up Water Intake Point Should Be Considered The Jurisdictional Intake For Purposes Of § 316(B).

Many cooling water ponds and reservoirs, such as at the Four Corners Plant, utilize intake structures on "waters of the United States" as the source of make-up water for reservoir level and chemistry maintenance. Therefore, these facilities are required to operate and maintain "in-take" structures on two separate water bodies to operate the same facility.

Based on our review of the economic development documents presented in EPA's docket for this rule package, EPA has not considered the economic impacts on facilities that would be required to implement § 316(b) controls at two waterbodies.

Because cooling water ponds and reservoirs have been designed expressly to supply cooling water as closed-cycle recirculating cooling water systems and to minimize adverse environmental impact, only the make-up water intake point should be considered the jurisdictional intake for the purposes of § 316(b).

EPA Response

See response to 316bEFR.006.001. The comment is correct that in development of this rule EPA generally assessed the cost of implementing 316(b) requirements for one source waterbody per cooling water intake. However, the jurisdictional intake point for purposes of section 316(b) depends on where the facility uses a cooling water intake structure to withdraw water from waters of the U.S. As indicated in the referenced response, this determination will be made on a case-by-case basis.

Definition: Waters of the U.S.

The Rule Should Recognize That Ecosystems In Constructed Cooling Water Ponds And Reservoirs Are Contrived.

Many cooling water ponds and reservoirs, such as the ones used by PNW, were constructed specifically to support the operation of power plants. Often these ponds and reservoirs are constructed in areas where aquatic ecosystems were not previously present. The designs recognize the important role that recirculating cooling systems serve in conserving water when compared to other types of plant cooling systems, including cooling towers.

With no natural "lake" flora or fauna, these reservoirs support a combination of introduced and adaptive species. The fisheries of the publicly accessible reservoirs are usually stocked and managed by parks and wildlife agencies, such as the Arizona Game and Fish Department in Arizona, to support sport fishing. The usual fish stocking regimes include predator species, strains and hybrids (largemouth bass, catfish, crappie, etc.) and prey species and hybrids (sunfish, minors, shad, etc.). Most of the stocked sport fish species must be restocked because of fishing pressure and low naturalization.

With little natural seed bank and no managed vegetation stocking programs, the aquatic flora develops slowly and can result in unbalanced and/or low diversity plant communities. Many of these reservoirs become increasingly impacted by nuisance plants and these nuisance plants often have a negative effect on the fisheries by altering the available nesting/spawning areas, influencing recruitment of certain species, and decreasing the depth of light penetration and the associated swings in dissolved oxygen concentrations.

In areas where PNW operates, climate also has a major impact on reservoir water quality and fisheries. Prolonged droughts and daily high ambient temperatures of over 100˚F for extended periods often result in dramatic increases in water temperature and drops in reservoir volume. This impacts fisheries by reducing or eliminating quality habitat, reducing recruitment, altering nesting locations and patterns, and eliminating available habitat.

From the above description, it is easy to see that such reservoirs represent a contrived ecosystem. The fisheries are created, modified, and managed for a variety of human needs, with little natural material or conditions to build from. These reservoirs are also subject to wide swings in fishery populations, distribution, and makeup because of their comparatively simple ecosystems. As important as recreation and sport fishing have become on these types of reservoirs, the parks and wildlife agencies where PNW operates have never identified impingement as an impact of concern on the fisheries of power plant cooling water pond and reservoirs. Further, EPA's concepts of "baseline studies" and "compliance monitoring" are difficult is not impossible to implement in reservoirs and ponds where the ecosystems are so unnatural and inherently unstable.

EPA Response

See response to 316bEFR.006.001. See also 316bEFR.025.018. In addition, the requirements and implementation provisions of the final rule, in combination with existing relevant NPDES program regulations, provide permit writers with sufficient flexibility to consider and accommodate the specific characteristics of cooling water source waterbodies as appropriate. With regard to "baseline studies," EPA notes that the Comprehensive Demonstration Study is not required under every compliance alternative, and its components are applied only as appropriate under each alternative. Moreover, the point of these efforts to characterize the waterbody and any impacts to the waterbody is to understand the specific waterbody and environmental impacts, including any unique or unusual factors. Under the NPDES program regulations, Directors have reasonable discretion to apply these requirements as appropriate to achieve regulatory requirements and program objectives. Thus, EPA does not agree that such studies would be difficult or impossible to conduct. Nor does EPA agree that compliance monitoring would be difficult or impossible. Compliance monitoring under the rule also is dependent on the compliance alternative selected, and also allows the applicant to propose and the Director to determine the specific aspects of such monitoring. Thus, this too can easily accommodate application to unique waterbodies. The rule also allows compliance in certain circumstances under a Technology Installation and Operation Plan, which focuses on installation and proper operation of appropriate technologies.

Performance standards

Determination Of Impingement Mortality Cannot Be Applied To All Impingeable Species In The Waterbody.

In determining whether a technology will reduce impingement mortality by 80-95%, the analysis cannot be applied to all impingeable species in the waterbody. Any reduction standard or threshold should be applied to certain species that are impingeable and representative of species in the waterbody that need to be protected. In previous arguments presented by the Utility Water Act Group (UWAG) these species have been referred to as "Representative Indicator Species" (RIS). EPA must recognize that it is simply not feasible to design an intake technology that will ensure protection of every impingeable species.

Moreover, fisheries experts agree that not all species are of equal value, both from the perspective of ecosystem stability and from the perspective of fisheries management. The loss of some species will not harm the aquatic community. Impingement of forage species, for example, may be far less important than the impingement of commercial or recreational species.

EPA Response

EPA agrees with the commenter that, in most circumstances, it is not feasible to implement a deploy a design and construction technology that will be equally protective of all species present in the waterbody. EPA disagrees, however, that forage species may be far less important than commercial or recreational species. EPA does recognize that forage species are often present in larger numbers than commercial or recreational species, but also acknowledges that forage species are an integral part of any aquatic ecosystem and cannot be dismissed out of hand as unimportant.

Please see response to comment 063.005 for a discussion of the methods of determining compliance with today's rule, as well as the preamble.

Subject Matter Code 6.08

Non-aquatic impacts

Author Name Scott Davis

Organization Pinnacle West Capital Corp

Exotic species, especially nuisance species, may not be valuable to a waterbody at all. Based on experiences at various PNW facilities, some fisheries managers taught the benefits of CWIS in managing the populations of some nuisance species.

Exotic species that are regarded as a “nuisance” should be given special consideration in the § 316(b) decisions. Certain exotic species, such as common carp, shad, or Asiatic clam are viewed as nuisance species by natural resource managers for some waters. In such cases, entrainment should not be regarded as a problem. Further, given state fishery resource managers’ often extensive efforts to get ride of these species and EPA’s own expressed concerns about their effects, cropping by CWISs should not be considered an “Adverse Environmental Impact” (“AEI”), as discussed in the proposed rule.

EPA Response

Today's rule presents five compliance options. These are discussed in the preamble to the final rule. In addition, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see EPA’s response to comment 316bEFR.063.005. How to account for nuisance species can be considered in the context of these provisions, all of which are subject to decisions by the Director.

Special definitions

The Seven-Day Retention Time In The Definition Of "Lake Or Reservoir" Is Not Appropriate for Application To Constructed Water Bodies.

In EPA's proposed definition of "lake or reservoir" the water body is required to have a hydraulic retention time of seven days to be considered a lake or reservoir. Water bodies with shorter hydraulic retention times are otherwise defaulted to be defined as rivers. This "more than seven days" cutoff may not be appropriate. EPA does not provide a technical basis for this argument in the proposed rule or in the technical support and development documents. Further, EPA is not clear how the retention time is to be calculated, and the definition does not distinguish between inflows from make-up water sources, return flows from recirculating cooling water systems, evaporation, and infiltration. Therefore, in the arid southwest, where overland outflows are very small or absent, and evaporation/infiltration rates are high, hydraulic retention times could be inappropriately described as shorter than the prerequisite seven days to be defined a reservoir.

Therefore, it could be interpreted that EPA intends inflows and outflows generated by a recirculating cooling water system to be considered when calculating hydraulic retention time. Under those circumstances, many hydraulically isolated waterbodies designed as closed-cycle cooling water ponds and reservoirs would incorrectly be defined as rivers under the proposed rule. EPA should clarify that only surface water inflows from and outflows to a "water of the United States" should be used in the calculation of hydraulic retention time.

EPA Response

For the purpose of today's rule, EPA has defined a freshwater river or stream as having an average hydraulic retention time of 7 days or less, and a lake or reservoir as having an average hydraulic retention time of greater than 7 days (see definitions at § 125.93). EPA's definitions of freshwater river or stream, and of lake and reservoir in the final rule are standard definitions that have been used historically to provide general guidelines for distinguishing between the waterbody types. Retention time is not a function of recycled cooling water system flows, but of natural water flows including precipitation. See EPA's response to comment 316bEFR.006.001 for more information on categorizing waterbodies in today's final rule.

Subject Matter Code 3.03

Definition: Waters of the U.S.

Author Name William E. Driscoll

Organization TXU Generation Company

TXU has worked closely with the Texas Parks and Wildlife Department (TPWD) in cooperation with their activities to monitor and manage the fisheries. For this reason, TXU reservoirs have provided a continuous and successful source of recreational fishing to the public. At no time, however, has the TPWD ever expressed a concern or identified a problem related to a possible impact of our cooling water intake structures on the fisheries, or a reservoir's biological community as a whole.

TXU is very concerned with the "one size fits all" approach found in several key components of the proposed regulations. In particular, the grouping of reservoirs and lakes is inappropriate. Furthermore, reservoirs across the country vary widely and should not be subject to national criteria. For reasons described in the attached comments, TXU believes that cooling water reservoirs should be considered as closed-cycled cooling systems and not subject to these proposed regulations.

EPA Response

See response to 316bEFR.006.001. In addition, the final rule includes five compliance alternatives, including the ability for a facility to seek a site-specific determination of best technology available and, therefore, EPA does not agree that it constitutes a "one size fits all" approach. With regard to grouping waterbody categories, EPA recognizes that the categories used in the final rule are broad and that there will be a certain level of variation within each category (e.g., due to differences in waterbody size, hydrology, location, use, and numerous other factors). Nevertheless, for purposes of this rule EPA has grouped lakes and reservoirs together, as defined in § 125.93, because these waterbodies have sufficiently similar characteristics relevant to the environmental concerns posed by cooling water intake structures and can employ similar available technologies to minimize the environmental impacts associated with these concerns. Also see response to 316bEFR015.003.

Definition: Waters of the U.S.

TXU has several serious and legitimate concerns over the “one size fits all” approach found in several key components of the proposed regulations. In particular, the grouping of reservoirs and lakes is inappropriate and appears to be based more on hydrology than biology. Since the focus of this issue is on the flora and fauna of a waterbody, biology should be the primary determinating factor.

A second related concern is the agency’s belief that all reservoirs across the country should be subject to the same criteria. Again, from a biological standpoint this concept is ill conceived. In addition to biology, many other important factors such as climate, hydrology, water quality, fisheries, and reservoir/fisheries management techniques vary widely from region to region and sometimes from state to state. In many other water related programs, the agency has acknowledged and embraced the concept of regional differences. These proposed regulations, especially in light of the tremendous scope and cost, should also acknowledge and incorporate the difference between source water bodies in different regions of the nation.

The following discussion on inland water bodies in Texas is provided to give the agency an appreciation of the uniqueness of both its reservoirs and the region. It is also provided to help illustrate and quantify many of the general and specific comments on the proposed regulations that follow the discussion.

Inland Water Bodies of Texas in General.

Of the 212+ “lakes” in Texas, only one is natural, Caddo Lake. It is located in the far eastern portion of the State, is shared with Louisiana, and was created by seismic activity about 400 years ago. All of the other "lakes" are actually manmade reservoirs constructed for single or multiple purposes to provide potable water sources, flood control, recreation (i.e. boating, swimming, skiing, sports fisheries, etc.) and/or industrial use. Many of these reservoirs were constructed specifically to support the operation of power plants, recognizing the important role that recirculating cooling systems serve in conserving water when compared to cooling tower systems.

In general, the power plant reservoirs are relatively shallow (< 30 ft average depth), with gently sloping bottoms over a wide variety of substrates. The water volumes are controlled by either mechanical tainter gates or passive overflow structures, and subject to significant annual pool level variation due to seasonal climatic conditions. Occasionally there is also some form of continuous flow-through to maintain downstream conditions; however, retention times are very long (ranging from weeks to years).

With no natural lake flora and fauna present, Texas reservoirs support a combination of introduced lacustrine and adaptive riverine species. The fisheries of the publicly accessible reservoirs are usually stocked and managed by the Parks and Wildlife Department to support sports fishing, a major recreational industry in the State. The usual fish stocking regimes include predator species, strains and hybrids (e.g. largemouth bass, catfish, crappie, etc.) and prey species/hybrids such as sunfish, minnows and shads. Over time, and at various locations, the State has also introduced striped bass, redfish, carp, and other non-native species. Most of the stocked sports fish species, however, must be re-stocked periodically because of high fishing pressure, low naturalization, and to increase genetic diversity. For example, in 1998 the Texas Parks and Wildlife Department's Inland Fisheries Division stocked over 8 million Florida-strain largemouth bass, and over 9 million fingerlings of other species.

With little natural seed bank, and no managed vegetation stocking program, the aquatic flora develops slowly and can result in unbalanced and/or low diversity plant communities. In recent years, many Texas reservoirs have become increasingly impacted by exotic nuisance plants (e.g., water hyacinth, hydrilla, giant salvinia, eurasian water milfoil, etc.). These invasive plants often have a negative effect on the fisheries by altering the available nesting/spawning areas, influencing recruitment of certain species, decreasing the depth of light penetration and the associated dissolved oxygen levels. Heavy infestations can also alter species distribution and limit recreational access.

Texas waterbodies are also under continuous threat from exotic aquatic fauna. The list of exotic fauna is long and seems to be growing each year. Apart from the expanding number of fish species, the list of exotics also includes invertebrates such as clam, mussel and snail species. Recently, a species of estuarine mud crab has been found to be reproducing in at least four different reservoirs that are several hundred miles from the coast. Each of these uninvited exotics presents new problems and future challenges to each reservoir in which they occur.

As mentioned earlier, the climate also has a major impact on Texas reservoir water quality and fisheries. Prolonged droughts, and daily high ambient temperatures of ~100 F for extended periods, often result in dramatic drops in reservoir volume. This impacts the fisheries by reducing recruitment, altering nesting locations and patterns, and eliminating available habitat. It also subjects the fisheries to additional stresses, such as higher salts concentrations, which necessarily weakens the population. It can take years for the fisheries to return to pre-existing levels following a drought episode. Then there are the floods, as experienced in July of 2002, which alter the water quality, redistribute or introduce populations, decrease survivability, and impact historical nesting areas.

Natural conditions can also combine to negatively impact the fisheries. A prime example is the recent occurrence of golden algae blooms in several Texas inland reservoirs. Golden algae (Prymnesium parvum), is a naturally occurring saltwater tolerant species. When in a "bloom" or period of rampant growth, it causes water discoloration and can be toxic to fish. The toxin released from the algae, and concentrated during a bloom, affects the gills by reducing their oxygen intake and asphyxiating the fish. The toxin appears to affect scaled fish the most. In the golden algae blooms over the past few years, estimates range from 60% to 95% mortality of the scaled fish in each reservoir. The effects of golden algae blooms appear to be lingering in some reservoirs, and the length of time needed for the fish populations to recover to previous levels is not yet known.

An additional natural factor to consider is the gradual decline of a reservoir's fisheries. Reservoirs typically experience an initial "boom" in fisheries the first years following impoundment. Following the initial boom, the fisheries generally begin to slowly decline over the years. The National Reservoir Research Program (administered by the U.S. Fish and Wildlife Service) established that this cycle is related to nutrients. As the reservoir is developed, nutrient levels are very high because of the newly inundated soils and vegetation. In subsequent years, however, the watershed is not able to sustain that same level of nutrients. As the nutrient levels decline, so do the fisheries. Since most of the cooling water reservoirs in Texas are >30 years of age, they are all essentially in the decline phase.

From this description, it is easy to see that such reservoirs represent a contrived artificial ecosystem. The fisheries are created, modified, and managed for a variety of human needs, with little initial natural material or circumstances to build from. Texas reservoirs are also subject to wide swing in fisheries populations, distribution, and makeup because of their comparatively simple ecosystem. These reservoirs do, however, provide a highly valued perennial habitat where historically there may have been only an intermittent streambed. It is very important to note that as important as sport fishing is, the Texas Parks and Wildlife Department has never identified impingement or entrainment as an impact or concern on the fisheries of these power plant reservoirs.

Most of the power plant reservoirs in the state were built specifically to support that use. Because of the high value of water in Texas, re-circulating cooling systems (which conserve water when compared to cooling tower systems), are preferred. In a practical sense these reservoir are an extension of the plant intake that was installed for multiple uses including cooling and water storage/reuse. Most serve as classic “cooling ponds” although changes in state regulations and interpretations have in time changed their designation to “waters of the State”.

As artificial systems, it makes little practical sense to consider such reservoirs in the same manner as the other waterbodies in EPA’s proposal. Other than the generic term “reservoir”, Texas waterbodies share few characteristics with those on the Ohio River (cited by the Agency as the case study for losses and benefits in the proposed rule). They do not share the same flows, water quality, fisheries, climate, vegetation, management objectives, or concerns. It is even more difficult to equate a manmade waterbody with a natural lake. Even if a natural lake has been modified to control the water, it still has a significantly higher developed ecosystem, and much different physical circumstances.

It is apparent from this discussion that the proposed Existing Facility regulations are inappropriate for Texas waterbodies (and probably for other regions of the country). For instance, the establishment of a true “baseline” would be virtually impossible, and its subsequent applicability tenuous from year to year.

As proposed in the regulations, such a baseline would serve only as a “snapshot”. Dramatic changes to the fisheries, especially ones beyond the control of the power plant, can and do occur with surprising speed and can have longterm effects on the fisheries population and distribution. If they occur before, during, or after the establishment of the “baseline”, that information becomes necessarily useless. In any attempt, the baseline should not be a moving target.

For example, exotic fauna presents one of the more difficult problems. Their presence should not “count against” the permittee. By State law it is unlawful to possess many of these species unless they have been eviscerated, and it is the goal to remove them from Texas waters. Their presence does, however, alter the biology of the reservoir. It is an essentially similar situation for exotic flora. Its presence often does alter the biology, particularly the fisheries.

Any requirement to compare year to year conditions to the “baseline” is a basis for failure. A permittee should not be subjected to meeting a standard that, because of anthropogenic and natural factors, are beyond their ability and beyond their control.

The appropriateness and applicability of the proposed control methods is also in question for Texas waters. Cooling towers are wasteful, create new wastestreams, and extremely expensive to retrofit (if physically possible). The other technologies have never been applied on any realistic scale to southern waters. Apart from the expense, there are serious concerns about their ability to function in the biologically rich waters of Texas reservoirs.

Considering that most power plant reservoirs in Texas were built specifically for that purpose, do not support commercial fishing, do not contain endangered/threatened species, have an excellent history of providing public access and supporting sports fisheries managed by the State, the imposition of these regulations is unwarranted. The need and application of any regulations addressing this issue should be determined by the State. The State has the regional knowledge, and the experience, to apply any such requirements where and when needed.

EPA Response

See responses to 316bEFR006.001, 015.003, and 016.001. EPA also notes that under the final rule (i.e., § 125.90(c)) a State may administer alternative regulatory requirements where such requirements will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment that would otherwise be achieved under § 125.94.

With regard to "baseline studies," EPA notes that the Comprehensive Demonstration Study is not required under every compliance alternative, and its components are applied only as appropriate under each alternative. Moreover, the point of these efforts to characterize the waterbody and any impacts to the waterbody associated with cooling water intake structures is to understand the specific waterbody and any environmental impacts, including any unique or unusual factors. Thus, the Comprehensive Demonstration Study can be used to identify variability and other important characteristics of the waterbody, including characteristics that perhaps there is reason to discount or distinguish, as well as to support decisions regarding how to most appropriately assess cooling water intake structure impacts, and distinguish non-cooling water intake impacts. Under the NPDES program regulations, Directors have reasonable discretion to apply these requirements as appropriate to achieve regulatory requirements and program objectives. Reasonable application of these rule requirements can accommodate unique waterbodies and, thus, EPA does not agree that such studies would be difficult or impossible to conduct, or of little value.

Definition: Waters of the U.S.

Cooling Water Reservoirs

Of the estimated 60 in-scope facilities in Texas, the majority utilize cooling water reservoirs. Over half are on cooling water reservoirs that were built, and are operated, specifically to supply cooling water. Many of the remaining facilities are on reservoirs that were constructed in part as cooling water reservoirs. As discussed previously, these reservoirs are an essential component of the facility's cooling water system, equating to a close loop cooling system. As part of the project construction approval process, most cooling water reservoir projects, and the associated generating facility, have already undergone an extensive review by various government entities to insure minimal adverse environmental impact. Older cooling water reservoirs constructed before the requirements for review to evaluate adverse impacts have the benefit of history to show that the operation of the CWIS (cooling water intake structure) has had minimal impact. In fact, Texas cooling water reservoirs usually have thriving populations.

Based on these, and other reasons already discussed, cooling water reservoirs should be considered as closed-cycle cooling systems and not subject to these proposed regulations.

EPA Response

See response to 316bEFR.006.001.

Comment ID 316bEFR.016.004

Subject Matter Code 10.02

Benefit Estimation Methodology

Author Name William E. Driscoll

Organization TXU Generation Company

Benefits Analyses

Cooling water reservoirs, and the surrounding properties, are owned and operated by the facility to supply cooling water. Often, when access is allowed for recreation it is by permission of the facility through a state, county, municipal, etc., park leased (usually for a symbolic payment of $1/per year) or donated by the facility as a good neighbor gesture. In these cases, public recreation is more correctly considered a cost. In determination of Benefits, such facilities should not be subject to inclusion of public recreation value.

EPA Response

EPA has estimated benefits of public recreation to recreational anglers who benefit from increased catch rates in the public water bodies affected by power generating facilities. The Agency has not included benefits to people who recreate on property owned by the facilities. Thus, this comment is irrelevant to EPA's benefit analysis.

RFC: Use of previous demonstration studies

Previous Demonstration Studies

The EPA should allow the use of pervious demonstrations studies, and grant a waiver for facilities that have been successful in showing minimal adverse impact. The waiver would only be granted if past demonstration reflects that the current conditions of the water body have not materially changed, and that CWIS location, design, construction, and capacity have not changed.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule. Please see response to comment 316bEFR.040.001 for details.

Comment ID 316bEFR.016.006

Author Name William E. Driscoll

Organization TXU Generation Company

Subject Matter Code 6.08

Non-aquatic impacts

Impingement of exotic or nuisance species should not count in determining the percent reduction (or in establishment of any baseline) value. As described previously, exotic and nuisance are a frequent and significant problem in Texas reservoirs. Their presence creates a number of problems for the fisheries because the populations can expand rapidly (often at the expense of other desirable species), and the State has set a goal for their eradication.

EPA Response

Please see response to comment 316bEFR.015.005.

Organization TXU Generation Company

Subject Matter Code 6.01

Overview of I & E effects on organisms

The regulations must also address the impingement of weakened or dead fauna. The induced current of a CWIS, and sometimes its location in relation to predominate winds, often make it a collection point in the event of a die-off or illness in the water bodies fauna. In those events, the facility should not be required to include the numbers in their evaluation of a either the CWIS impacts or a technologies effectiveness.

EPA Response

EPA acknowledges that intake structures can impinge or entrain organisms which may have already died. The Verification Monitoring Plan must include a proposal on how naturally moribund fish and shellfish that enter the cooling water intake structure would be identified and taken into account in determining compliance with § 125.94. By applying to naturally moribund fish and shellfish, the proposal needs to consider whether these organisms died prior to any influence of the cooling water intake structure and not due to a prior pass through the same cooling system and reenters the cooling system due to the circulation of water currents.

Burden on permitting agencies (general)

Impact on State Permitting Agency

TXU is concerned about the impact of these proposed regulations on state permitting agencies. While the Company feels strongly that the flexibility found in these proposed regulations is important and necessary, it also feels that several of the requirements may not be needed for every instance. This is particularly true with many of the studies and the volume of information required. In many cases where there already exist a large body of knowledge on a water body, the process could, and should, be streamlined. Any reduction in the volume and process will result in a cost saving to the agency.

The need and application of any regulations addressing this issue should be determined by the State. The State has the regional knowledge, and the experience, to apply any such requirements where and when needed. This will allow the agency to apply its resources in the most efficient manner, and focus on the identification of problem water bodies.

EPA Response

See response to comment 316bEFR.034.005 for a discussion of the many streamlining efficiencies added to reduce burden in today's final rule.

Existing State 316(b) programs may be approved under today's final rule per the requirements in 125.90(d). See response to comment 316bEFR.023.001 for a discussion of State program approval.

Organization TXU Generation Company

Subject Matter Code 21.09

Permit applications/implementation schedule

Permit Process

The proposed regulations provide little detail on actual permitting process/schedule, and a great deal more detail and guidance will be needed from the EPA before the true impact of the process can be assessed. Considering the scope, the number of affected facilities, and time involved in each stage, TXU's initial impression is that permitting process will be very labor intensive and time consuming for both the permittee and the state agency.

In developing this guidance, the agency must consider several factors. Examples of such factors include the impact on state permitting agency, the real lack of existing expertise and equipment, the uncertainty inherent in predicting the efficiency of a technology on a site specific basis, and the initial escalation in difficulty these factor present when a large number of facilities are affected at once.

EPA Response

As outlined in section 9 of the preamble to today's rule, EPA has clarified the timeframe for submitting the required studies. Please see response to comment 316bEFR.034.066 for a discussion.

In addition, EPA has added many efficiencies to today's final rule since the proposal and NODA to provide options for streamlining application requirements and speeding permitting. Please see response to comment 316bEFR.034.005.

Comment ID 316bEFR.016.010

Subject Matter Code 21.09

Permit applications/implementation schedule

Author Name William E. Driscoll

Organization TXU Generation Company

The EPA must also consider the cost and efficiency of requiring the application of relatively untested technologies on a large scale. It would be disastrous for any company with similar facilities to target a technology for multiple sites and then find out that it is ineffective. A related issue is the timing of technology installation for multiple sites and its potential impact on the reliability of the power network.

Each of these factors and potential problems illustrate the need for a gradual and well conceived permitting strategy. The strategy should acknowledge both the difficulty and the potential economic impacts to the permittee, the state permitting agency, and society. The most logical and workable process would be for the permittee to submit their plans for establishing the baseline, reviewing technologies, etc., with the application. Those plans could then be incorporated into the permit and implemented during the course of the permit.

EPA Response

As discussed in the preamble and ICR to today's final rule, EPA expects that some facilities may opt to conduct pilot studies for certain technologies to ensure appropriateness to the site conditions prior to full installation. This will assist in minimizing risk to the facility and provide a level of confidence in the technology. Plans for the use of technologies should be included in the Proposal for Information Collection for review by the Director. Timing of technology installations should be discussed with the Director and could also be raised in the Proposal for Information Collection. Please see response to comment 316bEFR.034.066 for a discussion of the timing of submitting the required studies.

Comment ID 316bEFR.016.011

Subject Matter Code 21.09

Permit applications/implementation schedule

Author Name William E. Driscoll

Organization TXU Generation Company

The agency must develop a permitting process that has a defined end point. It is absurd that this entire effort would again be required with each subsequent permit round. Once a facility has completed the process, regardless of the option selected, it should not be subjected to the exercise again unless there is a change in the CWIS location, design or construction.

EPA Response

Under 125.95(a)(3) of today's final rule, a facility may apply for reduced application requirements if conditions at the facility remain substantially unchanged from the previous permit issuance. Please see response to comment 316bEFR.034.005 for a discussion.

Comment ID 316bEFR.016.012

Subject Matter Code 21.01

Submittal of required information

Author Name William E. Driscoll

Organization TXU Generation Company

TXU is also very concerned about the CWIS design and construction information/drawings required for the permit application. The agency must consider the national security risk associated with a requirement to provide that level of information critical to the operation of the nation's power plants in a public document format. CWIS, especially on public water bodies, are perhaps the most vulnerable point of a facility and would present the least risk to anyone who wished to disrupt the facilities operation

EPA Response

EPA appreciates the concern regarding a possible security risk in submitting CWIS design and construction information with the permit application. A facility may designate any part of its application as confidential business information (CBI) for review by authorized personnel only. If designated as CBI, the information will be housed in a secure facility with access by authorized personnel only.

Comment ID 316bEFR.016.013

Author Name William E. Driscoll

Organization TXU Generation Company

Subject Matter Code 21.01

Submittal of required information

Flexibility in Required Studies

The agency should provide the opportunity for both the permittee and the permitting agency to take advantage of occasions that might present an economy of scale. For example, if a facility has multiple CWIS on the same water body and in the same proximity, the permittee should be given the option to apply the baseline evaluation of the most utilized CWIS to all. It is even conceivable that a company that has several similar CWIS on the same type of water body, in the same region, could opt to apply the results from one facility's CWIS to each applicable site.

EPA Response

EPA agrees with the commenter and notes that the definition of calculation baseline in 125.93 allows a facility to estimate the calculation baseline using historical impingement and entrainment data from it's facility or another facility with comparable design, operational, and environmental conditions; current biological data collected in the waterbody in the vicinity of the cooling water intake structure; or current impingement mortality and entrainment data collected at its facility. EPA believes that this definition provides ample flexibility for the facility.

RFC: Regulating limited capacity facilities

Author Name William E. Driscoll

Organization TXU Generation Company

Low Capacity Facilities

EPA should also provide a waiver for facilities that have historical low capacity factors, sometime less than annual capacity factors. These low capacity factor sites are generally only brought into service during extraordinary or atypical circumstances. Most often, the extraordinary or atypical circumstances are the result of extremes in weather (winter ice storm or extended summer heat waves). As described by the agency, it is generally accepted that the peak winter or summer periods will not be the most crucial for aquatic organisms.

The agency must also appreciate the difficulty in designing and executing any form of sampling or monitoring plan (e.g., baseline) for a facility with low capacity. Since their operation is often based largely on unplanned events, the extent of their operation is dependent on the duration of the unplanned event. As a result, the window of opportunity to mobilization and execution of sampling and monitoring efforts will be very small and the facility may not operate for a sufficient period of time to complete the effort.

EPA Response

The Agency has considered the historical nature of capacity factors in determining those facilities that would qualify for the reduced requirements associated with low capacity utilization rates. Specifically, the Agency requires that the capacity factor analysis be based on several years of historical annual performance.

The Agency does not agree that a "waiver" should be granted for low capacity facilities. The Agency considers the relief for low capacity facilities from entrainment requirements to be a considerable reduction in burden for these facilities. See DCN 6-3586 for an analysis of the cost to revenue of facilities for a variety of capacity utilization thresholds. This reference outlines that impingement controls for low capacity facilities are reasonable in cost-to-revenue ratios. Further the Agency's analysis of the economic impacts of the rule (which included impingement only requirements for those facilities with low capacity) showed the rule to be economically practicable.

The Agency, by removing the entrainment requirement for those facilities falling below the capacity utilization rate threshold has also removed the entrainment monitoring requirements. Monitoring for impingement can be a very straight-forward exercise, when compared to entrainment monitoring. Monitoring for impingement is still feasible, however, as the intermittent nature of the operation of the plant should make the monitoring even more straight-forward and more affordable. Mobilization can be a concern, but with simple planning and contingency (that afforded by the fact that monitoring is intermittent, and therefore rarely is the full expense incurred) a facility with intermittent operation can and should be able to monitor. If the duration is so short that rigorous monitoring reasonably cannot occur, then the reasonable expectation is that significant impingement of organisms could be easily observed, noted, and qualified. Hence, by nature of the fact that the plant operates infrequently and has only impingement requirements, the burden of the monitoring program is greatly reduced, and the commenter's concerns have been met.

Option: Site-specific determination of BTA

125.94(a)(3) Site Specific Determination

TXU agrees with the EPA's belief that it is important to have a site specific option. This option is necessary and needed for those cases of exceptionally high cost and/or minimal benefits. The Company also believes it would be very useful for the agency to develop standards for the Comprehensive Cost Evaluation Study. The standards should, however, be flexible and in the form of a guidance document. This would help to minimize the impact of these regulations on both the permittee and the regulatory agency.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

For more information on EPA's expectations for the costing efforts, please refer to section IX of the preamble to the final rule.

Performance standards

Author Name William E. Driscoll

Organization TXU Generation Company

125.94(b)(4)(i) - Impingement Mortality for Facilities Withdrawing from a Lake or Reservoir

The use of the 80 to 95% reduction value for impingement from the baseline should be established as a target, not a firm performance standard. As described at several points in the discussion of Texas water bodies above, a number of factors beyond the control of the facility can, and do, affect the fisheries and their distribution in a reservoir. Any change in one or more of these factors from those that existed during establishment of the baseline value can, and will, alter the numbers of fish that are impinged. It is entirely conceivable that due to circumstances and conditions beyond the control of a facility that a performance standard will not be met on an occasional basis, regardless of the temporal unit of measure.

The circumstances are ill-suited to establish a firm performance standard for a technology that has been reviewed and approved in good faith by both the facility and the agency. It would also be inappropriate to impose such a performance range or limit on the technologies identified since they are unproven in many of the conditions and situations in which they will now be applied. The agency itself, in discussing the development of a performance range, acknowledges that there is "...uncertainty inherent in predicting the efficiency of a technology on a site specific basis".

Special definitions

125.94(b)(4)(ii) Natural Thermal Stratification

The occurrence of a "natural thermal stratification" in many Texas cooling water reservoirs is neither reliable nor significant. Apart from the question of whether or not the agency has the authority to regulate the existence or location of the "natural thermal stratification" is the question of the effects of any disruption of that zone. Since the intent of these proposed regulations is to minimize adverse environmental impacts, the criteria should not be based on if a disruption is or is not beneficial, but if a disruption would or would not be detrimental to the fisheries. The language found in 125.95(b)(2)(ii) already reflects the distinction.

EPA Response

The standard found in § 125.94(b)(3) states that "If your facility withdraws cooling water from a lake (other than one of the Great Lakes) or a reservoir and you propose to increase the design intake flow of your cooling water intake structures, your increased design intake flow must not disrupt the natural thermal stratification or turnover pattern (where present) of the source water, except in cases where the disruption is beneficial to the management of fisheries." This standard reflects EPA's original intent with regards to disruption of natural thermal stratification: a facility should only be permitted to disrupt the natural stratification if a third-party fish or wildlife agency determines that it will benefit the management of fisheries in that waterbody. EPA therefore disagrees with the commenter that disruption of a waterbody's natural thermal stratification should be allowed even if it is not beneficial, or merely "not harmful."

Organization TXU Generation Company

Subject Matter Code 21.06.01

Implications for nuclear facilities

125.94(f) Nuclear facilities

The Company appreciated the EPA's recognition of the unique safety issues associated with CWIS operation and purpose at nuclear facilities. The agency should also acknowledge that these issues will also negatively impact the agency's estimates of the time and cost for all aspects of the proposed rule. The evaluation and installation of new technologies at nuclear facilities will necessarily require significantly more study, and will also necessarily result in significantly higher cost. Because of these same concerns, even the baseline sampling will be more difficult to design and execute than for traditional facilities.

EPA Response

The Agency disagrees that baseline sampling of a waterbody in the vicinity of a nuclear station will be significantly more difficult than that for non-nuclear facilities. The commenter provides no data to support the assertion that baseline sampling will be more difficult at nuclear stations, nor does the commenter provide a logical argument as to why it could be the case. The Agency notes that it has analyzed a multitude of biological sampling data from nuclear facilities in the record of this rule. Many nuclear stations across the country have demonstrated that sampling a waterbody in the vicinity of the intake is a straight-forward and widely practiced exercise.

The Agency has included additional cost factors for installing and operating intake technologies at nuclear facilities. These factors account for the additional costs of construction and labor associated with nuclear facilities. See the Technical Development Document for more information on the Agency's approach to estimating technology retrofit costs at nuclear stations. The commenter's concerns have been met.

Submittal of required information

125.95 Permit Application Requirements

A general comment concerning the requirements of this section is that it should be clarified that facilities that are identified as requiring only impingement technologies are not required to address entrainment in the various studies identified. This will allow both the facility and the agency to reduce the cost and effort associated with development and review.

EPA Response

EPA has clarified the preamble and rule language to reflect that facilities must submit studies containing impingement mortality and/or entrainment data, as appropriate to relevant performance requirements for that facility.

General statement of support

Performance Contracting, Inc. agrees with the need and direction of Proposed Rule 316(b) for existing facilities. Clearly, most existing water intake screens have excessively high approach velocities and hence are detrimental to young aquatic wildlife. Further, in reviewing the history of this rule, it appears that the EPA has conducted thorough research to justify the need for a new rule. In general, as a company participating in the free market system, PCI also agrees with the EPA's recommending the best technology available as the solution for plants not currently in compliance. This allows for creativity and ingenuity to achieve least cost solutions, a hallmark of the free enterprise system.

EPA Response

EPA notes the comment. No response necessary.

Determination of compliance

However, we at PCI believe that no regulation is meaningful until its objectives are defined in clear, measurable terms. This proposed rule begs the question: What will be measured at sites to confirm compliance? In the draft, this appears to be completely ignored. As engineers, we need to know how to design and measure the various solutions implemented as compliant, or not, before the best solutions can be implemented. The most disappointing aspect of this draft is its lack to define, in clear terms or otherwise, the acceptance criteria facilities shall be expected to meet when inspected for compliance.

EPA Response

Author Name Gordon H. Hart

Organization Performance Contracting, Inc

Subject Matter Code NEW

Comment on new (Phase I) facility rule

In the Rule 316(b) for new facilities issued on December 18, 2001, the EPA was more prescriptive, specifying a maximum allowable approach velocity of 0.5 fps. PCI would strongly recommend that the EPA list this maximum allowable approach velocity as the recommended solution so as to make it easier and clearer for facility engineers to determine an acceptable solution for their particular existing facility. Otherwise, the solutions could become unnecessarily cumbersome, complex, and of questionable impact.

EPA Response

EPA agrees that reducing a facility's intake velocity may be an effective method to reduce impingement and entrainment. However, EPA does not believe that a prescriptive intake velocity standard is appropriate for all Phase II existing facilities, as some facilities may find that other solutions are more effective or more cost-effective for existing intakes. EPA would prefer to allow a higher degree of flexibility for facilities to meet the performance standards.

EPA does note, however, that a facility can demonstrate compliance with the impingement performance standards under § 125.94(a)(1)(ii) by demonstrating that it has, or will, reduce its maximum through-screen intake velocity to 0.5 ft/sec or less.

RFC: Definition of "adverse environmental impact"

DP&L recognizes that U.S. EPA has not included within the Proposed Rules a definition of Adverse Environmental Impact ("AEI"). Given that the CWA statutory language requires a minimization of AEI in the location, design, construction, and capacity of cooling water intake structures, the interpretation of what constitutes AEI is of vital importance in regulating cooling water intake structures ("CWIS"). DP&L is aware that many commenters may advocate a definition of AEI that equates AEI with "one dead fish." Using that definition, the best technology available ("BTA") for minimizing AEI could be interpreted to require the installation of wet cooling towers at all applicable existing facilities as a minimum or even dry cooling towers in the extreme. DP&L strongly opposes such an approach to the extent it is presented and possibly considered by the Agency for incorporation in the final rule. DP&L insists that any definition of AEI that may be included in a final rule be one that specifies that adverse environmental impact is a phenomenon that occurs on a population level as a result of CWIS operation and significantly affects a population's ability to sustain itself. Anything in terms of a more severe definition of AEI is clearly counter to various federal statutes and mandates that specify that cost be considered in government decision making. These include Executive Order 12866 (1.a, 1.b (5), (6), (7)), the Unfunded Mandates Reform Act, 2 U.S.C. 1501 et seq., and the Small Business Regulatory Fairness Act, 5 U.S.C. 601 note.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

Comment ID 316bEFR.018.002

Author Name Athan A. Vinolus
Organization Dayton Power and Light Company

Subject Matter Code 3.02
Definition: Cooling Water Intake Structure

Preamble Section II.B (67 FR 17128-17129) What is a Cooling Water Intake Structure?

U.S. EPA includes a discussion of the definition of cooling water intake structure. The definition specifically includes the intake pumps as part of the CWIS under EPA's argument that they are an essential component of the CWIS "...since without them the intake could not work as designed." DP&L disagrees that the pumps are a component of the CWIS and, instead, insists that they are part of the cooling water system (CWS). Under U.S. EPA's mistaken theory, other components of the CWS could similarly be erroneously considered part of the CWIS simply if they are integral to its design and operation. This would include piping, valves, condensors, cooling towers (if the plant is so equipped), etc. The definition of CWIS should be limited to only those components that are actually physically part of the structure at which water is drawn into the plant.

EPA Response

EPA disagrees. As discussed in section II.B. of the preamble to the final rule and at 66 FR 65287 of the final Phase I rule (12/18/01), the explicit inclusion of the intake pumps in the definition reflects the key role pumps play in determining the capacity (i.e., dynamic capacity) of the intake. Under 316(b), the capacity of a cooling water intake structure is one of four specific aspects of the intake structure that must reflect the best technology available for minimizing adverse environmental impact. These intake pumps, which bring in water, are an essential component of the cooling water intake structure since without them the intake could not work as designed. EPA believes its definition of “cooling water intake structure” is reasonable given the wording and objectives of section 316(b).

Organization Dayton Power and Light Company

Subject Matter Code 6.01

Overview of I & E effects on organisms

Preamble Section V (67 FR 17136-17137) Environmental Impacts Associated With Cooling Water Intake Structures

U.S. EPA discusses the environmental impacts associated with CWIS, including both impingement and entrainment. The discussion of entrainment impacts, in addition to including the types of impacts, cites specific mortality rates for various entrained organisms. However, the discussion of impingement, while speculating on the types of impacts, offers no mortality or injury data to support the assumption that significant adverse impingement impacts occur as a direct result of large quantities of water being withdrawn for cooling purposes. While a number of the facility examples that follow in Section V.A of the Proposed Rules do include cursory data on number of individuals impinged at specific facilities, impingement mortality data seems to be lacking.

EPA Response

EPA did not review impingement survival studies as extensively as entrainment survival studies because the impingement studies are less controversial. However, the topic of impingement mortality was investigated in the section 316(b) Phase I new facility rule, and EPA considered those studies in taking final action in Phase II. Please see Section VI in the preamble to the Phase I rule for the discussion on impingement survival. The discussion of environmental impacts in the preamble of today's final rule focuses on those organisms killed as a result of impingement and entrainment by the cooling water intake structure. Although EPA did not have the time to extensively review impingement survival studies, EPA encourages Permitting Authorities to give these studies the same level of scrutiny as EPA did with entrainment survival studies.

Subject Matter Code 6.02

Impacts of multiple intake structures on watersheds

The discussion in this section of the preamble also indicates that U.S. EPA is concerned about the cumulative overall degradation of the aquatic environment as a consequence of the following: (1) multiple intake structures operating in the same watershed or in the same or nearby reaches; and (2) intakes located within or adjacent to an impaired waterbody. As the primary example of this concern, the Agency states that the Atlantic States Marine Fisheries Commission has been requested by its member States to investigate the cumulative impacts on commercial fishery stocks attributable to cooling water intakes located in coastal regions of the Atlantic Ocean. While DP&L believes it may be admirable for this Commission to undertake such an investigation at the behest of its member States, DP&L believes this provides very weak justification for U.S. EPA to promulgate a significant rulemaking such as the. 316 (b) Phase II Proposed Rules. This is particularly true as U.S. EPA provides no data to justify the Agency's perceived concern since the referenced study presumably has yet to be undertaken.

EPA Response

The investigation by the Atlantic States Marine Fisheries Commission on the cumulative impacts of cooling water intake structures has not been completed to date; therefore, reference to it has not been included in the preamble to today's final rule. EPA continues to be concerned about the potential cumulative impact of multiple intake structures operating in the same watershed and intakes located within or adjacent to an impaired waterbody. See response to comment 316bEFR.099.004. Please see section IV of the preamble for the discussion on environmental impacts associated with cooling water intake structures.

Comment ID 316bEFR.018.005

Author Name Athan A. Vinolus

Organization Dayton Power and Light Company

Subject Matter Code 6.03

Impacts of CWIS on impaired waterbodies

U.S. EPA further believes that cooling water intakes potentially contribute additional stress to waters already showing aquatic life impairment from other sources such as industrial discharges and urban stormwater. Specifically, U.S. EPA notes that the top four leading causes of waterbody impairment are siltation, nutrients, bacteria, and metals and that they affect aquatic life uses of a waterbody. U.S. EPA speculates that since organisms subject to the effects of cooling water withdrawals reside in impaired waters, they are therefore more susceptible to the cumulative impacts from a variety of physical, chemical and anthropogenic stressors (presumably including CWIS). DP&L does not dispute that there may be some contribution by cooling water intake structures to the total stress born by aquatic life in a particular waterbody. However, DP&L sees this as weak justification for a potentially significant 316 (b) rulemaking in light of U.S. EPA's admission that other more prevalent causes of impairment affect aquatic life use of a waterbody. If U.S. EPA truly believes that siltation (presumably from non-point source runoff), nutrients (presumably from agricultural runoff), bacteria (presumably from combined sewer overflows) and metals (presumably from various point source discharges or natural background sources) are the leading causes of impairment and that CWIS only serve to add incremental stress to the aquatic life, then U.S. EPA should implement additional regulations or enforce existing regulations to control the sources responsible for these impairments. Establishing regulations to control CWIS in an attempt to improve water quality and reduce impairment for aquatic life caused by other sources does not address the real source of the perceived problem.

Additionally, U.S. EPA admits there is much uncertainty and work to be done as to the contribution that any one stressor makes to a structural change in an ecosystem including the extent to which CWIS induce changes. As a result, there would appear to be incentive to resolve these issues prior to promulgating a potentially costly rulemaking.

EPA Response

Please see the response to comment 316bEFR.025.018 for the discussion regarding the environmental impacts associated with cooling water intake structures.

Author Name Athan A. Vinolus

Organization Dayton Power and Light Company

Subject Matter Code 7.02

Performance standards

Preamble Section VI.A.1-A.1.a (67 FR 17140-17142) What is the Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities?

The Proposed Rules set technology-based performance requirements for minimizing adverse environmental impact at Phase II facilities. As proposed by U.S. EPA, facilities with cooling water intake structures that meet certain criteria would be required to reduce fish and shellfish impingement mortality by 80 to 95 percent. Facilities meeting certain additional criteria would be required to reduce fish and shellfish entrainment by 60 to 90 percent in addition to reducing fish and shellfish impingement mortality by 80 to 95 percent. DP&L commends U.S. EPA on its decision to forego requiring specific technologies and allowing industry to meet the requirements of reducing impingement and entrainment using whatever technologies best fit the plant-specific situation. DP&L further appreciates U.S. EPA's flexibility in proposing regulations that specify a range of impingement and entrainment reductions that serve to meet the BTA requirements. However, DP&L has concerns with the decision criteria that permitting agencies may use in determining whether a particular facility has met the impingement and/or entrainment reduction standards. Specifically, U.S. EPA states at 67 FR 17141-17142 that

"EPA is proposing performance ranges rather than a single performance benchmark because of the uncertainty inherent in predicting the efficacy of a technology on a site-specific basis....

EPA anticipates that facilities will select technologies or operational measures to achieve the greatest cost-effective reduction possible (within today's proposed performance range) based on conditions found at their site, and that Directors will review the facility's application to ensure that appropriate alternatives were considered....

EPA invites comment on whether the Agency should establish regulatory requirements to ensure that facilities achieve the greatest possible reduction (within the proposed ranges) that can be achieved at their site using the technologies on which the performance standards are based. EPA also invites comment on whether EPA should leave decisions about appropriate performance levels for a facility to the Director, provided that the facility will achieve performance that is no lower than the bottom of the performance ranges in today's proposal."

By not proposing specific mandated technologies and by proposing a range of reduction standards, U.S. EPA is allowing facilities to use the best combination of technologies to meet the optimal level of performance for that particular location. DP&L is concerned that permitting authorities will require additional impingement and/or entrainment reductions over and above those determined to be optimal by the regulated facility. By way of example, if a facility governed by the CWIS regulations as proposed arrives at an approach that will reduce impingement mortality by 85% and entrainment by 65%, it should by deemed to have met the standard. However, conceivably the permitting authority (for some reason possibly unbeknownst to the facility) could determine that those performance levels are not acceptable and could determine that additional controls are required to meet a higher performance standard. If U.S. EPA has determined that a performance standard range is acceptable in meeting the impingement mortality and/or entrainment reductions and as long as the facility's proposed BTA implementation will reduce impingement mortality and/or entrainment to a level within that range, the permitting authority should not have the authority to require additional controls.

EPA Response

As many commenters have noted, a determination of what constitutes Best Technology Available (BTA) for minimizing adverse environmental impact can be a highly site-specific inquiry. For this as well as other reasons, EPA has authorized site-specific determinations to be based on cost-cost and cost-benefit considerations. In addition, EPA recognizes that requirements of state, tribal or other federal laws might influence the determination of what is the best technology available for minimizing adverse environmental impact for any given facility. Today's rule acknowledges this type of site-specific analysis at 125.94(e).

Organization Dayton Power and Light Company

Subject Matter Code 7.01.02

Option 2--Implement performance requirements

Preamble Section VI.A.1.c (67 FR 17143) How Could a Phase II Existing Facility Use Newly Selected Design and Construction Technologies, Operational Measures, and/or Restoration Measures to Establish Best Technology Available for Minimizing Adverse Environmental Impact?

U.S. EPA solicits comment on whether the Proposed Rules should specify that proper design, installation, operation and maintenance of design and construction technologies and operational measures would satisfy the terms of the permit, in cases where the measures were properly installed and maintained but were not achieving compliance with the applicable performance standard. The preamble states that the permitting authority would have the option of modifying the permit requirements in such cases. In the meantime, the preamble states that the facility would be considered in compliance with its permit (assuming it was satisfying all other permit conditions). DP&L believes that the Proposed Rules should specify that proper design, installation, operation and maintenance should satisfy the terms of the permit at least until the permit is reissued pursuant to a revised Design and Construction Technology Plan. Given that wide-spread implementation of impingement and entrainment control technologies to meet a specific range of standards has not been required in the past, there is limited basis upon which to confidently predict whether a particular measure will be successful at a particular location. As a result, as long as the permittee complies with the requirement to submit a Comprehensive Demonstration Study as specified in proposed 125.95(b) and implements the measures described therein as approved by the permitting authority, the permittee should be deemed to be in compliance with the permit. As U.S. EPA points out, proper design, installation, operation and maintenance of design and construction technologies and operational measures would be a permit condition (as opposed to compliance with the performance standards).

EPA Response

EPA has included in today's final rule several alternatives for achieving compliance, including demonstrating compliance with a Technology Installation and Operation Plan. Please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Facility & firm-level costs/Econ. Practicability

Preamble Section VI.A.3 (67 FR 17144-17145) Economic Practicability

U.S. EPA discusses its belief that the requirements of this proposal are economically practicable. As a demonstration of that belief, the Agency describes its examination of the annualized post-tax compliance costs of the Proposed Rules as a percentage of annual revenues to determine whether the options are economically practicable. At the facility level, U.S. EPA states that 409 out of 550 facilities subject to the rule (74%) would incur annualized costs less that 1% of revenues. Eighty-two facilities (15%) would incur costs between 1% and 3% of revenues and 46 facilities (8%) would incur costs greater than 3% of revenues. At the firm level, U.S. EPA states that "compliance costs will comprise a very low percentage of firm-level revenues." Specifically, U.S. EPA estimates that 104 entities would incur compliance costs less that 0.5% of revenues, 12 entities would incur compliance costs between 0.5 and 1% of revenues, 10 entities would incur compliance costs between 1% and 3% of revenues, and 3 entities would incur compliance costs of more than 3% of revenues. U.S. EPA appears to be basing its determination of economic practicability on the fact that its estimates of cost impacts would result in facilities and firms incurring costs that represent a small percentage of their revenues. However, just because an entity would be required to spend what U.S. EPA calculates and considers to be a small percentage of an entity's revenue on an endeavor does not necessarily make that endeavor economically practicable. As a medium sized utility, DP&L generates approximately $1,186 million in annual revenue. Based on U.S. EPA's moderate estimate of economic impact being 0.5% of revenue, this could result in an annualized cost to DP&L of $5.93 million. The higher estimate of 3% of revenue would equate to over $35.5 million in annualized costs. DP&L submits that this figure is not insignificant. In section VIII.A.1 of the Proposed Rules (67 FR 17181), the Agency estimates the total annualized post-tax compliance costs for facilities subject to the Proposed Rules to be $178 million. Furthermore, U.S. EPA estimates that the annualized benefits of the Proposed Rules would be $70.3 million for impingement reductions and $632.4 million for reduced entrainment (67 FR 17145). Based on these cost and benefit estimates, the average annualized entity cost is $1.36 million in order to achieve an average per entity benefit of $0.54 million in reduced impingement and $4.83 million in reduced entrainment. DP&L questions the economic practicability of the reduced impingement and even the reduced entrainment given the variability of site specific conditions and the uncertainty of the cost estimates.

EPA Response

Please refer to the response to comment 316bEFR.005.021 in subject matter code 9.01 for a discussion on EPA's economic practicability determination.

The commenter further "questions the economic practicability of the reduced impingement and even the reduced entrainment given the variability of site specific conditions and the uncertainty of the cost estimates." EPA notes that in the context of Section 316(b) of the Clean Water Act, the concept of economic practicability, among other things, refers to the rule's impacts on the economic viability of facilities and firms subject to the regulation. Benefits are irrelevant to the determination of economic practicability for Section 316(b) regulation. See also response to comment 316bEFR.060.060 in subject matter code 9.01.

RFC: "Significantly greater" for eval. alt. req.

Preamble Section VI.A.4 (67 FR 17145-17146) Site-Specific Determination of Best Technology Available

The Proposed Rules allow for a site-specific determination of BTA if the owner or operator can meet one of two cost tests - (1) its costs of compliance with the applicable performance standard would be significantly greater than the costs considered by the Administrator in establishing such performance standard, or (2) its costs of complying with such standards would be significantly greater than the environmental benefits at the site (emphasis added). DP&L supports the option of a site-specific determination of BTA. However, DP&L has concerns with the potential application of this option given the fact that a cost standard of significantly greater is required and no definition of significantly is proposed. DP&L questions why costs have to be significantly greater than the costs considered by U.S. EPA or the costs have to be significantly greater than the benefits. Strictly speaking, an option that allows site-specific BTA based on a cost/benefit analysis should base its findings on the simple results of the analysis, not a qualitative significantly greater cost. As drafted, the Proposed Rule leaves open to interpretation the value of significantly. As a result, a permitting authority may interpret significantly as a much higher threshold to meet than does a regulated entity. As a consequence, potential site-specific technologies which may have beneficial environmental benefits at lower costs to the regulated community, may be eliminated from consideration simply because they do not meet the significantly greater cost test.

EPA Response

See response to 316bEFR.006.003. For the reasons noted in that response, EPA believes it is appropriate to set a distinct standard in this rule, one that is lower than the standard used in the Phase I rule but remains reasonable in the context of that rule. EPA also believes that, given the complexity and lack of absolute precision associated with the methods and data needed to conduct cost and benefit assessments, the Phase II standard should require a clear margin of distinction between costs or costs and benefits.

Performance standards

Preamble Section VI.A.5 (67 FR 17146-17148) What Is the Role of Restoration Under Today's Preferred Option?

U.S. EPA solicits comment on the role of restoration as an option in lieu of reducing entrainment and/or impingement mortality. DP&L supports the concept of restoration as an alternative approach under the Proposed Rules. Permittees subject to the requirements of this rule should have the flexibility to achieve compliance with the requirements in a number of ways. U.S. EPA specifically invites comment on whether restoration measures should be allowed only as a supplement to technologies or operational measures. Restoration should be allowed as a complement to technologies or operational measures in order to achieve the entrainment/impingement reduction targets but should not be limited to that role. If the permittee is able to demonstrate to the permitting authority's satisfaction that restoration provides benefits to the aquatic community comparable to technologies or operational measures, then restoration should be allowed as the sole strategy for satisfying the regulations.

EPA Response

EPA appreciates the comment and notes the inclusion of restoration measures as a component of today's final rule. For a more detailed discussion on the scope and applicability of restoration in today's rule, please see the preamble to today's rule.

RFC: Appropriate spatial scale for restoration

Author Name Athan A. Vinolus

Organization Dayton Power and Light Company

In addition, U.S. EPA seeks comment on the most appropriate spatial scale under which restoration efforts should be allowed. DP&L posits that restoration efforts should be allowed on the broadest spatial scale possible. Restricting the application of restoration to the waterbody at which a facility's intakes are sited, artificially limits the potential benefits the restoration effort may achieve. It may be appropriate to give priority to waterbody-specific restoration, but watershed or State boundary level restoration efforts should be allowed as well, if feasible.

EPA Response

For a discussion of the appropriate scale on which to conduct restoration measures, see EPA's response to comment 316bEFR.212.001.

RFC: Monitoring frequencies

Author Name Athan A. Vinolus

Organization Dayton Power and Light Company

Preamble Section VI.A.6.b (67 FR 17149) What Should Be the Minimum Frequencies for Impingement and Entrainment Compliance Monitoring?

U.S. EPA requests comment on including minimum sampling frequencies and durations in order to characterize impingement mortality and entrainment for determining compliance. While sampling to determine compliance is appropriate, site specificity of the aquatic environment should be the determining factor in what the frequency and duration of such sampling should be. What may be appropriate sampling frequencies at one facility may be too often or not often enough at another location. Similarly, what may be adequate sampling duration at one facility may be too long or too short at another location. U.S. EPA should not articulate specific sampling frequency or duration as a one-size-fits-all approach, but should allow site-specific determination of such monitoring.

EPA Response

More Stringent Requirements

Preamble Section VI.A.9 (67 FR 17150-17151) When Could the Director Impose More Stringent Requirements?

U.S. EPA is considering the establishment of additional criteria for when more stringent requirements would be appropriate, namely when compliance with the Proposed Rule would - (1) result in unacceptable effects on migratory and/or sport or commercial species of concern, and (2) not adequately address cumulative impacts caused by multiple intakes or stressors within the waterbody of concern. DP&L appreciates that there may be specific circumstances when more stringent criteria may be appropriate. However, there is the possibility that CWIS may be held accountable for impacts to the waterbody resulting from non-related stressors. It is not clear whether the cumulative impacts U.S. EPA refers to in item (2), above, are impacts related to CWIS or whether they could be impacts associated with other stressors, etc. To the extent that U.S. EPA is considering instituting more stringent requirements on CWIS to compensate for inadequacies in controlling other non-related environmental stressors, DP&L opposes this consideration. DP&L appreciates U.S. EPA's attempts to provide a holistic approach to environmental regulation, but CWIS owners/operators should not bear the brunt of the blow for the Agency's failure to adequately control other pollutant sources.

EPA Response

RFC: 5% threshold and supporting documents

Preamble Section VI.A.10 (67 FR 17151) Discussion of the 5% Flow Threshold in Freshwater Rivers

U.S. EPA solicits comment on the threshold of 5% of the mean annual flow of a freshwater river or stream as the determinant as to whether a facility is required to reduce entrainment by 60-90%. Other options the Agency is considering are (1) 5% of the mean flow measured during the spawning season; (2) 10% or 15% of the mean annual or spawning season flow; (3) 25% of the 7Q10; and (4) a species-specific flow threshold. DP&L believes that whatever flow threshold is used to trigger compliance with the entrainment requirements, it should be based on a valid scientific determination. To arbitrarily select a flow value that potentially triggers significant compliance costs by the regulated community without scientific justification is inappropriate and unreasonable.

EPA Response

EPA believes it has presented ample evidence demonstrating a significant decrease in the level of entrainment when intake flow is minimized in relation to the flow of the source waterbody. The documents DCN# 2-013L-R15 and 2-013J support the proposition that flow is related to entrainment. EPA believes the intake capacity standard established under today's final rule provides an adequate level of protection and is economically practicable and technically available to all Phase II facilities.

Option: Site-specific determination of BTA

Preamble Section VI.A.12 (67 FR 17152-17153) Comprehensive Cost Evaluation Study

U.S. EPA solicits comment on the burden that reviewing site-specific cost studies poses for permitting authorities and on its belief that site-specific provisions to address cases of unusually high costs or unusually low benefits are necessary. DP&L agrees with the Agency position that while many or most facilities will choose to comply with the presumptive standards, the option of a site-specific determination of BTA for minimizing adverse environmental impact based on high costs or limited benefits is important to the regulated community. DP&L realizes that the availability of this option could potentially impose additional review costs on permitting authorities but this cost may be overshadowed by the overall benefit to society and the aquatic environment that such an option affords. DP&L urges U.S. EPA to maintain the flexibility that this option provides.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA agrees that few facilities will opt for a site-specific determination of BTA. Please refer to the response to comment 316bEFR.202.002 for more information.

Option: Reduce capacity comm. with closed-cycle

Preamble Section VI.B.1 (67 FR 17154-17155) Intake Capacity Commensurate with Closed-Cycle, Recirculating Cooling System for All Facilities

U.S. EPA discusses its consideration of closed-cycle recirculating cooling systems as BTA for minimizing adverse environmental impact and its decision not to require facilities to meet performance standards for reducing impingement mortality and entrainment based on a reduction in intake flow to a level commensurate with that which can be attained by a closed-cycle recirculating system. DP&L supports this decision. Clearly the costs of retrofitting and operating such systems at facilities which do not now have them is disproportionate to the potential benefits derived. For one DP&L-operated facility, the capital costs to install closed-cycle recirculating systems on three of the four generating units that do not have them was estimated to be over $126 million in 1979. Escalating this estimate to current dollars results in a present value cost of approximately $250 million.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161). Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to section VII.E of the preamble for more information on why EPA rejected this alternative.

Option: Technol. to reduce I&E regardless of WB type

Preamble Section VI.B.4 (67 FR 17158-17159) Impingement Mortality and Entrainment Controls Everywhere

U.S. EPA discusses an additional alternative under consideration whereby the Agency would establish national minimum performance requirements for the location, design, construction, and capacity of CWIS based on the use of design and construction technologies that reduce impingement and entrainment at all Phase II existing facilities without regard to waterbody type and with no site-specific compliance option available. Under this scenario, all Phase II existing facilities would be required to reduce impingement mortality by 80-95% for fish and shellfish and reduce entrainment by 60-90% for all stages of fish and shellfish. This alternative would not base requirements on the percent of source water withdrawn and entrainment performance requirements would be applicable to all Phase II existing facilities located on freshwater rivers or streams. While U.S. EPA does not discuss it, DP&L presumes that this option also would not take into account a facility's capacity factor in determining applicability of the regulations (as the current proposal does). Finally, under this alternative, restoration could be used only as a supplement to the use of design and construction technologies or operational measures, not as an option to them. DP&L opposes this alternative. To impose performance standards on all facilities without regard to their percent of the waterbody withdrawn or their level of operation (capacity factor) runs counter to U.S. EPA's presumption that CWIS impact is proportional to the amount of water withdrawn; i.e. the assumption that the aquatic community is randomly dispersed throughout the water column and a facility that withdraws 15% of a waterbody's volume has the potential to impact 15% of the waterbody's organisms (see 67 FR 17151, Preamble section VII.A.10). U.S. EPA estimates the post-tax annualized compliance cost for this option to be $191 million and the benefits to be $64.5 million/year for reduced impingement and $0.65 billion/year for reduced entrainment. Compared to the proposed requirements (compliance costs of $178 million and benefits of $70.3 million for reduced impingement and $0.63 billion for reduced entrainment (see 67 FR 17208, Preamble section IX.F.2, Exhibit 34)), the incremental benefits are disproportionate to the potential costs and verify that this option should not be selected.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161). Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

Sample site-specific rule (p.17159-61)

Preamble Section VI.C.1 (67 FR 17159-17160) Sample Site-Specific Rule

In its Site-Specific Alternative: Sample Rule, U.S. EPA discusses the use of a previously conducted 316(b) demonstration if certain conditions are met. Among these conditions is that "[t]he available evidence shows that there have been no significant changes in the populations of critical aquatic species." DP&L proposes that the word negative or adverse be inserted prior to significant changes. This would allow the use of previously conducted 316(b) demonstrations (as long as the other applicable criteria are met) in situations where the populations of critical aquatic species have actually increased (for whatever reason) since the demonstration was conducted.

EPA Response

EPA did not adopt the sample site-specific rule language in the proposed rule. While EPA rejected a purely site-specific approach, EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

With respect to previous studies, a goal of today's rule is to set national minimum performance standards that reflect the best technology available for minimizing adverse environmental impacts. Given that previous determinations of best technology available were not made in reference to the national performance standards, EPA believes that the Director should not rely entirely on historical determinations. EPA believes that these national requirements will promote more effective and consistent implementation of section 316(b) requirements, and ultimately minimize adverse environmental impacts associated with the use of cooling water intake structures by Phase II existing facilities.

RFC: Definition of "adverse environmental impact"

Preamble Section VI.C.5.a.4 (67 FR 17164) Questions for Comment on the Determination of Adverse Environmental Impact

U.S. EPA invites comment on various aspects pertaining to the definition of adverse environmental impact and on which approach the Agency should use if it adopts a site-specific approach for the final rule. DP&L believes the definition of adverse environmental impact needs to incorporate the following concepts. First, AEI should be determined to be those impacts that occur at a population or community level. The threshold for AEI should not be the simple occurrence of impingement and/or entrainment such that a single organism is harmed. Secondly, AEI (as defined in this rulemaking) must be the result of the operation of a cooling water intake structure. The alternative definition language as offered in VI.C.5.a (2) does not refer to AEI as being the result of CWIS operation.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

RFC: Use of previous demonstration studies

Preamble Section VI.C.5.b.4 (67 FR 17165) Questions for Comment on Using Previous Demonstration Studies

U.S. EPA solicits comment on whether the final rule should permit the use of a previous section 316(b) demonstration for determining whether there is AEI and the BTA for minimizing AEI. Previously conducted 316(b) demonstrations should be allowed to be used in determining AEI and BTA, subject to certain conditions. Specifically, in order to be applicable, the results of a previously conducted demonstration must be representative of current conditions both in regard to the biological conditions in the waterbody and the current location, design, construction and capacity of the CWIS. In short, DP&L endorses the UWAG recommendation regarding the use of previous demonstration studies.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule. Please see response to comment 316bEFR.040.001 for details.

Process for determining site-specific BTA

Preamble Section VI.C.5.c.4 (67 FR 17166) Questions for Comment on a Process for Determining the Best Technology Available for Minimizing Adverse Environmental Impact and the Role of Costs and Benefits

U.S. EPA invites comment on the standard that would be included in any site-specific final rule for determining BTA for minimizing AEI, including the appropriate role for a consideration of costs and benefits. DP&L endorses the UWAG recommendation as outlined in section VI.C.5.c.3.A of the preamble. As described by UWAG, inclusion of a consideration of costs and benefits is appropriate for determining BTA for minimizing AEI. Furthermore DP&L reiterates its position that due to the uncertainty with the interpretation of wholly disproportionate and significantly greater, the technology with the greatest net benefit would be the best technology for a specific site.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161). Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information. For reasons stated in the response to UWAG's comments, EPA rejected the suggestion that framing the cost-benefit compliance alternative in terms of greatest net benefit.

RFC: Discretionary restoration approach

Preamble Section VI.E.1.b (67 FR 17169-17170) Restoration Approaches Being Considered for the Existing Facilities Rule

U.S. EPA discusses various approaches to implementing restoration under the section 316(b) regulations. As is currently proposed, restoration would be allowed as one means of satisfying the compliance requirements. Also under consideration by U.S. EPA are discretionary restoration (whereby the permitting authority would have the discretion to specify appropriate restoration measures but would not be required to do so), mandatory restoration (whereby the use of restoration would be a required element of all 316(b) cases), and restoration banking (whereby restoration credits could be purchased by the permittee from an approved bank). DP&L does not oppose the concepts of discretionary restoration (assuming the regulated party has some recourse if it feels the discretionary application of restoration by the permitting authority is not appropriate) or restoration banking.

EPA Response

For a discussion the extent to which restoration measures are voluntary under the final rule, see EPA's response to comment 316bEFR.060.022.

All restoration measures must meet the requirements for restoration measures as described in the final rule.

For a discussion of trading programs, see EPA's response to comment 316bEFR.074.020.

Organization Dayton Power and Light Company

Subject Matter Code 11.11

RFC: Mandatory restoration approach

DP&L does have concerns with the concept of mandatory restoration. U.S. EPA envisions mandatory restoration as a supplement to the installation of control technologies to compensate for those organisms not protected by those technologies. DP&L considers this a method of de facto elimination of adverse environmental impact instead of minimizing AEI as required by the statute. Presumably the selection, design, installation and operation of impingement and entrainment control technologies would be the result of careful consideration by the regulated facility (with oversight and/or approval by the permitting authority) toward the goal of minimizing adverse environmental impact. To require additional mitigation through mandatory restoration measures goes beyond minimizing and should not be required. Conversely if the regulated entity determines that the best option for minimizing adverse environmental impact is to utilize restoration in lieu of installing control technologies, it should have the choice to pursue that alternative. In addition, restoration banking provides a valuable option for both the regulated community and the permitting authority to consider in selecting the appropriate approach to minimizing adverse environmental impact. The use of banking and credits has proven to be a workable concept in other environmental protection programs - namely the Acid Rain Program and the Wetlands Mitigation Banking Program.

EPA Response

Permit applicants need to meet the requirements for restoration measures as described in the final rule. For a discussion of the permitting authorities role in the assessment of restoration measures, see EPA's response to comment 316bEFR.060.026.

For a discussion of the extent to which restoration measures are voluntary in the final rule, see EPA's response to comment 316bEFR.060.022.

For a discussion of trading programs, see EPA's response to comment 316bEFR.074.020.

RFC: Should EPA include impingement trading?

Preamble Section VI.E.2.a (67 FR 17170) Entrainment Reduction vs. Impingement Reduction as a Basis for Trading

U.S. EPA discusses entrainment trading/entrainment reduction vs. impingement reduction as a basis for trading and states its belief that a trading program based on entrainment is more viable than one based on impingement. DP&L in general would be supportive of an entrainment trading program as a component of the 316(b) regulation to the extent it enhances flexibility in achieving the goals of the regulation and to the extent it is workable. However, the language contained within the preamble describing the Agency's concept of entrainment trading is confusing. The Agency states that the concept of trading "would enable smaller facilities that cannot afford to install more costly technologies to reduce their costs by trading with other Phase II existing facilities that face relatively lower costs of entrainment reduction." Under an entrainment trading program, U.S. EPA envisions the authorized State setting a discrete watershed performance standard within the range of 60-90% for all life stages of entrained fish and shellfish. The preamble goes on to say that

[a]ll facilities located in the watershed would need to reach the performance standard through the installation of technologies to reduce entrainment (or, potentially, restoration measures to compensate for entrainment loses at the facility). A facility that can afford to implement technologies to reduce entrainment above the performance standard would have entrainment reduction credits to sell to other facilities that cannot afford or choose not to meet the performance standard by technology alone.

DP&L has the following questions related to the inclusion of an entrainment trading program in the 316(b) regulation as described by U.S. EPA.

-What is the reasoning for having the State set a discrete watershed performance standard within the range of 60-90%? It is DP&L's understanding that under the Proposed Rules, the entrainment reduction performance standard is in fact a range and not a discrete standard within the range. A facility that achieves an entrainment reduction (vs. the baseline) anywhere within the range is deemed to have met the standard. Now U.S. EPA is proposing that for an entrainment trading program to function the permitting authority must establish a specific standard within that range. If a discrete watershed performance standard is necessary to implement a trading program it should be the minimum entrainment reduction within the range (i.e. 60%). Facilities controlling entrainment to a greater degree (>60%) would generate credits for sale.

-What is the reasoning for requiring all facilities located in the watershed to reach the performance standard through the installation of technologies to reduce entrainment? If all facilities meet the performance standard through the installation of technologies, there would be no need for a trading program at all. The purpose of a trading program is to allow those facilities that find it too expensive or infeasible to install control technologies to purchase credits from those facilities that over-control. Having all facilities meet the performance standard to begin with negates the value of a trading program.

EPA Response

Please see response to comment 316bEFR.034.027 regarding the role of trading in today's final rule.

Subject Matter Code 20.04

RFC: Potential trading units/ credits

Preamble Section VI.E.2.c (67 FR 17171-17172) What Should Be the Unit (Credit) for Trading?

U.S. EPA discusses the potential units (credits) that could be used to implement an entrainment trading program. Units under consideration include 1) Species Density, 2) Species Counts and 3) Biomass. Entrainment credits would be created through the implementation of entrainment control technologies by Phase II facilities. DP&L has no specific comments on the type of units that should be used as the trading commodity. In addition to installation of control technologies, restoration measures should be an available means of generating credits. DP&L sees no reason why the implementation of restoration measures to establish or enhance a watershed should not carry value equal to those technology measures used to reduce entrainment in terms of creating tradable credits.

EPA Response

Please see the response to comment 316bEFR.077.052 for the discussion on the appropriate unit for trading. EPA has left to the discretion of the permit director any decisions regarding the nature of a potential trading program including whether restoration projects can be traded. EPA notes that there are uncertainties associated with quantifying the performance of restoration projects in relation to specific reductions of impingement mortality and entrainment; for this reason, in § 125.94(c), EPA requires only that restoration measures produce ecological benefits at levels that are substantially similar to the level achievable through attainment of the impingement mortality and/or entrainment requirements. Under § 125.90(c), meanwhile, alternative regulatory requirements for which EPA approval is sought must achieve performance that is comparable to the reduction in impingement mortality and entrainment required by § 125.94. In the case of restoration measures, this would mean substantially similar performance. EPA notes, however, that including restoration in a trading program can pose risks to trade participates: if a restoration project fails to perform as expected, the purchaser of trading units runs the risk of having insufficient units to meet its baseline requirements.

RFC: Include Phase I facilities in trading program

Preamble Section VI.E.2.e (67 FR 17172) Trading Option for New Facilities

U.S. EPA discusses considering extending a 316(b) trading program to include new facilities covered under the Phase I rule. DP&L supports this. As U.S. EPA has stated, a new facility is able to incorporate entrainment reduction measures into the design of the facility more easily and as a result, could more easily install reduction technologies that achieve entrainment reductions. Including new facilities in a trading program would have the potential to create greater overall entrainment reduction benefits since a broader range of facilities would be eligible to participate in the program. The ability to generate and sell credits could potentially entice Phase I facilities to control entrainment to a greater degree. There is no reason for the exclusion of new facilities from an entrainment trading program.

EPA Response

Please see response to comment 316bEFR.005.045 regarding new facilities and voluntary trading programs.

Applicability to facilities subject to NPDES permit

Preamble Section VII.A (67 FR 17173) When Does the Proposed Rules Become Effective?

U.S. EPA discusses that facilities subject to the requirements of Subpart J of the Proposed Rules would need to comply with the requirements of the subpart when an existing NPDES permit is reissued, modified or revoked and reissued. This is articulated in proposed 40 CFR 125.92. DP&L has two concerns with the implementation of this section. First, if the requirements to comply with Subpart J are not applicable until a permit containing requirements consistent with the subpart is issued to the facility, then there is nothing in the regulations that triggers the submission of information to the permitting authority in order to issue the permit containing the requirements for 316(b) compliance. Secondly, and more importantly from a permit-holder's perspective, U.S. EPA should clarify that compliance with the applicable requirements should be consistent with the terms and conditions of the permit. Presumably some time would be allowed, according to a schedule articulated in the permit, for a facility to implement control measures or restoration features to reduce impingement and entrainment. Permit holders should not be subject to potential immediate enforcement action due to misinterpretation of this language to mean that compliance is required commensurate with final permit issuance.

EPA Response

The application requirements in the final rule will become part of 40 CFR 122.21, not Subpart J. With regard to compliance and timing, EPA has not specified in this rule that compliance must be consistent with the terms and conditions of each permit because this requirement is a generally applicable requirement of the NPDES program, and it is addressed in existing regulations (see, 40 CFR 122.41(a)). As for the timing of implementation, as always, this must be consistent with the permit conditions, and also will be dependent on the compliance alternative selected. Some alternatives under this rule provide for the allowance of time for aspects of implementation. Under existing NPDES regulations, permits may, when appropriate, specify a schedule of compliance leading to compliance with the CWA and regulations. See, 40 CFR 122.47. Under this provision, any schedule of compliance shall require compliance as soon as possible but not later than the applicable statutory deadline under the CWA. See also preamble to the final rule.

CWIS data

Preamble Section VII.B.2 (67 FR 17174) Cooling Water Intake Structure Data (40 CFR 122.21(r)(1)(ii))

U.S. EPA discusses information required to be submitted regarding a facility's CWIS as part of the application process, including a flow distribution and water balance diagram that includes all sources of water to the facility, recirculating flows, and discharges. U.S. EPA should clarify that the water balance diagram required as part of existing NPDES permit application Form 2-C requirements would also be sufficient to satisfy this obligation under the 316(b) regulation.

EPA Response

EPA agrees that the water balance diagram from NPDES application Form 2-C requirements would meet the water balance diagram requirements under section 316(b) as long as the diagram clearly depicts the proportion of intake water used for cooling, make-up and process.

Subject Matter Code 21.01.04

Comprehensive demonstration study (7 parts)

Preamble Section VII.B.4 (67 FR 17174-17178) Comprehensive Demonstration Study (125.95(b))

As discussed in this section of the preamble and articulated in proposed 40 CFR 125.95(b), facilities subject to the Phase II existing facility requirements would be required to submit to the permitting authority a Comprehensive Demonstration Study ("Study"). Elements to be included in the Study are (1) Proposal for Information Collection, (2) Source Waterbody Flow Information, (3) Impingement Mortality and Entrainment Characterization Study, (4) Design and Construction Technology Plan, (5) Information to Support Proposed Restoration Measures (if the facility proposes to use restoration to meet the performance requirements), (6) Information to Support Site-specific Determination of Best Technology Available for Minimizing Adverse Environmental Impact (if applicable), and (7) Verification Monitoring Plan. U.S. EPA is proposing that this information be submitted at least 180 days prior to the expiration of an existing permit. DP&L has grave concerns with the proposed timing of this requirement both in general and with regard to specific elements of the Study.

In general, the proposed requirements are excessively burdensome. If the Proposed Rules become final near the time a facility's NPDES permit is up for renewal, there is no way the information required as part of the Study would be able to be obtained for inclusion with the NPDES permit renewal application. The information U.S. EPA is proposing to require could easily necessitate several years to gather, particularly since, as U.S. EPA recognizes, impingement and entrainment are dependent on site-specific conditions and are likely to vary from year to year. As a result, any representative characterization of a facility's CWIS impact on the biota of the waterbody would need to encompass at least two years, if not more, of monitoring and sample collection. To require this information without allowing facilities impacted by the regulations sufficient time to gear up is simply unrealistic. A possible solution would be to make the requirements for specific Phase II facilities applicable beginning with their 2nd NPDES permit after the effective date of the final regulations.

In addition, neither the preamble nor the Proposed Rules covering the Comprehensive Demonstration Study make clear whether the information to be submitted is required with each NPDES permit renewal. Proposed 40 CFR 125.95(a) states

You must submit to the Director the application information required by 40 CFR 122.21(r)(2), (3) and (5) and the Comprehensive Demonstration required by paragraph (b) of this section at least 180 days before your existing permit expires, in accordance with 122.21(d)(2).
(emphasis added)

However, there is no clarification as to whether the "existing" permit referred to is only the permit in place at the time the regulation becomes effective or whether the "existing" permit is the effective permit in place at any time in the future (and therefore would require a submission of the information with each subsequent renewal request). DP&L cannot envision that what U.S. EPA had in mind was the regeneration of this extensive data requirement each time a permit comes up for renewal. If in fact this is what U.S. EPA intended, DP&L ardently opposes this as a burdensome requirement with no commensurate environmental benefit. If this is not what U.S. EPA intended, then clarifying language should be included.

Preamble section VII.B.4.a (proposed 40 CFR 125.95(b)(1)) requires that a Proposal for Information Collection be submitted for approval by the permitting authority. As envisioned, the information collection proposal would include a description of the proposed and/or implemented technology(ies), operational measures, and/or restoration measures to be evaluated in the Study, a list and description of any historical studies of impingement and entrainment, summary of relevant consultations with fish and wildlife agencies, and a sampling plan for any new field studies. Again, DP&L has concerns with the timing of such a requirement. If permitting authority approval of the information collection proposal is a prerequisite and there is no specified timeframe for permitting authority approval, a permittee may not have sufficient time to implement the data gathering phase prior to its deadline for submission of the NPDES permit renewal application. If approval of the information collection proposal is deemed necessary, a timeframe for this approval should be specified. Alternatively, no prior regulatory approval of the information collection proposal should be required.

Preamble section VII.B.4.c (proposed 40 CFR 125.95(b)(3)) requires that an Impingement Mortality and Entrainment Characterization Study by submitted (as part of the NPDES permit renewal application). Among the items to be included in this impingement mortality and entrainment characterization study are (1) taxonomic identifications of those species of fish and shellfish and their life stages that are in the vicinity of the CWIS and are most susceptible to impingement and entrainment, (2) a characterization of those species including a description of the abundance and temporal/spatial characteristics in the vicinity of the CWIS, based on the collection of a sufficient number of years of data to characterize annual, seasonal and diel variations in impingement mortality and entrainment, (3) documentation of the current impingement mortality and entrainment of all life stages of fish and shellfish at the facility and an estimate of the impingement mortality and entrainment under the calculation baseline, and (4) an identification of species protected under law that might be susceptible to impingement and entrainment (emphasis added). It is obvious by the scope of these requirements that adequate data collection to characterize the impact of a particular CWIS on the local biota will take some time (possibly several years). It is also evident that the collection of such data (to the extent it is not already available) is contingent upon permitting authority approval under proposed 40 CFR 125.95(b)(1). Again, DP&L has concerns with the expectation that such information will be available to be included with the NPDES permit renewal application.

Preamble section VII.B.4.d (proposed 40 CFR 125.95(b)(4)) requires that if a facility chooses to use design and construction technologies or operational measures to meet the performance standards, it would need to also submit a Design and Construction Technology Plan with its NPDES permit renewal application. This plan would be required to demonstrate that the facility has selected and would implement the design and construction technologies to reduce impingement mortality and/or entrainment to the levels required. This compliance option would necessitate significant engineering studies to evaluate the feasibility, costs, and validity of possibly several impingement and entrainment control technologies in comparison to the calculated baseline. Such a task would involve significant time and expenditures in order to determine the optimal recommendation. Consequently, DP&L again expresses its concern with the requirement that such evaluations are to be completed in time to be submitted with the NPDES permit renewal application.

Preamble section VII.B.4.e (proposed 40 CFR 125.95(b)(5)) discusses the information submission requirements necessary should a facility opt to use restoration as a means of complying with the performance standards. Among the elements to be included with this submission are (1) a list and narrative description of the selected restoration measures, (2) a quantification of the combined benefits from implementing design and construction technologies, operational measures and/or restoration measures and the proportion of the benefits attributed to each, (3) a plan for implementing and maintaining the efficacy of the restoration measures selected and supporting documentation to show that the restoration measures will maintain the fish and shellfish in the waterbody, including community structure and function, (4) summary of relevant consultation with appropriate fish and wildlife agencies, and (5) design and engineering calculations, drawings and maps. As with the previous requirements with the Comprehensive Design Study, DP&L has concerns with the requirement that such information be included with the NPDES permit renewal application. Restoration measures will take time and effort to develop and verify. To require this information upon the first NPDES permit renewal application subsequent to the effective date of the final 316(b) regulations is not feasible.

Finally, preamble section VII.B.4.f (proposed 40 CFR 125.95 (b)(6)) discusses the information to be submitted by a facility if it chooses to request a site-specific determination of BTA for minimizing AEI because of costs significantly greater than those U.S. EPA considered in establishing the requirements or because of costs significantly greater than the benefits. Among the items to be submitted under this option are (1) a Comprehensive Cost Evaluation Study that documents the costs of the facility's Design and Construction Plan under 125.95(b)(4) and the costs of alternative technologies and operational measures proposed for the site (including detailed engineering cost estimates), (2) a Valuation of the Monetized Benefits of Reducing Impingement and Entrainment using a comprehensive methodology to fully value the impacts of impingement mortality and entrainment at the site and the benefits achievable by complying with the applicable requirements of 125.94, (3) a Site-Specific Technology Plan based on the results of items (1) and (2) above containing a narrative description of the design and operational technologies, operational and restoration measures, and an engineering estimate of the efficacy of the proposed and/or implemented measures, documentation to demonstrate that the measures would reduce impingement mortality and entrainment to the extent necessary, and design calculations, drawings and estimates. Once again DP&L has significant concerns with the availability of this information relative to the timing of the NPDES permit renewal application. Such analysis and documentation would take considerable time and to expect that a permittee would be able to submit it with the renewal application is not realistic.

EPA Response

EPA disagrees that the application requirements set by today's final rule are excessively burdensome. See response to comment 316bEFR.034.005 for a discussion of the many streamlining efficiencies added since the proposal and NODA, to reduce burden in today's final rule. For a discussion on the timing for submittal of the Comprehensive Demonstration Study, see § 125.95(a) of the final rule and accompanying preamble. With regard to the suggestion that EPA should make the requirements for specific Phase II facilities applicable beginning with their second NPDES permit after the effective date of the final regulations, EPA disagrees. Facilities are required to comply with permit conditions upon issuance of their new or renewed permits unless the permit expires before 4 years after the date of publication in the Federal Register. In that event, a facility may request that the Director approve an alternate schedule for submitting the information. In addition, EPA has provided facilities with the opportunity to reduce burden associated with the permit renewal cycle. Please refer to EPA's response to comment 316bEFR.034.005 for details on how facilities may request reduced submittal requirements following the first permit term. Finally, EPA disagrees that facilities requesting a site-specific determination of best technology available (BTA) lack ample time to conduct the required analysis and documentation.

Monitoring requirements

Preamble Section VII.D (67 FR 17179) What Would I Be Required to Monitor?

U.S. EPA discusses the monitoring required by Phase II existing facilities to demonstrate compliance with the applicable requirements. DP&L has no issue with appropriate monitoring to demonstrate compliance. Virtually all environmental regulations require self-monitoring by the permittee. However, DP&L does question the language included in the preamble that states "[m]onitoring requirements could be imposed on Phase II existing facilities that have been deemed to meet the performance standard in 125.94(b)(1) to the extent consistent with the provisions of the NPDES program." Section 125.94(b)(1) indicates that one method of meeting the performance standard is by reducing intake capacity commensurate with the use of a closed-cycle, recirculating cooling system. If a facility is already meeting the performance standard through the use of a closed-cycle, recirculating cooling system (i.e. cooling tower), there is no purpose and/or need for imposing monitoring on that facility. How are the monitoring data to be used? DP&L can only think of one such use - to impose additional impingement and/or entrainment reduction requirements on that facility should U.S. EPA determine that the impingement and/or entrainment have not been reduced sufficiently. In addition, the meaning of "to the extent consistent with the provisions of the NPDES program" is vague and undefined. DP&L recommends that U.S. EPA include specific citations to the NPDES permitting regulations referencing the monitoring provisions applicable to this Proposed Rules.

EPA Response

In today's final rule, EPA has determined that facilities that choose compliance alternative 1, flow commensurate with closed cycle cooling, will not need to submit any components of a Comprehensive Demonstration Study and will not be required to monitor further to verify compliance with the performance standards (see § 125.94(a)(1)(i)).

Facilities not covered by today's proposal

The applicability section of the proposed rule should be revised to clarify that manufacturing facilities are not covered by the Phase II rule.

Section 125.1 of the proposed rule provides a description of what existing facilities are covered by the Phase II rule. Wording is contained in several sections of the preamble indicating that the Phase II rule does not apply to manufacturing facilities including this statement contained in section IV, "Today's rule does not apply to facilities whose primary business activity is not power generation, such as manufacturing facilities that produce electricity by co-generation." Under the proposed section 125.1, it is not clearly evident that power generation activities meeting the criteria stated in that section would be exempt from the rule if the power generation was owned or operated by, and used, solely for the support of the manufacturing facility. As discussed in the preamble, a provision stipulating that these facilities would be exempt from the Phase II rule should be added to the applicability section (125.1) of the rule.

EPA Response

Subject Matter Code 3.05

Facilities not covered by today's proposal

The provision requiring best professional judgment (BPJ) requirements for all existing CWIS not covered by the Phase II rule should be eliminated.

Section 125.90(c) requires that existing facilities not covered by the Phase II rule must meet 316(b) requirements as determined by the Director on a case-by-case, best professional judgment (BPJ) basis. Inclusion of this subpart is unnecessary and could be interpreted to mean that all existing CWIS not covered by the phase II rule require BPJ based requirements for their CWIS, regardless of their size, location, etc. In addition, since EPA is not providing any guidance on how to apply BPJ requirements to these CWIS, the provision will cause confusion and uncertainty for both the permit writers and the regulated facilities. Since the existing provisions of 316(b) already cover permitted facilities and a Phase III CWIS rule will be forthcoming, there is no need to include this provision.

EPA Response

See response to 316bEFR.063.021.

Subject Matter Code 3.06.01

Withdrawal threshold of 50 MGD

Actual flow should be considered in the threshold for applicability.

A permittee whose actual CWIS flow is less than the 50 MGD threshold should be allowed to request exemption from the Phase II rule. Facilities may choose to operate at flow volumes below the design flow of the CWIS and should not be penalized for this voluntary flow reduction. If a facility chooses to select this option, EPA could institute maximum flow limits in the rule or individual permit to ensure that the threshold flow is not exceeded. Also, the facility would likely be covered under the Phase III CWIS rule thereby ensuring adequate environmental protection.

EPA Response

EPA has retained in the final rule the 50 MGD threshold based on design intake flow, rather than actual flow, for several reasons. Design intake flow is a fixed value set based on the design of the facility's operating system and the capacity of the circulating and other water intake pumps employed at the facility. This allows a clear and timely classification of facilities. The design intake flow does not change, except in those limited circumstances when a facility undergoes major modifications or expansion, whereas actual flows can vary significantly over sometimes short periods of time. EPA believes that an uncertain regulatory status is undesirable because it impedes both compliance by the permittee and regulatory oversight, as well as achievement of the overall environmental objectives. Further, using actual flow may result in the NPDES permit being more intrusive to facility operation than necessary since facility flow would be a permit condition and adjustments to flow would have to permissible under such conditions and applicable NPDES procedures. It also would require additional monitoring to confirm a facility's status, which imposes additional costs and information collection burdens, and it would require additional compliance monitoring and inspection methods and evaluation criteria, focusing on operational aspects of a facility.

Proposed standards for lakes and reservoirs

Cooling ponds or lakes created specifically for cooling purposes should be considered as closed-cycle cooling systems.

Cooling ponds or lakes that were created specifically for cooling purposes should considered as closed-cycle cooling systems. The cooling ponds or lakes should be considered as part of cooling water treatment systems of the facility, not as "waters of the United States." In these situations, the CWIS flow determination should be measured at the CWIS used to provide the makeup water for the cooling pond or lake, not by the cooling water flow through the facility.

EPA Response

Please see the response to comment 316bEFR.006.001 for a discussion of the regulatory status of cooling ponds.

Subject Matter Code 7.02

Performance standards

The proposed performance standard is based upon technology standards, which fail to consider if adverse environmental impact is occurring.

The proposed performance standards are based upon entrainment and impingement reductions that could be achieved if certain technologies are implemented. Although the proposed rule does not specify what technology must be used to meet the performance standard, the standard is technology based with an option to use restoration measures to supplement or replace implementation of technologies. The proposed rule with its performance standard, as well as the technology based approaches under consideration, both ignore the fact that adverse environmental impact may not be occurring in all cases. Therefore both of these approaches may result in significant expenditures of resources that are unwarranted by site-specific conditions.

In addition, EPA states that the performance standard of reduction of impingement and entrainment is a "relatively easy and certain metric". While impingement and entrainment studies may be relatively easy and certain, the performance standard being proposed requires the use of a "calculation baseline" from which the impingement and entrainment reductions are compared to demonstrate compliance. We believe that there is no scientifically sound manner to calculate that baseline where there is an existing CWIS in-place, therefore the assessment of the performance standard can be seriously flawed.

EPA Response

For a more detailed discussion on the scope and applicability of restoration in today's rule, please see the preamble to today's final rule.

For a discussion of the attainability of the performance standards as well a site-specific alternative, please see response to comment 316bEFR311.002.

For discussions on the basis for and implementation of the calculation baseline, please see response to comments 316bEFR.308.014 and 316bEFR.063.022, as well as the preamble to today's rule.

Subject Matter Code 17.06
Option: Site-specific determination of BTA

A site-specific approach should be used to determine if adverse environmental impact (AEI) is being caused by an existing CWIS, and for determining the best technology available (BTA) to minimize the adverse impact if it is occurring.

EPA stated in its 1977 draft guidance document for evaluating adverse impact of CWIS that, "The environment-intake interactions in question are highly site-specific and the decision as to best technology available for intake design, location, construction, and capacity must be made on a case-by-case basis." EPA also recognizes that there are major impact differences associated with CWIS based upon waterbody types (i.e., freshwater streams and rivers, lakes and reservoirs, tidal rivers and estuaries, and oceans). It should be obvious that there are also many other site-specific factors that affect potential CWIS impacts that cannot be dealt with in a prescriptive manner. EPA indicates that it is considering various site-specific based options for the Phase II rule. Eastman agrees that a site-specific based approach is the most appropriate method for determining BTA, and also believes the site-specific approach is also most appropriate for determining AEI. We offer the following specific comments related to the site-specific based options under consideration published in section VI.C. of the proposed rule.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Comment ID 316bEFR.019.007

Subject Matter Code 17.08

Option: UWAG's recommended approach

Of the site-specific based alternatives described, Eastman supports the Utility Water Act Group (UWAG) approach.

Specifically, Eastman supports the UWAG definition of adverse environmental impact (AEI) and their proposed options for making determinations of AEI, the use of de minimis criteria to exempt small cooling water users that pose no appreciable risk of causing AEI, and the option to use voluntary enhancements and/or restorations for minimizing AEI. Specific comments on each of the items are provided below.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Author Name Richard J. Guinn

Organization Eastman Chemical Company

Subject Matter Code 18.01.01

UWAG definition of "adverse environmental impact"

Site-specific determination of adverse environmental impact

Eastman agrees with the concepts of both the UWAG and PSEG definitions of AEI in that the focus should be on the health of critical aquatic populations or ecosystems and not based upon absolute numbers of fish impinged or entrained. EPA's current definition of AEI has often been interpreted in terms of absolute numbers of impinged or entrained fish without regards to impacts, or lack there of, to populations or overall ecosystem health. EPA's is soliciting comment on their proposed alternative definition of AEI. The alternate definition is an improvement over the definition provided in the 1977 draft guidance, however, the portion of the alternative AEI definition stating "entrainment or impingement of significant numbers of critical aquatic organisms" could continue to be interpreted in terms of absolute numbers instead of impacts on populations and used independently as a determination of AEI.

EPA Response

Please see the response to comment 316bEFR.002.019 for the discussion on the definitions EPA rejected for adverse environmental impact in this rulemaking.

Comment ID 316bEFR.019.010

Author Name Richard J. Guinn

Organization Eastman Chemical Company

Subject Matter Code 18.01.01

UWAG definition of "adverse environmental impact"

Eastman also supports the UWAG definition of AEI incorporating the use of representative indicator species and risk assessment approaches to ensure that populations can sustain themselves to provide commercial or recreational harvests or to maintain community structure and function.

We also support the three optional UWAG approaches for demonstrations of "no adverse environmental impact". The first of those approaches is the use of previous 316(b) demonstration studies. If a permittee has made a previous 316(b) demonstration that was accepted by the permitting authority it should only have to document that the biological conditions at the time of the study reflect current conditions, and that the CWIS operation or design has not been significantly altered. We also support UWAG's "Protective Criteria for Determining Adverse Environmental Impact" approach. We believe that each of the individual physical or biological criteria can be used as an independent conservative indicator of a lack of AEI. Eastman also supports the option of using a structured AEI decision-making process consistent with EPA's ecological risk assessment guidelines.

EPA Response

Please see the response to comment 316bEFR.002.019 for the discussion on the definitions EPA rejected for adverse environmental impact in this rulemaking. Since this is a new rule with new standards, all prior section 316(b) determinations must be revisited to be sure they coincide with the provisions in today's final rule. It is unclear in this comment what the author means by a structured AEI decision-making process consistent with EPA's ecological risk assessment guidelines as this was not a option presented in the section 316(b) Phase II proposed rule.

RFC: Test: benefits should justify the costs

Site-specific process for determining the best technology available for minimizing adverse environmental impact and the role of costs and benefits

Eastman believes that an evaluation of cost-effectiveness (i.e., the incremental cost to benefit) should definitively be a component of the analysis to determine best technology available (BTA) for minimizing adverse environmental impact (AEI). We also believe that a test based upon the "benefits should justify the cost" would be more appropriate than the "wholly disproportionate" cost-to-benefit test currently used, or the "significantly-greater" cost to benefit test proposed in the sample-site specific rule. We also believe that EPA should not establish minimum standards by regulation for cost evaluation studies due to the complexities involved with a site-specific approach. However, we encourage EPA to develop guidance for conducting these types of studies and provide examples of a variety of methods that may be used at the option of the permittee.

EPA Response

See the preamble for a discussion of the site-specific compliance alternative.

Please see preamble section VII for a discussion of the incremental comparison of the waterbody-based capacity option versus the preferred option (i.e., the final rule).

For EPA's response to comments on application of the cost-benefit test to assessing the value of alternative CWIS technologies, please see comment #316bEFR.005.020.

For EPA's response to comments on application of the "significantly greater then" and "wholly disproportionate" test to assessing the value of alternative CWIS technologies, please see comment #316bEFR.006.003.

RFC: Proposed use of restoration measures

Voluntary Restoration Measures or Enhancements

Eastman supports the option for facilities to undertake restoration or enhancement projects in combination with, or in lieu of, technologies to minimize AEI. There are certainly cases where much greater environmental benefit can be achieved by these types of projects. We agree with UWAG's approach that the objectives of enhancement or restoration projects should be established and agreed upon in advance, and appropriate monitoring and/or reporting obligations would be conducted to confirm that the objectives of the projects have been achieved.

EPA Response

For a discussion of the use of restoration measures in the final rule, see EPA's response to comment 316bEFR.060.023.

EPA agrees with the commenter that the objectives of restoration measures should be established and agreed upon in advance, and that appropriate monitoring and reporting should be conducted to confirm that the objectives have been achieved. EPA believes the requirements for restoration measures in the final rule include these activities, which can reduce uncertainty associated with restoration projects and enhance their overall performance.

Monitoring requirements

Compliance Monitoring Issues

Eastman believes that once a facility and the permitting authority have agreed upon the appropriate BTA and it has been properly installed, operated, and maintained, the facility should be considered in compliance with the conditions of their permit. If compliance monitoring indicates that a performance standard or restoration/enhancement objectives are not being achieved, this should not be considered as non-compliance with the provisions of the permit. Because of the time and inherent variability involved with monitoring fish populations over multiple seasons, or the success or failure resulting from restoration/enhancement projects, we do not believe that re-opening of permits would be necessary except in extreme cases. Therefore, any modifications to 316(b) requirements should be dealt with during the normal permit renewal process.

EPA Response

Burden on permitting agencies (general)

Burden to Regulatory Agencies from Site-Specific Decision Making

EPA has expressed concerns about the burden that will be placed upon regulatory agencies if a site-specific approach is adopted. The promulgation of new CWIS rules for existing facilities will place burdens on both permittees and the regulating authorities, regardless of the approach adopted. However, we believe that any burdens arising from a site-specific approach may be less than the potential costs of complying with a prescriptive performance standard. We also believe that greater environmental benefit will be achieved with the use of a site-specific approach. It is also likely that the use of a scientifically sound, site-specific approach will result in fewer legal challenges, thereby reducing some of the burden to the regulatory agencies that may occur under a prescriptive approach. EPA has also invited comment on whether the resource requirements of the site-specific approach serve as a disincentive to a comprehensive revisiting of section 316(b) permit conditions during each renewal, despite advances in technologies for reducing impingement mortality and entrainment. We believe that once a facility has installed BTA there is no need for a comprehensive review at each permit renewal. It is unlikely that possible advances in technologies for prevention of entrainment and impingement will improve to the point that would warrant retrofitting of technology during each five-year permit cycle, nor would it be practical to expect permittees to make expensive technology changes on such a frequent basis. A facility should only have to demonstrate during permit renewal that there are no significant changes in the operation of the permitted BTA, and that conditions in the waterbody are similar to those occurring during the original 316(b) demonstration. If comprehensive reevaluations are deemed necessary, they should be conducted on a minimum of a ten-year cycle (every other permit renewal), which would reduce the burden to the permitting authority.

EPA Response

In today's final rule, EPA has preserved the site-specific determination of BTA option for facilities whose costs of compliance with the final rule may be significantly greater than the costs estimated by EPA, or whose costs may be significantly greater than the benefits of complying with the national performance requirements in 125.94(b). In addition, EPA has added four other compliance alternatives to provide flexibility for streamlining the permitting process (e.g., the pre-approved technology alternative at 125.94(b)(4)). EPA believes that this approach will provide the combined benefit of addressing site-specific concerns and also ensuring that permits are finalized in a timely manner. See response to comment 316bEFR.034.005 for a discussion of the many streamlining efficiencies added to reduce burden in today's final rule.

EPA also believes that the compliance alternatives available under today's final rule should yield determinations of BTA that are legally defensible provided that the supporting studies and subsequent monitoring show the necessary reductions in impingement mortality and entrainment (as appropriate). EPA recognizes that in many situations, a comprehensive review may not be necessary at each permit renewal once a facility has installed BTA and conditions have not changed substantially at the waterbody or facility. Per 125.95(a)(3) of today's final rule, the facility may apply for reduced application studies in subsequent permit terms. The decision to accept reduced application studies is up to the Director.

Implications for nuclear facilities

Author Name Marvin S. Fertel
Organization Nuclear Energy Institute

From the time the first reactor was built, the nuclear power industry has been concerned first and foremost about the safety and health of the people and the environment surrounding our power plants. Comprehensive water and air sampling programs ensure that nuclear power plants meet the strictest emission requirements in the electric industry. The nuclear energy industry's programs to minimize environmental impacts start before plant construction, long before power is generated. The U.S. Nuclear Regulatory Commission (NRC) performs a National Environmental Policy Act (NEPA) review during licensing. For existing nuclear plants, the NRC's NEPA analyses considered the effects of cooling water intake structures' (CWIS) operations, and the NRC included, as appropriate, requirements in a licensee's operating license to address any unacceptable effects. In addition, because nuclear power plants do not emit criteria pollutants or greenhouses gases, they contribute to achievement of the nation's goals in clean air and climate change mitigation.

The proposed CWIS rule for existing facilities provides a sound starting point for establishing a regulatory framework that will ensure power plants meet necessary requirements to minimize adverse environmental impacts in an efficient and economic manner.

EPA Response

EPA appreciates the support of the Nuclear Energy Institute.

Comment ID 316bEFR.020.002

Subject Matter Code 17.06
Option: Site-specific determination of BTA

Flexibility of Implementation

Every nuclear power plant in the U.S. today uses water to cool the nuclear reactor in a process that transfers the heat energy via steam to electricity generators. Access to an ample supply of water is not only necessary for electricity production, but critical for the safe operation of the nuclear reactor.

There are 103 operating nuclear units that generate 20% of the nation's electricity. Sixty-four of these units (62%) use once-through cooling systems and will be affected by this rule. Cooling water intake structure designs vary widely among the nuclear fleet. The plants are located on a variety of water body types with different flow and surge characteristics. Plants were built at different times, need different intake flows and have very different intake structures, ranging from shoreline intakes to submerged offshore intakes. Some intake designs incorporate fish deterrents and/or fish return systems. <FN 2> Because the NRC conducts NEPA reviews during licensing, all plants were designed to mitigate environmental impacts. Furthermore, some of the once-through nuclear plants likely meet the proposed rule with their existing designs and technologies.

For those plants that do not meet the proposed rule, it is important that EPA allow flexibility in the use of technologies and measures to be employed, individually or in combination, to minimize the adverse environmental impact that may result from impingement and/or entrainment of aquatic organisms by a CWIS. The fact that cooling water intake structures are so varied means that the technology additions appropriate for one plant may not be appropriate for another due to environmental, economic, and/or safety reasons.

By creating rules that establish realistic performance standards and are not prescriptive with respect to the technologies to be employed to meet those standards, EPA will encourage innovative and economic solutions.

Footnotes

2 The word "fish" is used to mean all aquatic life forms.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA also notes that 125.94(f) allows for a site-specific determination of best technology available if conflict with Nuclear Regulatory Commission safety requirements.

Cooling system costs (e.g., dry, wet, recirculating)

Any changes to the proposed rule that mandate closed-cycle cooling or dictate, without flexibility, the retrofit of other specific technologies will not only increase the cost of implementation, but also could jeopardize regional power supplies and National Ambient Air Quality Standards (NAAQS) attainment strategies. Specifically, mandating the use of closed-cycle cooling systems could well be prohibitively expensive for some plants, causing premature nuclear unit closures, and would certainly increase outages at plants forced to adopt such technology. If nuclear power plants shut down because mandated, expensive retrofits to meet new Clean Water Act requirements caused them to become uncompetitive, the lost base load capacity would be replaced by coal- and gas-fired generation. The proposed rule under §316(b) addresses impacts on aquatic ecology, but it should not cause increased air emissions, and it makes little sense to resolve a presumed water use issue by creating new air quality problems.

Retrofitting closed-cycle cooling on a plant with a once-through system may cause the overall environmental impact to increase. It could negatively affect the air, as noted above, and the subject water body itself. Closed-cycle cooling increases water consumption by 67% <FN 3> - 80% <FN 4> and may have greater impact on a water body than other technologies that could be retrofitted onto a once-through system.

The analyses used by the EPA when drafting the proposed Phase II rule significantly underestimates the time and capital outlays required to retrofit an existing nuclear unit with impingement/entrainment reduction technologies, particularly a closed-cycle cooling system.

Detailed risk assessments and multi-system harmonization studies must be conducted during the design stage of such a retrofit, and these analyses are unique to or significantly more rigorous for a nuclear plant. This process would increase design costs and lead times. After the analysis is complete, the nuclear industry estimates it could take two prolonged outages to retrofit a closed-cycle system, potentially one for foundation blasting and definitely one for system tie-in. Because of their length, these outages could overlap either winter or summer peak electricity demand seasons, which could put electricity reliability at risk and increase costs to consumers.

According to EPA's Technical Development Document (TDD) for the Proposed Section 316(b) Phase II Existing Facilities Rule (EPA 821-R-02-003, April 2002), EPA has data on closed-cycle cooling retrofit costs for only one nuclear facility: the Palisades Nuclear Generating Plant. This case study, based on experience thirty years ago, is not a valid representation of a closed-cycle retrofit at a nuclear plant today, nor does it even appear to support EPA's conclusions about the extent of a likely outage associated with retrofitting a nuclear plant.

The capital and operating costs of retrofitting a closed-cycle cooling system on an existing nuclear facility have been underestimated. From the TDD, the average mean annual and summer peak energy penalties calculated by EPA for use in estimating future operating costs are lower than those EPA calculated for Palisades and significantly lower than those NRC and Consumers Energy (owner of Palisades) calculated. (Please refer to the table on the next page.)

Wet Tower vs. Once-Through Cooling System Energy Penalty <FN 5>

Average Annual Energy Penalty	
Consumer Energy's Palisades Estimate	7%
NRC's Palisades Estimate	3%
EPA's Palisades Estimate	1.8%
EPA's Average Estimate Applied to EPA's Economic and Benefit Analysis (EBA)	1.7%

Furthermore, the summer peak energy penalty EPA calculated for Palisades (2.7%) is 40% greater than the average summer peak penalty (1.9%) used in EPA's Economic and Benefit Analysis (EBA) supporting the Phase II Proposed Rule. Even just 0.10% difference in an estimated energy penalty changes lost annual revenue by hundreds of thousands of dollars. Underestimating the energy penalty causes incorrect predictions in the EBA of individual nuclear unit approaches to compliance and, therefore, an underestimation of total industry cost.

In calculating the capital cost of adding closed-cycle cooling systems to nuclear units with once-through cooling in the EBA, EPA used estimates below all actual cost estimates of the Palisades retrofit in the early 1970s without considering the subsequent significant regulatory changes imposed on the nuclear energy industry in the 1970s and 1980s. For example, Appendix B quality assurance requirements, which require safety-grade equipment for systems critical to reactor safety, like service water flow, went into effect in 1970. Similarly, the emergency core cooling system regulation (10 CFR 50.46), which the CWIS changes would affect, was implemented in 1974. Neither of these regulations affected the closed-cycle cooling retrofit at Palisades, which was granted its construction permit in 1967. Because of the significant changes in NRC regulations that have been implemented since, it would be much more costly to make changes to an existing nuclear unit today than it was in 1973 when Palisades built and connected its closed-cycle cooling system.

Footnotes

3 The EPA in the Phase II proposed rule, 67 Fed. Reg. 17,157

4 EPRI

5 Technical Development Document, pages 5-2, 5-36 and 37.

EPA Response

The Agency notes that the final rule includes neither (1) requirements based on closed-cycle recirculating cooling or (2) mandates for retrofit of any technologies. In fact, the final rule includes provisions that, should traditional design and construction technologies (i.e., screens, nets, etc.) and operational measures (such as voluntary capacity modifications) not be acceptable for certain applications and sites, then alternatively or partially in lieu of these technologies, restoration measures may be utilized to meet compliance with the rule requirements. Therefore, the commenter's primary concerns have been met and national/regional electrical supplies will not be jeopardized.

The Agency notes that the actual capital costs of the Palisades cooling tower retrofit compare favorably with those estimated by the Agency for the proposal and NODA (see DCN 4-2526). However, the commenter is correct to point out that the operating energy penalty of the Palisades plant, as reported to the Agency generally exceeds those estimated by the Agency for the NODA and proposal analysis. As noted by the commenter, the Agency found the reported annual average energy penalty of Palisades to be erroneous. The Agency concedes that it only found the value of 7 percent to be an outrageous value, and notes that the NRC generally agreed with this through their estimate of 3 percent. Nonetheless, the Agency notes that the Department of Energy determined that annual average energy penalties estimated by the Agency for the proposal and NODA analysis generally agreed with their independent analysis. Regardless, the Agency notes that the 3 percent estimate for Palisades from the NRC does exceed the energy penalty estimate for Palisades calculated by the Agency and notes that if this value were projected to other nuclear plant retrofit analyses, that the overall national costs would increase accordingly.

The commenter's observation is noted that subsequent to the Palisades retrofit in the early 1970's, significant regulatory changes were imposed on the nuclear energy industry. The Agency did not consider this when comparing its analysis of the historical actual costs of Palisades to those developed by the Agency for the proposal and NODA. The subsequent safety-related regulations were not considered by the Agency in analyzing the historical Palisades cost data. The Agency agrees that these subsequent regulations could increase construction costs for nuclear facilities beyond those reflected in the capital costs of the Palisades retrofit project.

Subject Matter Code 10.1

General: cost tests

In addition. EPA's Economic and Benefit Analysis also misrepresents the outage time required to retrofit a closed-cycle system. The EBA suggests a plant would require a four-month outage to tie in a new cooling system, less than half that experienced at Palisades.

For all these reasons, it is essential to retain the cost-cost test and the cost-benefit test [§125.94 (a) (3) and (c) (1), (2) and (3)] in any final Phase II rule. If the term "significantly greater" has judicious meaning, then these provisions provide the necessary flexibility to ensure compliance with the intent of the rule, the protection of aquatic life, without imposing unwarranted cost on the nuclear industry. Some guidelines should be set around the term "significantly greater." Guidelines have been suggested by several industry associations and individual companies. The nuclear energy industry urges EPA to carefully consider these proposed guidelines as the final rule is prepared.

As the Phase II Proposed Rule stands, the flexibility for each generating station to meet Clean Water Act requirements in a plant-by-plant appropriate way largely exists; it is essential that the final rule incorporates provisions, such as the cost-cost and cost-benefit tests, and standards not tied to particular technologies that retain and ensure this flexibility.

EPA Response

The final rule is not based on recirculating wet cooling towers and the Agency determined that cooling towers were not an acceptable basis for requirements of the final rule, in part due to the potential for extended construction downtimes (such as in the Palisades example above). EPA notes that the downtime it analyzed for cooling tower outages at nuclear plants in the Notice of Data Availability was considerably longer than that referenced by the commenter. As such, the analysis of the cooling tower downtimes and the Agency's rejection of regulatory alternatives based on cooling tower reflects the comments.

The Agency has included cost-cost and cost-benefit provisions in the final rule. As such, the commenters concerns have been met.

Organization Nuclear Energy Institute

Subject Matter Code 17.06

Option: Site-specific determination of BTA

The nuclear energy industry urges EPA: (1) to allow plants seeking NPDES permit renewals to choose those measures (technology or restoration) best-suited for environmental protection; and (2) to adopt reasonable definitions for the cost-cost and cost-benefit tests that are pre-requisites to submitting a site-specific demonstration. The inclusion of a site-specific option will allow each nuclear operator to address impingement and entrainment at plants, if necessary, in ways that will not compromise the nuclear plants' ability to provide economic, reliable, emission-free electricity. The nuclear energy industry strongly encourages the EPA to retain the flexibility mechanisms in the final rule.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA also notes that 125.94(f) allows for a site-specific determination of best technology available if conflict with Nuclear Regulatory Commission safety requirements.

For information on the role of restoration, please refer to sections VII and VIII of the preamble to the final rule.

Please refer to the responses to comments 316bEFR.005.020 and 316bEFR.410.001 for a discussion of the application of the cost-benefit and cost-cost tests.

Implications for nuclear facilities

Nuclear Safety

The nuclear energy industry welcomes the inclusion in the proposed Phase II rule of §125.94 (f), which allows the NRC to intervene during the NPDES permitting phase if it finds that methods used to meet this Phase II rule could jeopardize nuclear reactor safety. Because many facilities utilize a common CWIS for circulating and service water and the service water system supplies cooling water to the reactor and other safety-related systems at all times, regardless of generating status, safety issues and increased risk may result from some impingement/entrainment reduction technologies. Including this section in the final Phase II rule will alleviate potential regulatory conflicts that could arise. It also ensures that the health and safety of the public and the environment remains the dominant consideration.

The nuclear energy industry also urges EPA to consider the negative impacts of prescribed retrofit technology as it relates to nuclear reactor safety. Currently, nuclear plants are required to evaluate design changes against existing plant configurations under 10 CFR 50.59. Certain changes require NRC pre-approval.

Significant changes to balance-of-plant systems could trigger technical considerations as yet unknown to the nuclear plant operators, NRC or EPA. Specifically, the EPA should be sensitive to the unintended consequences of prescribing any retrofit technology, especially new or immature technology that would be imposed on a proven integrated power generation system. Circumstances could exist under which the EPA rule would unintentionally reduce the margin of reactor safety. The EPA must obviate this consequence by providing flexibility in the rule for nuclear plant operators.

EPA Response

Today's final rule allows for a site-specific determination of best technology available if requirements conflict with Nuclear Regulatory Commission safety requirements (see § 125.94(f)).

Comment ID 316bEFR.020.007

Author Name Marvin S. Fertel

Organization Nuclear Energy Institute

Subject Matter Code 17.06

Option: Site-specific determination of BTA

In conclusion, EPA should promulgate a final rule that promotes flexibility in compliance options and explicitly recognizes the primary jurisdiction of the NRC over any issue that could affect the safe operation of a nuclear facility. EPA should not mandate a specific technology because 1) different technologies will work differently at different plants; 2) the incentive for creating new, more efficient and economic solutions will be taken away, and 3) certain technologies at certain plants may produce adverse effects including increased air pollution, increased water consumption, and other impacts on electric power reliability.

Allowing nuclear power plants flexibility in meeting the CWIS rule will accomplish the equally legitimate goals of minimizing any adverse environmental impact of generating facilities while minimizing impacts on the price and supply of the nation's electricity.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA also notes that 125.94(f) allows for a site-specific determination of best technology available if conflict with Nuclear Regulatory Commission safety requirements.

Notes

UWAG (316bEFR.041)

Comment ID 316bEFR.021.001

Author Name William L. Neal

Organization The Large Public Power Council

Subject Matter Code 7.01

RFC: Three-option framework for determining BTA

The LPPC and APPA support EPA's proposed regulatory approach. EPA indicates in the proposed rules that it considered other technology-based options. These options are: 1. Intake Capacity Commensurate with Closed-Cycle, Recirculating Cooling Systems for All Facilities, 2. Intake Capacity Commensurate with Closed-Cycle, Recirculating Cooling Systems Based on Waterbody Type, 3. Intake Capacity Commensurate With Closed-Cycle, Recirculating Cooling System Based on Waterbody Type and Proportion of Waterbody Flow, and 4. Impingement Mortality and Entrainment Controls Everywhere. The LPPC and APPA don't agree that a closed-cycle recirculating cooling system is an available technology for facilities that currently have once-through cooling water systems. For most existing facilities it is neither financially nor spatially feasible to replace a once-through with a closed-cycle cooling water system. Further EPA itself notes that even for option 3 (the most limited application of closed-cycle recirculating cooling water systems), the incremental costs of this option significantly outweigh the incremental benefits. Options 2 and 3 would also significantly concentrate the costs of compliance with this rule among facilities located in coastal areas. The LPPC and APPA also favor the proposed option over option 4 as it offers a site-specific compliance option.

EPA Response

Please refer to the preamble for a description of the framework of today's rule. EPA appreciates the commenter's support of the regulatory approach in the proposal, and notes that the final rule uses a similar approach.

EPA elected to not adopt any of the alternative technology-based options discussed in the proposed rule (67 FR 17154-17159). Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

While EPA has concluded that cooling towers are not available to all existing facilities and, therefore, are not the technology bases for these national categorical rules, EPA recognizes that conversion of a once-through cooling system to a closed-cycle, recirculating cooling system has occurred at several facilities (see the Phase II proposed rule) and therefore may be available on a site-specific basis.

Organization The Large Public Power Council

Subject Matter Code 21.09

Permit applications/implementation schedule

The proposed rule states that 316(b) requirements for Phase II existing facilities would be implemented through the NPDES (National Pollutant Discharge Elimination System) permit program. Facilities subject to the proposed rule would comply with Phase II rules when an existing NPDES permit is reissued or, when an existing permit is modified or revoked and reissued. This implementation plan presents some significant scheduling problems for facilities where NPDES permits expire in the next several years. A NPDES permit renewal application is due 180 days prior to expiration. The proposed rule states this application would include new information requirements for a facility: physical data to characterize the source waterbody in the vicinity where the cooling water intake structures are located; data to characterize the design and operation of the cooling water intake structures; information describing the design and operating characteristics of the cooling water systems and how they relate to the cooling water intake structures at the facility; and all facilities (except those that already use a closed-cycle, recirculating system) must submit a Comprehensive Demonstration Study.

The Comprehensive Demonstration Study has seven components: proposal for information collection; source waterbody flow information; impingement mortality and entrainment characterization study; design and construction technology plan; information to support proposed restoration measures (only for facilities proposing to use restoration measures); information to support site-specific determination of best technology available for minimizing adverse environmental impact (only for facilities choosing a site-specific standard); and a verification monitoring plan. For the first component of the study, a facility would be required to submit a proposal to the Director for review and approval stating what information would be collected to support the study. Several of these components could likely require source waterbody studies conducted over multiple seasons and more than one year to obtain representative data. The data acquired will also require some time for analysis and the development of a report. The LPPC and APPA position is that any facility subject to Phase II with a NPDES permit expiring 3 years or less after the issuance of the final rule should not be subject to these requirements until the subsequent NPDES permit renewal. This staggering of the imposition of the requirements for the final Phase II rule will also allow States to better plan for the resources necessary for their implementation.

EPA Response

EPA has added many efficiencies to today's final rule since the NODA and preamble to provide additional flexibility and speed permitting. Please see response to comment 316bEFR.034.005 for a full discussion.

Comment ID 316bEFR.021.007

Author Name William L. Neal

Organization The Large Public Power Council

Subject Matter Code 12.02

RFC: Monitoring frequencies

EPA requested comment on minimum frequencies for verification / compliance monitoring, specifically, for at least two years following initial permit issuance, impingement samples at least once per month over 24 hours and entrainment samples at least biweekly over 24 hours during primary period of reproduction, larval recruitment, and peak abundance. The LPPC and APPA position is that once the best technology available to meet the required performance standards (or site-specific requirements) has been determined and installed, a facility should only have to conduct monitoring to show the equipment (or other measures) are operated or utilized in accordance with permit conditions. Verification / compliance monitoring will be satisfied by monitoring the operations of the best technology available.

EPA Response

EPA disagrees that monitoring should cease after the installation of protective technologies. Today's final rule requires that monitoring be conducted in accordance with the verification monitoring plan (125.95(b)(7). Specific study parameters may be proposed by the applicant for review and approval by the Director. The Director may also consider additional monitoring requirements. Facilities that demonstrate compliance with a Technology Installation and Operation Plan may do so in place of complying with numeric performance requirements. Please see the final rule preamble for a discussion of the Technology Installation and Operation Plan. For a detailed explanation of EPA’s monitoring requirements, please see EPA’s response to comment 316bEFR.307.027. Please also see EPA’s response to comment 316bEFR.074.023.

Comment ID 316bEFR.021.008

Author Name William L. Neal

Organization The Large Public Power Council

Subject Matter Code 21.09

Permit applications/implementation schedule

The proposed rule indicates that at each NPDES permit renewal, the same Phase II information requirements will be in place. The LPPC and APPA position is that once best technology available has been implemented for a facility, unless there have been significant changes to the waterbody / aquatic community, that technology remains best technology available. To interpret otherwise would mean a facility could be faced with the design and installation of a new best available technology at each NPDES permit renewal. A facility should not be required to submit a comprehensive data study with each permit renewal.

EPA Response

EPA agrees. Under 125.95(a)(3) of today's final rule, a facility may apply for reduced application requirements if conditions at the facility remain substantially unchanged from the previous permit issuance. Please see response to comment 316bEFR.034.005 for a discussion.

Submittal of required information

With respect to the source water physical data, the comprehensive demonstration study, and any other biological studies, the LPPC and APPA believe that the Director should be given authority to determine which studies, and their parameters, are necessary and to determine which species are of concern.

EPA Response

EPA agrees that for many aspects of the study submission requirements, decisions should be made by the Director. EPA agrees that the Director should review the Proposal for Information Collection and decide which studies are necessary, the study parameters, and the specific species to consider. EPA believes that the Director is most familiar with site conditions in his/her purview and would be best positioned to make these decisions. During the permit application process, a facility may propose a methodology detailing these measures in the Proposal for Information Collection. However, the source water physical data is an application requirement that applies to all facilities (40 CFR 122.21(r)(2)). Source water physical data will be used by the Director to help characterize the facility and evaluate the waterbody type and assist in evaluating the appropriateness of design and construction technologies, operational measures, and/or restoration measures proposed by the applicant to reduce impingement mortality and/or entrainment.

RFC: Proposed use of restoration measures

Author Name William L. Neal

Organization The Large Public Power Council

The LPPC and APPA support EPA's recognition of the importance of voluntary restoration measures in maintaining a healthy fishery. Because the Director and the affected facility are the most familiar with local water body conditions and history, the LPPC and APPA position is that it be at the Director's discretion as to whether and what extent voluntary restoration is a part of best technology available for a facility to meet the performance standards of the Phase II rule.

EPA Response

For a discussion of the permitting authority's role in the approval of restoration measures, see EPA's response to comment 316bEFR.034.029.

Proposed standards for lakes and reservoirs

A number of public power electric generating facilities use cooling ponds or reservoirs that have been constructed off of a main watercourse channel. Water withdrawn from the cooling reservoir is used for non-contact cooling and discharged back into the reservoir from which it can be withdrawn and recirculated. Such manmade cooling reservoirs or ponds are supplied with makeup water pumped from a nearby source, such as a river. Such cooling water ponds often provide a valued asset due to the enhanced aquatic habitat and recreation opportunities that they offer.

A cooling pond or reservoir meets the definition of a “closed-cycle recirculating system,” which as set forth in Section II, Scope and Applicability of the Proposed Rule [Page 17129] Section G “means a system designed, using minimized makeup and blowdown flows, to withdraw water from a natural or other water source to support contact and/or non-contact cooling uses within a facility. The water is usually sent to a canal or channel, lake, pond, or tower to allow waste heat to be dissipated to the atmosphere and then is returned to the system. New source water (make-up) water is added to the system to replenish losses that have occurred due to blowdown, drift and evaporation.”

Although closed-cycle, recirculating cooling is not one of the technologies on which the presumptive standards are based, the proposed rules recognize that the use of a closed-cycle, recirculating cooling system would readily achieve such standards. For that reason, the proposed rule, [124.94(b)] would allow the performance standard to be satisfied by reducing the “intake capacity to a level commensurate with the use of a closed-cycle, recirculating cooling system.”

Based on the above, the LPPC and APPA readily conclude that those existing facilities, which are located on and use cooling water from a closed-cycle, cooling pond are in compliance with the proposed Phase II rule. This conclusion appears to be further bolstered in EPA’s assessment of impacted facilities [page 17142] in which EPA concludes based on an analysis of survey data that “the proposed rule would not require any changes at approximately 69 large existing facilities with recirculating wet cooling systems (e.g., wet cooling towers or ponds).”

However, what appears to be clear cut is muddled in the discussion on cooling ponds vis a vis “waters of the United States.” Under Section C., Is My Facility Covered If It Withdraws From Water of the US., EPA states that they “do not intend this proposal to change the regulatory status of cooling ponds.” EPA further clarifies that “cooling ponds are neither categorically included nor categorically excluded from the definition of waters of the United States at 40 CFR 122.2.” Accordingly, EPA has concluded “facilities that withdraw cooling water from cooling ponds that are waters of the U.S. and meet other proposed criteria for coverage would be subject to today’s proposed rule.”

In that a number of cooling ponds provide recreational and fishing opportunities for both in-state and out-of-state visitors, i.e., support interstate commerce, they often will meet the definition of waters of the United States. The issue, however, should not be whether or not they are defacto waters of the United States but, rather, whether they are a system that satisfies the performance standard or a system that must meet the performance standard. Or more simply put, are they part of the solution or part of the problem.

The uniqueness of a man-made, off-channel, closed-cycle, recirculating cooling pond is such that we believe they should not be lumped together with lake and reservoirs-regardless of whether or not they are determined to be waters of the United States. More appropriately, these man-made resources, which often provide a valued habitat and fishery that otherwise would not exist and allow a cooling water intake capacity at a level commensurate with the use of a closed-cycle, recirculating cooling system, should be explicitly defined as meeting the performance standards of this rule.

EPA Response

Subject Matter Code 7.02

Performance standards

With respect to the performance standard for reduction in impingement mortality of 80 - 95%, the LPPC and APPA offer the comment that this level of reduction may be possible ONLY with the use of advanced technologies that are not applicable to all water bodies, particularly so with regard to detritus-laden fresh water rivers. The Director should be given discretion on determining best technology available for a facility that may not meet the 80-95% impingement mortality reduction performance standard.

EPA Response

EPA disagrees with the commenter's assertion that the performance standards may only be met with the use of advanced technologies. Several of the technologies discussed in the Technology Development Document are not considered "advanced" and have been available and documented over the last 30 years. High-debris waterbodies may require additional measures to prevent debris from impacting the performance of the technology but EPA believes such issues can be successfully addressed.

Today's rule authorizes the Director to make site-specific determinations of Best Technology Available (BTA) for minimizing adverse environmental impacts.

Comment ID 316bEFR.021.013

Subject Matter Code 10.09

RFC: Does today's proposal allow for 'backsliding'

Author Name William L. Neal

Organization The Large Public Power Council

EPA has expressed concern that the proposed performance standards could create an opportunity for "backsliding" from current impingement mortality and entrainment performance levels. The LPPC and APPA do not believe this concern is justified and that facilities will not remove or disable currently installed technology from their cooling water intake structures.

EPA Response

The final rule does not alter the existing anti-backsliding provisions that are part of the NPDES program regulations (e.g., 40 CFR 122.44(l)). In general, comments addressing this issue did not identify it as a concern based on the existing federal and state restrictions, the significant level of environmental protection provided by the final rule, and the expectation that facilities would be unlikely to abandon significant prior investment in cooling water intake technologies. EPA would add that the final rule allows existing facilities to rely on such prior investment in cooling water intake technologies to a significant degree (e.g., see, 40 CFR 125.94(a)(2)).

Comment ID 316bEFR.021.014

Author Name William L. Neal
Organization The Large Public Power Council

Subject Matter Code 21.0
Implementation

The LPPC and APPA believe the final rule should include a provision to cover facilities that will be decommissioned within 10 years (a period that also coincides with the timing for significant investment for air emission controls currently under consideration) after the Phase II rule becomes final. If the Director obtains necessary assurances that the facility (and its cooling water intake structure) will cease operation within a time certain, the final NPDES permit(s) should be renewed without the requirements imposed by the Phase II rule.

EPA Response

EPA disagrees that the final rule should include a provision to exempt all facilities that will be decommissioned within 10 years. Nevertheless, there are several ways for a facility that is scheduled to go off-line to be subject to minimal requirements. For example, during the permit application process, the facility may request a cost-benefit variance through the site-specific compliance alternative. If the facility demonstrates that the costs are significantly greater than the benefits of complying with the rule (due in part to the fact that the facility will be closing), that facility will be subject to less stringent and costly requirements. An additional factor that Directors consider is the capacity utilization rate. A facility that is in the process of decommissioning will experience reduced intake flow, and as such will be subject to less stringent requirements. A facility with no intake (decommissioned) will have no intake flow, and as such will not be subject to 316(b) requirements. For these reasons, EPA believes that it is not necessary to formally exempt facilities that will be decommissioned within 10 years, because the rule provides mechanisms to protect such facilities against unreasonable costs.

Option: UWAG's recommended approach

Author Name J. Michael Childers

Organization Mirant Corporation

Of the alternative options EPA is proposing, Mirant believes that site specific approaches based on the UWAG or PSEG recommendations would serve as the best approach for the Phase II Rule. These site-specific approaches are based on aspects of successful State programs or concepts to facilitate effective decision making. Mirant, however, believes that EPA's preferred approach is workable with certain clarifications and could be enhanced with a certain modifications.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Comment ID 316bEFR.022.002

Subject Matter Code 19.0

Dry Cooling

Author Name J. Michael Childers

Organization Mirant Corporation

Dry Cooling Technologies are not appropriate for this rulemaking. There are few facilities in the U.S. that currently utilize this technology. Currently we do not believe there is sufficient understanding of potential operational problems or environmental disbenefits with these technologies. Additionally, the high capital and operational costs, and the energy penalty associated with the technology are significant.

EPA Response

EPA agrees that dry cooling technologies are not appropriate for this rulemaking. However, the Agency somewhat disagrees that "few facilities in the U.S." currently utilize the technology. Dry cooling is a potentially viable alternative for some new facility installations. The important point, in the Agency's view, is that dry cooling is not a feasible technology for retrofitting into existing facilities of the size of those within the scope of the rule.

Dry cooling towers would probably be infeasible in certain locations. For instance, the turbine back pressure could increase beyond recommended manufacturer specifications for a number of existing units and would require severe curtailment of normal operations, or a redesign of the circulating water system and associated equipment. Modeling conducted by the DOE shows that during hot weather the dry cooling tower would not be able to safely (due to the operation of the existing turbines above back pressure design limits) supply sufficient cooling at a significant number of existing power plants .

Even if a company were able to use dry cooling as a retrofit option, the land area footprint would be very large and create other land use, and construction issues. For instance, a representative dry cooling tower installation at an existing power plant located in the Eastern United States would have a footprint area that is 50 percent to 100 percent the size of a typical power plant footprint. For a number of existing power plant facilities, this amount of additional space is simply not available.

Further, the DOE analyzed the energy penalties and air emissions resulting from retrofitting a power plant with once-through cooling to indirect-dry cooling towers ("Energy Penalty Analysis of Possible Cooling Water Intake Structure Requirements on Existing Coal-Fired Power Plants" June 14, 2002). The report concludes that dry cooling towers are not a viable option to be used as retrofits for once-through cooled plants. The primary reasons for such a stark assessment of this technology option are as follows: at the peak time of summer electricity demand many of the existing power plants' turbines could not perform safely; energy penalties associated with a dry cooling tower retrofit could range from 9 to 16 percent at times of peak electricity demand; the dry cooling tower system may require significant plant modifications to retain the integrity of power plant operations; secondary impacts of increased air emissions are significant (could be as great as 4 to 8 percent higher) for a dry cooling tower system; and, retrofit difficulty in a number of plant locations would be too great to warrant continued operations of the power plant.

RFC: EPA rationale to not require closed-cycle

Retrofitting existing facilities with wet closed-cycle cooling is similarly inappropriate not only due to the significant cost and energy penalties, but environmental disbenefits such as consumptive water use. Mirant is engaged in a project to add additional generation at its Dickerson Station on the Potomac River in Montgomery County, Maryland. Wet closed-cycle cooling has been proposed for the new combined cycle units and the consumptive water associated with the cooling towers has been the most significant environmental concern for the Project due to current drought conditions and forecasts for increased water demands to accommodate growth. Mirant has agreed to not operate the new combined cycle units during drought emergencies unless it releases stored water to compensate for evaporative water loss. However, if the existing 500 MWe of baseload generation at this power plant were forced to retrofit with wet-closed cycle cooling, the result would be the loss of significant baseload generation during periods of peak summer demand when power is most needed. Further, Mirant's Potomac River Station in Alexandria and Lovett Station in New York are sited in areas with severe space constraints that preclude installation of cooling towers at these sites. However, we fully support EPA's decision to consider those Phase II facilities that employ use of wet closed-cycle cooling to be deemed in compliance.

EPA Response

The Agency has not based the final rule on wet closed-cycle cooling technology retrofits. As such, the commenter's concerns have been met.

Available I&E technologies

Proposed Technologies and the Performance Standards

Mirant's assets have been innovative in developing new technologies to reduce impingement and/or entrainment and recommends that there are several points that EPA should consider regarding the use of alternative technologies such as those specified by EPA in the Phase II rule. The technologies developed at Mirant's assets, in particular the Gunderboom, are likely to have wide application for use by facilities for compliance with the proposed performance standards. However, these and other alternative technologies proposed by EPA generally are not likely to be feasible at some sites and may not be effective at others and at still others may be feasible and effective but at a cost that far exceeds their benefit. Mirant therefore believes that one of the most essential elements of EPA's proposal is the site specific alternative.

EPA Response

EPA agrees with the commenter that the Gunderboom technology (aquatic filter barrier) offers great promise in reducing both impingement mortality and entrainment but may not be the optimal choice for all facilities. Thus far, aquatic filter barrier technologies have proven most successful in sheltered areas of waterbodies (coves, canals) with lower debris loads. EPA recognizes that research and development of this relatively new technology is ongoing and leaves open the possibility that aquatic filter barriers may become more widely deployable in the future.

Today's rule provides five compliance alternatives. Compliance alternative 2 allows the facility to demonstrate that its current design and construction technologies, operational measures and/or restoration measures meet the performance standards. Compliance alternative 3 allows the facility to demonstrate that it has selected design and construction technologies, operational measures, and/or restoration measures that will, when implemented, meet the performance standards. In both cases, EPA has refrained from making a determination of what combinations of technologies or measures constitutes Best Technology Available (BTA) in recognition of the fact that site-specific factors may warrant different determinations for different facilities.

Compliance alternative 4 allows a facility that meets certain operational and siting criteria to install and properly operate an approved technology. Today's rule designates cylindrical wedgewire screens as an approved technology for facilities meeting the criteria listed at § 125.99(a). Today's rule also reserves the right of the Director to approve other technologies as BTA for all facilities within his or her jurisdiction. For further discussion please see section V of the preamble and § 125.99(b).

Benefit Estimation Methodology

Benefits Quantification

Mirant believes that it is important that the benefits quantification be conducted correctly in this rulemaking. Not only is this essential to place the costs associated with compliance in perspective but it is important in establishing the basis for use of the cost benefit test for not only the preferred approach, but also for the other alternatives considered by EPA. Mirant is concerned that the quantification of benefits conducted in the proposal greatly overstates the proposed benefits. Specifically, the multiple compounding of a series of conservative assumptions is the basis of Mirant's concern.

EPA Response

EPA agrees that it is important for benefits quantification to be conducted correctly. EPA's approach to benefit cost analysis of the final Section 316(b) Phase II rule is consistent with principles outlined in the EPA's Guidelines for Preparing Economic Analyses, United States EPA (EPA 240-R-00-003)(DCN #6-1931).

The commenter asserts that EPA's benefits estimates are "grossly overstated" because of "multiple compounding of a series of conservative assumptions," but provides no specific criticism of EPA's analysis. Therefore, the Agency is unable to respond to this comment. For EPA's response regarding multiple conservative assumptions, please see the response to comment #316bEFR.074.042.

Documented facility examples of CWIS impacts

Statements made by EPA indicating that impingement and entrainment numbers listed for facilities used in the analysis could be low and that actual numbers may be much higher. On the contrary, based on our own studies and analysis Mirant believes the opposite is true. Specifically impingement studies at our Chalk Point Station indicated that when samples were collected on a weekly or less frequent basis (as was commonly done in many facility studies) and extrapolated to an annual estimate, the estimate was an order of magnitude higher than a complete census based on daily sampling (details provided in Mirant's Coolfont Paper presented to EPA at the EPRI workshop). Similarly, when detailed studies of fish behavior were conducted to incorporate behavioral factors into entrainment effects models it was found that these factors resulted in the ability of larval fish to avoid entrainment at much earlier life stages than was originally assumed in the models. It is likely that similar overestimates resulted in model projections conducted in other studies that did not incorporate behavior factors into the models. Finally, many facilities chose to use life history parameters for broad life-stage categories to estimate production foregone or equivalent results EPA used such terms in its analysis. When analyzing this approach for the Chalk Point Station it was determined that this process may overestimate losses if not done properly. There is insufficient documentation to determine if this is the case.

EPA Response

EPA notes the commenter's assertion that extrapolated I&E data produced an overestimate of I&E rates at Chalk Point. However, the commenter does not provide the data referred to, and therefore EPA is unable to confirm or refute this assertion.

Likewise, although EPA agrees with the commenter that fish behavior may influence entrainment vulnerability, EPA is unable to comment on this assertion without seeing the data upon which it is based. In any case, it appears that the commenter is referring to a model of entrainment losses, not empirical data such as those used by EPA in its regional analysis for the final rule.

EPA notes that even if these assertions about Chalk Point data proved to be true, it does not mean that such patterns hold at other facilities.

Finally, EPA appreciates the commenter's concern about data uncertainties, as discussed by EPA in Chapter A6 of Part A of the Phase II Regional Study Document.

Use of Replacement Costs (HRC and hatchery-based)

The use of Habitat Replacement Costs (HRC) to estimate benefits - UWAG, EEI and EPRI all retained natural resource economists to assists in preparation of comments. In addition, a utility member of EPSA hired an economist to assist with a facility that was also used in an EPA case study. Each of these four economists quickly pointed out that HRC is a method to quantify costs for creation of projects to offset an environmental effect and that costs are not benefits. HRC derived costs are simply not appropriate as a basis for analysis of benefits. While fish direct replacement costs, such as those developed by the American Fisheries Society (AFS), are deficient for the same reason, if replacement costs were to be used for benefits quantification analysis, Mirant believes it would be far more logical to use those costs than HRC costs for two reasons. First, they directly state the value to replace fish and second if one were using costs one would logically use a lower of two alternatives to replace a resource rather than a more costly method. Mirant does note that AFS has issued cost tables for various species of adult and juvenile fish but has not issued replacement cost values for early life stages. However, it would not be illogical to estimate the number of equivalent juvenile fish in order to be able to take advantage of the AFS replacement value tables (conversion to equivalent juveniles is used since juveniles are the earliest life stage included in the AFS tables). Again, Mirant believes the best course of action for EPA is to avoid confusing costs and benefits and use the generally accepted methods for natural resource benefits quantification as discussed in more detail in UWAG's comments.

EPA Response

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule.

Please see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method. Please also see EPA's response to comment #316bEFR.005.035.

Valuing Forage Species (incl non-use and non-landed)

The assumption that a 0.5 factor is appropriate for quantification of non-use — Mirant notes there is a great deal of uncertainty involved in any attempt to estimate non-use benefits. EPA acknowledges this in the proposal and attempts to address the issue by inserting a nominal 0.5 adjustment factor to adjust for this error. Mirant sees no basis for the 0.5 factor and finds it inconsistent in the overall benefit analysis to not include a similar adjustment factor for entrainment survival or compensation that are also known to occur but which have uncertainty. Mirant strongly recommends the benefits assessment be revised and based on accepted natural resource quantification methods and use of a consistent methodology for addressing uncertainty.

EPA Response

For EPA's response to comments on the use of the 50% rule-of-thumb to estimate non-use benefits, please refer to EPA's response to comment #316bEFR.005.034.

Please also refer to EPA's response to comments on the HRC methods (316bEFR.005.035) and the SRP methods (316bEFR.005.006); the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003); and to EPA’s Guidelines for Preparing Economic Analyses (EPA 240-R-00-003).

For EPA's response to comments on entrainment survival and compensation please refer to the response to comment 316bEFR.306.506. Also refer to Part A of the case study document for the final rule (DCN #6-0003), Chapter A7: Entrainment Survival.

RFC: Proposed use of restoration measures

Restoration

Based on Mirant's experience with restoration measures, Mirant believes the greatest benefit for use of this approach will be achieved if flexibility is provided in terms of species specificity and geographic siting of projects. In the case of the Chalk Point Station, aquaculture was one of the primary methods used to compensate for entrainment losses. The bay anchovy was the primary species of concern at Chalk Point. However, at the same time, striped bass had been declared threatened and endangered by Maryland Department of Natural Resources (MDNR). Striped bass were entrained in very low numbers due to their spawning much further upstream and were also impinged in very low numbers. One of Maryland's concerns over anchovy entrainment losses was that since anchovies are a striped bass food source, the striped bass population might be affected. MDNR asked that the Chalk Point Aquaculture Center to focus on production of striped bass directly rather than anchovies. As the striped bass began to recover in the Patuxent, MDNR had striped bass produced at the aquaculture center released in the Choptank and Nanticoke Estuaries on the eastern shore of the Chesapeake Bay rather than in the Patuxent where Chalk Point was located. This decision was made because MIDNR believed restoration of striped bass in the Bay could be best achieved by focusing on those restoring populations in those waterbodies. Later on MIDNR changed aquaculture production focus to American shad and hickory shad both of which had nearly disappeared from the Patuxent. All commercial fishing for these species continues to be banned. In addition, Atlantic sturgeon, another species that Maryland is contemplating for State threatened and endangered species status, has been reared for aquaculture at MIDNR's request. Neither the shad species nor the sturgeon are entrained, yet they are considered by MIDNR far more important for restoration focus than anchovy, naked goby or Atlantic silverside which make up the vast majority of entrainment. Mirant encourages EPA to allow flexibility in terms of species selected for replacement and geographic focus when using restoration measures to offset impingement and/or entrainment. This will continue to allow state natural resource management agencies the flexibility to obtain the greatest benefit to restore important depleted stocks and allow stocking or habitat creation projects to be located where they will provide the greatest benefit within state waters.

EPA Response

For a discussion of the use of restoration measures that address organisms other than those impinged and entrained by a particular cooling water intake structure (out-of-kind restoration), see EPA's response to comment 316bEFR.206.055.

Permit applicants may undertake restoration measures that produce fish and shellfish, while maintaining community structure and function, in their facility's waterbody or watershed. These restoration measures must produce ecological benefits at a level that is substantially similar to the level that would be achieved through compliance with the applicable impingement mortality and entrainment reduction requirements under section 125.94. For additional discussion of the spatial scale in which restoration may take place, see the preamble to the final rule.

EPA believes the requirements for restoration measures in the final rule provide a significant amount of flexibility to permitting authorities and permit applicants.

For a discussion of the extent to which restoration measures may support state natural resource management goals, see EPA's response to comment 316bEFR.099.029.

Comment ID 316bEFR.022.014

Author Name J. Michael Childers

Organization Mirant Corporation

Subject Matter Code 11.01

RFC: Proposed use of restoration measures

Mirant also believes facilities that made use of restoration to compensate for impingement and/or entrainment under state regulatory programs should be allowed credit for the benefits of those restoration efforts. EPA has appropriately allowed facilities to take credit for use of technologies installed to reduce CWIS losses in determining their baseline. Just as EPA provides an opportunity for credit for those facilities that selected BTA to reduce CWIS impacts, similar credit should be allowed for those facilities that chose the restoration option.

EPA Response

For a discussion of the use of existing restoration measures, see EPA's response to comment 315bEFR.034.032.

Comment ID 316bEFR.022.015

Author Name J. Michael Childers

Organization Mirant Corporation

Subject Matter Code 11.01

RFC: Proposed use of restoration measures

Further, to facilitate use of restoration EPA should allow facilities and states some flexibility in scaling projects to impingement and/or entrainment losses. Based on quantification of impingement and entrainment losses in determining the baseline, Mirant believes facilities and states agree on reasonable and appropriate aquaculture production levels to offset losses or scaling of habitat creation or enhancement projects to offset those losses. Scaling of habitat replacement projects in particular is not an exact science and this would be especially true on species by species fish for fish basis. The costs associated with attempting to quantify habitat projects or aquaculture of species of unlike kind on such a basis would divert significant resources that could be better applied to restoration efforts.

EPA Response

EPA believes the requirements for restoration measures in the final rule allow permitting agencies and facilities flexibility in their determination of the appropriate scale of a restoration measure. There are a variety of methods available for scaling. The permitting authority has the responsibility to determine if a restoration measure designed according to a particular scaling method is appropriate.

All restoration measures must meet the requirements described in the final rule, including those under sections 125.94 and 125.95. EPA believes these requirements are important for helping to ensure that restoration measures are well designed and well considered before significant resources are devoted to their implementation. The requirements are particularly important in light of the uncertainties associated with restoration projects. EPA agrees with the commenter that there are uncertainties associated with scaling of habitat replacement projects. For a discussion of the types of uncertainties associated with restoration measures, see EPA's response to comment 316bEFR.206.055.

RFC: Should EPA include impingement trading?

Trading

Mirant supports use of trading in the 316(b) program. Trading has been successfully used in EPA air programs and the potential to provide a similar benefits to water programs. It brings market forces to bear in addressing compliance issues with the potential to provide a greater environmental benefit.

EPA Response

Please see response to comment 316bEFR.034.027 regarding the role of trading in today's final rule.

San Francisco Bay Delta

Comments on the San Francisco Bay/Delta Estuary Case Study

General — After careful review of the subject case study, Mirant Corporation believes that EPA in the case study significantly overestimates the economic losses due to impingement and entrainment of striped bass and special status species fish at its Pittsburg and Contra Costa plants located in Contra Costa County, California. Significant overestimation of current I&E losses causes EPA to significantly overstate the economic benefits of implementing proposed Section 316(b) Phase II regulations at these two Mirant plants. EPA has significantly overestimated E&I losses for the Pittsburg and Contra Costa facilities by making the following three erroneous assumptions for its I&E economic loss estimates:

1. EPA improperly uses 1978/1979 I&E data as its baseline for striped bass (recreational species) losses - As EPA acknowledges on pages E2-4 through E2-6 of the case study report, both plants implemented a best technology available (BTA) program after 1978/1979 to reduce the losses of striped bass. As indicated in Table E2-3 of the case study report, annual reductions in striped bass losses due to the application of the BTA program averaged 86.9 percent during the 1995 — 1999 five-year period. Accordingly, Mirant believes the EPA should have reduced the raw striped loss numbers reported in Tables E3-2, E3-6, E3-l0, and E3-14 by a factor of 86.9 percent to reflect the current striped bass baseline for these two facilities. These reductions in striped bass I&E losses should then have been factored in all subsequent EPA loss calculations (e.g., determination of Age 1 equivalents, determination of production foregone).

2. For special status fish, EPA inappropriately averaged impingement and entrainment data collected prior to installation of design and operational measures with data collected after deployment of such measures - Mirant believes that the 1978/1979 I&E data should not be used to represent current conditions at the cooling water intake structures at the two plants. These earlier data predates the striped bass BTA program which has direct benefits in reducing special status species fish I&E losses. Accordingly, Mirant recommends that only the 1987 through 1990 impingement data and 1987 through 1992 entrainment data be used for determining special status fish losses. In addition to making the mistake of using one year's (i.e., 1978/1979) of pre-BTA data, EPA made the mathematical error of averaging one year's of late 1970's data with an average representing a multi-year subsequent period.

3. EPA used an improper methodology to set the economic value for special status fish and additionally made a serious calculation mistake in applying this flawed methodology - To value special status species fish in Chapter E5 of the case study, EPA used a societal revealed preference approach. In Table E5-3, a low and high range of special status species fish is determined by summing the habitat restoration costs with water use foregone cost and dividing this sum by the number of fish that will be restored. Using this approach, EPA calculated an annual water use foregone cost ranging from $465,000,000 to $1,700,000,000 which results in fish values ranging from $83.72 to $288.28 per fish. Mirant believes there are two major problems with this approach as follows:

a. Mirant opposes use of replacement values as a means of economically quantifying the benefits of environmental regulations. As stated previously in these comments replacement values are costs, not benefits. Even if one were to decide to use replacement costs for this purpose one would logically use the most direct and lowest cost method of replacement rather than use a high cost method. In the case of Pittsburg and Contra Costa such values would be fish replacement costs developed by the American Fisheries Society Fisheries Society Special Publication 24 (1992) rather than much more costly habitat replacement cost used in the analysis. Mirant points out that California Department of Fish and Game (CDFG) established a cost for replacement of striped bass and that value has never exceeded $2.00 per fish of equivalent 150 mm size. Mirant expects special status fish could be reared for similar or lower cost if EPA were to continue to pursue use of costs as benefits the figure EPA should use for special status fish should be based on replacement costs for these species. AFS tables could be one way to estimate such costs.

b. EPA made the error of assuming that all water use foregone costs are for the purpose of restoring special status species fish. As stated in Section E5-3 of the case study report, “The Bureau had to cut back on the supply to its CVP customers to comply with various water needs and restrictions of the Federal Endangered Species Act (FESA) and the California Endangered Species Act (CESA), the CPV Improvement Act (CPVIA) and the new bay-delta water quality standards issued in 1995 by the State Water Resources Control Board”. Therefore, it is evident that the cost of foregone water use is not just for the restoration of special status species. Mirant believes that 20.05% of the water foregone cost is a more appropriate measure of the fraction used to restore special status species since this is the mid-range percentage of the CALFED cost used for special status species fish protection. This percentage was determined by dividing the $3.81 billion reported in the second paragraph of page E5-3 by the $19 billion total estimated CALFED cost.

General — Since Mirant believes that EPA has greatly overestimated the I&E losses at the Pittsburg and Contra Costa facilities due to the three broad errors discussed in the previous comment, we have recalculated the losses using more appropriate assumptions. Mirant’s revised economic loss calculations are presented in four Exhibits that accompany these comments:

[see hard copy for figures]
Exhibit 1 — Revised Striped Bass Economic I&E Losses for the Pittsburg Plant

Exhibit 2— Revised Striped Bass Economic I&E Losses for the Contra Costa Plant

Exhibit 3— Revised Special Status Species Fish I&E Economic Losses for the Pittsburg Plant

Exhibit 4— Revised Special Status Species Fish I&E Economic Losses for the Contra Costa Plant

As can be seen in the two tables presented below, Mirant’s revised I&E losses are significantly less than those reported by EPA. Nevertheless, Mirant believes that its estimates are more accurate since they account for post-BTA striped bass loss numbers; more representative special status species fish loss numbers, and correct a significant error in EPA’s societal revealed preference value for special status species fish. Although Mirant continues to believe that habitat restoration costs are not an appropriate method for valuing special status fish, we use this method in the Exhibit 3 and 4 calculations to illustrate our dual concerns with EPA’s overestimates of special status fish I&E losses and value per fish.

Comparison of EPA and Mirant Revised Striped Bass I&E Estimates

	Pittsburg Plant		Contra Costa Plant	
	Impingement	Entrainment	Impingement	Entrainment
Low EPA Value	$167,201	$1,888,844	$204,531	$640,185
High EPA Value	$259,518	$2,931,750	$317,462	$933,657
Mirant Value	$24,015	$271,635	$29,430	$92,070
% of Low EPAValue	14.36	14.38	14.39	14.38
% of High EPA Value	9.25	9.27	9.27	9.86

Comparison of EPA and Mirant Revised Special Status Species Fish I&E Estimates

	Pittsburg Plant		Contra Costa Plant	
	Impingement	Entrainment	Impingement	Entrainment
Low EPA Value	$9,730,441	$16,901,645	$2,409,210	$5,646,988
High EPA Value	$33,505,631	$58,198,831	$8,295,843	$19,444,774
Mirant Value	$1,139,888	$677,254	$192,640	$617,083
% of Low EPAValue	11.71	4.01	8.00	10.93
% of High EPAValue	3.40	1.16	2.32	3.17

General — For practicality, Mirant has not commented on every section of the case study (or other EPA documents relating to the 316(b) Phase II proposed regulation) where Mirant believe its revised Pittsburg and Contra Costa I&E loss data should be used in lieu of EPA's I&E data. Accordingly, we encourage EPA to use Mirant's alternative I&E data throughout its studies and reports, including those that assess and report on the economic benefits of the Phase II regulations on the Pittsburg and Contra Costa plants.

General — Although Mirant has modified the water use foregone cost value used for the two facilities by proposing that the EPA use a more realistic value, Mirant is by no means endorsing the societal revealed preference approach for valuing special status fish species. Mirant has only commented on selected items and asks that EPA consider comments regarding the appropriateness of this method from UWAG, EPRI, and others with more expertise in valuing special status fish species I&E economic losses.

Page E1-7, Section E1-3.4 — The $3-5 million annual range for Bay Area tourism value appears to be extremely low.

Page E3-10, Section E3-3 — The sentence "Data for the 1-year monitoring period in 1978-1979 and the average for 1987-1090 (for impingement) and the average for 1986-1980 (for entrainment)" should read "Data for the 1-year monitoring period in 1978-1979 and the average for 1987-1990 (for impingement) and the average for 1986-1992 (for entrainment)".

Section E3-4 — As previously commented, only post-BTA striped bass and special status species fish impingement data should be considered for the case study.

Page E3-12, Table E3-6 — The table contains three values reported incorrectly from Appendix B in the draft Habitat Conservation Plan (Southern Energy Delta, LLC, 2000). The 1978-1979 value for Chinook Salmon should be 763, not 1,083. The 1978-1979 value for Steelhead should be 0, not 38. The Avg. 1987-1990 value for Longfin Smelt should be 366, not 336.

Section E3-5 — As previously commented, only post-BTA striped bass and special status species fish entrainment loss data should be considered for the case study.

Page E3-14, Table E3-1O — The table contains a value reported incorrectly from Appendix B in the draft Habitat Conservation Plan (Southern Energy Delta, LLC, 2000). The 1978-1979 value for Delta Smelt should be 65,239,484, not 65,839,484.

Page E3-15, Table E3-14 — The table contains a value reported incorrectly from Appendix B in the draft Habitat Conservation Plan (Southern Energy Delta, LLC, 2000). The 1978-1979 value for Delta Smelt should be 20,565,741, not 21,755,741.

Page E4-2, Table E4-1 — The1995 Agreement for the Monitoring and Mitigation of Striped Bass with the California Department of Fish & Game (CDFG) established a mitigation cost for the I&E loss of striped bass at the Pittsburg and Contra Costa facilities. This payment for striped bass mitigation has never exceeded $2.00 per fish since the program began in 1995. Mirant believes that the value ($9.11/fish to $14. 14/fish) EPA places on this recreational species using the “willingness to pay” methodology is valid. However, for consistency in valuation methods, it may be more appropriate to use a striped bass value closer to the CDFG replacement cost if EPA continues to insist on using the HRC method for valuing special status fish.

Pages E5-3 and E5-4, Section 5-3 — As previously commented, EPA made the error of assuming that all water use foregone costs are for the purpose of restoring special status species fish. As stated in Section E5-3 of the case study report, “The Bureau had to cut back on the supply to its CVP customers to comply with various water needs and restrictions of the Federal Endangered Species Act (FESA) and the California Endangered Species Act (CESA), the CPV Improvement Act (CPVIA) and the new bay-delta water quality standards issued in 1995 by the State Water Resources Control Board.” Therefore, it is evident that the cost of foregone water use is not just for the restoration of special status species. Mirant believes that 20.05% of the water foregone cost is a more appropriate measure of the fraction used to restore special status species since this is the mid-range percentage of the CALFED cost used for special status species fish protection. This percentage was determined by dividing the $3.81 billion reported in the second paragraph of page E5-3 by the $19 billion total estimated CALFED cost.

EPA Response

I&E rates for the Pittsburg and Contra Costa facilities were used as part of the California Regional Study for EPA's final analysis for the 316b Phase 2 rule (DCN # 6-0003). In this regional study, EPA's analysis of I&E for these facilities was revised as suggested by the commenter.

For a discussion of the societal revealed preference analysis presented at proposal, please see EPA's response to Comment 316bEFR.005.006. This analysis was not included in EPA's final analysis.

For a discussion of replacement costs, please see the document entitled "The Habitat-Based Replacement Cost Method" (Docket #6-1003) and EPA's response to Comment 316bEFR.005.035.

Role of States and Tribes (alt./equiv. programs)

Our comments here focus on the need for this rulemaking to retain a state's flexibility to implement the 316(b) rule for specific waterbodies. The Clean Water Act and its implementing regulations include repeated expressions of Congressional intent to delegate broad discretion to the States to implement programs that protect the quality of our waters. The 316(b) rule is among those provisions where Congress intended to provide the States with flexibility to address site-specific concerns while achieving the Clean Water Act's goal of protecting aquatic life in those waterbodies. As competitive suppliers of electricity to a deregulated marketplace, Midwest Generation supports the development of sound environmental regulatory programs that provide flexibility to enable affected facilities to meet the overall intent of the 316(b) rule through cost-effective, environmentally beneficial solutions that are based on site-specific circumstances.

The 316(b) rule for existing facilities can establish the necessary standards to protect the environment, while still allowing each State to use its own policies and procedures to implement the 316(b) standards for specific waterbodies. The 316(b) rule for existing facilities can and should address the States' flexibility needs. We offer the following comments in further support of that goal.

In developing the proposed 316(b) rule for existing facilities, Midwest Generation encourages EPA to build on the solid foundation created by years of state experience with site-specific decision-making under section 316(b) of the Clean Water Act. For nearly thirty years, the States have been allowed to apply sound science and judgment to site-specific data and conditions in order to implement section 316(b) standards. While improved consistency of decision-making can and should be brought to the regulatory framework presently used by some states to implement the 316(b) rule, the current methodology, particularly in Illinois, contains a number of features that should be retained because they provide for sound, scientifically credible decisions. The current Illinois methodology reflects a holistic approach to assessing how to ensure the environmental protection required by the 316(b) rule in site-specific situations.

EPA Response

As stated in the preamble to today's final rule, EPA recognizes that some States and Tribes have invested considerable effort in developing and implementing section 316(b) regulatory programs and acknowledges that some existing programs and determinations have been successful in reducing adverse environmental impacts to waters of the United States. As such, this final regulation allows States and Tribes to use these programs to fulfill section 316(b) requirements where the State/Tribe demonstrates to the Administrator that such programs will achieve comparable environmental performance (see § 125.90(d)). Specifically, the final rule allows any State/Tribe to demonstrate to the Administrator that it has adopted alternative regulatory requirements that will result in environmental performance within each relevant watershed that is comparable to the reductions in impingement mortality and entrainment that will be achieved under § 125.94. The watershed level was selected to ensure protection of ecological resources within a hydrologic unit and for consistency with NPDES permitting efforts that place controls at the watershed level. A State or Tribal section

316(b) regulatory program should also consider reductions in impingement mortality and entrainment at the relevant watershed level. In addition, the final rule does not limit the ability of a State/Tribe to adopt or enforce more stringent controls (see § 125.90(e)) as per Section 510 of the Clean Water Act (33 USC 1370). In this way, today's final rule provides a reasonable degree of flexibility for States and Tribes to implement existing effective programs. See also 125.94(e), which allows States to establish more stringent BTA requirements if necessary to comply with State, Tribal, or other federal law.

RFC: Use of previous demonstration studies

The proposed rule fails to provide a suitable means for allowing the States to rely on the body of environmental and technical information they have developed over the years to implement the 316(b) rule for existing intake structures. The final rule should include a process for approving existing intake technology as Best Technology Available (BTA) if it can be shown that the facility is not causing adverse environmental impact or the technology has been deemed BTA by the state. For many electric generating facilities, extensive supporting data already has been collected at significant cost and effort to demonstrate that the facility is not creating an adverse environmental impact. This extensive supportive data may still be representative of existing site-specific conditions. The proposed 316(b) rule nevertheless would require a comprehensive 316(b) demonstration study to be performed as if both the State and existing facility were working from a “blank slate” rather than an extensive database. This proposed approach will result in duplicative data gathering efforts and redundant costs to again determine that no adverse environmental impact is occurring in the waterbody. There is no environmental benefit obtained by ignoring an established and reliable record showing that no adverse environmental impact exists.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today’s final rule; however, existing data that is reflective of current conditions may be used to support the required studies. Please see response to comment 316bEFR.040.001 for details.

Subject Matter Code 21.08

Burden on permitting agencies (general)

Author Name Basil G. Constantelos

Organization Midwest Generation EME,LLC

Further, the States will be unnecessarily burdened by the need to spend their limited time and resources to oversee and evaluate a new, but repetitive, 316(b) demonstration study for each existing facility in the state without regard to whether such a study will provide any new information. The proposed 316(b) rule should be revised to allow existing, relevant studies and data concerning the impact on aquatic life of existing intake structures to be deemed sufficient to satisfy the “comprehensive study” requirements of the proposed rule.

EPA Response

Today's final rule does allow the use of historical data provided that it is reflective of current conditions at the facility. Please see response to comment 316bEFR.040.001 for additional discussion.

Comment ID 316bEFR.023.004

Author Name Basil G. Constantelos
Organization Midwest Generation EME,LLC

Subject Matter Code 21.05
Role of States and Tribes (alt./equiv. programs)

The States are already empowered to take a comprehensive look at adverse environmental impacts. While the States consider the impact on individual organisms, that impact is also evaluated in relationship to the overall health of the affected population and the water quality of the waterbody. This holistic approach enables the State to improve its assessment of what is happening in the waters where cooling water intakes are located. Cross-media environmental impacts generally have also been considered by the States when making the appropriate technology choices for minimizing the entrainment and impingement of fish. Consequently, the States have been able to achieve the primary intent of section 316(b) without compromising other environmental priorities. The proposed 316(b) rule wrongly assumes that this is not the case.

Many States have a well-established approach to evaluating technology choices that consider cost-effective alternatives for achieving positive environmental outcomes. This is especially important because of the huge cost differential between certain technologies and correspondingly different levels of environmental benefits. The States' goal has been, and continues to be, to ensure the protection of the environment based on the application of sound science and engineering, while avoiding the imposition of unwarranted financial burdens on regulated facilities. Because both water and fisheries quality are site-specific factors, and the design, location, and circumstances of each power plant are unique, a site specific decision framework is the best approach to achieving the most cost-effective and environmentally beneficial outcome.

A specific example of such a unique situation involves Illinois waterbodies into which Midwest Generation plants discharge. In Illinois, there is currently a joint effort by the U.S. Fish and Wildlife Service, U.S. Army Corps of Engineers, Illinois Department of Natural Resources and other aligned groups to create a barrier zone in the Chicago Sanitary and Ship Canal which would be made devoid of, and impassible to, all aquatic life (through chemical, physical or other means). The purpose of this barrier is to prevent the migration of aquatic nuisance species into or out of the adjacent waterway systems, which include Lake Michigan. The current exotic invader, the Asian Carp, has the ability to decimate the aquatic ecosystem of Lake Michigan and the rest of the Great Lakes. Infiltration of this species also would destroy the popular sport fishing industry that has taken the States so long to build in these waterbodies. Midwest Generation has several open cycle power plants located on this particular waterway (the Chicago Sanitary and Ship Canal and adjoining Chicago River and Lower Des Plaines Rivers) that are subject to the proposed 316(b) rule.

Under the proposed 316(b) rule, these facilities should not be required to install control technology to minimize impingement and entrainment down to the proposed performance standards when state and federal agencies are simultaneously taking steps to create a "dead zone" in this waterway. The cost of adding any new control technology under such circumstances is clearly unnecessary. In the absence of the aquatic community that is intended to be protected under section 316(b), the proposed 316(b) rule imposes additional regulatory and financial burdens without realizing any additional environmental protection whatsoever.

EPA Response

EPA agrees that States should work collectively with other Federal and State agencies to address site specific issues within the State, where necessary. Under today's final rule, EPA is allowing approval of existing State 316(b) programs that meet the requirements of the final rule (see 125.90(c)). See response to comment 316bEFR.023.001 for additional detail.

Subject Matter Code 17.06

Option: Site-specific determination of BTA

The proposed 316(b) rule should allow the States to exercise discretion appropriate to the needs of the particular waterbody. As proposed, the 316(b) rule threatens to impose inflexible requirements on the States. The Chicago Sanitary and Ship Canal, as well as the adjoining waterways discussed above, are currently designated as Secondary Contact waters due to their inability to meet the "fishable/swimmable" standards required by the Clean Water Act. These waterways have been either created or significantly altered by human disturbances over the past more than one hundred years, and function largely as conveyances for treated effluents and barge transport, while still supporting a fair assemblage of aquatic organisms which are suited to this particular environment. The types of species expected to be entrained and/or impinged by power plants on these waterways are largely rough, low quality fish such as common carp, buffalo and gizzard shad, in addition to the invasive species noted above. These species do not warrant the same kind of protection as more desirable or ecologically important species, such as game fish, threatened or endangered species or other species important to the support of the food chain and/or recreational industry in any particular waterway. State natural resources management agencies have long been allowed to give greater protection to those waterbodies which can support the greatest diversity of quality aquatic species. This is another important example of why flexibility is required to allow the States to direct their limited resources to the protection of the most ecologically important waterways. The proposed 316(b) rule, as presently written, will result in the broad application of uniform controls for waterbodies without the necessary consideration of whether a comparable environmental benefit is attainable.

States should be allowed to make a determination on the overall quality of a particular waterbody, based on current 305(b) report data, and use this to support whether or not the imposition of 316(b) requirements is required for improvement of the indigenous fish community. If factors other than power plant operations are influencing the overall quality and biological potential of the system, then states should be empowered to make the determination that 316(b) requirements would not result in any overall environmental benefit. This determination should be accepted by U.S. EPA and documented in a given facility's NPDES permit in lieu of the imposition of 316(b) BTA controls and/or study requirements. This determination would remain in effect until significant changes occur either in the waterbody or in the facilities' operations, which could potentially effect the current 316(b) determination.

EPA Response

A facility may choose to seek a site-specific determination of BTA using the cost-benefit test and demonstrate that any expenditure by the facility is unwarranted due to the minimal benefits expected to be gained by any compliance action taken.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

In conclusion, Midwest Generation believes that the ultimate decisions made by the U.S. EPA in this rulemaking have the potential to adversely affect energy costs and supply in our region of the country. These effects are potentially significant and may not be justified or necessary for all site-specific situations and circumstances. Accordingly, Midwest Generation urges the U.S. EPA to devise a workable, site-specific approach that gives to the states the necessary flexibility to make sound choices given the complexities of the issues involved.

EPA Response

EPA's economic impact analysis does not show any significant impacts to energy costs and supply as a result of the final Phase II rule. In the Midwest, less than 100 MW of incremental capacity closures are projected as a result of the final Phase II rule. In addition, projected increases in energy costs and prices are small (less than 1.0%). For responses to comments on a site-specific approach, please refer to subject matter code 2.04.

Comment ID 316bEFR.024.001

Subject Matter Code 7.03

Available I&E technologies

Author Name Thomas J. Steinke

Organization JohnsonScreens

Passive intake screening technology is considered as best available technology in EPA's 316(b) Phase I. The Phase I rule, published December 18, 2001, requires the maximum design through-screen velocity at each cooling water intake structure, be no more than 0.5 ft/sec (Section V.B.1.b.i. page 65274 and Subsection 125.84.b.2.). However, this technology is not mentioned in the current version of 316(b) Phase II. Additionally, Phase I identifies EPA case studies that implemented wedgewire screens for cooling tower intakes. (Section V.B.2.d., page 65279 – 65280).

Phase II also restricts the application of wedgewire screens to source waters with minimum current of 1.0 ft/sec, to allow debris to be carried past the intake screen, thereby preventing accumulation on the screen. Wedgewire screen technology has been improved over the years, allowing successful applications in rivers and streams with current velocity less than 1.0 ft/sec and in oceans, reservoirs, and lakes with no ambient current.

EPA Response

Compliance alternative 4 allows a facility that meets certain operational and siting criteria to install and properly operate an approved technology. Today's rule designates cylindrical wedgewire screens as an approved technology for facilities meeting the criteria listed at § 125.99(a). Today's rule also reserves the right of the Director to approve other technologies as BTA for all facilities within his or her jurisdiction. For further discussion please see section V of the preamble and § 125.99(b).

EPA agrees with the commenter that wedgewire technology has improved over recent years and is able to be deployed under a wider set of circumstances. Through consultations with vendors and laboratory analysts, EPA has determined that the requirement of a minimum ambient current of 1.0 ft/sec is too restrictive to apply to all cases. Instead, today's rule requires "sufficient ambient counter currents exist to promote cleaning of the screen face". EPA recognizes that the optimal ambient current may vary between facilities depending on debris loading, among other factors.

Comment ID 316bEFR.024.002

Author Name Thomas J. Steinke

Subject Matter Code 7.02

Performance standards

The rule does not require surface water intake systems to meet the industry-accepted standard of a maximum through slot velocity of less than 0.5 ft/sec. We would suggest language allowing any facility with an intake system that does not exceed a maximum through slot velocity of 0.5 ft/sec be approved as meeting Phase II requirements.

For further reference, please review the attached documents.

EPA Response

Compliance alternative 1 allows a facility that reduces its design intake flow to 0.5 m/s or less to be considered compliant with the today's rule.

Comment ID 316bEFR.024.003

Subject Matter Code 7.03

Available I&E technologies

Author Name Thomas J. Steinke

Organization JohnsonScreens

The rule does not mention Ranney well collector or infiltration gallery technology as an option to reduce impingement and entrainment in cooling water intake systems. We would suggest that this technology be mentioned in the rule to allow facilities to make an informed decision by having access to all available technologies that would serve to meet the requirements of the rule.

EPA Response

EPA did not discuss the technologies mentioned by the commenter due to the limited availability of performance data for them and instead focused on technologies that have a history of successful operation and wide use within the industry. EPA notes that today's rule does not prohibit the use of any technology in meeting the performance standards. Compliance alternatives 2 and 3 do not specify any design and construction technology or operational measure that must or must not be used to satisfy the performance standards. EPA and encourages the use of innovative technologies to address impingement mortality and entrainment losses and welcomes the submission of any data demonstrating their value.

Section II.G. page 17130.

This section defines the Design Intake Velocity of the intake system. Reference is made here to a design through-screen velocity being restricted to an average of 0.5 ft/sec. To ensure minimum impingement of species on the surface of the screen, the maximum through slot velocity should be no greater than 0.5 ft/sec. Allowing the average through screen velocity to be no greater than 0.5 ft/sec creates the possibility that local through slot velocities will be much greater than 0.5 ft/sec at some points along the length of the screen. We would suggest requiring a maximum through slot velocity of 0.5 ft/sec at any point on the intake structure. Additionally, we would suggest that any facility that meets a design maximum through slot velocity of less than 0.5 ft/sec, meets the requirements of the Phase II rule.

The rule also identifies a “zone of influence” around the screen without a clear definition of the “zone of influence”. Our experience and testing indicates that although a “zone of influence” does exist around the screen, defining the “zone of influence” can be difficult. By defining the proper maximum through slot velocity of the screen, the “zone of influence” becomes arbitrary, because the through slot velocity is the determining factor in ensuring protection of living organisms in the water column. We would suggest the removal of any language referring to the “zone of influence”.

For further reference, please review the attached documents.

EPA Response

For the purpose of today’s rule, EPA is treating the through-screen velocity limit of an average of 0.5 feet per second as a design criteria. EPA does not intend to require facilities to monitor the intake velocity at every slot on a screen face, but rather to ensure that their intake configurations are equipped to handle an intake velocity averaging 0.5 ft/s. EPA chose to make today’s final rule based upon these design criteria, realizing that in-situ circumstances may affect the actual velocity, such as turbidity, biofouling, and ambient waterbody flow. Furthermore, extensive research was conducted on the intake velocity issue during Phase I. At that time, EPA concluded that the velocity standard of 0.5 ft/s is sufficiently protective and eliminates significant potential for entrapping fish (see DCN #2-028 in the Phase I Docket). As this data shows, most fish can escape a 0.5 ft/s intake velocity. Therefore, even if the fish does not quickly or readily detect the intake, it still has every opportunity to escape the intake structure. EPA also notes that the intake velocity requirements are based upon the design through screen velocity. Due to the amount of open space in an intake screen face, a 0.5 ft/s through screen velocity will effectively reduce approach velocities to values lower than 0.5 ft/s. As such, the velocity in the vicinity of the intake will be further reduced, affording poor swimming fish an additional safety margin to escape an intake flow.

Additionally, EPRI’s Technical Evaluation of the Utility of Intake Velocity as an Indicator of Potential Adverse Environmental Impact under Clean Water Act Section 316(b) stresses the important relationship between intake velocity and injury to aquatic life when it states stating that “[t]here is a substantial literature of laboratory and field data that points to increased impingement with increased intake velocities.” The report also recommends that 0.5 ft/s be adopted on a national scale as a “screening value for the regulatory purposes of suggesting low potential adverse environmental impact.” EPA’s own research confirms both statements.

As evidenced by the data collected for the Phase I NODA and other material in the record of this rulemaking, the 0.5 ft/s requirement is scientifically based, is protective of aquatic resources with a reasonable margin of safety, and is technically available and economically practicable (as demonstrated for certain existing facilities by the fact that it is frequently achieved at recently built facilities). As such, EPA has concluded that it is an appropriate component of best technology available for minimizing adverse environmental impact at existing facilities.

EPA would emphasize that the final rule provides a site-specific alternative to the four national categorical compliance options. If the permit applicant proves through a cost-cost or cost-benefit test that it cannot meet the velocity requirement, the applicant can seek to demonstrate comparable performance through other means, including techniques which account for different intake designs and intake technologies. This site-specific provision in analogous to the variances authorized for existing direct dischargers under Clean Water Act 301(c), 301(g) and 301(n). Under these provisions, existing direct dischargers may obtain site-specific determinations of best available technology that is economically achievable; under today's rule, a qualifying facility can obtain a site-specific determination of best technology available for minimizing adverse environmental impact.

In response to the comment that EPA should remove language referring to an intake’s zone of influence, EPA disagrees. It is EPA’s position that such a zone of influence does exist at intake structures, and must be taken into account in today’s final rule. EPA concurs, however, that the zone of influence will differ from site to site. Therefore, EPA has decided to leave to the Director the determination of the range of their facilities’ zones of influence.

RFC: Three-option framework for determining BTA

Section VII. C., page 17178

We would suggest the following option be provided to facilities to meet the requirements of the rule: Facilities that have fine slot, wedgewire cooling water intake systems with maximum through slot velocities of 0.5 ft/sec or less, would meet the requirements of the rule and would not be subject to further performance standards. Facilities that have incorporated infiltration gallery technology would meet the requirements of the rule and would not be subject to further performance standards.

For further reference, please review the attached documents.

EPA Response

Please refer to the preamble for a description of the framework of today's rule. EPA notes that facilities using approved design and construction technologies (such as a wedge-wire screen in certain freshwater river environments) may demonstrate compliance with the rule under § 125.94(a)(4) or may request that the Director approve additional technologies under § 125.99(b).

Chapter 3 – Attachment A, page A-13, Fact Sheet No. 5: Wedgewire Screens.

Design Considerations comments.

Although locating an intake screen in an ambient current of at least 1 ft/sec is a typical application criterion, recent advances in air backwashing technology (Johnson Screens Hydroburst System) have improved the effectiveness of the cleaning cycle. Additionally, improvements of open pipe flow modifier technology (such as the Johnson Screens dual pipe flow modifier) allows placement of smaller diameter screens for a given flow, decreasing the likelihood of siltation of the screen barrel. These improvements have increased the applicability of Johnson Screens into water sources with low or no ambient current. Finally, Johnson Screens design considerations require the placement of the wedgewire screen to be greater than ½ the diameter of the screen above the bottom of the water source to aid in preventing siltation into the screen.

For further reference, please review the attached documents:

Fact Sheet No. 5 identifies that: A uniform velocity distribution along the screen face is required to minimize the entrapment of motile organisms and to minimize the need of debris backflushing. This design consideration becomes more critical if an allowance is made to use restricted flow modifier pipes – such as slotted pipe or perforated pipe, etc. – inside the intake screen. Restricted flow modifier pipes will not have radial symmetry and therefore will require a 3-D consideration of the through slot velocity. Intakes with open modifier pipe technology allow radial symmetry of the flow through the screen.

Restricted flow modifier pipes also create a potential plugging problem in the annular spacing between the wedgewire screen and the orifices of the restricted flow modifier pipe. Plugging of this space would create a difficult to clean condition, resulting in continued operation of a screen with through slot velocities higher than the maximum design through slot velocity.

Finally, restricted flow modifier pipes operate with a differential headloss that is up to 10 times greater than the headloss of open modifier pipe technology. Although the higher headloss of restricted flow modifier pipes can be overcome with larger pumps, operational costs will be increased as compared to open modifier pipe technology. For example, at 200,000 gpm withdrawal rate, each additional foot of head loss is roughly 0.5 million KW/hr per year in pumping costs.

Limitations section comments.

This fact sheet calls out some limitations of wedgewire screens, referencing a document from 1980 (Mussalli et al, 1980). This document does not accurately reflect the advances in intake screening technology that have occurred since 1980. Some of these technology advances have addressed the technology shortcomings called out by Mussalli. Siltation of the screen has been effectively removed with improved air backwashing systems (Johnson Screens Hydroburst System) that ensure removal of the material and improved modifier pipe designs.

For further reference, please review the attached documents.

Biofouling of the screen has been effectively addressed with the use of copper alloys (Johnson Screens Z-alloy Intake Screens). These copper alloy screens have successfully controlled zebra mussel infestation of the intake screen and other biological fouling of the intake screen. Additionally, copper coatings have been used in the marine industry for coating ship/boat hulls for many years. These applications of copper have been shown to be effective for the control of biofouling.

EPA Response

The Agency has reviewed the attached and referenced documents. The Agency notes that it included wedgewire screens in the analysis and basis of the rules requirements to some degree. For further information on wedgewire screens and the Agency's technology analysis, see the Technical Development Document.

General statement of support

The New Regulation Has Many Favorable Features

EPA is to be commended for the considerable effort that has been put toward this regulation. There are a number of positive elements in the rule that we endorse and hope will be part of the final requirements. We appreciate that closed cycle cooling and dry cooling will not be mandatory requirements. We are grateful that the proposed framework has more flexibility and is willing to consider prior 316(b) studies to determine facility impacts. A 'baseline' approach that uses a rudimentary intake concept on which to base performance, cost and benefit tests to determine technology feasibility and allowing environmental enhancements in place of technologies are all positive developments.

EPA Response

EPA notes the comment. No response necessary.

Subject Matter Code OPP
General Statement of Opposition

However, there are a number of significant problem areas and concerns with the proposed rule that we must bring to your attention. They relate to the basis for the rule and how the proposed regulations can be successfully implemented. They relate to our belief that a nationwide standard is not appropriate as proposed and that more site-specific considerations are needed. Finally, there are glaring issues that undermine the cost and benefit aspects of the proposed rule.

EPA Response

Each issue is addressed individually in subsequent responses.

RFC: Definition of "adverse environmental impact"

The Regulation Needs a Definition of 'Adverse Environmental Impact'

The statutory language of Section 316(b) in the Clean Water Act has been cited often in this debate and we might suggest the emphasis has been intentionally misplaced. The law says the following:

Any standard established pursuant to section 301 or section 306 of this Act and applicable to a point source shall require that the location, design, construction, and capability of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact. (emphasis added)

The legal challenges that resulted in these new regulations were driven by a belief that §316(b) is absolutely a technology-forcing requirement. EPA has created a massive rule that is based on strict numerical performance through the use of technologies that are comparable to closed cycle cooling and it has avoided the rest of the statutory language. A major shortcoming in this regulation is the absence of a definition of adverse environmental impact. To have a regulation that is based on it and purports to reduce it yet refuses to define it is disingenuous at best. We strongly suggest that the final rule include a definition of this important statutory and regulatory term.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

Overview of I & E effects on organisms

EPA Should Recognize That There is Much Long-Term Information That Shows Many Plants Have Negligible Environmental Impact

We accept that there is a need for regulation of the impacts of cooling water intake systems. Some facilities do create adverse environmental impacts. Others might have assessed their impacts but it was long enough ago to warrant reconsideration at this time. However, at the same time, EPA must consider any comprehensive, long-term, valid monitoring program that has confirmed an absence of adverse environmental impact. The full body of information on this subject does not justify this one-size-fits-all approach. In fact, these conditions and the extensive body of work already conducted promote a site-specific approach to this issue.

EPA Response

Today's final rule contains many compliance approaches and is not a "one-size-fits-all approach". The approaches focus on reducing impingement mortality and entrainment and do not require the confirmation of a presence of adverse environmental impact attributable to the cooling water intake structure. If a facility is impinging or entraining a very small number of organisms, then a site-specific determination of best technology available is possible as a compliance approach. Please see the response to comment 316bEFR.025.018 for the discussion regarding the environmental impacts of cooling water intake structures.

Comment ID 316bEFR.025.005

Purpose of Rule (General, incl. bckgrd., history)

The former guidance and regulations required site-specific considerations. There is no basis to change EPA's and Congress's 30-year record that recognizes consideration of site-specific factors.

EPA Response

Today's final rule includes a site-specific compliance alternative. Please see § 125.94(a)(5).

Comment ID 316bEFR.025.007

Author Name Michael J. Wallace

Organization Constellation Energy Group

Subject Matter Code 18.02

RFC: Use of previous demonstration studies

Prior [site-specific] determinations should be considered if they are still valid. Also, if there are data that already show there is so little entrainment or impingement that the community is not affected or the economic impact is exceeded by the cost of a comprehensive study, there should be no need for further evaluation.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule. Please see response to comment 316bEFR.040.001 for details.

Additionally, in today's final rule, EPA offers a site-specific compliance alternative (see 125.94(a)(5)) in which an applicant may receive a determination of BTA from the Director for its facility provided it meets one of two cost tests. EPA believes that this alternative will provide additional flexibility for facilities who may find that the other compliance alternatives are not suitable for their site.

Comment ID 316bEFR.025.008

Author Name Michael J. Wallace
Organization Constellation Energy Group

Subject Matter Code 17.06

Option: Site-specific determination of BTA

Just because the proposed rule distinguishes certain water body types does not mean that everything after that is the same and amenable to one type of solution. Plants are still different, as are water bodies and their surrounding landscapes. In fact, one might suggest that no two plant sites are the same. Every locality has its distinctive environmental characteristics, independent of the facility. Aquatic populations vary and the technologies and control options that are feasible will not perform the same way in certain environments.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Role of States and Tribes (alt./equiv. programs)

Allow states that regulate intakes well to continue — EPA should acknowledge that some states have had successful programs and have developed considerable data on certain facilities. They should be encouraged to continue what has worked.

EPA Response

EPA agrees with the commenter and has provided flexibility in today's final rule to approve State 316(b)programs that meet rule requirements at 125.90(d). Please see response to 316bEFR.023.001 for additional detail.

Comment ID 316bEFR.025.010

Author Name Michael J. Wallace

Organization Constellation Energy Group

Subject Matter Code 17.06

Option: Site-specific determination of BTA

EPA wants to include consideration of the impaired status of the affected [even nearby] water bodies and the presence of threatened or endangered species to justify regulation of CWIS [p. 17136-7]. Yet, these arguably unrelated elements are by their very nature site-specific considerations that further support site-specific solutions.

EPA Response

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Impaired waters and the presence of threatened and endangered species are factors that may be considered in determining best technology at a particular facility. The Director may, if necessary to meet the requirements of state, tribal or other applicable federal law, make BTA determinations based on the potential for cumulative stresses upon organisms in these waterbodies.

Both the Director and the facility remain accountable for compliance with the Endangered Species Act (ESA), when applicable. The determination of best technology available, including for example, the selection of technologies, valuation of benefits, and monitoring requirements should reflect compliance with the ESA.

Option: Site-specific determination of BTA

We strongly urge EPA to craft a rule that allows for more site-specific determinations and factors into the analysis the extensive work that many plants and their state regulators have already done. If some plants have not yet conducted the studies and assessed the impact of their cooling water intake systems, EPA should not conclude this is a reason to make others revisit an issue that has been demonstrably resolved.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

A goal of today's rule is to set national minimum performance standards that reflect the best technology available for minimizing adverse environmental impacts. Given that previous determinations of best technology available were not made in reference to the national performance standards, EPA believes that the Director should not rely entirely on historical determinations. EPA believes that these national requirements will promote more effective and consistent implementation of section 316(b) requirements, and ultimately minimize adverse environmental impacts associated with the use of cooling water intake structures by Phase II existing facilities.

RFC: Entrainment vs. entrainment mortality

The Regulation Should Consider Entrainment Survival

EPA is aware of numerous studies that show the presumption of 100% mortality is unjustifiably conservative. Power plants in many of the affected water body types have data that confirm substantial survival in many species. EPA should not determine impacts and benefits based on 100% mortality of entrained organisms if that is not what actually happens.

Asking for studies of entrainment survival as they relate to your preferred technologies [p. 17149] is not the point. There are not many examples of full-scale demonstrations of these controls. There are many more studies that confirm there is entrainment survival at plants without controls. EPA should have a complete understanding of entrainment survival when all forms of technologies and operational measures are applied as well as when no changes are made to cooling water intake systems. Only then will we have an understanding of whether the required alternatives are worth installing.

EPA Response

Please see response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule. It is unclear how the commenter can expect EPA to have a complete understanding of entrainment survival when all forms of technologies and operational measure are applied when, as the commenter asserts, there are not many examples of full-scale demonstrations of entrainment survival with different controls in place.

Proposed standards for Great Lakes

The Great Lakes are unique but that does not make them uniquely sensitive. There are reasons to believe otherwise. The fishery has a disproportionate number of introduced species. Trout and salmon populations exist entirely because of stocking. This is one highly managed fishery. Due to the presence of zebra mussels, inshore regions have fewer fish because the planktonic food sources are depleted. The life history characteristics of the Great Lakes fish of concern [commercial and recreational species] are not put at risk by power plant operations. Therefore, the Great Lakes should be subject to the same requirements as other lakes and reservoirs.

EPA Response

Facilities located on the Great Lakes (and having a capacity utilization rate greater than 15%) are subject to additional requirements, as these waterbodies are similar to estuaries in that they have areas of high productivity and sensitive habitat.

EPA continues to believe that the Great Lakes are a unique system that deserve additional protection from the impact of cooling water intake structures. The Great Lakes are each a large waterbody with a variety of habitats. While EPA recognizes that not all habitats in the Great Lakes may be as sensitive as others, there are many areas that are similar to an estuary in terms of productivity, and therefore similar in sensitivity. EPA also notes that the more sensitive areas are often located in the nearshore areas of larger waterbodies, which is also a common location for cooling water intake structures. Facilities may also be located in proximity to migratory pathways.

EPA recognizes that the species present in a waterbody may not reflect natural or "pristine" conditions. With their presence, nuisance species and introduced species will affect the impingement and entrainment rates. Today's final rule requires that monitoring be conducted in accordance with the verification monitoring plan (125.95(b)(7), the Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5). A site-specific compliance option might also be available. The Director may consider additional monitoring requirements as well. Specific study parameters may be proposed by the applicant for review and approval by the Director.

EPA agrees that the biological communities in some waterbodies are not natural and are, in fact, heavily influenced by human management or by nuisance species. However, EPA remains responsible for the protection of water quality under the Clean Water Act and continues to believe that national performance standards are appropriate for these waterbodies. EPA also notes that these waterbodies likely still are considered to be waters of the United States and therefore subject to regulation under section 316(b).

Proposed standards for tidal rivers and estuaries

Estuaries, because of their productivity and popularity, seem to be viewed as especially vulnerable to the activities of mankind. Because they are productive, they experience considerable commercial and recreational fishing pressure. Because of this, we urge EPA to acknowledge the substantial impact over-fishing has had on populations.

Estuaries, by their nature, often have wide-ranging salinity and temperature conditions. That the creatures that live there thrive despite these challenges speaks to their durability. Also, many important estuarine species reproduce by broadcasting vast quantities of eggs and larvae into the environment. This strategy makes then susceptible to entrainment but not necessarily endangered by it.

Estuaries are often areas where human populations are concentrated. The waters can experience the effects of development with its wastes and runoff. However, that many estuaries continue to be productive in spite of over-fishing, pollution and habitat degradation speaks to their resilience not their sensitivity. Unless a power plant is located in a migratory, spawning or nursery area, there are few characteristics of estuaries that make them uniquely susceptible to power plant impacts. We suggest that the proposed regulations reflect this.

EPA Response

EPA disagrees. Facilities located on estuaries and tidal rivers (and having a capacity utilization rate greater than 15%) are subject to additional requirements, as these waterbodies have areas of high productivity and sensitive habitat. EPA examined the issue of increased potential for adverse environmental impact in estuaries and tidal rivers in the Phase I NODA and included several documents to support the assumption. These documents (DCN 2-013 A through O) include information on larval densities in selected estuaries and tidal rivers, impingement and entrainment rates for facilities located in these areas, conditional mortality rates of organisms in selected estuary and tidal rivers (requires calculation of larval densities), and discussions of the life history and reproductive strategies of marine and estuarine organisms that are relevant to EPA's consideration of whether these locations may be sensitive to impingement and entrainment impacts associated with cooling water intake structures. EPA has concluded that estuaries deserve the most stringent protection because of the abundance and diversity of aquatic life they harbor. Estuaries are also an important habitat for the vast majority of commercial and recreational important species of fin fish.

EPA acknowledges that other factors such as overfishing or declining water quality may also affect fish populations. However, these factors do not diminish the increased potential for adverse environmental impact from cooling water intake structures in tidal rivers and estuaries.

Fish Population Modeling

The Regulation and its Implementation Should Recognize the Existence of Compensation in Aquatic Populations

Compensation is an accepted cornerstone of fisheries management science. The NMFS and every state natural resource agency use compensation-based principles and regulations in their operations. The proposed regulation must acknowledge that aquatic populations have the capacity to offset variations in mortality. This will help put power plant impacts in perspective.

EPA Response

Although EPA's I&E analyses do not consider density dependent compensation or stock recruitment dynamics, EPA does not maintain that stock dynamics are, in fact, density independent. Rather, EPA believes that use of a static model can provide reasonably valid estimates of foregone harvest projected directly within a cohort.

The knowledge required to model compensation reliably, and hence refine EPA's estimates of foregone harvest, include current, stock-specific understanding of relevant stock-recruitment relationships. This information is unavailable for most of the species that are vulnerable to impingement and entrainment.

Another reason for omitting compensation from the 316b benefits assessment is that any population stressor, including I&E mortality, that might lead to a compensatory response does so at the cost of removing some portion of the population's compensatory reserve. It is not possible for a population to absorb a limitless set of stressors through biological compensation. As such, if compensatory mechanisms were included in EPA's analysis, then EPA would be required to discount the associated benefits by an amount associated with the loss of compensatory reserve. It is unknown what this amount might be for any particular stock.

Because information on compensation and compensatory reserve is not available for the majority of the fish stocks impacted by I&E, EPA concluded that quantitative estimation of compensatory response was not a practical option for the 316b benefits analysis. EPA acknowledges that, in principle, compensatory responses to I&E can occur, but EPA does not believe that inclusion of compensation in its analysis would necessarily lead to better benefits estimates.

EPA agrees that density dependent population regulation and the concept of compensation are accepted in general terms. However, without knowledge of the underlying mechanisms that govern how compensation occurs, the realizable compensatory response of a given fish population to CWIS losses remains subject to substantial uncertainty.

Indeed, natural recruitment variability makes it necessary to have a very long time series of population data to detect any potential density dependence. Even when such data are available, there may be no clear relationship between spawning stock and recruitment. In some cases there is so much variability in the available data that a statistically significant density dependent relationship cannot be detected. Even with a long time series of observations, it can be very difficult to determine the shape of a stock-recruitment curve and project compensatory population response over a range of environmental conditions.

EPA acknowledges that omission of compensation from its analysis may cause benefits estimates for some particular fish stocks to be overestimated. However, considering the wide variety of factors that could overwhelm compensatory mechanisms, EPA does not believe that overestimates are substantial or common.

RFC: Regulating limited capacity facilities

The 15% 'Capacity Utilization Rate' Threshold Should be Higher

A capacity factor of 15% is below what some energy agencies use to describe "peaking facilities." It is unreasonable to place this kind of requirement and the potential for expensive capital additions on a plant that operates so seldom. This would be even more true for plants in winter peaking regions where operations would not coincide with spawning activity.

EPA Response

The Agency notes that the definition of the capacity utilization rate threshold has no bearing on whether or not a facility is a "peaking facility" by another entity's definition. As a matter of fact, the point made by the commenter (if it were valid) could be used to justify a "lower" threshold. For instance, the general definition of a "peaking facility" according to the Agency's air program is 10% capacity utilization. For this water regulation, the Agency, instead, prefers to base its threshold on an analysis of the facilities and their characteristics within the scope of the rule and not an unrelated definition pertaining to another media or regulatory body. The principle of the threshold cutoff is unrelated to whether or not a facility is termed a "peaking facility", but rather relies on the analysis the Agency conducted for the Notice of Data Availability and the final rule (see DCN 6-3586).

Subject Matter Code 21.05

Role of States and Tribes (alt./equiv. programs)

The Preamble [p. 17180] recognizes that some states already have substantial regulatory programs of their own and suggests they will be permitted to continue these programs if they demonstrate “that such programs would achieve comparable environmental performance” [emphasis added]. If this is the case, just about every state program in the union would not qualify because EPA appears to suggest that it is about nothing but numbers and technology “If the state doesn’t already require cooling towers or technologies that reduce entrainment and impingement to the degree that cooling towers do, the program is not acceptable." We do not agree. We do not believe that a state has to demonstrate that its program is “functionally equivalent” if that means comporting with the numeric percent reduction standards in the rule. There are comprehensive programs that emphasize larger scale conditions, population effects and adverse environmental impacts. These programs have succeeded and should not have to be reconstituted to force-fit a new EPA standard.

EPA Response

EPA recognizes that some States have worked diligently over the years to develop comprehensive 316(b) programs. However, EPA's goal under today's final rule is to set national minimum performance requirements for cooling water intake structures that reflect the best technology available for minimizing adverse environmental impact. EPA believes that these clear national standards will promote more effective and consistent implementation of section 316(b) requirements and ultimately result in reducing impingement mortality and entrainment at these structures. In today's final rule, EPA has allowed approval of State programs that meet rule requirements at 125.90(c). See response to 316bEFR.023.001 for additional detail.

Overview of I & E effects on organisms

Constellation Energy operates on the Chesapeake Bay and its tributaries. This is one of the premier estuaries on the planet, a major commercial and recreational fishing ground and breeding area for many important species. Before the Clean Water Act was passed [1971], the State of Maryland established the Power Plant Research Program (PPRP) within the Department of Natural Resources. It exists to review and evaluate the impacts to Maryland's environment from the construction and operation of electric power generating stations. The agency takes particular interest in the resources of the Chesapeake Bay. The state Department of the Environment has promulgated its own regulations to address entrainment and impingement impacts at power plants [COMAR 26.08.03.03-.05].

Over the past 25 years, dozens of studies have been conducted on power plant entrainment, impingement and discharge effects in Maryland. Assessments have included determinations of the value of the lost resources based on dollar figures also codified in state regulations [COMAR 08.02.09.01]. Together, the studies conducted by PPRP and the utilities have thoroughly documented the impacts from electric generation facilities to the aquatic environment and supported operational changes and/or mitigation where it was warranted.

Since 1975, PPRP has published eleven reports that summarize the current knowledge of acute and cumulative impacts from electric utility facilities. With regard to impingement, the reports note that the dominant fishes that are impinged are all abundant, ubiquitous species that occur throughout the mesohaline reaches of the Bay and its tributaries. No important commercial or recreational species spawn in the mesohaline zones. In addition, trawl studies confirm that impingement is a non-selective cropping mechanism - species are impinged at a rate proportional to their abundance in the plant vicinity.

Over the years, PPRP reports have compared impingement losses to natural die-offs, commercial and recreational landings, predation and the natural densities that some fish demonstrate in the region. The reports conclude that impingement losses are small compared to mortality from other causes. Because the populations are large, widely distributed and demonstrate the ability to survive impingement, the agency has concluded that impingement does not adversely affect the region's aquatic populations.

With regard to entrainment, the conclusions are the same.

"Results of these studies show that while operations of individual power plants impact various ecosystem elements in various ways, those impacts, taken together, have had no identifiable substantive cumulative impact on Maryland's aquatic resources to date. Although large entrainment losses of some types of aquatic organisms have been measured frequently, no consistent depletions in numbers of organisms have been found… At Wagner [Constellation Energy Group's 4-unit fossil plant], data from field studies reveal the actual entrainment impacts are substantially less than predicted by computer screening models, and PPRP concluded that mitigative measures at this facility are not warranted"

[Maryland Power Plants and the Environment, PPRP-CEIR-10, January 1999, pp. 49-50].

The following was published in a peer-reviewed scientific journal:

“At the Calvert Cliffs Nuclear Power Plant, which is located on the mainstem of the Chesapeake Bay, nearly two decades of studies were conducted during the construction and initial operation of the two units that comprise the facility. Entrainment at the plant was determined not to be a major concern because the cooling water intake was not located in a spawning area of significance SNAC model estimates of economic loss due to entrainment were $200 annually, with overall ecological loss being 0.1% of net primary productivity. Naked goby eggs and larvae made up a large proportion of the ichthyoplankton entrained, primarily because this species colonized the rip-rap used to line the intake embayment and their eggs and larvae were being released into the cooling water withdrawal flow.

“Impingement at Calvert Cliffs was initially substantial… Those … episodes were associated with low dissolved oxygen in the intake embayment, a problem resolved in part by removal of several skimmer wall panels. Monetary value of fish lost to impingement averaged less than $25,000/year as a result of the relatively high survival of many species impinged and as well as the relatively low value of the dominant species. No CWIS modifications were required in the Calvert Cliffs permit. However, over a 14-year period, BGE optimized their intake, screening structures and operations such that impingement losses in the early l990s were 10 to 50% of the losses in the 1970s.”

[R.McLean, W. A. Richkus, S. P. Shreiner & D. Fluke. 2002. Maryland Power Plant Cooling- Water Intake Regulations and Their Application in Evaluation of Adverse Environmental Impact. The Scientific World JOURNAL, 2:573-583]

We suggest that the EPA rules need to recognize the millions of dollars that some utilities have directed toward* investigating and mitigating their cooling system impacts, the substantial regulatory attention that some states have directed to this issue and the sound science that has been applied to determine that adverse environmental impact has not occurred.

EPA Response

In EPA’s assessment of environmental impacts associated with cooling water intake structures (see section IV, Environmental Impacts Associated with Cooling Water Intake Structures, of the preamble to today's final rule), EPA aimed to highlight the types of impacts that occur and did not intend to fully assess the specific impacts of each facility within the scope of today’s final rule. EPA notes that most facility-sponsored studies in the past 30 years have not shown a significant impact to fish populations that can be directly attributable to a specific cooling water intake structure. However, EPA does not believe that the facilities are causing zero impact to fish populations and the studies point more to the fact it is extremely difficult to prove that the cooling water intake structure is at fault; indeed, it may be impossible unless a facility commences or significantly changes operation and the nearby populations instantly crash in response. Many anthropogenic factors work concurrently on the environment. It is extremely difficult to separate the effects of any one factor. A facility will always be able to blame another factor and claim it is not the real source of the problem. In addition, the changes in populations may be masked by the considerable natural variation in the size of fish populations. The intention of section 316(b) of the Clean Water Act is to minimize the adverse environmental impact specifically of cooling water intake structures and does not seek to eliminate stress on fisheries due to overfishing, invasive species, habitat degradation, dredging, coastal development, overfishing, industrial pollution, nutrient pollution, wastewater runoff and climate change. Therefore, it was not necessary to include a quantitatively determine the proportion of degradation due to each of these stressors in a rule that seeks to minimize the adverse environmental impact of cooling water intake structures. There are other sections of the Clean Water Act that seek to reduce other environmental stressors to improve fishing and swimming in the waters of the United States.

Section 316(b) of the Clean Water Act seeks to minimize adverse environmental impact of cooling water intake structures because they can have a significant negative impact on aquatic organisms by culling very large numbers of aquatic organisms from the aquatic ecosystem. The Agency believes that it is necessary to minimize impingement mortality and entrainment of the large numbers of aquatic organisms without waiting for a detectable decline at the population level. Structural changes at the population level are influenced by a large number of forces at work within the ecosystem. Many cooling water intake structures have been in operation for decades. During these years, fish populations have been affected by other factors such as overfishing, habitat alteration and water quality changes. Because of the large number of anthropogenic forces and the complexity of their interactions, ecologists find it difficult to determine the contribution of any one stressor to a structural change in an population. In order for a change in the population level to be detectable and attributable to a particular cooling water intake structure, when so many factors are simultaneously affecting populations of aquatic organisms, the change would have to be so great that the extent of the damage would likely be irreversible. EPA has received data which indicate that billions of fish are killed by cooling water intake structures yearly. Populations of aquatic organisms in the vicinity of cooling water intake structures may appear to remain stable despite the impingement and entrainment of vast numbers; however, this stability may be due to improvements in water quality and implementation of fishery management plans, which should result in a steady increase in fish populations. At the same time, habitat degradation may be reducing fish populations. There are a number of different stresses acting on the nation's fisheries at any one time. Section 316(b) is an important tool to reduce one stressor recognized by Congress: the continued killing of billions of fish yearly by cooling water intake structures. This rule will complement fishery management plans and water quality improvements that aim to reduce stress on the nation's fisheries. EPA has determined that reducing impacts by cooling water intake structures by reducing the numbers of organisms impinged and entrained is appropriate. See preamble today's rule for a discussion regarding why EPA chose impingement and entrainment. These reductions will reduce stress on fish populations which EPA believes is the intention of section 316(b).

EPA acknowledges that some permitting authorities are doing a good job implementing section 316(b) of the Clean Water Act. Under § 125.90 of today's final rule, the State may demonstrate that it has adopted alternative regulatory requirements in its NPDES program that will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment that would otherwise be achieved under § 125.94. See also the preamble to the final rule for a discussion of site-specific compliance alternatives.

Permit applications/implementation schedule

Utilities Need Clear Guidance Regarding the Effective Date and Implementation Requirements in the Rule

There is considerable vagueness in the proposed rule with regard to the implementation and compliance requirements. We know little more than the rule will be final in August Of 2003. We need an effective date that recognizes what the permit holder has to do and not some reference to the time when the permit is issued [67 FR 17173; proposed §125.92].

The rule proposes that a permit renewal application should include all the information required under 40 CFR 122.21(r)(2) — Source water physical data, (r)(3) - Cooling water intake structure data, (r)(5) — Phase II existing cooling water system data and 40 CFR 125.95 — The Comprehensive Demonstration Study. We should not be expected to have all of this information completed, absent final regulatory guidance, six months before a permit expires if that expiration date is anywhere close to August, 2003.

States will need more than time to revise their own regulations. It's fine to give them a year to do this and two years if they have to make statutory changes [p. 17180], but a rule as comprehensive and complex as this is requires implementation guidance. EPA even says it will develop implementation guidance but we should not expect it before 2004.

Since the proposed rule is so vague about effective dates and the necessary guidance we will need, we suggest that it would be better to make the schedule for compliance a permit condition so the clock can begin with the renewed permit. This alternative will lay out a clear five-year plan within the time frame of the new permit — two years to study the affected populations and the facility's impacts, along with a study of the engineering/economic feasibility of control options; one year to propose and install control technologies or make the case for a site-specific determination; two years to monitor the effectiveness of the changes that are made. This alternative will allow time for the states to establish their programs and review the applicant's key steps as they occur.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies and permit compliance issues in today's final rule. See response to comment 316bEFR.034.066. The preamble to the final rule also describes how compliance with the rule will be determined.

Performance standards

The Rule Needs a Better Definition of 'Calculation Baseline' and Guidance on How it is Determined

While we appreciate that there will be a primitive basis to which the proposed performance standards will be applied, the regulatory definition at § 125.93 is particularly vague. If it is about impingement, it should mention the presence of some sort of [3/8"]? screens. Further, there must be acknowledgement that many cooling water intake systems have always had features that are improvements on [or just different from] the 'baseline' condition. We need guidance on how the important 'calculation baseline' should be derived.

EPA Response

For discussions on the basis for and implementation of the calculation baseline, please see response to comments 316bEFR.308.014 and 316bEFR.063.022, as well as the preamble to today's rule.

Comment ID 316bEFR.025.021

Author Name Michael J. Wallace

Organization Constellation Energy Group

Subject Matter Code 10.1

General: cost tests

As noted earlier, we are encouraged that EPA has included cost and benefit considerations in the proposed rule. There has to be some reasonable bounds for the potential capital expenses based on the cost of the technologies and the value of the resources saved. It is most important that these provisions are retained in the final regulations.

We refer the agency to the positions articulated by UWAG, EEI and EPRI regarding the costs of retrofit technologies and related economic considerations. We would only add that, at nuclear facilities, the size, cooling water volumes, safety and other regulatory considerations would further compound the chances for cost-effective solutions.

EPA Response

EPA has included cost-cost and cost-benefit provisions in the final rule. Therefore, the commenter's primary concerns have been met. The Agency has addressed the comments of UWAG, EEI, and EPRI in the respective response to comment sections. The point regarding nuclear facilities has been addressed by the Agency in its costing analysis, as the Agency fully considered whether nuclear fuel plants had specific costs associated with complying with the rule. The Agency found that for some cases, the compliance costs of nuclear plants is higher than that for non-nuclear plants and has incorporated these factors into the final rule analysis. See the Technical Development Document for specific documentation of the development of compliance costs and how they may individually differ for nuclear plants.

RFC: Appropriateness of "significantly greater"

"Significantly Greater" Must be Defined and Quantified

We welcome an economic test that improves on the 'wholly disproportionate' model. However, 'significantly greater' is a vague, subjective alternative that clearly needs clarification. Without some numeric basis (e.g. 2:1 or Maryland's 'five times the value of the fish lost in a single year'], we face different interpretations across the country and the potential for regulators to say "the difference is not significant enough."

EPA Response

See response to 316bEFR.006.003.

Monitoring requirements

Compliance Monitoring — Two Years for Verification of Technology Success is Not Always Necessary

Verification monitoring will be required to demonstrate that the performance standards are being met [125.95(b)(7)]. While the rule states that a minimum of two years of monitoring is needed, there can be situations where compliance is assured in less time. Conversely, there are environments that are highly variable where more time might be needed [this is presumed as EPA refers to the two-year requirement as ‘minimum’]. However, if the performance requirements are to be met with environmental enhancements and mitigation, considerable regulatory discretion will be needed to craft a monitoring program that answers the right questions but doesn’t burden the applicant with perpetual studies.

EPA Response

See EPA’s response to comment 316bEFR.074.023.

Comment ID 316bEFR.025.024

Author Name Michael J. Wallace

Organization Constellation Energy Group

Subject Matter Code 21.09

Permit applications/implementation schedule

Also, there is no good reason to consider a “comprehensive reevaluation” of the §316(b) demonstration every time a permit is renewed. Once a successful §316(b) demonstration is made, maintaining the technology for the life of the plant should be enough.

EPA Response

EPA agrees that a comprehensive demonstration study may not be necessary at every permit renewal. Under 125.95(a)(3) of today's final rule, a facility may apply for reduced application requirements if conditions at the facility remain substantially unchanged from the previous permit issuance. Please see response to comment 316bEFR.034.005 for a discussion.

Comment ID 316bEFR.025.025

Subject Matter Code 21.04

Determination of compliance

Author Name Michael J. Wallace

Organization Constellation Energy Group

Compliance Monitoring — Failure of a Control Technology to Meet the Performance Standard Should Not be Considered a Violation of the NPDES Permit

Verification monitoring should continue long enough to show that the performance standards are met. Once compliance is demonstrated [performance within the required range], no further biological monitoring should be required. We agree that the permit writer has the option to modify the permit further but this should not happen until the next-renewal cycle. After two years of monitoring, unfavorable performance [especially for restoration/enhancement measures] should not be a cause to reopen the permit. The facility should be considered to have done enough for one round. There needs to be some latitude and judgment applied that recognizes we are dealing with natural systems and the variability that is inherent with them.

If a technology is not achieving reductions that meet the performance standards, it is reasonable to require additional study to determine why. However, failure to meet the performance standards for a technology that was approved by the agency and installed/operated in good faith should NOT be considered a violation of the permit.

EPA Response

EPA disagrees that monitoring should be conducted only to gather information or should be discontinued if a facility achieves the performance standards. EPA also disagrees that good faith should be tantamount to compliance with today's final rule. However, EPA has included in today's final rule several alternatives for achieving compliance, including demonstrating compliance with a Technology Installation and Operation Plan in place of numeric performance requirements. For a discussion of how compliance is to be determined, please see the preamble to the final rule EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's responses to comments 316bEFR.307.027 and 316bEFR.063.005. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Organization Constellation Energy Group

Subject Matter Code 21.06.01

Implications for nuclear facilities

The Rule Must Acknowledge Nuclear Operations Issues

Another reason to allow for more flexibility and site-specific considerations — nuclear implementation issues. Clearly, we need to allow for the consideration of how proposed control options will impact safety-related systems, as the proposed rule appears to do at §125.94(f). An example would be fabric filter barriers and their potential, if they broke loose, to block the service water intakes. We suggest that a more credible assessment of implementation costs be applied to nuclear plants given their operating and regulatory requirements. Bottom line — retrofits are more problematic and more expensive at nuclear plants. Outages are longer and more expensive at nuclear plants.

EPA Response

Today's final rule allows for a site-specific determination of
best technology available if requirements conflict with Nuclear Regulatory Commission safety requirements (see § 125.94(f)). The five compliance alternatives are also available to these facilities.

The concern that fabric filter barriers might break loose and block service water intakes at nuclear facilities is not supported by evidence or logic. Filter systems have not show evidence in their deployment to experience catastrophic failures such as those theorized by the commenter's concerns. In fact, fabric barrier net systems have been deployed nation wide for better than three decades, and sometimes at nuclear facility intakes. There is no discussion of this deployment in the commenter's unsubstantiated concerns. Further, a fabric filter system could potentially save catastrophic service water intake blockages such as those that commonly occur due to migratory and periodic fish events, such as alewife surges on the great lakes. Nonetheless, the Agency points out that technology selection is not prescriptive in the final rule. Facilities may choose from a wide variety of measures (and combination of measures) that meet the entrainment and impingement requirements of the final rule. As such, even if an aquatic filter barrier system were to have implementation issues for a nuclear plant (which is not proven by this comment), then this rule would not force any facility to install such a barrier, as many other technology options are open to complying facilities, including intake screening technologies, cylindrical wedgewire t-screen systems, fish avoidance systems, fish handling and return systems, acoustic and light deterrent systems, relocation of intakes to far offshore, operational flow reduction measures, and restoration measures, to name but a few.

RFC: Proposed use of restoration measures

Allowing Restoration and Environmental Enhancements is Good Policy

We appreciate the compliance options that are possible with this voluntary alternative to control technologies. On a site-specific basis, these measures have more potential to achieve net environmental benefits for a water body than many CWIS technologies. A liberal application of banking and trading options should also be encouraged if it will result in net environmental benefits. We agree with UWAG [and the environmentalists] that environmental enhancements are not “intake structure technologies”; therefore, §316(b) can not require them. However, if there is adverse environmental impact and the technology options are too costly or show little benefit, enhancements could be considered. Also, EPA should show an understanding that the approved enhancement and its verification monitoring would not be based on entrainment/impingement performance standard. More appropriate evaluations of the enhancement’s efficacy should be encouraged.

EPA Response

EPA acknowledges the commenter’s appreciation of the compliance alternatives that are possible with the inclusion of restoration measures in the final rule. EPA believes that including restoration measures in the final rule provides the benefit of additional compliance flexibility for permit applicants and permitting authorities.

For a discussion of the extent to which restoration measures are voluntary, see EPA’s response to comment 316RFR.060.022.

Restoration measures must meet the benefit level requirements described in section 125.94.

EPA believes design and construction technology and operational measure performance forms an appropriate basis for setting the performance requirements for restoration measures. For a discussion of how performance requirements for restoration measures are based on the performance standard for impingement and entrainment reduction technologies, see EPA’s response to comment 316bEFR.060.025.

Under the final rule, state permitting agencies may develop trading programs. For additional discussion of trading programs, see the preamble to the final rule.

EPA believes that restoration measures are an aspect of cooling water intake structure design and disagrees with the commenter on this point. For discussion of restoration measures as an aspect of cooling water intake structure design, see the preamble to the final rule.

Miscellaneous comment

Section V Environmental Impacts

The primary concern of the District is the possibility that the proposed rule will merely transfer environmental and water resource impacts from one source to another, a topic which is not addressed in the document. The proposed changes may result in existing sea-water cooled plants losing their source, which then may need to be replaced with a freshwater source. Withdrawals in southwest Florida from freshwater sources, especially ground water, are at or beyond sustainable yield in many areas. Overuse of these sources has caused adverse environmental impacts to wetlands, lakes, and streams, as well as induced salt-water intrusion. If the true cumulative impact of withdrawals for cooling water purposes is to be assessed, it must include an evaluation not only of the potential impacts of the existing source, but also of potential replacement sources. This important element is lacking in the proposed rule.

EPA Response

EPA does not anticipate that a significant number of facilities will be forced to change their intake from a saltwater source to a freshwater source as a result of the 316(b) final rule. However, if such transfer is deemed necessary, the facility should consult with his or her permitting Director well in advance of permit expiration.

RFC: State or Tribal alts. achieve comparable perf.

Section VI A. 11. State or Tribal Requirements

The District supports an allowance for State or Tribal agencies to propose alternative requirements. In keeping with the comment made in 1, above, we do not feel that such alternatives should be limited to demonstrating performance at a watershed level, but rather that a more wholistic, regional approach be allowed. Allowing impacts to occur in one area that prevents greater impacts occurring at another through environmental impact transfer should be considered. Additionally, positive environmental benefits of site location (e.g., creation of thermal refuge for endangered manatees) should be allowed to be taken into consideration.

EPA Response

Please see response to comment 316bEFR.099.020.

Comment ID 316bEFR.026.003

Author Name E.D. Sonny Vergara
Organization Southwest Florida Water

Subject Matter Code 17.02
Option: Reduce capacity comm. with closed-cycle

Section VI. B. Other Technology-based Options

The District generally supports economically feasible requirements that reduce overall cooling-water consumption, such as closed cycle cooling, wet/dry or dry cooling, or increased recycling of cooling water. However, an allowance should be made for facilities co-located with a desalination plant where the intake and discharge quantities are important to the feasibility of the desalination facility.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to section VII.E of the preamble for more information on why EPA rejected this alternative.

If a desalinization plant is a permitted point source and uses some of the water it withdraws for cooling, then the 316(b) regulations (Phase I or Phase III) could apply to it. The Phase II regulations apply only to facilities that generate and transmit or sell power and, therefore, would not apply to desalinization plants unless they share an intake with a power plant.

Apparently there are two different methods for taking salt out of water -- reverse osmosis and distillation. The distillation plants use water for cooling, but they probably also use the cooling water for process water, so they probably would not meet the threshold for national regulation established in Phase I. Under the Phase I regulations, facilities are covered by the national rule if they have a design intake flow of more than 2 MGD and if 25% of their intake is for cooling, but facilities do not need to count water withdrawn for cooling if it is recycled and used for another process. Facilities that do not meet the threshold requirements regarding the amount of water withdrawn for cooling purposes must meet any requirements established on a case-by-case, best professional judgment basis.

Depending on the regulatory thresholds established in Phase III, existing distillation plants that are point sources and use water for cooling nonetheless could be excluded from the national rule if EPA determines not to count water withdrawn for cooling if it is recycled and used for another purpose -- as EPA did for the Phase I rule. Reverse osmosis is a process which does not require cooling water, and because it is more energy efficient, new desalinization plants are likely to use that method. Therefore, the universe of desalinization plants that are potentially subject to a 316(b) regulation are likely to be existing distillation plants.

Some desalinization plants share intakes with power plants. In such situations, the 316(b) regulations would apply to the intake flow attributed to a desalinization plant if the intake flow exceeds whatever regulatory threshold is established in the Phase I, II, or III regulations, but the power plant would be the permitted entity. For example, in Tampa, co-location of a 100 MGD intake/50 MGD freshwater output desalinization plant at a large once-through power plant allows the desalinization plant to use power plant cooling water as its intake without increasing overall water withdrawals and impingement and entrainment from Tampa Bay. The desalinization plant discharges 50 MGD brine to the power plant's large discharge flow, which minimizes the salinity impacts on Tampa Bay (no more than 0.1 part per thousand increase at the outfall and no change from background a short distance from the outfall). There may be more situations like this in the future because of the availability of a large piece of waterfront industrial property or an existing intake structure that the desalinization plant can use without having to go through the permitting process and NEPA/SEPA reviews, or because of some other useful feature of the power plant.

Organization Southwest Florida Water

Subject Matter Code 10.03.03

Tampa Bay

Section IX. E. 5 Case Studies - Tampa Bay

The adverse economic impact of impingement and entrainment at Big Bend presents an incomplete picture as it does not account for the benefits of creation of a thermal refuge for manatees. Additionally, the benefits due to co-location of a desalination plant at the site were not addressed (were the 25 MGD developed from a freshwater source instead of the desal facility, adverse environmental impacts would likely occur to wetlands, lakes, streams and associated wildlife at that location of withdrawal).

EPA Response

The final regulation does not require technologies that will change water temperatures. For a discussion of the effect of hot water discharges and manatees, please see EPA's response to comment 316bEFR.051.016. Desalination plants are discussed elsewhere in this comment response document.

Subject Matter Code 7.01

RFC: Three-option framework for determining BTA

Background

The EPA is promulgating standards for the location, design, construction and capacity of cooling water intake structures (CWIS). Under the Clean Water Act, the EPA is directed to determine whether a power station's CWIS demonstrates the Best Technology Available (BTA) for minimizing adverse environmental impacts (AEI). It is under a Consent Decree (Riverkeeper Inc, et al. v. Whitman, No. 93 Civ 0314) to have final rules by August 28, 2003. Comments on the proposed regulations are due to the EPA by August 7, 2002.

The final rules, if approved as proposed, will establish BTA requirements for power producing facilities that utilize at least 25% of their water intake for cooling purposes and that (1.) have or are required to have an NPDES permit and (2.) have a design intake flow of 50 million gallons or greater of water per day. The design intake flow is defined as the value assigned (during the facility's design) to the total volume of water withdrawn from a source water body over a specific period of time. As mentioned above, all KeySpan plants are included by these criteria.

Under the proposed rule, a plant would have three options to establish that its CWIS is BTA: 1) demonstrate the existing system and operation currently meets the proposed specified performance requirements; 2) select, design and construct technologies and/or operational measures or restoration measures that meet the specified performance standards; or 3) demonstrate that the facility qualifies for a site-specific BTA determination because its costs of compliance are either significantly greater than those developed by EPA or the costs of compliance would be significantly greater than the environmental benefits of compliance with the proposed performance standards Facilities may also use restoration measures in addition to or in lieu of technology measures to meet performance standards or to establish BTA on a site-specific basis.

As we interpret this, our plants regulated under the above inclusive criteria must follow the following basic BTA determination process:

1.) First, answer the questions:

a.) Does the existing facility currently meet the proposed (estuarine) performance standards:
Intake capacity equivalent to a closed-cycle, recirculating system, or
Reduce impingement mortality 80-95% and entrainment 60-90%, from baseline.

If yes, then approval of the CWIS as BTA should be granted.

b.) If no, the following are options to meet the standards.

2.) Demonstrate (through new studies?) the plant currently meets the performance standards in 1a, or

3.) Select and implement design and construction technologies, operational measures and/or restoration/mitigation measures that meet the standards, or

4.) Demonstrate that the facility qualifies for a site-specific determination of BTA because its costs of compliance are significantly higher than estimated by EPA or significantly greater than benefits of compliance.

5.) In any event, it appears that a two-year study to demonstrate the CWIS is BTA would be required.

The proposed regulations also specify studies that must be implemented to document Impingement and Entrainment (I&E), and goes into detail on various methodologies, including economic models, to determine whether a plant may be employing BTA. Case studies are used as templates for the rationale behind I&E reduction.

EPA Response

Please refer to the preamble for a description of the framework of today's rule, which largely follows the approach discussed in the proposed rule. Facilities now may choose between five compliance alternatives. For a discussion of these alternatives, please refer to the preamble to the final rule.

EPA notes that the Consent Decree has since been amended and that final action for Phase II existing facilities is now due by February 16, 2004.

Organization Keyspan Corporation

Subject Matter Code 6.01

Overview of I & E effects on organisms

BTA Determination

We feel that the process of determining BTA is flawed in that it appears to only allow for demonstration of BTA by meeting specific percentage reductions in fish impingement mortality and total entrainment numbers (not a reduction in entrainment MORTALITY). The process as proposed is inappropriately skewed toward the application of engineering controls for determining BTA. It makes no allowance for a demonstration that the plants may have been historically operating for decades without a demonstrable adverse impact on populations of fish in the adjacent waterbodies (even though EPA does acknowledge that reductions in I&E at certain locations may have benefits at population, community or ecosystem levels of ecological structures).

Our plants, and others, have been extensively studied over the years and those results have been scrutinized by regulators at the state and federal level as well as the lay public.

In our case, at least, it was determined that the plants demonstrated BTA as there was no discernable impact upon indigenous populations and Representative Important Species (RIS). Adult equivalent models were utilized that found that losses due to I&E were de minimis when compared to sport and commercial landings. The CWIS were declared BTA.

EPA Response

Please see response to comment 316bEFR.025.018 for the discussion regarding environmental impacts associated with cooling water intake structures. For the discussion regarding entrainment mortality and compliance with the performance standards, please see the response to comment 316bEFR.305.001. See the preamble to the final rule regarding the availability of site-specific compliance alternatives.

Author Name A.Christopher Gross

Organization Keyspan Corporation

Subject Matter Code 12.03

RFC: Entrainment vs. entrainment mortality

It should be noted that these models were run assuming 100% I&E mortality when, in fact, subsequent studies demonstrated that mortality of many impinged and entrained species were far less than 100% and that survival was, in fact, quite good. We note that EPA has discounted entrainment survival as being unsubstantiated. We choose to differ; our studies, and others, have proven that survival is real and can approach 100% depending on the species and the time of year and plant operating characteristics. At the very least, EPA should allow for site-specific data on survival of species impinged and entrained at a specific plant, as well as extrapolation of survival data to nearby facilities with similar operating characteristics.

EPA Response

Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis. Due to the high variability and unpredictability of entrainment survival estimates, EPA does not support the extrapolation of survival data to nearby facilities with similar operating characteristics.

Comment ID 316bEFR.027.004

Subject Matter Code 10.01.02.02
Fish Population Modeling

Author Name A.Christopher Gross
Organization Keyspan Corporation

We also believe that it is inappropriate for EPA to disregard compensation as a legitimate mechanism that serves to maintain populations at or near equilibrium despite cropping pressures from natural sources as well as power plants and other anthropogenic sources (e.g.: recreational and commercial fishing). Compensation is a well-established natural mechanism, and applicants should be allowed to include it where it occurs in a relevant species.

EPA's sole determinant of CWIS impact and determination of BTA seems to rely on the "body count" of numbers of fish, fish eggs and larvae impinged and entrained. As noted, we encourage EPA to allow these numbers be adjusted by applying survival and compensation factors to determine ultimate impact to the total population, as has been successfully implemented and accepted in the past. If the ultimate population will not benefit from a reduction in power plant -induced predation on individual fish, neither the population nor the rate-paying public is well served by non-effective expenditures on alternate technologies.

EPA Response

Please see responses to Comment 316bEFR.005.009 on fish population modeling and Comment 316bEFR.025.015 on compensation.

Comment ID 316bEFR.027.005

Author Name A.Christopher Gross

Organization Keyspan Corporation

Subject Matter Code 7.01

RFC: Three-option framework for determining BTA

While EPA states that they will not specify any individual technique, structure or operational strategy as being BTA at a facility, the emphasis on body count reduction limits BTA options to very few, including various straining/filtering devices or cooling water flow reduction. Implementation of intake filtering, devices at salt-water sites is problematic as the marine environment is replete with a wide variety of aggressive fouling organisms that will likely occlude any filtering system in short order. Flow reduction techniques can cause an increase in cooling system discharge temperature exposure that might ensure that entrainment mortality is 100% rather than some lower percentage. And finally, off stream cooling forces a shifting of impact from the water to the land and air if cooling towers are employed.

EPA Response

EPA disagrees. To determine compliance with the performance standards, a facility is not required to use a specific methodology (e.g., body count, total biomass, etc.) to determine the reduction in impingement and entrainment. Please refer to section IX of the preamble to the final rule for more information on determining compliance and monitoring requirements.

EPA acknowledges that biofouling can be a problem at some intakes. However, EPA also notes that a variety of design and operational techniques (e.g., nickel alloy screens, air burst systems, chemical treatments, etc.) can reduce the negative effects of biofouling organisms.

EPA recognizes that the use of flow reduction measures or closed-cycle recirculating cooling can produce some secondary impacts. However, today's rule focuses on section 316(b) and applicable portions of the Clean Water Act. EPA has considered these other impacts in promulgating the final rule.

Comment ID 316bEFR.027.006

Author Name A.Christopher Gross

Organization Keyspan Corporation

Subject Matter Code 10.02.03

Use of Replacement Costs (HRC and hatchery-based)

The calculation of the economic benefits and costs of applying BTA play a crucial role in whether or not existing facilities would qualify for site-specific BTA determinations. In addition, the manner in which the economic calculations are considered m the decision process also is critical to which technologies will be required for the site-specific cases We are concerned that EPA has employed inappropriate methodology and models in development of their economic criteria For instance, EPA appears to have employed avoided costs as a measure of benefits, which assumes that individuals would voluntarily pay those replacement costs. We seriously question that assumption and do not believe it is supported in the literature or in practice. We also question the validity of using habitat replacement costs to measure benefits. It seems basic economic principles have been misapplied. It would seem to be more appropriate to apply actual costs of production lost against mitigation costs. And finally, we believe that EPA has seriously underestimated the costs of providing off-stream cooling or other mitigative measures to plants located on saline waters. Once again, we will leave the detailed analyses and critique of the economic analyses to the comments that will be provided by EPRI, UWAG and EEI.

EPA Response

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule. Please see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method. Please also see EPA’s response to comment #316bEFR.005.035.

In the analyses for the NODA and the final rule, EPA no longer uses hatchery costs to estimate impacts on forage species. Instead EPA translates foregone production among forage species into foregone production among harvested species that are impinged and entrained using an assumed trophic transfer ratio, and then translates foregone production among these harvested species to foregone yield. Further information on the methods EPA used to estimate forage losses is provided in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003). See Chapter A5: Methods Used to Evaluate I&E.

Subject Matter Code 21.09

Permit applications/implementation schedule

Author Name A.Christopher Gross

Organization Keyspan Corporation

The Process

After review of the proposed BTA determination process summarized above, we are unsure of the sequence and timing of activities required on the part of the applicant and the agency to demonstrate and determine BTA for a plant. We submit that demonstrations of compliance should be triggered by incorporation of such a requirement in the NPDES permit renewal process. In other words, if the permit administrator or his designee, upon review of the applicant's renewal application, determines that the applicant's CWIS may not be BTA, the issue could be addressed through a formal process and, if necessary, the permit could be modified to include a condition that the applicant then demonstrate, through studies or other means, that the CWIS is BTA. Absent such a process, the applicant would have to presume that his CWIS did not meet the BTA standard and would unnecessarily expend considerable time, effort and resources on a speculative assessment of risk.

EPA Response

EPA has clarified timing requirements in today's final rule. Please see response to comment 316bEFR.034.066.

Comment ID 316bEFR.027.008

Subject Matter Code 21.0

Implementation

Author Name A.Christopher Gross

Organization Keyspan Corporation

Applicability

We must assume that the proposed rules are intended to be implemented by EPA or designated representatives on a consistent basis. We are concerned that individual state permit administrators will not be constrained by the proposed rules but may use them as a stepping stone to force ever tightening restrictions on an applicant. With deregulation of the industry this could put certain regions or companies or individual plants at a competitive disadvantage, which could ultimately create an adverse impact upon electric reliability and cost to the consumer. We urge that EPA require consistency of approach and evaluation on a national or at least regional scale. Failing such a leveling of the playing field, regulators may advance individual agendas which could cause excessive energy costs and diminish energy reliability without commensurate improvement to aquatic populations.

EPA Response

EPA disagrees that it should prevent States from mandating more stringent performance standards than those set by today's rule, and it also disagrees that allowing States to set more stringent requirements will cause excessive energy costs. With the promulgation of the 316(b) Phase II final rule, EPA has set national performance requirements for the reduction of impingement mortality and entrainment that are based on a facility's flow and source surface waterbody type. EPA understands, however, that the original intent of the Clean Water Act includes broad authority for States to implement CWA requirements. Thus, EPA has left a great deal of discretion to the individual state permit administrators (Directors) in setting the appropriate requirements for their facilities, as long as the requirements are not less stringent than minimal federal requirements established by today's rule. While States are obligated to ensure that the facilities in their jurisdiction comply with minimum federal requirements, they are also authorized to set more stringent standards if they desire. EPA does not believe that allowing States to set more stringent requirements will negatively affect energy costs or reliability. Facilities have five alternative through which they may comply with the today's requirements. For examples, if a facility can demonstrate that its costs of compliance with the rule's performance standards would be significantly greater than the costs considered by the Administrator when establishing such performance standards, or that its costs would be significantly greater than the benefits of complying with the national performance requirements, it may be granted a site-specific determination of best technology available. This site-specific option addresses cases of exceptionally high costs or minimal benefits, and protects facilities against excessive costs and problems with energy reliability. This provision ensures that the costs of the rule are economically practicable and that there is a reasonable relationship between the costs of cooling water intake technology and the environmental benefits associated with its use.

Comment ID 316bEFR.027.009

Author Name A.Christopher Gross

Organization Keyspan Corporation

Subject Matter Code OPP

General Statement of Opposition

The document leaves many questions unanswered and it does not allow applicants to consider scientifically verified aspects of natural population dynamics such as entrainment survival and compensation. We respectfully submit that any regulation that will significantly affect the cost and reliability of electrical energy must incorporate the best scientific information available. We are concerned that the proposed regulation does not do so; instead, it will raise costs to achieve benefits that good science suggests will be illusory.

EPA Response

For information on entrainment survival, please refer to the entrainment survival chapter in the Regional Studies document (DCN 6-0003 in OW-2002-0049, the docket for the final rule).

For information on compensation in fish populations, please refer to the response to comment 316bEFR.025.015.

EPA disagrees that the final rule will have adverse effects on the energy supply and cost, and also disagrees that the rule will result in minimal environmental benefit. Please refer to sections XI and XII of the preamble to the final rule, as well as the Economic and Benefits Analysis (DCN 6-0002) and the Regional Studies document (DCN 6-0003) in the docket for the final rule.

Non-aquatic impacts

An introduction to public power and "green power":

In public debates about environmental protection, the various energy sources are often identified as either "dirty" or "green" power. However, electricity generation has a broad spectrum of environmental impacts. Each electricity generation source has distinct environmental impacts across the broad spectrum of generation sources, within certain generation sources, and between different sectors of the electric utility industry. Green power sources or programs are those that minimize negative impacts to the environment.

What is 'green power' and why is it important?

Public Power utilities have a great stake in generating energy in a manner that minimizes harm to the environment while promoting economic growth. The environmental impacts of generating power by a local, publicly owned electric utility affect its customers and its owners who are, in fact, one and the same.

APPA and conventional environmental impacts:

-Public power emissions rates of sulfur dioxide per Btu are 53 percent lower than IOUs and 37 percent lower than co-ops;
-Public power emission rates of nitrogen oxides are 18 percent lower than IOUs and 23 percent lower than co-ops;
-Public power emission rates of carbon dioxide are 5 percent higher than IOUs and 1 percent lower than co-ops;
-Public power has a greater mix of generation from sustainable resources, including hydro power and other renewable fuels;
-Many public power utilities, particularly large utilities, have begun to offer green pricing programs to their consumers;
-Over 56 percent of public power's operating coal units are less than 20 years old, while only 23 percent of the IOU coal units are under 20 years of age; and
-Public power has many other utility-specific programs to protect the environment and improve the sustainability of our energy resources.

EPA Response

Organization American Public Power Assoc

Subject Matter Code 17.06

Option: Site-specific determination of BTA

APPA is encouraged that the EPA proposal explicitly recognizes that alternative technology selection may be warranted based on site-specific factors that affect the technical practicability of meeting the proposed standards. Specifically, the EPA recognizes that there may be situations where the costs of meeting the proposed standards at a specific facility may be significantly higher than the costs considered by the EPA in establishing these standards. In those instances the proposal provides the facility with the opportunity to justify an alternative technology selection.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

RFC: Appropriateness of "significantly greater"

APPA is encouraged that the EPA proposal explicitly recognizes that alternative technology selection may be warranted based on site-specific-factors that indicate that the costs of meeting the performance standards are not warranted by the projected benefits at that facility. The proposed rule allows facilities to select an alternative level of compliance where the costs of compliance with the EPA's performance levels would be significantly greater than the expected benefits of achieving these levels. This explicitly recognizes the site-specific variations in the waterbodies (with varying ecological conditions) and can help account for controls already in place at many facilities.

EPA Response

Comment supports rule. See section VII of the preamble to the final rule for a discussion of site specific determinations of BTA under this rule.

Option: Site-specific determination of BTA

APPA is encouraged that the Agency has chosen a flexible approach to compliance that allows facilities to meet the performance standards through a number of options, including creation or restoration of habitats and other non-traditional approaches. This approach allows for continued innovation in addressing the potential adverse environmental impacts associated with impingement and entrainment at power generating facilities. This also leaves significant discretion in determining how best to comply with the standards to state permitting authorities and facilities managers who have developed a great deal of expertise on these issues over the past 25 years. APPA is a strong believer in deferring, where possible, to the states.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

For information on the role of restoration, please refer to the preamble to the final rule.

Permit applications/implementation schedule

APPA urges EPA and the states to implement the new 316(b) requirements with coordination with Regional Transmission Organizations (RTOs) to ensure reliable grid operations. APPA is very concerned with the unintended consequences of downtime in the utility industry when 316(b) requirements are implemented. If the EPA and states attempt to do these too quickly or at the same time, there may be electricity price spikes as public power generators purchase power from IOUs or other public power entities during a one to three month down time. The final rule should encourage state flexibility in setting sensible deadlines for 316(b) retrofits when the utility would have scheduled outage, maintenance or have lower demand. APPA believes that the EPA's proposed rule ignored this potential consequence that could be serious in a region (or watershed) where several utilities face NPDES permit renewal, imposition of 316(b) requirements, and planned outages in the same year. If not timed wisely, the region's customers could face unexpected utility bill increases—particularly during a peak use time such as mid summer or mid winter.

APPA believes that the EPA and states should take a common sense approach to new 316(b) requirements. This common sense approach would minimize potential cost spikes and energy disruptions and would avoid placing too high a demand on the few dozen consulting engineering firms that have considerable expertise in biological studies and the various intake technologies. These are not trivial concerns.

EPA Response

EPA expects Regional Directors and States to coordinate with Regional Transmission Organizations for downtime issues, as appropriate.

Other regulatory requirements

ASSESSMENT OF EPA'S UNFUNDED MANDATES ANALYSIS ON PUBLIC POWER

Summary

The 316(b) Phase II regulation will impose greater compliance costs on in-scope public power systems than those estimated by EPA in the analyses required by the Unfunded Mandates Reform Act of 1995 (UMRA). Unfunded mandates pose a particular problem for local governments at this time, and the compliance costs have the practical effect of mandating a raise in the rates of the customers of municipally-owned systems. This equates to a tax increase at a time when many state and local governments are already raising taxes due to economic conditions. These rate increases deserve to be fully considered in the EPA analyses.

These comments address concerns with the EPA analyses in the following areas:

-The total estimated cost of the proposed option;

-Costs disproportionately borne by small power producers;

-The omission of the alternative with the greatest net benefits; and

-The effects of the rule on small governments.

UMRA requirements

Title II of UMRA requires that EPA conduct a series of economic analyses for any rules, proposed or final, that would impose unfunded mandates of $100 million or more in any one year on state, local, and Tribal governments, or on the private sector. The required analyses take two forms:

-A comprehensive benefit-cost analysis that considers a variety of alternatives. If EPA does not select the least-costly, most cost-effective alternative it must explain why in writing.

-An analysis of the regulation's effects to determine if the regulation will "significantly or uniquely" affect small governments. A finding that the regulation will "significantly or uniquely" affect small governments would necessitate that the Agency prepare a small government agency plan.

Both requirements are discussed in the following comments.

Issues of concern

1. EPA's benefit-cost analysis underestimates the costs of compliance, and does not include the most cost-effective alternative

The first requirement for a regulation meeting the $100 million threshold is a cost-benefit analysis that evaluates the proposed option and a "reasonable number" of regulatory alternatives. Section 205 of UMRA directs the Agency to adopt "the least costly, most cost-effective, or least burdensome alternative" that achieves the objectives of the rule. <FN 1>

APPA commends the Agency for proposing the alternative that maximizes net benefits according to EPA's analysis. Two issues remain, however:

-EPA substantially underestimates the costs of the proposed option, particularly as it applies to small businesses/public power systems; and

-The costs of the proposed alternative can be significantly reduced without a commensurate reduction in benefits.

2. EPA underestimates the costs of the proposed option for small facilities

The EPA analysis assumes that all of the costs are borne as easily by small facilities as by large ones. Most of the costs, however, are fixed costs that affect facilities equally, regardless of facility size. The resources available to large facilities permit greater flexibility in the resource shifts required to comply with the new requirements. EPA cannot fully determine the costs of compliance without adjusting the cost categories to reflect the fact that fixed compliance costs have a disproportionately greater impact on small facilities.

Two categories that the Agency needs to consider are provided below.

a) Permitting costs

Permitting costs are fixed costs incurred by all facilities regardless of size. In large facilities, environmental compliance staffs have the capability to more easily absorb the additional workload. Conversely, APPA members (predominantly small facilities) typically have environmental compliance staffs of 1-3 people (or full time equivalents). Small entities of this size have greater difficulty absorbing the labor/overhead costs of compliance associated with items such as:

-Preparing a compliance plan;
-Commissioning/overseeing the necessary scientific studies;
-Shepherding the applications and reapplications through the permitting process; and
-Complying with the various verifications and updates required by the permit.

EPA’s Economic and Benefits Analysis does not provide any indication that it takes into account the size of the firm/facility when calculating average costs. Correctly calculating the costs to small firms is particularly important as EPA fulfills its statutory requirements to consider the economic impact on small governments (UMRA) and small businesses (RFA/SBREFA).

B. The costs of downtime

EPA’s analysis assumes that compliance technologies will, on average, take only one month to install. EEI and others have commented that this is an optimistic figure – two months represents a better estimate of installation time. Public power systems, many of which are small and cannot make up production shortfalls by simply increasing generation from within their own systems, are obligated to provide uninterrupted service to specific territories. Consequently, when shutdowns occur, these systems must purchase power to balance the production loss. The public power system would be exposed to potentially volatile wholesale prices. This results in higher electricity costs for the population served by the public power system – a circumstance not accounted for in the EPA analysis.

c) Including a presumption of compliance for approved technologies will reduce the costs of the rule without reducing the benefits, thereby furthering the goals of UMRA

EPA's analysis is predicated upon the carefully vetted conclusion that the evaluated technologies will, in fact, result in the anticipated reductions in impingement and entrainment. The compliance requirements, however, still mandate that extensive studies take place after facilities install the approved technologies. Facilities must evaluate a defined set of baseline conditions at the facility (some of which may not even exist), model the effectiveness of the control technologies (which EPA claims to have already done), and monitor continued effectiveness.

A considerable percentage of the costs of the rule would be eliminated if the regulation permits the assumption of compliance when facilities install one of the EPA-approved technologies. Given EPA’s stated confidence in its evaluation of the modeled technologies, the Agency should be willing to forgo the substantial additional costs resulting from the post-installation demonstrations of efficacy. Facilities should only need to demonstrate that they properly installed the control technologies and continue to operate them effectively. If the facility meets these simple tests it should be deemed to be in compliance.

Such a presumption would significantly reduce the cost burden for both facilities and the State permitting agencies. It would not, however, reduce the benefits at all, presuming that EPA correctly evaluated the technologies.

Facilities that elect to install technologies other than the suites pre-approved by the Agency would still be required to provide a comprehensive, site-specific evaluation of the impingement and entrainment effects, thereby ensuring compliance.

3. EPA incorrectly determines that small governments would not be significantly or uniquely affected by the proposed rule

a) The UMRA Process

In order to fulfill the second of its UMRA responsibilities, EPA must determine whether or not the regulatory requirements will significantly or uniquely affect small governments. If compliance will impose significant or unique effects, the Agency must develop a small government agency plan in accordance with Section 203 of UMRA. The plan must provide for:

-Notifying potentially affected small governments;

-Enabling officials of affected small governments to have meaningful and timely input into the development of the rule; and

-Informing, educating, and advising small governments on the compliance requirements.

b) EPA’s determination

EPA determines that the proposed rule would not have significant or unique effects on small governments. The Agency reaches this conclusion after a cursory and flawed analysis summarized by the following statement:

The per-facility average compliance cost incurred by facilities owned by small governments is less than the per-facility compliance costs incurred by facilities owned by large governments and privately-owned facilities subject to the proposed Phase II rule. <FN 2>

EPA bases this conclusion upon Table B5-6: <FN 3>

[see hard copy for table]

These numbers present a meaningless snapshot of relative costs, and do not address either the “significant” or the “unique” thresholds mandated by statute.

a) “Significant” effects

EPA never defines "significant" as it applies to the evaluation of economic impact on small governments, such as public power. In the absence of a definition, a simple comparison of per-facility costs cannot possibly determine whether or not small governments will incur significant costs as a result of compliance. For example, all of the facilities, small-government owned or not, may be "significantly" impacted, thereby rendering the comparison irrelevant.

A reasonable definition of “significance” might include whether or not:

-The costs will be sufficient to affect the economic viability of the facility;

-The costs will place “significant” financial or legal pressure on the affected governments (e.g., breach of contract with the service area); and/or

-Compliance will disproportionately affect small-government-owned facilities.

At the very least, EPA must describe the criteria by which the Agency determines that the costs to small governments are "insignificant." Why does EPA believe that the per-facility cost is the accurate measure? Would the Agency have considered a higher per-facility cost “significant?” If so, how much higher must it be? How many facilities would have to close? According to a recent APPA study, governments running small public power utilities (defined as those under $100 million) make significant payments to a local government. The median value of the net payments from the utility to the government’s general fund is 5.7% of the total electric operating revenue. <FN 4>

The additional costs of compliance with this rule could erode or completely erase those payments.

Small governments would then be forced to decide between two damaging measures – increasing electricity rates or increasing taxes. Either option could constitute a “significant” impact, depending upon the severity of the shortfall. EPA clearly needs to consider the ramifications of depleting these payments prior to determining that compliance will not “significantly” impact small governments.

b) “Unique” Effects

EPA once again fails to define what would constitute “Unique Effects” on small governments. What would a unique effect look like? Since EPA cannot possibly make an UMRA-compliant certification without defining “unique”, the Agency should inform the regulated public what definition it uses to make the determination of “no effect.”

APPA feels that a reasonable definition would take into account:

-The potentially “unique” impacts of the contractual obligations public power facilities have with their service areas to provide reliable electricity; and

-The substantial revenue generated for the city by the power facilities, and the subsequent effects on the rate base should compliance costs significantly affect a given public power system.

Both of these criteria reflect the circumstances that make public power systems unique in the utility industry. Given the captive nature of the population served and the interdependent relationship between the municipality/government entity and the electric utility, APPA feels that there are certainly “unique” effects that deserve special consideration.

Conclusion regarding the EPA “Unfunded Mandates Act Analysis”

A regulation that forces local governments to raise rates at a time when they can ill-afford to do so certainly deserves careful scrutiny prior to promulgation. Small public power systems frequently face additional friction when increasing the cost of power to cover the costs of compliance. For example, some have rate contracts that can only be changed through rate hearings. A comprehensive UMRA analysis will help the Agency to fully account for these and other economic impacts of the Phase II regulation. EPA needs to make the following additions to its benefit-cost analysis:

-A more rigorous examination of economic costs disproportionately borne by small businesses; and
-The inclusion of the technology-based option that would reduce the costs associated with permitting, monitoring, and uncertainty, yet would not reduce benefits.

In addition, APPA believes that the Agency needs to revisit its determination under Section 203 of UMRA by both reconsidering the effects on small governments and explicitly stating the Agency’s assumptions and definitions. Small governments, with their unique status, face significant challenges that deserve consideration prior to the promulgation of the rule.

SBREFA requirements

ASSESSMENT OF THE ECONOMIC IMPACTS ON SMALL BUSINESSES

Summary

EPA does not accurately assess the probable economic impacts of compliance with the 316(b) proposed rule on small businesses for the following reasons.

-The methods used to determine economic effects are inaccurate and poorly defined, resulting in highly questionable conclusions. These methodological flaws are correctable using widely-accepted economic principles that are consistent with EPA's own guidance.

-The definition of "small business" as it applies to the industry is too narrow and requires revision. APPA provides an alternative definition that provides the opportunity for a more comprehensive evaluation of the proposed rule's true impact on small businesses.

RFA/SBREFA Requirements

The Regulatory Flexibility Act as amended by the Small Business Regulatory Enforcement Act of 1996 (RFA/SBREFA) requires that EPA determine whether or not the proposed rule will have a significant economic impact on a substantial number of small entities. If the Agency determines that the rule will not have a significant economic impact, it must certify that finding. If, however, the Agency finds that the rule will impose a significant economic impact on small businesses, it must undertake further analysis and provide for additional public comment.

EPA SBREFA Analysis

For the purposes of the 316(b) Phase II proposed rule, "small entity" is defined as one with the following characteristics:

-A small government jurisdiction that is a government of a city, county, town, school district or special district with a population of less than 50,000;

-A small organization that is a not-for-profit enterprise which is independently owned and operated and is not dominant in its field; or

-For private firms, the size threshold is 4 million MWh, and is set by the Small Business Administration (SBA) size standards.

For 316(b) Phase II, EPA certifies that the proposed standards would not have a significant economic impact on a substantial number of small businesses based upon three findings:

1. The limited absolute number of small entities expected to incur compliance costs (28 total

facilities);

2. The low percentage of all small entities in the entire electricity generating industry expected to incur compliance costs (1.3 percent); and

3. The insignificant magnitude of compliance costs as a percentage of sales revenue (no facility incurs compliance costs of more than 5.3 percent, and 17 faced less than 1 percent).

Issues of concern

1. EPA needs to expand the definition of "Small Business" for Public Power utilities

To meet the current definition, a public power producer must have a service area of fewer than 50,000. This definition is too narrow to include all of the public power systems that have significant small business characteristics. The EPA analysis of the small business universe for the Phase II rule found that 39.4 percent of the municipalities, municipal marketing authorities, and political subdivisions that would be defined as "small" under the threshold for private utilities (4 million MWh) did not meet the population threshold for public entities. There is no reason why facilities producing fewer than 4 million MWh should have to meet an additional threshold that results in exclusion from the small business universe. These facilities face the same relevant small business issues as their private counterparts.

APPA recommends that the following threshold be implemented

-Eliminating the population threshold altogether and base inclusion solely on the generation ceiling

This change will result in an additional approximately 90-100 public power facilities <FN 5> meeting the definition of “small business” in the final Phase III rule. EPA has the authority to change the small business definition through consultation with SBA and affected industry, provided that all parties agree.

2. EPA’s certification of “No Effect” is flawed

APPA believes that EPA has incorrectly analyzed the effects of the regulation on small businesses by neglecting both basic economic theory and EPA’s own guidance for determining economic impact. The three findings listed above do not accurately reflect the true economic impacts of the regulation, leading to a potentially erroneous determination that a “substantial number” of small businesses will not suffer “significant economic impact” as a result of the rule.

a) Determination of a “substantial number” of small businesses

The EPA analysis concludes that a “substantial number” of small businesses will not be affected. This conclusion is based upon an analysis that identifies only 28 facilities. As stated earlier, APPA believes that this number is too low because of the criteria EPA used to define “small business.” <FN 6>

In addition, APPA believes that a finding based upon numbers alone is insufficient to meet the

RFA/SBREFA test – EPA also needs to consider the effects resulting from geographic distribution. EPA's own Revised Interim Guidance for EPA Rulewriters clearly states that the threshold for a "substantial number" should be lowered in those instances where region-specific costs are "substantial."

It is appropriate for EPA to consider whether alternative approaches to defining "substantial number" should apply because:

"Where the extent of the impacts, measured in economic or non-economic terms, would be of sufficient magnitude (e.g., potential collapse of a viable regionally-concentrated fraction of an industrial sector)..." <FN 7>

EPA did not assess whether or not the unique nature of municipal/state-owned facilities will result in substantial regional impacts, despite the fact that its own guidance explicitly directs the Agency to do so. Given that EPA's analysis indicates that all 28 of the "small" in-scope facilities are owned by municipalities, political subdivisions, or rural electric cooperatives, EPA clearly needs to reassess the definition of a "substantial number" to potentially include the local and regional effects resulting from the cost impacts of compliance.

b) The estimated compliance costs would significantly erode the contributions from Public Power systems to municipal governments.

The cost of compliance of this rule could equal a significant portion (if not all) of the utility's contribution to the municipality. Any shortfall in the expected payments would have to be made up, either through rate increases to the municipality's power customers or by raising taxes in another sector. Neither option is a popular one from the perspective of the affected public.

c) EPA's methodology used to determine "no significant impact" is inappropriate

EPA's methodology for determining significance of economic impact is inappropriate. EPA uses the ratio of compliance costs to sales revenue as the criterion to determine whether or not the proposed regulation would impose a "significant" economic impact on the in-scope small businesses. EPA evaluates each category of small entity individually, and concludes that the regulation will not "significantly impact" any of the small business segments.

Table B4-5 of the Economics and Benefits Analysis Document provides the results: <FN 8>

[see hard copy for table]

This test is insufficient in two ways. First, EPA does not consider the full range of costs that compliance will impose on small businesses. A list of these costs is described in detail in the UMRA section of these comments. Second, EPA evaluates the costs through the Cost-To-Revenue Test (CRT), also known as the "sales test" method, which calculates the ratio of the annualized post-tax compliance cost for each firm or facility against the firm/facility's total annual gross revenue. If this ratio is smaller than three percent, the entity is judged not to be "significantly impacted" as a result of the rule.

i. The method is not economically sound

The CRT method cannot, except through sheer chance, provide a meaningful estimate of economic effect. The CRT compares annualized compliance costs against annual gross revenues for each facility. Gross revenue is a meaningless measure of economic viability -- a large company can have annual gross revenues exceeding hundreds of millions of dollars, and yet still have negative annual net revenues when costs and debt are taken into consideration. The net margins within the electric power markets are low (this is consistent with most commodity markets), and are expected to shrink even further in the wake of expanding deregulation.

ii. A better method exists

An effective analysis of the economic impact of compliance on firm/facility viability must examine compliance costs against some form of net revenue in net present value terms. In the case of investor-owned utilities, this takes the form of profit. Public power systems do not operate on a “profit” basis. However, a public power system’s responsibilities to its parent entity (municipality, political sub division, etc.), generally involves making transfers to the “general fund” of the parent in the form of net payments and contributions. These net payments are approximately equal to the amount by which the system’s revenues exceed its costs of production, and are generally factored into the parent entity’s expected revenue stream as a form of return on investment.

iii. Illustration of misleading results from the application of the Cost-to-Revenue Test (CRT)

This is particularly the case in industries, like electric utilities, with low net margins. The example below illustrates the misleading nature of CRT in the utility industry and the importance of basing economic impact evaluations on a relevant form of net revenues.

Hypothetical Public Power Example

-Annual Gross Revenues: $12.0 million

-Annual Outflows (O & M costs, debt servicing, etc): $11.44 million

-Annual Net Payments and Contributions to Municipality: $564,000

-Net Payments to the General Fund: 4.7 percent

Assume that the facility described above would only incur the average EPA-estimated compliance cost per small government-owned facility of $273,000. EPA would conclude from the CRT analysis that the firm is not significantly affected by the imposition of compliance costs since the ratio of cost of compliance to gross revenue is less than 2.3 percent - well short of the 3.0 percent threshold.

If the analysis is done correctly, however, the conclusion is exactly the opposite. As a result of compliance, annual net payments and contributions to the municipality decrease by 51.6 percent. This shortfall in the expected revenues of the municipality must then be recovered, either through a rate increase or additional taxes.

iv. EPA's guidance shows a preference for the alternative method

EPA does, in fact, recognize that measuring costs of compliance against some measure of net revenues is the best available measure. In the 1999 Revised Interim Guidance for EPA Rulewriters, EPA states that:

"Conceptually, we believe that a profits test represents the most accurate screening analysis for determining whether a regulation will pose a significant economic burden on small businesses…" <FN 9>

"Our goal is to develop a profits test that may be used in addition to, or in preference to, the sales test when there are sufficient reliable data to support it..."

Comparing the cost of compliance against this margin provides a better estimate of economic impact than the CRT. The transfers to the general fund are a very important source of funds to the municipality/political subdivision, and represent a reasonable approximation of public sector "profit."

v. The necessary data is available for public power systems to construct an alternative analysis

The EPA guidance explains that the profits test is generally prohibitively difficult to implement because it requires that EPA either obtain actual profit information from a given industry or estimate those profits off of incomplete data. In the case of this regulation, however, the universe of small government-owned businesses is composed of facilities/firms that must report net payments as a matter of public record through the city budgets. Since the Phase II universe of small businesses is exclusively composed of public power systems, the net payments data for the entire small business impact evaluation is available.

Conclusions regarding the EPA analysis of "significant impact"

The CRT is an unreliable method of assessing the economic impact of a regulation on a specified population. Given the availability of the net payment/contribution data, a comparison of compliance cost to net payments/contributions is entirely consistent with both generally accepted economic principles and EPA's own internal guidance. In addition, EPA should factor the full range of costs, including those that are unique to small businesses, into the net effects calculation. This adjusted analysis should be done prior to EPA certifying that the regulation will have not have "a significant economic impact" on small businesses.

Footnotes

5 Based upon EIA's 767 2000 analysis of facilities with < 50 MGD average withdrawal rate.

6 It is possible that EPA's number is too low because the EIA database or EPA Detailed Questionnaire did not cover all public power facilities.

EPA Response

BACKGROUND

The results of EPA's small-entity impact analysis for the final 316(b) Phase II rule show that the rule will not have a significant economic impact on a substantial number of small entities (see Chapter B4 of the Economic and Benefits Analysis Document, DCN 6-0002). EPA disagrees with the commenter's statement that EPA has incorrectly analyzed the effects of the 316(b) Phase II rule on small businesses.

For the proposed 316(b) Phase II rule, EPA estimated that 28 total entities were small. EPA has updated its analysis for the final Phase II rule and estimated that only 25 Phase II entities are considered small. This estimate is not materially different than that estimated for the proposed rule (see Chapter B4, DCN 4-0002). Final rule estimates of the number of small entities with cost-to-revenue ratios in certain ranges and the percentage of all small entities affected are also not materially different from the proposed rule. EPA's response to this comment on proposal results therefore equally applies to the final rule.

The commenter raises two principal issues:
(1) "The definition of "small business" as it applies to the industry is too narrow and requires revision."
(2) "The methods used to determine economic effects are inaccurate and poorly defined, resulting in highly questionable conclusions." (p. 10 of original comment)

EPA's responses to both issues are provided below.

(1) DEFINITION OF "SMALL BUSINESS"

The commenter states "EPA needs to expand the definition of "Small Business" for Public Power utilities." The commenter argues that instead of using the small government threshold of a population of 50,000 or less, EPA should have used the Small Business Administration threshold for SIC code 4911 of 4 million MWh.

EPA response: EPA notes that its approach of using the population threshold of 50,000 or less for municipalities and political subdivision is consistent with the definition of "small government" specified by the RFA/SBREFA. However, for the final 316(b) Phase II rule, EPA conducted a sensitivity analysis of the entity size determinations for publicly owned power producers (i.e., municipalities and political subdivisions) based on the Small Business Administration threshold for SIC code 4911 of 4 million MWh. Based on this alternative size determination criterion, an additional 14 municipal entities would be considered small (these are considered large based on population). Overall, the number of small governments would increase from 16 to 30; the number of all small entities subject to Phase II regulation would increase from 25 to 39.

EPA believes that this number is still small, both in an absolute sense and compared to the total number of small entities in the industry. EPA also notes that ten of these additional 14 entities have cost-to-revenue ratios of less than 0.5 percent, two have ratios between 0.5 and 1.0 percent, two have ratios between 1.0 and 3.0 percent, and none have ratios of 3.0 percent or greater. Based on the results of this sensitivity analysis, 39 total entities are small, with only one entity expected to incur compliance costs greater than 3.0 percent of revenues. EPA also estimated that the rule will affect only 1.3 percent of the universe of small entities that own electric power generating facilities. This sensitivity analysis shows that EPA's finding of no significant economic impact on a substantial number of small entities is still valid under the alternative definition of a small entity. (See the Appendix to Chapter B4 for the results of this sensitivity analysis; DCN 6-0002.)

In reference to using electricity sales as the appropriate criterion for determining entity size, the commenter states:
"This change will result in an additional approximately 90-100 public power facilities meeting the definition of "small business" in the final Phase III rule." (p. 11 of original comment). EPA notes that this final rule pertains to Phase II facilities and does not address Phase III issues.

(2) EPA'S FINDING OF "NO EFFECT"

The commenter asserts that "EPA has incorrectly analyzed the effects of the regulation on small businesses by neglecting both basic economic theory and EPA's own guidance for determining economic impact." (p. 11 of original comment) The commenter cites several reasons for this claim:

(a) Determination of a "substantial number" of small businesses.

The commenter argues that EPA underestimated the number of small entities because of the criteria used to define small business and because EPA's analysis may not have covered all public power facilities. For a response to the first point, please see the discussion in Section (1) above. EPA disagrees with the claim that its analysis may have excluded some public power facilities. EPA performed a census of all utility power plants, including public power plants, with at least one non-retired steam-electric generator (based on the 1995 Form EIA-860). EPA then applied sample weights to account for non-responses, although it should be noted that the response rate was close to 100 percent. EPA is confident that this approach captured the universe of facilities, as of 1995, that must comply with the Phase II rule. For further details, please see also EPA's response to comment #316bEFR.072.202 in subject matter code 9.0.

The commenter further suggests that "the threshold for a 'substantial number' should be lowered in those instances where region-specific costs are 'substantial.'" EPA notes that the 25 small facilities are located in 16 states, including only one state where more than two facilities are located (four facilities are located in three Michigan counties). Given the broad regional distribution of the small Phase II facilities, EPA judges that affected small entities are not sufficiently concentrated regionally to warrant adjustment to the concept for determining a 'substantial number' of small entities.

(b) The estimated compliance costs would significantly erode the contributions from Public Power systems to municipal governments.

The commenter states that "[t]he estimated compliance costs would significantly erode the contributions from Public Power systems to municipal governments." (page 12 of original comment). EPA refers the reader to the following section for a response concerning the appropriateness of using the sales test method to assess the economic impacts on small entities. For a discussion of the impacts of rule on municipal government entities please see comment #316bEFR.028.008 in subject matter code 22.03.

(c) EPA's methodology used to determine "no significant impact" is inappropriate.

The commenter states that "[a]n effective analysis of the economic impact of compliance on firm/facility viability must examine compliance costs against some form of net revenue [...]" (p. 13 of original comment). EPA disagrees that such an analysis is required for the SBREFA analysis in support of the final Phase II rule. The analysis conducted by EPA is a standard screening mechanism to assess the likelihood of a "significant economic impact on a substantial number of small entities." It is generally accepted that significant economic effects are unlikely below a cost-to-revenue ratio of three percent.

The commenter cites EPA's "1999 Revised Interim Guidance for EPA Rulewriters" (p. 20; DCN 6-4104):

"Conceptually, we believe that a profits test represents the most accurate screening analysis for determining whether a regulation will pose a significant economic burden on small businesses."

However, the commenter omitted the sentence immediately following this text, which states EPA's current preference for use of the sales test.:

"However, because of procedural and operational issues associated with the implementation of a profits test, a sales test remains our preferred quantitative guideline at this time."

The discussion continues, as the commenter's second excerpt from the guidance document indicates (p. 20):

"Our goal is to develop a profits test that may be used in addition to, or in preference to, the sales test when there are sufficient reliable data to support it..."

However, the commenter, again, excluded the last part of this sentence, which reiterates the need to resolve certain issues before adopting the profits test as the preferred approach:

"...and the procedural and operational issues have been resolved"

In addition to these existing concerns over using some measure of net revenue as a basis for measuring the impact of compliance costs on small entities, data are not readily available that would allow a consistent profits test approach to be employed across all entity types. EPA corrects the commenter's following statement:

"Since the Phase II universe of small businesses is exclusively composed of public power systems, the net payments data for the entire small business impact evaluation is available." (page 14 of original comment).

EPA notes that for the proposed rule, the universe of small entities consisted of government entities (i.e. municipalities) as well as cooperatively owned businesses. For the final 316(b) Phase II rule, the sample of small entities analyzed includes two privately owned facilities and six cooperatively owned facilities, in addition to 16 municipalities and one political subdivision. This scenario reflects the concern stated in the 1999 Revised RFA/SBREFA Guidance for EPA Rulewriters (pp. 20-21):

"Because data on profits are limited, especially for small businesses, routine use of a profits test would require us to estimate profits for small businesses where there are currently insufficient data. For example, sufficient data are unlikely to exist across all SIC codes that a regulation affects. This would limit our ability to rely on consistent information to determine the magnitude and scope of economic impacts on small business [...]"

EPA therefore believes that its decision to use the sales test in support of its Phase II SBREFA analysis is appropriate.

Subject Matter Code OPP

General Statement of Opposition

The EPA's proposed Rule seeks to apply § 316(b) to "existing" facilities, effectively compelling the retrofitting of most "base load" and many "peaking" electric-generating stations with extremely costly technologies, such as cooling towers, to offset presumed impingement and entrainment losses due to cooling water intake structures ("CWISs"). To do so, EPA has proposed so-called "performance standards," which compel facility owners to reduce, in a manner commensurate with closed-cycle cooling, impingement mortality by approximately 80-95%, and entrainment mortality by approximately 60-90%, as compared to a "baseline" condition established by EPA.

EPA Response

Each issue is addressed individually in subsequent responses.

Subject Matter Code 2.04

EPA's legal authority to:

There are multiple, systemic flaws with the proposed Rule. It ignores the statutory language, which does not support application of § 316(b) to existing, as distinct from new, facilities, particularly in the context of National Pollutant Discharge Elimination System ("NPDES") permits. Even assuming for argument's sake that the Rule is applicable to existing facilities, the Rule's flaws remain significant and pervasive. Among these several flaws, EPA erroneously concludes that existing facilities subject to the Rule, some of which have studied the fisheries communities for three decades, invariably have a demonstrable adverse environmental impact ("AEI") on those communities.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

RFC: Test: benefits should justify the costs

The Rule fails to establish that, even accepting EPA's presumption that individual losses resulting from entrainment and impingement constitute an AEI, such impacts reasonably warrant the installation of costly technologies. This is particularly the case to the extent EPA seeks to require, through poorly veiled "performance standards," cooling-tower retrofits, for which the costs of compliance may be disproportionately greater at nuclear facilities than at fossil-fuel facilities, and which implicate questions of nuclear safety within the sole jurisdiction of the Nuclear Regulatory Commission (the "NRC").

EPA Response

EPA disagrees that a determination of whether an adverse environmental impact is occurring is a preliminary step in implementing 316(b). Please refer to the response to comment 316BEFR.313.001 for more information on EPA's position on minimum impacts at existing facilities.

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to section VII.E of the preamble for more information on why EPA rejected this alternative.

EPA also notes that 125.94(f) allows for a site-specific determination of best technology available if conflict with Nuclear Regulatory Commission safety requirements.

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

EPA grossly underestimates the costs of such technology, which, if appropriately estimated, cannot reasonably be compared to the nominal possible benefits to aquatic communities of reducing entrainment and impingement attributable to once-through cooling.

EPA Response

EPA has decided not to base the requirements of the final rule on cooling tower technology.

Comment ID 316bEFR.029.005

Subject Matter Code 10.02

Benefit Estimation Methodology

Author Name Elise N. Zoli

Organization Godwin Proctor Counselors at Law obo Entergy Corporation

EPA grossly overstates the social and economic benefits of its select technologies and the Rule.

EPA Response

The commenter asserts that EPA's benefits estimates are "grossly overstated". The Agency disagrees. EPA’s approach to benefit cost analysis of the final Section 316(b) Phase II rule is consistent with principles outlined in the EPA’s Guidelines for Preparing Economic Analyses, United States EPA (EPA 240-R-00-003). In fact, the Agency believes that its analysis provides lower bound estimates of the final rule’s benefits. Please see the final Phase II Regional Studies Document (DCN # 6-0003).

Comment ID 316bEFR.029.006

Author Name Elise N. Zoli

Organization Godwin Proctor Counselors at Law obo Entergy Corporation

Subject Matter Code 10.02

Benefit Estimation Methodology

EPA fails to provide a cogent basis in the administrative record for the benefits-costs analysis that is the crux of the Rule.

EPA Response

EPA disagrees that its benefits-costs analysis is poorly documented. The Agency followed standard docket compilation procedures that govern how background and supporting materials should be provided to the public docket. EPA believes that its administrative record provides adequate information.

Comment ID 316bEFR.029.007

Mkt-level impacts/Reliability/EO 13211: Energy Effects

Author Name Elise N. Zoli

Organization Godwin Proctor Counselors at Law obo Entergy Corporation

EPA fails to adequately account for the differential impact on regulated, as distinct from unregulated, facilities, with the result that a superficial consistency produces perhaps unintended, but no less troubling, differential impacts. Indeed, apparently under the mistaken impression that EPA's role is to "correct" the market, EPA creates inequities that have the potential to fundamentally alter the electric-power supply for the nation.

EPA Response

EPA disagrees with this comment. EPA believes that in a deregulated market, the distinction between utilities and nonutilities is no longer relevant. While such a distinction may have been important in the past, when only a few unregulated nonutilities competed with regulated utilities, this is no longer the case. The share of Phase II facilities that are owned by unregulated entities has increased from 2 percent in 1997 to 31 percent in 2001. By the time the final rule will take effect, even more Phase II facilities that currently operate under a rate-based system will be operating in a competitive market. Furthermore, EPA does not believe that nonutilities will be differentially impacted compared to utilities, even in the case that deregulation might not have taken effect in all markets by the time this rule is implemented. Competitive pressures, even in regulated environments, will reduce the ability of utilities to pass on costs to their consumers.

Other technology-based opt. under consideration

None of these shortcomings, moreover, is addressed by EPA's "alternative" approaches to §316(b) decision making, which purport to allow the Agency flexibility where the costs of meeting the performance standards are "significantly greater" than either the benefits of complying or the average costs that EPA has developed. While Entergy supports the concept of flexibility as essential to the proper implementation of the Rule, it does not support the ambiguous standard EPA has proposed, particularly one that does not establish a clear 1:1 ratio for a sound benefits-costs analysis. Indeed, anything that compels a standard in excess of economic "practicability" contravenes the legislative history for § 316(b) and, therefore, must be rejected.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the preamble for more information.

For more information on the use of the term "significantly greater," please refer to the response to comment 316bEFR.006.003.

Subject Matter Code 17.06

Option: Site-specific determination of BTA

Rather, Entergy supports the concept of site-specific determinations, consistent with nearly three decades of EPA and state practice. This approach is important, in the case of nuclear facilities, to maintain consistency with the NRC's approach in facility relicensing. It is essential as a scientific and, therefore, as a sound policy matter.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b) determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact associated with cooling water intake structures.

EPA also notes that 125.94(f) allows for a site-specific determination of best technology available if conflict with Nuclear Regulatory Commission safety requirements.

Subject Matter Code 2.04

EPA's legal authority to:

EPA'S PROPOSED RULE FOR EXISTING ELECTRIC-GENERATING STATIONS IS ULTRA VIRES.

The single-sentence mandate of § 316(b) provides in its entirety:

Any standard established pursuant to section or section and applicable to a point source shall require that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact.

33 U.S.C. § 1326(b).
In the Rule, EPA sets forth the purported "legal authority" for the Rule, see 67 Fed. Reg. at 17124-25, which it proposes to implement through NPDES permits. See Id. In those few and unconvincing paragraphs, EPA necessarily concedes:

-Section 316(b) does not fall within the legal limits of EPA's (or states') authorization to issue NPDES permits under § 402 of the CWA. See 67 Fed. Reg. at 17125 ("NPDES permits restrict the types and amounts of pollutants, including heat, that may be discharged from various industrial, commercial, and other sources of wastewater.").

-Section 316(b) does not fall within the legal limits of 301 or 306, both of which solely govern discharges. See, e.g., 67 Fed. Reg. at 17125 ("Section 306 of the CWA requires that EPA establish discharge standards for new sources.") (emphasis supplied); id. ("Sections 301, 304, and 306 of the CWA require that EPA develop technology-based effluent limitations guidelines and new source performance standards that are used as the basis for technology-based minimum discharge requirements in wastewater discharge permits.").

Without statutory authority, EPA nonetheless maintains that § 316(b) somehow is "closely linked" to "several of the core elements" of the NPDES permit program and, therefore, that every existing electric-generating station, at each five-year permit-renewal, is subject to §316(b). See 67 Fed. Reg. at 17125.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Comment ID 316bEFR.029.012

Author Name Elise N. Zoli

Organization Godwin Proctor Counselors at Law obo Entergy Corporation

Subject Matter Code 2.04

EPA's legal authority to:

Section 316(b) Does Not Apply to Existing Facilities.

EPA's "closely linked" argument is baseless. Section 316(b), by its express terms, is not applicable to facilities with existing CWISs. <FN 3> Rather, as discussed below, § 316(b) mandates a one-time, pre-construction review of the "location, design, construction, and capacity" of a CWIS. See 33 U.S.C. § 1326(b) (emphasis supplied). The plain language of 316(b) confirms as much, by expressly including the term "construction," which simply cannot reasonably apply to facilities with existing CWISs. The plain language emphasizes the point, by linking the operative requirements of § 316(b), i.e., the location, design, construction and capacity, with the conjunction "and." This telling link confirms that all four factors are to be considered simultaneously. Since at least half of these factors could not reasonably apply to a facility with an existing CWIS, i.e., construction or location, it simply cannot be that the § 316(b) factors apply to existing facilities.

That the plain language of § 316(b) does not support its application to facilities with existing CWIS is hardly surprising. Certainly, Congress never contemplated that the "location, design, construction, and capacity" of CWIS for electric-generating stations, infrastructure that may cost tens to hundreds of millions of dollars to locate, design and construct, would be subject to modification at every five-year NPDES-permit-renewal cycle. See 33 U.S.C. § 1326(b) (emphasis supplied). The legislative history for § 316(b) confirms as much in a telling exchange among several then United States Senators. More particularly, in 1971, Senator Charles Mathias asked Senator Edmund Muskie, one of § 316(b)'s proponents, whether, in light of the EPA's attempts to require "new steam electric power plants" to build cooling towers, every power facility "to be built anywhere in the United States in the future would have a cooling tower." 117 Cong. Rec. 38855 (1971) (statement of Senator Mathias) (emphasis supplied). Senator Muskie responded: "In the case of power generating facilities, it is the discharges from the cooling towers, ponds, lakes and so forth, that the committee is concerned with, not the technology." Id.4 Senator Mathias's question demonstrates that Congress understood that, at the time of § 316(b)'s enactment, § 316(b) was limited to new facilities, i.e., those "new" facilities "to be built" sometime "in the future." Id. <FN 4> (emphasis supplied). Senator Mathias, undoubtedly concerned about the impacts of the statute on national power production, simply would not have asked the question as be did, if he believed that the statute applied equally to existing facilities. Likewise, had Senator Mathias's question revealed a fundamental misconception of the scope of § 316(b), Senator Muskie - as a proponent of § 316(b) and fully aware of its breadth—would have corrected Senator Mathias's misconception, clarifying the broader application of § 316(b) to existing facilities. In fact, no such correction occurred. <FN 5> Thus, the exchange provides a contemporaneous memorialization of congressional intent, which is that § 316(b) does not apply to existing facilities.

The legislative history is confirmed by other environmental laws. Indeed, § 316(b) is precisely the sort of pre-construction mandate typified by the National Environmental Policy Act, 42 U.S.C. § 4331, et seq. ("NEPA"), and its various state analogues. See, e.g., 42 U.S.C. §4332 (requiring detailed statement on environmental impact of major federal actions); 40 C.F.R.§ 1508.18 (defining, in NEPA context, major federal action to include “approval of specific projects, such as construction or management activities”); see also State Environmental Quality Review Act (“SEQRA”), N.Y. Envtl. Conserv. Law § 8-0109(2) (requiring environmental impact statement on any action that may have significant effect on environment); 6 N.Y.C.R.R. §617.2(b)(l) (defining action to include “projects or physical activities, such as construction or other activities, that may affect the environment by changing the use, appearance, or condition of a natural resource or structure”). The gravamen of these laws—each similar to § 316(b)—is that they apply to proposed projects or substantial expansions, not to existing facilities.

Footnotes

3 Substantial reconstruction or expansion of a CWIS, including at an existing facility, may trigger reconsideration under § 316(b).

4 The statement expressly provides that Congress’s disproportionate concern is with discharges, not CWIS. Id. EPA’s Rule would fundamentally reject that clear congressional direction.

5 The conclusion that § 316(b) does not apply to existing facilities is strengthened by Congress’s omission of any explicit grandfathering provision. If - as EPA contends - 316(b) were applicable to existing units, such a provision would have been customary. In fact, however, Congress simply never contemplated that such a provision contemporaneous memorialization of congressional intent, which is that § 316(b) does not apply to existing facilities. Was necessary for 316b because it did not - as the above exchange makes clear – understand 316b to apply to existing facilities

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Comment ID 316bEFR.029.013

Subject Matter Code 2.04

EPA's legal authority to:

Author Name Elise N. Zoli

Organization Godwin Proctor Counselors at Law obo Entergy Corporation

Section 316(b) Cannot Be Implemented in NPDES Permits.

The fact that § 316(b) does not apply to existing facilities is further supported by the absence of any statutory basis for implementing § 316(b) in NPDES permits—the primary mechanism for regulating existing facilities.

NPDES permits address surface water discharges, primarily through § 301 effluent limitations. See 33 U.S.C. § 1342, 1311. Indeed, effluent limitations solely regulate surface water discharges from point sources. See 33 U.S.C. § 1362(11). Section 316(b) is not an effluent limitation, because it does not govern surface water discharges. See Virginia Elec.& Power Co. v. Costle, 566 F.2d 446,449 (4th Cir. 1977) (it is "obvious" that regulations implementing § 316(b) are not effluent limitations); see also 33 U.S.C. § 1311(a) (omitting reference to § 316(b), but not various other standards regulating "discharges," as providing effluent limitations); 33 U.S.C. § 1365(f) (deeming certain standards "effluent limitations" for citizen-suit purposes, but not § 316(b)).

While NPDES permits also implement § 306 "standards of performance," these again may be addressed only as effluent limitations. See 33 U.S.C. § 1342, 1316. Even if one were to assume, as EPA does, see 67 Fed. Reg. at 17125, that § 316(b) is functionally analogous to § 306 "standards of performance," EPA's efforts to implement § 316(b) at existing facilities through NPDES permits must again fail. As EPA recognizes in the Rule, see 67 Fed. Reg. at 17142, §306 "standards of performance" apply solely to new, not to existing, facilities. See 33 U.S.C. § 1316; see also S. Conf. Rep. No. 91-1236, reprinted in 1972 U.S.C.C.A.N. 3776, 3804-05. (rejecting House bill proposal that § 306(a) should apply to modified existing facilities, with the goal that § 306(a) applies "solely to new construction"); 67 Fed. Reg.. at 17125 (acknowledging that § 306 establishes discharge standards for new sources). Indeed, EPA's position that §316(b) is most akin to CWA standards of performance, see 67 Fed. Reg. at 17125, necessarily concedes that § 316(b) is not properly applicable to existing facilities. <FN 6>

Footnotes

6 The truism that § 316(b) cannot be implemented in NPDES permits is not disproved by EPA's past practice of considering § 316(b) in NPDES permit renewals. Although EPA may have used NPDES permits to impose § 316(b) conditions, we are aware of no direct challenge to such practice by regulated entities. Further, there is a basis for concluding that a challenge to the application of § 316(b) in NPDES permits, were it now made, would be successful. See, e.g., Natural Res. Def. Council v. EPA, 859 F.2d 156, 169-70 (D.C. Cir. 1988) (noting, in another context, "[EPA] is powerless to impose permit conditions unrelated to the discharge itself'); cf Consolidated Edison Co. v. N.Y. Dep't of Envt'l Conservation, 726 F. Supp. 1404, 1410 (S.D.N.Y. 1989) (citing the NRDC decision to support the proposition that " case law conflicts over whether intake requirements can be imposed as a condition of a permit"); accord U.S. Steel Corp. v. Train, 556 F.2d 822, 850 (7th Cir. 1977) (Section 402(a)(l) of the CWA "implicitly requires the Administrator to insure compliance with § 316(b) permit conditions"), overruled on other grounds, City of West Chicago v. NRC, 701 F.2d 632, 644 (7th Cir. 1983); Hudson Riverkeeper Fund v. Orange & Rockland Utils.. Inc., 835 F. Supp. 160, 163-64 (S.D.N.Y. 1993) (accepting a NPDES permit condition mirroring § 316(b)); Cronin v. Browner, 895 F. Supp. 1052, 1059 (S.D.N.Y. 1995) (determining, solely for the limited purpose of determining jurisdiction, that "the issuance of a regulation under section 316(b) constitutes the issuance

of an ‘other limitation’ under sections 301 and 306”).

Author Name Elise N. Zoli

Organization Godwin Proctor Counselors at Law obo Entergy Corporation

Subject Matter Code 18.01

RFC: Definition of "adverse environmental impact"

EPA MUST DEFINE THE OPERATIVE TERM AEI. <FN 7>

In the Rule, EPA again declines to define the term "adverse environmental impact," despite the fact that the term is the triggering or operative mechanism for application of § 316(b). See 67 Fed. Reg. at 17136-40; proposed 40 C.F.R. §125 and 85 (WHAT SPECIAL DEFINITIONS APPLY TO THIS SUBPART?) (omitting any definition of AEI) and 93 (same). Rather, EPA dodges this threshold issue, by presuming an impact as a result of the entrainment and impingement of early life stages of fish and others aquatic organisms. See 67 Fed. Reg. at 17137 ("EPA believes that many cooling water intake structures clearly have a significant negative impact on aquatic organisms at the individual level.").

As discussed below, EPA's presumption is flawed as a matter of law and science. The plain language of § 316(b) expressly provides that AEI is a threshold issue and, therefore, must be definitively established prior to the application of any BTA analysis. See 33 U.S.C. § 1326; see also In the Matter of Pub. Serv. Co. of N.H., Case No. 76-7, Decision of the EPA Administrator (June 10, 1977), 1977 WL 22370 (E.P.A.),*6 (noting that, consistent with the preamble to the then-existing EPA regulations governing CWISs, at 40 C.F.R. Part 204, "the (determining, solely for the limited purpose of determining jurisdiction, that "the issuance of a regulation under section 316(b) constitutes the issuance of an 'other limitation' under sections 301 and 306").

Agency must identify or predict adverse environmental impacts and then select the most effective means of 'minimizing' ... the adverse effects"); see also 41 Fed. Reg. at 17387, 17388 (Apr. 26, 1976) (same). <FN 8> This is a common-sense approach, since - absent an AEI - there would be no reason for application of any control technology. This is particularly true for existing facilities, where the impacts, if any, of facility operations on the aquatic community are knowable, and may have been tracked over the operational life of the facility? <FN 9>

Further, the definition of AEI must be credible as a matter of science and sound policy. In the Rule, EPA proposes a narrow definition of AEI that is inconsistent with the plain language of §316(b), as well as its use and interpretation in other relevant environmental laws. Further, EPA ignores the weight of scientific evidence, which will not support the self-serving presumption that individual losses attributable to entrainment and impingement necessarily amount to an AEI. In doing so, EPA reveals a marked bias against entrainment and impingement by electric-generating stations, as distinct from severe ecosystem uses, such as surface water discharges and commercial fishing. See 67 Fed. Reg. at 17137 ("EPA notes that the top four leading causes of waterbody impairment (siltation, nutrients, bacteria, and metals) affect the aquatic life uses of a waterbody"). This weakness in EPA's conclusions is confirmed by its efforts to bolster an otherwise tenuous conclusion that impingement and entrainment, of themselves, constitute AEI by alluding to:

-A purported concern for "cumulative overall degradation" of a certain aquatic environment from multiple facilities, despite the fact that EPA acknowledges that such impacts, if any, are "largely unknown." See 67 Fed. Reg. at 17136.

-A purported concern that CWISs represent a "contribut[ing]" additional stress, in conjunction with the known causes of waterbody impairment as a result of discharges, which EPA identifies as siltation, nutrients, bacteria and metals, none of which correlates to electric-generating operations. See 67 Fed. Reg. at 17137.

As discussed below, none of EPA's attempts to narrowly construe the term AEI, including its cumulative and additional-stress arguments, has merit.

Footnotes

7 REMAINING COMMENTS ARE SUBMITTED, ASSUMING FOR ARGUMENT'S SAKE, THAT THE RULE IS NOT, AS IT IS, IN EXCESS OF EPA'S JURISDICTION AND INCONSISTENT WITH THE PLAIN LANGUAGE OF THE CWA.

8 As EPA previously has recognized, the burden of identifying AEI is on the regulator. Cent. Hudson Gas& Elec. Corp., OGC No. 63 (July 29, 2977); see also Administrative Procedures Act ("APA"), 5 U.S.C. §556(d) ("Except as otherwise provided by statute, the proponent of an ... order has the burden of proof") and 551(b) (defining an order to include a permitting or licensing decision).

9 Thus, for example, the owners of Indian Point 2 and 3 have undertaken extensive ongoing monitoring of the Hudson River for decades. Indeed, William Sorbello, Section Head—Biologist 3 Ecology, of the New York State Department of Environmental Conservation, in commenting on EPA's then-proposed Rule for new facilities, characterized the Hudson River aquatic communities data set created by the Hudson River Stations as "probably the best data set on the planet." Comment ID 3 I6bNFR.073.017. As further discussed below, an independent review by three leading national fisheries scientists of this unparalleled database confirms that the operations of Indian Point 2 and 3, as well as other facilities on the Hudson River, have not negatively impacted fish populations or the aquatic community.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define adverse environmental impact in today's final rule. EPA disagrees with this commenter that the plain language of section 316(b) provides for any threshold test that would require no technology unless an impact is determined to occur on an ecosystem, community or population level and be attributable to a particular cooling water intake structure.

RFC: Definition of "adverse environmental impact"

EPA's Interpretation of AEI Contradicts the Plain Statutory Language of §316(b) and Application of Similar Concepts in Other Environmental Laws.

The definition of AEI, to be credible, cannot be triggered by nominal impacts, such as those associated with early life stage entrainment and impingement. <FN 10> To the contrary, numerous environmental statutes, including both federal and state laws, employ and rely on, as a triggering mechanism, the concept of an "adverse environmental impact." See, e.g., NEPA, 42 U.S.C. §4332 (significant effect on the quality of human environment); Endangered Species Act ("ESA"), 16 U.S.C. § 1531 et seq., specifically § 1536(a)(2) (jeopardize continued existence of a species); SEQRA, N.Y. Envtl. Conserv. Law § 8-0109(2) (significant adverse effect on the environment). In each of these environmental statutes, and their accompanying regulations, the touchstone is that the term AEI characterizes the result of a searching inquiry of an array of impacts of a proposed action, including impacts to the human environment, e.g., view-shed or aesthetic concerns.

This fosters a full and fair analysis of potential impacts and their corresponding resolutions, ensuring a reasoned outcome.
Not surprisingly, therefore, none of the several laws employing an AEI-like trigger narrowly construes terms analogous to AEI to address a limited type of impact, such as EPA proposes in the Rule, i.e., by interpreting AEI as relating solely to entrainment and impingement. Indeed, to construe narrowly the term AEI fosters a deliberately bunkered analysis, allowing certain impacts to tip the scales, thereby creating potentially erroneous outcomes and opportunity for unanticipated or unaddressed environmental damage, e.g., electric-system-related impacts or increased emissions of criteria air pollutants.

EPA's proposed approach to AEI in the Rule cannot reasonably be reconciled with twenty-five years of interpretation of § 316(b) and routine permit issuance and re-issuance. See, e.g., Seacoast Anti-Pollution League v. Costle, 597 F.2d 306 (1st Cir. 1979) (upholding EPA's acceptance of once-through cooling, despite entrainment); New Jersey Dep't of Envtl. Prot., NJPDES Permit No. NJ 0005622, Salem Generating Station (June 29, 2001) (SPDES-permit renewal with once-through cooling); Maryland Dep't of Env't, NPDES No. MD0002658B, Chalk Point, Potomac Electric Power Co. (Apr. 29, 2001) (SPDES-permit renewal with once-through cooling). Further, we are aware of no sizeable existing nuclear facility that has been required to retrofit with cooling-tower technology in a NPDES-permit renewal solely on §316(b) grounds." <FN 11> Implicit in each of these permitting decisions is a rejection of a narrow focus on only entrainment and impingement impacts.

Given the plain language of 316(b) and relevant interpretation of other analogous laws, such as NEPA and the ESA, Entergy requests a more credible definition of AEI. First and at very least, AEI should be defined as a demonstrable adverse impact on fish populations or communities and directly attributable to CWIS, as distinct from commercial fishing, i.e., when the losses adversely affect the structure or function of the aquatic community. Again, this is necessary to ensure that § 316(b) is interpreted in a manner consistent with other environmental statutes with similar triggers. <FN 12>

Footnotes

10 Every project, particularly a large-scale project, has some impact on the natural world. Indeed, EPA routinely authorizes activities and projects that have an adverse impact on the environment. Thus, for example, under the CWA, EPA authorizes the discharge of pollutants to water-bodies, although EPA acknowledges in the Rule that such discharges remain the leading causes of water-body impairment, see 67 Fed. Reg. at 17137, which— again as EPA concedes—have a far more damaging impact on fisheries and individual fish. It Nonetheless, EPA routinely promulgates and amends regulations allowing such discharges, despite their significant adverse impacts, rather than implementing essentially a "no-discharge" standard.

11 EPA relies on the construction of cooling towers at Palisades from 1971 to 1974 as an example of open cycle to closed-cycle conversion. See Technical Development Document for the Proposed Section 316(b) Phase II Existing Facilities Rules (DCN: 4-0004) ("Phase II TDD"). The example is inapt. Before the Palisades facility was even constructed in 1971, citizens groups concerned about potential for radioactive discharge had intervened in its licensing proceedings. Id. Rather than delay the U.S. Atomic Energy Commission's decision to authorize an operating license for the facility, Palisades elected to enter into a settlement agreement on March 12, 1971, underwhich it agreed to employ wet-type cooling towers by January 1, 1974. See John Gulvas, Consumer Power's Responses to EPA Questions Regarding the Conversion of Palisades Nuclear Facility from Once-Through Cooling System to Cooling Tower System (2002). Indeed, although EPA maintains that the facility "began operation" in early 1972, engineering and procurement for cooling tower construction had already begun in 1971. Phase II TDD 4-3. Thus, this particular cooling-tower construction, planned for and begun before the facility was fully operational, is not a retrofit as EPA now uses the term and should not be EPA's basis for estimating retrofit costs. Additionally, though EPA reports Palisades's $18.8 million conversion in 2001 dollars, its cost escalation (which appears to track the Building Cost Index or similar, but unidentified, construction-related cost index) does not account for significant increases in nuclear power facility sitting and construction costs, including those resulting from the Three Mile Island incident in 1979.

12 In its request for a more credible definition of AEI, Entergy further relies on the plain language of 316(b). Certainly, had Congress intended that all power plants install cooling-tower equivalent technology, it would have provided as much directly, without requiring an AEI. Indeed, § 316(b) could and would have stated: "EPA shall require that the design of a cooling water intake structure employ the best technology available to eliminate entrainment and impingement of aquatic organisms." However, § 316(b) does not provide as much. Moreover, it is unlikely that EPA would have allowed the construction of perhaps hundreds of power facilities with once through cooling, had it then understood Congress's mandate as it now proposes to interpret it.

Subject Matter Code 18.01

RFC: Definition of "adverse environmental impact"

Any Determination of AEI Must Properly Be a "Net" AEI Recognizing and Accounting for Mitigation or Restoration Measures.

Consistent with other environmental laws, the definition of AEI must exclude alleged impacts to a fish population or community that are avoided through facility activities, e.g., hatcheries. For example, under NEPA, a finding of "significant impact" to the quality of human environment triggers certain legal requirements. 42 U.S.C. § 4332; see also 40 C.F.R. § 1508.14 (defining "human environment" to include "the natural and physical environment and the relationship of people with that environment); 40 C.F.R. § 1508.08 (defining "effects" to include effects to such things as population density, growth rate, and ecosystems). In that context, courts and agencies have not found a "significant impact" to the environment where the project mitigates potential harm to a population as a whole. See, e.g., Friends of the Payette v. Horseshoe Bend Hydroelectric Co., 988 F.2d 989(9th Cir. 1993) (upholding the Army Corps of Engineers' finding of no significant impact for hydroelectric project that mitigated destruction of wetlands by creating new wetlands, and mitigated power turbine's destruction of individual fish population by enhancing nearby fish habitat). It is, thus, settled that, where a "proposal is modified prior to implementation by adding specific mitigation measures which completely compensate for any adverse environmental impacts stemming from the original proposal, the statutory threshold of significant environmental effects is not crossed." Cabinet Mountains Wilderness v. Peterson, 685 F.2d 678, 682 (D.C. Cir. 1982) (upholding Forest Service's finding of no significant impact ("FONSI") for proposed mineral exploration project that offset potential impacts to grizzly bear through temporal limitations on drilling, reduction and elimination of certain timber sales and seasonal road closures).

Similarly, under the ESA, an offset of potential impacts precludes the finding that a federal project likely will jeopardize an endangered species, avoiding a consultation requirement. See 16 U.S.C. § 1536(a)(2); Greenpeace Action v. Franklin, 14 F.3d 1324, 1335 (9th Cir. 1993) (upholding Secretary's "no jeopardy" determination for NMFS's decision rendering a "total allowable catch" for pollock where harm to endangered sea lion was addressed by proposed "no-trawl zone" around sea lion breeding ground).

Just as, under NEPA and the ESA, an action is avoided when successful mitigation results in a finding of "no significant impact" or "no jeopardy," the BTA requirement under §316(b) should not be triggered where successful mitigation precludes the finding of AEI. This would occur, for instance, where a hatchery produces fish approximately equivalent to a realistic calculation of potential entrainment and impingement losses.

The "net" approach is recognized by leading legal scholars. See, e.g., Thomas Schoenbaum & Richard B. Stewart, The Role of Mitigation and Conservation Measures in Achieving Compliance with Environmental Regulatory statutes: Lessons from Section 316 of the Clean Water Act. 8 N.Y.U. Envtl. L.J. 237 (2000) (Appendix 1). As Professors Schoenbaum and Stewart's analysis confirms, such measures should be and often are taken into account in any assessment of AEI. Id. at 295-327.

Not surprisingly, therefore, permitting agencies, including EPA, frequently have considered and accepted restoration measures. See, e.g., EPA Region IV, Findings and Determinations re: NPDES Permit No. FL0000159, Crystal River at 7-8 (Sept. 1, 1988) (authorizing fish hatchery "in an attempt to replace fish and shellfish eggs, larvae, and juveniles entrained" by facility); EPA, NPDES Permit No. TN00054360, John Sevier (1986) (fish stocking program); Pittsburgh, Ca. RWQCB, NPDES Permit No. CA0004880 (Apr. 18, 1990) (fish stocking program); New Jersey Dep't Envtl. Prot, NJPDES Permit No. NJ0005 622, Salem Generating Station (June 29, 2001) (wetland restoration as condition for § 316(b) compliance); Hudson River Settlement Agreement (1980) (fish hatchery, donation of public park and research funding); Maryland Dep't of Env't, NPDES Permit No. MD0002658B Modified Permit, Chalk Point (Apr. 29, 1991) (financial contribution to state fish hatchery fund); Letter to Ca. RWQCB, Contra Costa (Apr. 13, 1993) (fish stocking program); SONGS, Final Report to the Coastal Comm'n (Aug. 1989) (wetlands restoration and construction of artificial reefs); NYDEC, Bureaus of Fisheries and Envt'l Prot., Region VII Comments on SPDES Permit No. NY0003875, Gondey (Aug. 23, 1983) (wetlands restoration and construction of artificial reefs); NYDEC, SPDES Permit No. NY0003 875, Goudey (Mar. 15, 1983) (development of fishing access at another site); Letter from Massachusetts Dep't of Envtl. Prot. to H.V. Oheim, Boston Edison Co., Oct. 15, 1998 (recommending restoration measures to offset alleged fish stock losses resulting from operation of Pilgrim Station).

While Entergy supports the use of voluntary mitigation or restoration projects, such as hatcheries or wetlands-restoration projects, that are proposed in appropriate circumstances by a regulated entity to offset claims of AEI, it cannot and does not support EPA's efforts to require regulated entities to undertake projects. Restoration cannot be mandated since it is not a technology relating to a CWIS, and the Agency has no authority to compel anything other than CWIS technologies. 33 U.S.C. § 1326(b).

Likewise, Entergy cannot and does not support EPA's efforts to compel projects which produce benefits greater than alleged impacts, i.e., a valuation of such projects at a ratio greater than 1:1. This is because the long-term benefits of some sorts of offset projects, particularly wetlands-restoration or other habitat-enhancement projects, may be perpetual, producing benefits long beyond the life of any station. Thus, restoration projects' future benefits should be recognized appropriately, with a ratio approaching, but not exceeding, 1:1. Similarly, AEI restoration projects, again such as wetlands-restoration or habitat-enhancement efforts, may produce a range of collateral benefits in addition to fish production. Such benefits may include, as EPA has recognized, see 67 Fed. Reg. at 17148, recreational benefits, habitat for aquatic and terrestrial species not impacted by CWIS, and open space, among others. These collateral, but important, benefits likewise support a ratio approaching, but not exceeding, 1:1.

The Agency also cannot equitably compel restoration measures that exceed a realistic calculation of identified impacts. See Exec. Order No. 12866, Regulatory Planning and Review, ("Order 12866") (compelling consideration of the distributional and equity effects of any proposed regulation); see also EPA, Guidelines for Preparing Economic Analyses ("EPA's Guidelines"), EPA 24C-R-00-003, at 5 (Sept. 2000) (recognizing this obligation). <FN 13>

Footnotes

13 As discussed below, to the extent that mitigation projects are employed in lieu of or in addition to technology, EPA should require restoration in lieu of technology at levels consistent with average least-cost compliance among any facilities

with comparable flows installing available technology; i.e., screens and fish returns at fossil-fuel facilities. Likewise, applicable monitoring requirements should remain simple and flexible. Thus, for instance, EPA should accept a project as complete, if it meets the agreed-upon requirements. This is because it may not be possible to monitor a particular wetland for production effectively.

EPA Response

In the final rule, EPA allows use of restoration to minimize or help to minimize the adverse environmental impacts that derive from impingement and entrainment of aquatic organisms. For a discussion of EPA's authority to include restoration measures as a compliance option in the final rule, see the preamble to the final rule.

For a discussion of the extent to which restoration measures are voluntary under the final rule, see EPA's response to comment 316EFR.060.022.

For a discussion of ancillary benefits, see EPA's response to comment 316bEFR.032.011. For a discussion of the permitting authorities role in assessing restoration measures, see EPA's response to comment 316bEFR.060.026.

UWAG definition of "adverse environmental impact"

To Be Credible, an AEI Must Be a Demonstrable Community-Level Fisheries Impact, Not Simply Presumed Individual Losses Attributable to Entrainment and Impingement. <FN 14>

As discussed above, the language of § 316(b), read in conjunction with the persuasive example provided by other environmental laws and EPA's past permitting decisions, does not support EPA's effort to equate AEI with entrainment and impingement losses that do not have a demonstrable adverse impact on a fish population or community. Likewise, as a matter of credible science, the loss of a single fish larva or a single egg, or even a large number of them, cannot reasonably be equated with AET. Instead, AEI properly should be construed as occurring when the loss of fish or other organisms is felt at the population or community level; i.e., when the losses are so substantial that they adversely and demonstrably affect the structure or function of the aquatic community. <FN 15>

This is because, as a matter of basic biology, substantial egg and larval losses occur with little or no effect on the vigor of the aquatic populations or community. These losses of eggs and larvae occur from natural causes, as well as human ones. <FN 16> Briefly, recognized and accepted biological concepts of compensation play a significant role in describing the absence of impact on fisheries populations of entrainment and impingement. Compensation also is accepted by those governmental authorities responsible for modem fisheries management, such as the National Research Council. Indeed, fisheries managers routinely consider compensation when establishing harvesting regulations. <FN 17> Given the overwhelming support for populations-level analysis among scientists and the governmental authorities, compensation should be reflected in EPA's effort to establish regulations for managing aquatic organisms susceptible to entrainment and impingement. The UWAG Comments, which address these concepts in detail, are hereby incorporated by reference.
To adequately assess fish populations and aquatic systems requires a discernible benchmark for adverse environmental impacts. Leading fisheries scientists have selected two critical benchmarks for existing activities: (1) relative abundance; and (2) diversity. The first allows a regulator to determine whether there has been a continuing decline, distinguishable from natural variability in abundance over time, as an indicator of impacted populations. The second allows a regulator to determine whether vulnerable species are being particularly or disproportionately impacted, again as an indicator of impacts to an aquatic community.

The importance of population-level analysis, using key indicators, with an understanding of the effects of compensation, is well documented, for example, in the Hudson River, including particularly with respect to the Hudson River's exploding striped-bass population. Three leading fisheries experts, Charles C. Coutant, Ph.D., a Senior Research Ecologist at Oak Ridge National Laboratory, Lawrence W. Bamthouse, Ph.D., the President and Principal Scientist for LWB Environmental Services, Inc., and Webb Van Winkle, Ph.D., an Environmental Consultant at Oak Ridge National Laboratory, have provided a consolidated depiction of the populations of representative indicator species of Hudson River fish, including certain keystone species, that have been the subject of almost thirty years of extensive biological monitoring. See Status and Trends of Hudson River Fish Populations and Communities Since the 1970s: Evaluation of Evidence Concerning Potential Impacts of Cooling

Water Withdrawals (Jan. 2002) ("Status and Trends of Hudson River Fish") (Appendix 3) As this depiction indicates, relative abundance and diversity, the operative measures for evaluating the health of fish populations and the aquatic ecosystem, have remained consistent (or improved) over the period of operation of the Hudson River facilities, including Indian Point 2 and 3. This information, simplified for purposes of this discussion, reveals that no adverse impact has occurred to Hudson River fisheries that is reasonably attributable to operation of electric-generating stations, such as Indian Point 2 and 3.

Status and Trends of Hudson River Fish (Appendix 3) also provides an independent review and evaluation of Hudson River fish population and community trends, which evaluates nearly three decades of Hudson River monitoring data for representative indicator fish populations, focusing on abundance and diversity as key measures of the health of fish populations and the Hudson River aquatic community.

More particularly, Drs. Coutant, Barnthouse and Van Winkle sought answers to two questions, employing the critical benchmarks of abundance and diversity: (1) Have measurable adverse changes to representative Hudson River fish populations occurred since the onset of operation of the Hudson River facilities that are potentially attributable to water withdrawals at Hudson River facilities, including Indian Point 2 and 3; and (2) would reductions in those withdrawals provide measurable benefits to that ecosystem? To evaluate the data, Drs. Coutant, Barnthouse and Van Winkle looked for a continued, long-term decline in susceptible populations that coincided with the approximate start-up of the Hudson River stations; i.e., relative abundance. Drs. Coutant, Barnthouse and Van Winkle also looked for reductions in species richness or diversity, including a changes in predator-prey balances that might be reasonably attributable to Hudson River station operations: What Drs. Coutant, Barnthouse and Van Winkle found, in the outstanding data set that the Hudson River monitoring program has provided, is that the representative indicator fish species for the Hudson River have experienced consistent abundance and diversity during the operations of the Hudson River stations, including Indian Point 2 and 3. Thus, the answer to question 1 is a resounding "no."

Drs. Coutant, Barnthouse and Van Winkle also evaluated whether a halt to once-through cooling would result in measurable improvements to the Hudson River fisheries. As they concluded, in clear and concise terms, the ecological benefits of mitigation proposals intended to reduce cooling-water withdrawals would be negligible. See Status and Trends of Hudson River Fish at 10 (Appendix 3). These leading national fisheries scientists reasoned: "If measurable changes attributable to cooling water withdrawals have not occurred over the past 25 years of operation of Bowline Point, Indian Point, and Roseton, then reductions in those withdrawals would be unlikely to result in measurable improvements such as increase in populations abundance abundance or species richness." Id. Thus, the answer to question 2 likewise is a resounding "no."

Drs. Coutant, Barnthouse and Van Winkle specifically addressed the circumstances of striped bass, a keystone species, because it is a pelagic spawner whose early life stages are abundant in the vicinity of the Hudson River stations, as well as a top predator and, therefore, vulnerable to the impacts of prey depletion. What they found, using four independent data sets, including a New York State Department of Environmental Conservation ("NYSDEC") data set, i.e., the NYSDEC's juvenile beach seine survey, is that there is no trend in striped-bass recruitment during the period of operation of the Hudson River stations. Since station operations only impact early life stages, this evidence confirms the effects of compensation and a corresponding absence of AEI, as it relates to the striped-bass population in the Hudson River. Importantly, Drs. Coutant, Bamthouse and Van Winkle noted, in reaching their conclusion, that the comprehensive independent metrics and data sets often and twenty-five years in duration were "unique" in their collective experience, and exhibited a noteworthy consistency, underscoring the validity of their conclusions." <FN 18> See id.

In short, density-dependence and compensation help to explain what thirty years of Hudson River monitoring confirms, namely that station operations on the Hudson River have not had a demonstrable adverse impact on fish populations or aquatic communities. On the Hudson River, therefore, power-facility-related entrainment may not be "adverse" to the aquatic ecosystem or fisheries community. This conclusion applies with considerable force to the striped-bass population, which has thrived during the period of power-facility operations on the Hudson, increasing ten-fold from 1982 to 1996, see id. at 9, and has reached its saturation point, insomuch as it has begun and will continue to impact other species by its predation. Thus, EPA's efforts to address alleged AEIs, including possibly by requiring the installation of hundreds of millions of dollars of cooling-tower technology at Indian Point 2 and 3, cannot reasonably be expected to benefit fish populations. <FN 19>

The same conclusion that no AEI has occurred applies to Pilgrim Station, which—under the continued oversight of a technical advisory committee consisting primarily of federal and state regulators—has monitored alleged entrainment and impingement impacts, again, for nearly three decades. This monitoring cultivated in ENSR's 316 Demonstration Report for Pilgrim Nuclear Power Station (Mar. 2000) (Appendix 4). In conjunction with a recent supplemental fish larvae study, ENSR demonstrates that Pilgrim Station's operations have had no demonstrable adverse environmental impacts on representative indicator species in proximity to Pilgrim Station. Indeed, using a highly conservative calculation not accounting for critical biological factors, including compensation or survivability, ENSR estimated conditional entrainment mortality for winter flounder, a representative indicator species, and concluded that theoretical impacts are less than 0.20% to 5.0% of the local winter-flounder population, itself only a portion of the actual relevant spawning population. Id. As ENSR concluded, "impingement and entrainment have caused no adverse impact to any [representative indicator species] population, or to the integrity of the aquatic ecosystem of Cape Cod Bay." <FN 20> Id. at 7-1.

In short, continuous ongoing monitoring during the operations at Indian Point 2, Indian Point 3 and Pilgrim support the conclusion that entrainment and impingement by those stations do not constitute an AEI. The same conclusion should apply to other facilities that have shown, as the Hudson River and Pilgrim facilities have, <FN 21> that entrainment and impingement do not adversely impact fisheries populations or communities. Again, a lack of AEI is confirmed where continued station operations have not shown a change in relative species abundance or diversity over time. Such circumstances are met, where: (i) a fish or aquatic community has been shown to have experienced population stability or growth over decades, despite entrainment and impingement (e.g., striped bass in the Hudson); or (ii) any decline in species is reasonably attributable to non-facility conditions or circumstances (e.g., commercial-fishing pressures, altered water quality, whether through reduced wastewater discharges or otherwise; and explosions of non-native or exotic species or loss of habitat).

Footnotes

14 EPA's calculation of entrainment and impingement losses is seriously flawed, as is EPA's national extrapolation. Entergy refers EPA to and hereby incorporates the UWAG Comments outlining its criticism of EPA's entrainment and impingement calculations. For a specific criticism of EPA's approach in the Pilgrim Case Study, Entergy refers EPA to the ENSR report

discussed below. See ENSR Imitational, Comments on Propped EPA 316(b) Regulations for Existing Facilities (Aug. 2, 2002) ("ENSR Comments") (Appendix 2).

15 Of course, absent a direct effect, EPA's litany of indirect effects, e.g., to birds as a result of fish losses, is unsupported. See Case Study Analysis for the Proposed Section 316(b) Phase II Existing Facilities ("Case Studies"), Ch. A4. EPA concedes as much, noting "EPA's review of these studies did not reveal any documented linkages between I&E and effects on bird populations ... ." See Case Study at A4-8. Despite the absence of any scientific support for the proposition, and in the face of an overwhelming weight of evidence to the contrary, EPA nonetheless holds to its highly speculative position that collateral impacts to bird populations somehow do exist. Id. Entergy suggests a view better grounded in sound science. More particularly, Entergy requests that EPA not recognize in its impact analysis highly speculative indirect effects.

16 At the ecosystem level, significant losses of adults, e.g., as a result of commercial fishing, may have an effect on the aquatic community. This is a premise of the Magnusen-Stevens Fisheries Conservation and Management Act, 16 U.S.C. § 1801 et seq. ("MSA"), and its associated regulations, which focus on "maximum sustainable yields" on a continuing basis.

17 Fisheries management rests on the premise that significant anthropogenic mortality (i.e., fishing harvests) can be imposed on fish populations without causing long-term harm to the populations. A recognized limit exists, however, beyond which additional mortality could jeopardize the ability of a fish population to maintain itself at desirable levels. The theory of compensation plays a central role in defining such limits (also referred to as biological reference points). Fisheries managers routinely evaluate whether an assumed future fishing mortality rate would result in declines in abundance, employing models that estimate stock biomass under specified conditions and relating them to biological reference points. See Nat'l Res. Council, Commission on Fish Stock Assessment Methods, Improving Fish Stock Assessments at 188 (1998). These methods can also be used to determine the impact of another source of early life stage mortality-such as an electric-generating facility-on fisheries stocks, and whether that impact jeopardizes a stock's ability to replace itself.

18 This is in direct contradiction to the indefensible statement in EPA's Economic and Benefits Analysis for the Proposed Section 316(b) Phase II Existing Facilities Rule (the "Phase II Eco/Ben Analysis"), in which EPA somehow presumes an impact to fish populations, including striped-bass populations, as a result of its calculation of worst-case theoretical entrainment and impingement predictions that were never intended to be used as the Agency proposes. See Phase II Eco/Ben Analysis at A2-8. Indeed, EPA's statement not only reveals the pitfalls of superficiality, but also offers a perfect illustration of the dangers of uninformed data extrapolation. For instance, rejecting almost fifteen years of subsequent monitoring, EPA targets the 1988 theoretical projection of entrainment mortality, selects the worst-case projections of 79% for striped bass and relies on this as an example of impacts. See 67 Fed. Reg. at 17138. Of course, were these projections even remotely defensible, the population of striped bass certainly would have experienced a demonstrable, if not acute, decline, not a population explosion. See Status and Trends of Hudson River Fish (Appendix 3). Thus, it is irrefutable that other factors are at work and that the projections cannot and should not, as a matter of sound science, be so employed. Of course, had the Agency sought Entergy's assistance in interpreting data relating to the Hudson River stations, a flawed conclusion could have been avoided.

19 What it will do, however, is foreclose continued operations of those Stations, with major adverse environmental results, including substantially increased emissions of criteria air pollutants and profoundly decreased reliability for the metropolitan New York electric system, which are discussed below.

20 As problematic is EPA's inexplicable failure to even mention, let alone account for, Pilgrim's winter flounder hatchery, despite the noteworthy fact that Entergy has tracked those successful releases through monitoring.

21 This is an equitable outcome, since the annual costs of such monitoring and analysis supporting the absence of an AEI is considerable. Indeed, under the 1981 Hudson River Settlement Agreement, the Hudson River facilities agreed to an annual collective investment in monitoring of approximately $2.0 million. These expenditures no doubt meet or exceed the annualized costs of certain equipment, such as Gunderbooms, that could be installed to meet EPA's performance standards at comparable fossil-fuel facilities.

EPA Response

Please see the response to comment 316bEFR.002.019 for the discussion on the definitions EPA rejected for adverse environmental impact in this rulemaking.

RFC: Entrainment vs. entrainment mortality

In Calculating AEI, EPA's Rejection of Survivability Is Unfounded.

In determining whether an AEI exists, EPA rejects, as it did in its 1977 Guidance for Evaluating the Adverse Impact of Cooling Water Intake Structures on the Aquatic Environment:

Section 316(b), P.L. 92-500, the scientific principle of survivability. <FN 22> See Case Studies at A7-1. Indeed, EPA maintains that survival rates of greater than zero should be viewed with "skepticism." Id. § A7-1.1.

EPA's conclusion contradicts sound science. ASA Analysis & Communication, Inc. ("ASA") concludes that EPA's assumption of one hundred percent mortality is not warranted. ASA, Comments on EPA Positions on Entrainment Survival as Described in Chapter A7 of the Case Studies Document (Aug. 2002) ("Entrainment Survival Report") (Appendix 5). Further, ASA concludes that a realistic assessment of survivability is possible and, therefore, should be examined in a careful A.EI assessment. Id.

These conclusions are confirmed in the survivability studies conducted at the Hudson River facilities, which EPA concedes are "the most comprehensive" of such studies that they evaluated. See Case Studies at A7-8. The Indian Point survivability studies included initial and latent survivability rates for striped bass, bay anchovy, white perch, Atlantic tomcod and herring, i.e., the majority of the representative indicator species subject to entrainment and impingement by the Hudson River stations. <FN 23> Indeed, survivability of striped bass-eggs, evaluated several times from 1979 to 1988, ranged from a low of 44% (96-hour latent intake survival) and 33% (discharge survival), to 82% (96-hour latent intake survival) and 47% (discharge survival). A subsequent sampling of striped-bass larvae revealed a total entrainment survival for PYSL striped bass of 76%. In other words, at Indian Point 2 and 5, many striped-bass eggs and most striped-bass larvae survive the entrainment process.

While EPA dismisses this study, see Case Studies at A7-8, it offers no scientific basis for doing so. EPA simply alludes to several, undiscussed "inadequacies" which, according to the Agency, warrant rejecting the studies in their entirety. Of course, it is implausible that, despite its wide scientific acceptance, no study of entrainment survivability will pass EPA's muster. Rather, it is more likely that EPA simply prefers its assumption of 100% mortality, despite the fact that such numbers are obviously over-conservative and contradicted by sound science.

Even if EPA's concern is that different study methodologies make a national conclusion difficult, as ASA Report and the Hudson River survivability studies demonstrate, there is simply no basis for rejecting the application of this obviously relevant information, where supported, in individual § 316(b) determinations.

Footnotes

22 EPA’s so-called guidance, as a draft, is entitled to no weight. See S. Utah Wilderness Alliance v. Dabney. 222 F.3d 819, 829(10th Cir. 2000) (holding that agency policies still in draft are not entitled to Chevron deference); South Camden Citizens in Action v. N.J. Dep’t of Envt’l Protection, 145 F. Supp. 2d 446, 476 (D.N.J. 2001) (recognizing that EPA guidance is not binding on a court but only relevant as evidence of EPA’s evolving policy), rev’d on other grounds, 274 F.3d 771 (3d Cir. 2002). Certainly, had EPA valued the so-called guidance, it would have made it final. Of course, given its scope, had it been finalized, it would have been subject to challenge as rulemaking in the guise of guidance.

23 As EPA has identified these studies in the Rule, they are part of the administrative record and, for this reason, are not attached as Appendices. The same applies to similar documents employed by EPA in its rulemaking and to published public documents.

EPA Response

Please see response to comment 306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule. Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis.

RFC: Definition of "adverse environmental impact"

AEI Should Not Include Mortality Attributable to Independent Causes.

Insomuch as the Rule is not clear, Entergy requests that exclusions from the concept of adverse environmental impact be provided for entrainment or impingement that is not within the control of a facility, such as impingement attributable to fish lethargy or mortality experienced during changes in ambient water temperature.

Such circumstances occur, for example, at Entergy-owned Arkansas Nuclear One ("ANO"), which uses Lake Dardanelle, a cooling-tower-related, constructed pond of approximately 14,600 ha (36,000 acres). At Lake Dardanelle the most frequently impinged fish are gizzard shad (Dorosoma cepedianum) and threadfin shad (D. petenense), which represent 99.25% of the total number of fish impinged and 95.34% of the total weight of fish impinged.

However, impingement is not attributable to ANO's operations. Rather, impingement occurs primarily during late fall, winter, and early spring, i.e., October through March, when shad become thermally stressed, as they do at temperatures less than 16° C (60° F). Temperature data collected at the ANO intake indicates that the water temperature is typically below 5° C (41° F) during January and February. Studies further concluded that shad impinged at the ANO intake during periods with cold water temperatures were dead or cold-stressed. In short, impingement at ANO is not properly attributable to ANO. In fact, impingement of these fish is attributable to their inability to withstand thermal stress during winter months.

EPA should account for this and analogous circumstances in the Rule, by providing that impacts, if any, must be attributable to facility operations.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define adverse environmental impact in today's final rule. Also please see response to comment 316bEFR.029.015 by the same author. The temperature effects described by the author of this comment should be investigated as part of a section 316(a) demonstration and not section 316(b) as they are temperature related effects which may be attributable to the thermal discharge of this facility.

Impacts of multiple intake structures on watersheds

EPA's "Cumulative" and "Additional-Stressor" Theories Are Not Grounded in the Statutory Language.

Apparently straining to support its conclusion that individual entrainment and impingement losses of early life stages alone somehow can be construed as a demonstrable AEI, EPA raises, without support, two concepts: "Cumulative" and "additional-stressor" theories. Both seek to exaggerate the impacts of entrainment and impingement.

Relative to the cumulative effects theory, EPA speculates "EPA is concerned about the cumulative overall degradation as a consequence of multiple intake structures operating in the same watershed or nearby reaches ...," then provides, " historically, impacts related to [CWIS] have been evaluated on a facility-by-facility basis." See 67 Fed. Reg. at 17136. As EPA is aware, the Hudson River stations have been involved in a cumulative analysis since 1981, i.e., for three decades. This unparalleled data set, as discussed above, refutes EPA's unsupported hypothesis that cumulative impacts are a factor.

Likewise unsupported, and simply inequitable, is EPA's "Additional-stressor" theory. Nothing in §316(b) compels electric-generating facilities to compensate for environmental damage created by other, and different, entities, particularly where those entities are also regulated by EPA.

In short, both theories should be eliminated from the Rule.

EPA Response

EPA disagrees with this commenter and continues to be concerned about the potential cumulative impact of multiple intake structures operating in the same watershed and intakes within or adjacent to impaired waterbodies. Please see section IV of the preamble to today's final rule for the discussion of the recent Final Environmental Impact Statement by NYSDEC regarding the cumulative impact of the cooling water intakes on the Hudson River. EPA agrees that nothing in section 316(b) compels facilities with cooling water intake structures to compensate for environmental damage caused by other factors; however, it does require that these facilities minimize the adverse environmental impact of the cooling water intake structure. This will aid in relieving the stress on nearby fisheries. See also the response to comment 316bEFR.025.018.

RFC: Definition of "adverse environmental impact"

In conclusion, to abide relevant interpretations of AEI in other environmental laws, EPA's nearly thirty years of implementing § 316(b), and the weight of scientific evidence, an AEI must rise to the level of a demonstrable impact on the fish populations or communities. To that end, Entergy supports the following definition of AEI, consistent with what has been proposed by UWAG: "Adverse environmental impact means a reduction in one or more representative indicator species that: (1) creates an unacceptable risk to the population's ability to sustain itself, to support reasonably anticipated commercial or recreational harvests, or to perform its normal ecological function; and (2) is attributable to the operation of the cooling water intake structure." Key measures of an adverse environmental impact are declines in relative abundance and changes in species diversity where reasonably and actually attributable to cooling water intake structures.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

Overview of I & E effects on organisms

Further, facilities should be allowed to demonstrate whether or not they are causing AEI through the use of a risk-assessment approach, similar to that of EPA's 1998 Ecological Risk Assessment Guidelines. Absent a verifiable demonstration of community-level impacts, EPA's effort to require installation of costly technology is, as it appears in the Rule, see Fed. Reg. at 17140ff, simple regulatory overreach, i.e., a poorly-veiled effort to implicate itself in the market economics of electric-generation, an area in which the Agency has neither expertise, nor jurisdiction.

Facilities that have demonstrated in the past or can demonstrate, through an entrainment and impingement study, that facility operations do not create on AEI should not be required to go through the rigorous BTA process prescribed in the Rule. This result eliminates the undue burden not only on the facilities, but also on regulators.

EPA Response

Please see response to comment 316bEFR.025.018 for the discussion on the environmental impacts associated with cooling water intake structures. Also, please see the response to comment 316bEFR.010.041 for the discussion regarding EPA's decision not to define adverse environmental impact in today's final rule. See the preamble to today's rule for a discussion regarding the availability of site-specific compliance alternatives.

Subject Matter Code 2.04.01

Require closed cycle cooling

EPA'S EFFORTS TO EQUATE BTA AND COOLING TOWERS IS SERIOUSLY FLAWED.

To our knowledge, in the approximately three decades since the passage of § 316(b), and throughout EPA's continuing site-specific implementation of the statutory language, EPA never has required an existing facility to be retrofitted with cooling towers solely to address perceived entrainment or impingement impacts. <FN 24> See footnote 11, supra.

Despite this long and settled history, EPA now proposes a very different tack, with a Rule so grounded in cooling-tower technology that it requires existing facilities to meet cooling-tower-equivalent performance standards. See 67 Fed. Reg. at 17140, 17221; see also proposed 40 C.F.R. § 125.94(b)(1) ("You must reduce your intake capacity to a level commensurate with a closed-cycle, recirculating cooling system ..."). As discussed below, a Rule grounded in cooling-tower technology is ultra vires, since § 316(b) does not authorize consideration of facility technology or operations, other than those reasonably construed as CWIS. For this reason, EPA lacks the authority to compel cooling towers, and, necessarily, to develop cooling-tower-based performance standards.

As importantly, EPA's assessment of cooling-tower costs, as it relates to existing facilities, is seriously flawed and, therefore, cannot support EPA's conclusions in the proposed Rule. To the contrary, as discussed below, there is strong evidence that, for many facilities, particularly nuclear facilities, retrofitting an existing station with cooling towers is too untried and too costly to be considered the "best technology available" to minimize perceived impacts resulting from station operations. See 33 U.S.C. § 1326(b) (emphasis supplied). As discussed below, this is certainly the case for the Entergy-owned stations that EPA impliedly criticizes in its Technical Development Document for the Proposed Section 316(b) Phase II Existing Facilities Rule (DCN: 4-0004) ("Phase II TDD").

Footnotes

24 EPA's premise appears to be that entrainment is correlated with CWIS intake flow capacity, and thereby proposes to establish performance standards to limit CWIS intake flow. See 67 Fed. Reg. at 17136-40. This oversimplification fails to account for site differences, e.g., differences among aquatic organisms at the site, including the swimming speed of fish and the ability of these fish to perceive the intake; whether the eggs present sink, float or adhere to available vegetation or surfaces; shape of the shoreline; and the character of river, estuarine, ocean or lake flow. See UWAG Comments at 14-15.

EPA Response

In this final rule, performance standards are not based on cooling tower technology, however, one of five compliance alternatives is the reduction of flow commensurate with the use of cooling towers, since such a level of performance meets the rule performance standards. See preamble to the final rule, particularly sections III, VII, and VIII.

Subject Matter Code 2.04.01

Require closed cycle cooling

EPA Lacks Authority to Require Cooling Towers.

Even if cooling-tower costs were much lower, and their benefits much higher, EPA could not, as a legal matter, require closed-cycle cooling under § 316(b). By its express terms, §316(b) addresses cooling water "intake structures," not cooling systems and not cooling water flow. 33 U.S.C. § 1326(b). Likewise, §316(b) allows EPA to consider technology, but not operations.

Because EPA cannot, by means of §316(b), require cooling towers, the Rule is infirm to the extent it seeks to implement a cooling-tower-based program. That is clearly what has occurred here. In the Rule, EPA states:

Under proposed § 125.94(b), any owner or operator able to demonstrate that a facility employs technology that reduces intake capacity to a level commensurate with the use of a closed-cycle, recirculating system would meet the performance requirements proposed in today's Rule.

67 Fed. Reg. at 17140; see also proposed 40 C.F.R. § 125.94(b) ("You must reduce your intake capacity to a level commensurate with the use of a closed-cycle, recirculating cooling system… <FN 25>

As this language demonstrates, the Rule implements a cooling-tower-based technology requirement. Indeed, its standards are specifically grounded in cooling-towers' water-reduction capabilities, as EPA estimates them. As such, the Rule exceeds EPA's statutory authority.

In further support of this position, Entergy incorporates by reference UWAG's comments and Appendices, dated November 9, 2000, as submitted on the then-proposed § 316(b) Rule for new facilities.

Footnotes

25 Several paragraphs later, EPA equivocates: "Therefore, although closed-cycle, recirculating cooling is not one of the technologies on which presumptive standards are based, use of a closed-cycle, recirculating system would achieve the presumptive standards." 67 Fed. Reg. at 17142. If, as EPA maintains, the performance standards are not cooling-tower-based, EPA has offered no credible alternative explanation for those standards and, on that basis, the Rule is likewise infirm.

EPA Response

In this final rule, performance standards are not based on cooling tower technology, however, one of five compliance alternatives is the reduction of flow commensurate with the use of cooling towers, since such a level of performance meets the rule performance standards. See preamble to the final rule, particularly sections III, VII, and VIII.

Subject Matter Code 2.04.01

Require closed cycle cooling

EPA's Reliance upon Its Prior Rulemaking Effort Is Inappropriate.

EPA's analysis of retrofit costs improperly relies on information developed for the § 316(b) Rule for new ("Greenfield") facilities published in 66 Fed. Reg. 65255 (Dec. 18, 2001) (the "Phase I Rule"). See Phase II TDD at B1-4 (referencing Technical Development Document for the Final Regulations Addressing Cooling Water Intake Structures for New Facilities (EPA821-R01-036) ("Phase I TDD")).

By relying on costs supporting the Phase I Rule, now in its final form, EPA has created a significant, if not insurmountable, hurdle to its serious reconsideration and modification of those costs. Indeed, any comment suggesting an alternate cost methodology necessarily would call into question the final Phase I Rule. It is, therefore, unlikely that specific comment on Greenfields costs will be appropriately considered or addressed. This approach contravenes the spirit of the APA and frustrates effective public involvement, not to mention informed agency action. See 5 U.S.C. § 553(e) (requiring EPA in rulemaking to solicit public comment, and consider all relevant matters so presented).

Nor is the Greenfields data obviously applicable. EPA assumes that the same cooling tower package, i.e., equipment, used for a Greenfields site would apply equally well to existing facilities. See Phase II TDD at 2-29. This is not the case. At very least, significant study is required to ensure proper design and installation to coordinate older existing technology with new cooling systems. See Daniel E. Yasi, & Thomas A. Adams, Stone & Webster, Inc., Engineering Cost Estimate for Retrofitting Closed-Cycle Cooling Systems at Existing Facilities at 5 (July 3, 2002) ("Retrofitting Cost Estimate"), UWAG Comments; see also NEI Comments. Among other things, such studies are necessary to allow a facility to determine whether parts of the existing cooling system can be re-used and, therefore, whether the condenser must be redesigned, as well as the extent to which existing components may be accessed for re-use and redesign, or must be removed. For example, where existing piping is embedded in concrete, UWAG Comments, Retrofitting Cost Estimate at 6, even re-use may require significant, additional expense. Finally, such studies will also determine the extent of any necessary excavation of existing facility materials. None of these factors are applicable to new facilities where integration is contemplated from the beginning of the design process.

EPA Response

See response to 316bEFR.029.024. With regard to costs, EPA has adjusted and revised cost estimates for cooling towers and other technologies throughout this rulemaking. These revisions and the applications of these cost estimates are discussed in the preamble to the final rule and in the supporting technical development documents and other documents in the record to the final rule. Finally, UWAG comments are addressed individually throughout the response to comment database/ document.

Subject Matter Code 21.06.01

Implications for nuclear facilities

Author Name Elise N. Zoli

Organization Godwin Proctor Counselors at Law obo Entergy Corporation

EPA's Phase I cost estimates are particularly inapplicable to nuclear stations, since EPA utilized only capital costs for cooling towers from fossil-fuel electric-generating stations in determining those costs. See Phase I TDD at 1-3. As EPA no doubt is aware from its coordination with NRC staff, see 67 Fed. Reg. at 17127, and as discussed below, water use at nuclear facilities represents a special concern, involving a more difficult sitting, design and construction process. See NEI Comments. Further, construction in and around nuclear facilities is highly regulated and complex, adding significant costs to and extending deadlines in what EPA mistakenly assumes is a simple process. Id <FN 26>. In particular, EPA's cost for retrofitting a nuclear power facility with fine-mesh traveling screens and fish-return system is approximately one-third of the actual cost, based on the separate retrofits of Indian Point 2 and 3. <FN 27> In short, EPA's attempts to apply non-nuclear station Greenfields costs to nuclear stations, without reason or justification, is indefensible.

Footnotes

26 EPA cannot simply escalate costs for nuclear facilities and maintain consistency. Rather, the Agency must provide an alternative approach for nuclear facilities, as discussed below.

27 EPA estimates that installation of fine mesh traveling screens, described on page 2-4 of the Phase II TDD, and a fish return system costs $8.1 million at a nuclear power facility with a once-through cooling system, a design intake flow of 870,000 gpm, and located in a freshwater stream. Phase II TDD at A-13 (Plant Code 325). Indian Point 2 and 3 each has substantially the same characteristics except each is located in an estuary. Indian Point 2 was retrofitted in 1991 with Ristroph screens, at a cost of $15.9 million in 1991 dollars. Indian Point 2 was retrofitted in 1997 with a fish return system at a cost of $4.7 million in 1997 dollars. The Building Cost Index ("BCI")-adjusted costs are $25.7 million in 2001 dollars. Indian Point 3 was retrofitted in 1994 with Ristroph screens and a fish-return system, at a cost of $20.5 million in 1994 dollars. The BCI-adjusted cost is $23.5 million in 2001 dollars.

EPA Response

First, EPA did not apply non-nuclear station greenfields costs to nuclear stations for the NODA and final rule. The Agency dramatically revised costs of retrofitting cooling water intake structure technologies (i.e., non-cooling tower technologies) for the NODA. As such, the assertion of the commenter that the Agency has underestimated fine-mesh screen costs is not applicable for the NODA or final rule. The Agency has developed special costs for the construction, installation, and operation and maintenance of intake retrofits for nuclear stations for the final rule that suitably exceed those for other fossil fuel plants (by 1.8 times for capital costs and by approximately 1.3 times for annual O&M costs). As such, the commenter's assertions regarding screening systems are not correct. See the Technical Development Document for more information on the nuclear facility cooling water intake structure retrofit costs considered for the final rule.

The final rule is not based on cooling tower retrofit technologies. See response to comment 316b.029.029.

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

EPA’s Estimate of Cooling-Tower Retrofit Costs Is Too Low.

In any event, EPA’s estimate of the costs of retrofitting certain existing facilities, including as they impliedly relate to Entergy-owned units, is grossly inadequate.

For existing facilities, EPA used its new facility estimates of the capital costs of installing cooling towers. See Phase II TDD at 2-17. <FN 28> These estimates were based on a number of factors, including an assumed design approach for cooling-towers of 10 degrees F, which EPA determined was appropriate for newer facilities constructed between 1997-2000, as distinct from existing facilities. <FN 29> See Phase II TDD at 2-22 (referencing Attachment C to Chapter 5 of the Phase II TDD). These estimates were than multiplied by a dubious “state-specific capital cost factor.” <FN 30> See Phase II TDD at 2-28 to 2-29. That result also was multiplied by a “retrofit” factor of 1.2, for which EPA again provides no foundation or explanation. See Phase II TDD at 2-29 to 2-30. According to the Economic and Benefits Analysis for the Proposed Section 316(b) Phase II Existing Facilities Rule (‘Phase II Eco/Ben Analysis”) at B1-4, EPA then applied a 10% contingency factor to this result. <FN 31> Again, however, no mention of such a factor, nor any explanation of its derivation, appears in the Phase II TDD.

The many flaws in EPA’s approach are discussed below. It bears mention that these fundamental flaws in the cost component of the cost-benefit analysis of the Rule have two potential effects:

-EPA’s methodology is skewed in favor of lower costs, as it wrongly assumes certain cost-saving measures, e.g., re-use of various structures and limited need for additional pumps and piping. This has the effect of tipping the scales in favor of benefits, against costs, as improperly calculated by EPA, and, therefore, installation of technology.

-EPA’s limited view of costs may cause regulators implementing the Rule to reject these critical additional and legitimate costs. This would be damaging in the calculation of whether costs are “significantly greater” than those considered by EPA, and may mean that legitimate costs are not factored into the assessment. This is particularly problematic for nuclear facilities, where such costs are likely to be significantly altered by site-specific requirements.

Footnotes

28 Nor do we understand it to be appropriate to rely on “the literature,” Phase II TDD at 2-20, where such “literature” is fundamentally the work of a single person, including any communications. Nor is this infirmity resolved by phone calls with two marketers of cooling tower producers, id. who stand to gain from work requiring cooling towers to be installed at existing plants.

29 EPA essentially concedes that its reliance on the new facilities design approach is inappropriate. Indeed, in assessing its national estimates, EPA states that it compared those estimates to the actual retrofit costs incurred by three existing facilities, and concluded that it compared favorably (within 25% or less), except that the design approach for new facilities is different from 10 degrees F. Phase II TDD at 2-22.

30 Apparently, the state-specific capital cost factor for 40 of the 45 listed states and the District of Columbia drove the “national average” capital costs down anywhere from 0.03% to 25%. See Phase II TDD at 2-28 to 2-29. Obviously, this means that EPA’s average is too low. Oddly, EPA also chose not to identify five states, i.e., Alaska, Alabama, Nebraska, North Carolina and North Dakota. See id.

31 The explanations of EPA’s cost methodology in the Phase II TDD and the Phase II Eco/Ben Analysis provide somewhat contradictory descriptions of the order in which these factors were applied. Compare Phase II Eco/Ben at B1-4 with Phase II TDD at 2-28, 2-29, 2-32, 2-33. Obviously, if EPA scaled its retrofit factor up or down by applying the state-specific cost factor to it, it reflects the assumption that these “retrofit” costs also will vary regionally. Until EPA explains how it derived its retrofit factor, however, Entergy cannot assess this assumption.

EPA Response

The state-specific capital cost factor has been replaced by much more specific (zip-code based) factors, as described in the Technical Development Document. See response to comment 316b.EFR.010.066.

Even though the commenter only addresses the Agency’s analysis of wet cooling tower costs (a technology not required by the final rule), the Agency takes exception to the commenters assertion of “EPA’s limited view of costs” as it generally pertains to a few costing principles. The Agency believes that its approach to areas specific capital cost factors and contingency is valid for the analysis of the final rule. In addition, the Agency has addressed nuclear facility cost factors in the final analysis and accounts for the possibility for site-specific factors related to construction at their sites. Therefore, the Agency believes that the commenter’s assertion that “legitimate costs are not factored” into the cost tests to not be invalid as it applies to the technologies considered under the requirements of the final rule.

Cooling system costs (e.g., dry, wet, recirculating)

EPA's Key Assumptions Are Not Supportable.

For its cost assumptions relating to the retrofitting of nuclear facilities with cooling towers, EPA offers a single and questionable example, the location, configuration and circumstances of which make extrapolation inappropriate. This limited available database is itself telling: EPA must rely on the Palisades example, because there is no other example available. We are aware of no circumstances in which a single example is statistically valid for extrapolation. Certainly, such a sample is inconsistent with sound principles of extrapolation and Executive Order 12866, § 1(b)(7) ("Each agency shall base its decisions on the best reasonably obtainable scientific, technical, economic, and other information concerning the need for, and consequences of an intended regulation."). <FN 32>

Moreover, scrutiny of the Palisades' circumstances confirms that it is not the example EPA believes it to be. Palisades understood, from its initial construction, that cooling-towers were in its immediate future. Indeed, well before the station was operating at full power, Palisades already had agreed to install cooling-towers. Further, the station never operated at full power until the towers were installed and operational. For those reasons, the example is not a "retrofit" as EPA now uses the word.

In any event, the Palisades example is hardly the "poster child" EPA is seeking. Despite effectively coincident facility and cooling-tower construction, the interconnection took approximately ten (10) months to complete. By contrast, EPA contends that interconnections could be handled within the period of scheduled outages, which currently are targeted for thirty (30) days. Likewise, the period from tower construction to operation was three years, again on a relatively small facility that had planned for the effort.

Other assumptions are equally problematic. For instance, EPA justifies its central assumption (i.e., that new facility capital costs are adequate surrogates for existing facility costs) based on certain additional assumptions, or "principles," see Phase II TDD at 2-17, as the Agency inappropriately characterizes them, including:

-Existing condensers can be used and operated successfully under a variety of conditions, with most of the existing condenser-conduit systems used for the cooling-tower systems. As a corollary, EPA maintains that existing CWIS can be used for supplying make-up water to the recirculating towers, and that existing piping runs can be used to reduce the amount of new circulating piping installed;

-tower structures can be constructed on-site before connection to the existing conduit system; and

-modification and branching of circulating piping is necessary for connecting the recirculating system to the existing conduits and for providing make-up water to the towers.

These assumptions noted above are not well-founded, and fail to account for site-specific conditions likely to be relevant, a fatal flaw in EPA's analysis. Each is discussed below.

First, EPA incorrectly states that recirculating systems can be connected to the existing condensers, likely using existing condenser conduit piping. In fact, existing condensers may not be used. Rather, due to condenser thermal design or efficiency limitations, a single-pass condenser may need to be reconfigured to a two-pass design, requiring extensive cooling-water conduit and piping modifications. See UWAG Comments, Retrofitting Cost Estimate at 7. Such modifications can pose significant safety and logistical problems, as they may require temporary bracing or demolition of piping and components. See id. at 6. Notably, such retrofits may also require extensive re-piping and an extended outage. See id. at 7. Further, because demolition of piping and components may be necessary, depending on the site-specific design of the facility, such piping and components also may not be available for re-use for the cooling tower system. EPA's failure to include the potential for these additional costs casts doubt on the validity of EPA's analysis.

Second, the Rule improperly assumes all facilities subject to the Rule have no land constraints preventing cooling towers from being constructed on-site before connection. On this basis, EPA does not include costs incurred to acquire additional, adjacent land at fair market value. In fact, facilities may face just such concerns. Further, in states that have experienced utility deregulation, generating companies' powers of condemnation do not continue, complicating the acquisition process and likely increasing costs. EPA also fails to account for the many other factors that may force a regulated entity to look off-site. For instance, a major natural gas pipeline runs through the Indian Point 2 and 3 sites. Construction would, of course, need to account for this fact, which undoubtedly will operate as a significant sitting constraint and substantially increase costs.

Therefore, the extent to which existing circulating piping may be modified and re-used is not clear, as existing circulating water systems are, at some stations, embedded in or supported by reinforced concrete foundations. See UWAG Comments, Retrofitting Cost Estimate at 6. Any re-use or installation of piping running to the cooling towers would not be as simple as EPA seems to believe, as it may require removal of existing facility equipment to gain access and extreme difficulty in moving or modifying existing concrete pipes, especially where embedded in a foundation. See id.

Footnotes

32 Thus for instance, EPA easily could have sought information on estimated cooling-tower retrofit costs from facility owners that have undertaken these analyses. This data would, of course, reflect important site-specific factors. EPA then could have extrapolated from this more relevant, more recent information, reaching a sound conclusion.

EPA Response

The comment raises reasonable questions regarding the assumptions EPA used in analyzing cooling tower retrofit costs. The Agency disagrees with the commenter's conclusion that because the Palisades plant did not operate at full capacity prior to re-constructing its cooling system that the post-operational retrofit of the cooling system from once-through to recirculating was not a "retrofit." This assertion is not based in sound technical principles, as the key elements of a retrofit project involve the key construction activities, all of which were conducted at Palisades.

The Agency notes that in seeking data on existing cooling system retrofits, as was its obligation, it attempted to learn of all examples of the technology application. As such, the Agency reported the facts that it learned and interpreted them through the proposal and NODA. The assertion by the commenter that EPA sought a "poster child" example of a cooling tower retrofit is repeated elsewhere in his comments with accusations of bias on the part of the Agency. These assertions are not borne out by the proposal, NODA, and final rule records which explore a variety of technologies and their costs of implementation for fish protection.

Costs

EPA Ignores Significant Additional Costs for Retrofitting a Nuclear Facility.

As discussed below and also addressed in UWAG's and NEI's Comments, EPA's cost assumptions are especially inappropriate as applied to nuclear facilities. Nuclear stations' service-water systems are safety-related. Thus, where service and cooling water employ a single intake structure, as is commonplace, these facilities likely would have to construct an entirely new intake structure to meet NRC's safety criteria, e.g., to ensure that intake flow is not compromised at any point. This construction will add significant additional costs and create significant additional environmental impacts, none of which EPA has accounted for in the Rule.

EPA's assumption that there will be re-use of "significant portions of conduit systems," presumably while the facility remains in operation, is likewise inconsistent with typical nuclear operations and licensing requirements. Anything that would alter or affect the flow of safety-related service water at a nuclear unit ordinarily requires an outage and might have to be completed during a refueling outage. Unit outages are mostly scheduled on an 18-month or 24-month frequency; extending these scheduled timelines would have serious financial impacts, a fact which EPA has not accounted for in its analysis. Indeed, Entergy's scheduled refueling outages at its nuclear facilities currently average less than thirty (30) days. This is consistent with information obtained from NEI, which indicates that the median duration of nuclear refueling outages in 2000 was 35 days. See NEI, Fuel/Refueling Outages (2002) at http//www.nei.org/doc.asp?catnum=3&catid=43.

As importantly, EPA fails to account for the complexity and duration of tie-in of the new and old systems. The UWAG Comments note that cooling system engineers estimate this would take up to six months to complete, see UWAG Comments at 32, and therefore would cause a considerable loss of generation, in routine retrofits. For nuclear facilities, the time periods are expected to be substantially longer. Indeed, the sole example of a nuclear tie-in in the rule, i.e.. at Palisades, took approximately ten months, even though the installation was effectively coincident with construction and anticipated prior to full scale operation.

Moreover, a retrofit could be complicated by the physical layout of the facility, the modifications required to the low water pressure system at the existing facility, and the lack of space for towers near the facility. It also should be noted that large construction projects at operating nuclear facilities such as constructing cooling towers, are obviously to be avoided. Costs skyrocketed in the 1980s and 1990s, including as a result of the Three-Mile Island incident, e.g., Indian Point 2 and 3 cost $500 million to construct in 1970s, while Nine Mile cost approximately $5 billion. Post-September 11th security measures require further access constraints, again increasing costs.

EPA Response

EPA notes that the comment specifically addresses cooling tower costs and the technology's feasibility. EPA is not basing the requirements of the final rule on this technology. The technical feasibility concerns raised by the commenter was one factor in this decision.

Subject Matter Code 9.0

Costs

EPA Ignores Relevant Costs.

Inexplicably, EPA also ignores obviously relevant factors and costs. <FN 33> For instance, EPA uses cost figures for mechanical towers, purportedly because capital costs for mechanical towers were the "median cost" choice. See Phase II Eco/Ben Analysis at B1-4. Such towers may not be appropriate in many circumstances. In particular, natural-cooling towers are more appropriate at some stations, especially at baseload facilities in northern locations, like Indian Point 2 and 3, Fitzpatrick Station and Pilgrim Station, due to reductions in long-term maintenance costs and improved reliability. See UWAG Comments, Retrofitting Cost Estimate at 4. Those alternative systems will have significantly different associated costs - costs which EPA has not accounted for to the obvious detriment of the regulated community.

Nor does EPA take into account significant additional costs at locations where blasting to remove rock or de-watering is required. See id. at 7. Even EPA concedes that its capital cost estimate does not account for costs for blasting, excavation, backfill, and other civil engineering costs from intake piping modification, which could be siginificant, except by use of an unjustified, across the board retrofit factor of 20%. Phase II TDD at 2-29. As discussed above, blasting at a nuclear facility is a major complication, which may require NRC approval and extensive safety analysis as well as extensive safeguards and an outage, all of which increase project costs. Blasting in or adjacent to a nuclear power facility would require significant safety analysis, and may not be permitted by the NRC. Further, per NEI, two prolonged outages are required to retrofit a unit: one to allow for blasting necessary to construct cooling tower foundations, a second for tie-in following construction.

Footnotes

33 EPA is not permitted to pick and choose among costs to its liking. Instead, EPA is required to consider "all costs." See Order 12866 (requiring all federal agencies to "assess all costs and benefits of available regulatory alternatives, including the alternative of not regulatory").

EPA Response

EPA recognizes that its cost estimates for cooling tower retrofits may have been underestimated in part because these cost estimates did not account for all of the costs relating to overcoming technical infeasibility problems. For this and other reasons, EPA is not basing today's rule on cooling towers.

Subject Matter Code 9.0

Costs

EPA also fails to include the significant energy penalty due to the shutdown of units during installation. The impact is particularly significant and in some cases compromising of the local electric system's reliability, if facilities shut down permanently because conversion is not economically feasible. EPA also fails to account for turbine back-pressure, which EPA concedes could significantly affect net facility capacity, see Phase II TDD Ch. 5.3, by assuming that turbine backpressure for a retrofitted facility would be the same as for a new facility with cooling towers. Impacts to system reliability and energy pricing is expected to be severe, as discussed below. Certainly, EPA's conclusion that impacts are nominal is patently erroneous, as applied to Entergy stations. See National Economic Research Associates ("NERA"), Electricity System Impacts of Nuclear Shutdown Alternatives, dated March 2002 (Appendix 6). Department of Energy (DOE), and others, concur. See Phase II TDD at 5-31 to 5-34.

By way of example, in the important peak summer period, Vermont Yankee Nuclear Power Facility sacrifices 9 megawatts to operate the cooling towers and an additional 20 megawatts due to increased condenser back pressure as a result of higher condensate temperatures. These megawatts represent 5.3% of Vermont Yankee Nuclear Station's available power. Further, this power generation represents the major source (i.e., 78%) of electric power in Vermont, with the result that impacts of any reduction would be severe for Vermont's electricity consumers.

EPA Response

EPA has considered the energy penalty issue raised by the commenter and it was one of the factors influencing EPA's decision to not base the requirements of the final rule on this technology.

Subject Matter Code 9.0

Costs

EPA's Retrofit Cost Estimates Fail to Include Social Costs Attributable to Cooling Towers.

EPA also does not take into account the significant social costs attributable to requiring cooling-tower retrofits. See Phase II TDD Ch. 6. This is surprising because EPA evaluates all conceivable costs of entrainment and impingement (i.e., the so-called benefits of the Rule). In many cases EPA's assessment apparently led it to conclude that the likely effects, including effects from increases in air emissions, water consumption, increased impingement mortality, plume and salt drift, noise, avian and wetlands impacts, would be minimal. These conclusions are flawed.

EPA Response

EPA considered these factors when deciding to not base the requirements of the final rule on cooling towers.

Organization Godwin Proctor Counselors at Law obo Entergy Corporation

Subject Matter Code 6.08

Non-aquatic impacts

EPA Should Properly Account for Adverse Air Impacts.

EPA ignores the fact that the Rule may result in unit shutdown, particularly for nuclear units where the costs of cooling-tower installations are grossly in excess of the costs for fossil-fuel units, and viable alternative technologies, such as the Gunderboom, are not available, in part because nuclear units rely on water for safety-related purposes. <FN 34> In such circumstances, power generated by nuclear units, constituting almost 20% of the nation's power, will need to be supplied by fossil-fuel units, reflecting the existing power profile.

The effects on air quality of shutdown of even some of these units is profound. Indeed, NEI has calculated the annual emissions of criteria air pollutants saved by nuclear operations and the benefits to energy consumers of those savings. See Nuclear Energy Inst., Meeting Our Clean Air Needs with Emission-Free Generation (Appendix 7). Operation of nuclear units nationally reduced emissions of carbon dioxide by 155 million tons, of NOx by 2.4 million tons, and of SO2 by 5.1 million tons. The estimated value of such savings, based solely on new nuclear generators between 1990 and 1995, are approximately $50 million in offsets annually, based on the publicly traded value of SO2 allowances in 1995 for the Acid Rain Program. See id. at 8.

This serious national impact is exacerbated in the high-demand, southern New York load pocket, where Indian Point 2 and 3 currently represent approximately 20% of the Consolidated Edison Company of New York, Inc.'s peak demand. Indeed, as set forth in the Emissions Avoidance Study prepared by TRC Environmental Corporation (August 2002) ("Emissions Avoidance Study") (Appendix 8), Indian Point 2 and 3 supply approximately 10% of New York State's total generation, assuming a 90% annual capacity factor. As TRC has identified, expected emissions increases (in percentages) as a result of taking Indian Point 2 and 3 off-line, using the existing fuel mix from the current New York State Energy Plan, dated December 2001, represent an approximately 70% increase of VOCs, a 42% increase of CO, a 29% increase of PM-10, a 20% increase of CO2 and a 19% increase of NOx, as compared to statewide electricity production. Localized impacts are even more severe, representing annual increases of approximately 147% for VOCs, 147% for CO, 145% for PM-1O, 123% for CO2, 119% for SO2, 112% for NOx, 59% for NOx in the Ozone Season, and 58% for mercury.

These increases impact an area already in severe non-attainment for certain pollutants, with the result that air-quality impacts in southern New York will be particularly acute. TRC has characterized the likely impacts in clear social and environmental terms. As TRC has identified, replacing Indian Point 2 and 3 will result in increased acidification of lakes (due to atmospheric deposition of SO2 and PM-b); accelerated building and structure decay (again, from SO2), soil degradation (again, froth SO2 and PM-10); visibility impairment, whether haze or smog (from SO2, NOx, VOCs or PM-10); reductions in crop yields, forest and facility damage; and increased impacts to susceptible groups, particularly children, the elderly, asthmatics and persons with heart disease, lung disease or influenza. See Emissions Avoidance Study, passim (Appendix 8).

None of these serious adverse impacts has been accounted for or evaluated by EPA in the Rule. Rather, EPA has relied upon a bunkered, superficial analysis that national impacts will be nominal, based upon an equably blinkered cost analysis in which the Agency compares grossly underestimated cooling-tower costs to the irrelevant gross revenues of each facility.

Of course, the Agency is incorrect. To that end, Entergy requests an appropriate accounting of the adverse environmental impacts of EPA's Rule, reflecting the possible shutdown of a reasonable percentage of affected nuclear units.

Footnotes

34 In fact, EPA's failure to differentiate between certain types of power-producers belies an overall weakness in the Rule and, perhaps, a bias against nuclear energy.

EPA Response

EPA notes that the commenter's assertion that the aquatic filter barrier technology (Gunderboom) is not feasible for nuclear units is not supported by the commenter's claims that the technology would interfere with safety-related water supply. The aquatic filter barrier technology has limited applications for extremely large intake flows, in cases where waterbody navigation is critical, when wave action is significant, or when potential excessive debris or ice could interfere. However, the Gunderboom technology's shortcomings do not relate to reliability of water supply when applied with consideration for its limitations.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

EPA's Energy-Impacts Analysis Is Superficial, and, Therefore, Fails to Properly Account for the Adverse Effect of the Rule.

In response to serous concerns about meeting electric demand, President George W. Bush issued an Executive Order Governing Actions that Significantly Affect Energy Supply, Distribution and Use (May 18, 2001) (the "Energy Executive Order"). In conjunction with Order 12866, the Energy Executive Order compels a "detailed" analysis of energy impacts for the Rule. Id.

Despite these Executive Orders, EPA also has failed to adequately address the direct electric-system impacts of the Rule, both as a result of cooling-tower use or in the event that the costs compel shut-down of nuclear units, such as Indian Point 2 and 3 in the southern New York high-demand, low-capacity "load pocket." By failing to consider such circumstances, EPA has proposed a Rule which fundamentally misconstrues the important environmental impacts of requiring installation of cooling towers at Indian Point 2 and 3, and other nuclear units.

More particularly, of the impacts to electric-system reliability and electric pricing in southern New York without operations of Indian Point 2 and 3, as well as six other New York nuclear units, using the "GE-MAPs" methodology customarily implemented by New York regulatory authorities, as well as a volatility analysis performed by NERA to account for market pricing impacts. Electricity System Impacts (Appendix 6). As NERA demonstrates, the impacts on the New York electric system of the loss of Indian Point 2 and 3 are substantial.

First, reliability plummets. The New York State Reliability Council has set a target reserve margin of 18% as necessary for proper system function; i.e., as the percentage decreases, system reliability decreases. Without Indian Point 2 and 3, that target reserve margin cannot be met. In practical terms, the calculated number of days where emergency measures would be taken to prevent blackouts, etc., would rise by 800%.

Likewise, pricing substantially increases at peak demand periods. <FN 35> As NERA concluded, if the six units are retrofitted with cooling towers in 2007, the downstate New York peak price for power in 2008 would increase by 38%. <FN 36> Permanent shutdown of six units further increases adverse the effects: i.e., the price of power would more than double (increase by 130%) in 2008, and the days in which emergency measures would be taken would increase to 55 days per year (an increase of 5500%). Yet, EPA has not recognized, nor accounted for, these substantial impacts in its analysis. <FN 37>

Finally, the loss of nuclear units also ensures a less functional market. It is well-recognized that nuclear units, through their contribution to profile diversity and their bidding behavior, stabilize deregulated markets. EPA has not recognized, nor accounted for, these factors in its analysis.

Footnotes

35 Modeling was done for July only, and assumed that each of the six units were shutdown for conversion that month.

36 NERA analyzed the increases in the downstate service territories for Central Hudson Gas & Electric, Consolidated Edison Company of New York Inc./New York Power Authority, and Orange and Rockland Utilities, Inc. The numbers in text were obtained by averaging these three territories.

37 Of course, indirect impacts, if considered, would further increase social costs.

EPA Response

EPA disagrees with the comment that it failed to adequately consider the broader energy market and reliability implications of the 316(b) regulation. EPA performed energy market model analyses of the preferred option and other compliance alternatives using the IPM, a peer-reviewed, OMB-approved model. While EPA did not perform an energy market model analysis using specifications that completely matched the preferred option at the time of proposal, this analysis was performed both for the Notice of Data Availability (see results at DCN 5-3002 and 5-3100) and the final Phase II rule (see results in EBA chapter B3, DCN 6-0002).

EPA notes that the final Phase II rule does not require installation of cooling towers. Based on EPA's analyses, the final rule also contains no requirements that are costly enough to "compel shut-down of nuclear units." EPA appreciates the information and analysis on potential consequences "to electric-system reliability and electric pricing in southern New York without operations of Indian Point 2 and 3." However, EPA notes that this is a hypothetical analysis that is in no way linked to the requirements of the final Phase II rule and therefore requires no changes to this rulemaking.

Organization Godwin Proctor Counselors at Law obo Entergy Corporation

Subject Matter Code 6.08

Non-aquatic impacts

Other Significant Impacts That Must Be Considered by EPA.

EPA fails to address the effects on the source waterbody due to evaporative losses from cooling towers. It has been estimated that evaporation causes a water loss of 0.5% to 1.5% of recirculating water. See UWAG Comments on the Phase I Rule at 183; see also William H. Desvousges at al, Triangle Econ. Res. Draft, The Role of Benefit-Cost Analysis in 316(b) Rulemaking at 11 (Feb. 28, 2002), UWAG Comments ("Role of Benefit-Cost Analysis"). Where the flow conditions and size of the waterbody are vulnerable to such losses, aquatic habitat may be affected. See UWAG Comments on the Phase I Rule at 183. Thus, for example, rivers increasingly affected by climatic changes may be particularly vulnerable. Further, because the water is not returned to the source waterbody, the percentage of organisms that die due to entrainment, across species, increases to virtually 100%. Id.

Nor does EPA properly consider aesthetic and safety impacts. Aesthetic impacts can be severe, impacting scenic overlooks and views of historic sites. See UWAG Comments on the Phase I Rule at 180; see also UWAG Comments, Role of Benefit-Cost Analysis, at 11. Salt drift, which occurs when cooling towers are used for an electric-generating station using brackish or saltwater, may spread sodium, calcium, chloride and sulfate ions along prevailing winds to soil, vegetation and other water bodies: This may damage vegetation, including crops, by accumulating on plants or soil. See UWAG Comments on the Phase I Rule at 182. Vapor rise from cooling towers and drift may cause hazardous conditions, including reduced visibility and icing, and harm vegetation.

Nor does EPA properly evaluate the significant noise impacts that may occur to neighboring uses. Cooling towers may cause 70-75 dB(A) at a distance of 100 feet from the towers – a potentially significant annoyance to nearby institutions, residential or commercial users. Id. at 183; see also UWAG Comments, Role of Benefit-Cost Analysis at 11.

Furthermore, EPA fails to consider displacement of wetlands <FN 38> that may occur where available land for cooling towers is wetlands. EPA likewise ignores increases in discharge temperature. UWAG Comments, Role of Benefit-Cost Analysis at 11. <FN 39>

In addition, avian mortality due to man-made structures such as cooling towers maybe of concern, particularly if a local population of any bird species is threatened or if the reduction in the numbers within any bird population significantly impairs its function within the local ecosystem. See Nuclear Regulatory Comm'n, NUREG 1437, Section 4.3.5.2.1.

These significant and serious failures by EPA are inconsistent with its mission and its stated goals: to minimize adverse environmental impact.

Footnotes

38 Wetlands are protected by federal, state and local law. Where cooling-towers may not be sited, based upon the existence of protected wetlands, increased costs may be incurred, including due to the distance of the cooling-tower from the facility and the potential need to buy land. Given that affected facilities are water-dependent uses, these impacts are expected to be

significant. EPA nonetheless has not considered this.

39 Based on Supplement 1 to Regulatory Guide 4.2 issued on September 2000 (specifically Section 4.1), water use conflicts at nuclear plants with cooling ponds or cooling towers using makeup water from a small river with low flow has been a concern in regard to impacts on instream and riparian communities. Specifically, 10 C.F.R. § 51.53(c)(3)(ii)(A) as it relates to license renewal requires, in part: “If the applicant’s facility utilizes cooling towers or cooling ponds and withdraws makeup water from a river whose annual flow rate is less than 3.15 x 1012 ft3/year (9 x 1010 m3 /year), an assessment of the impact of the proposed action on the flow of the river and related impacts on instream and riparian ecological communities must be provided. Cooling water for Entergy owned Arkansas Nuclear One, Units 1 and 2 (“ANO”) is supplied by Lake Dardanelle, which is served by the Arkansas River. The Arkansas River is classified as a small river according to the criteria established by the NRC and will have to be evaluated during the ANO Unit 2 license-renewal process since this unit has a cooling tower. Therefore, if the NRC assumes some potential impact to the instream and riparian ecological communities as a result of cooling tower withdrawal from a small river, then it appears that installing an additional cooling tower for Unit I at ANO would potentially increase the probability of an impact on instream and riparian ecological communities.

EPA Response

EPA has not based today's rule on closed-circuit cooling towers. Therefore, the commenter's concerns have been addressed.

Organization Godwin Proctor Counselors at Law obo Entergy Corporation

Subject Matter Code 23.02

TDD related comments

EPA's Sole Specific Application and Critique of Cost Estimates Prepared by a Facility Is Inaccurate and Cannot Be Substantiated.

EPA criticizes the cost estimate for the cooling-tower retrofit prepared for Bowline Station and included in the Draft Environmental Impact Statement ("DEIS") submitted in the pending SPDES-permit renewal proceeding before the NYSDEC for, among others, Indian Point 2 and 3, concluding cooling-tower retrofit costs for Bowline Station were overstated (by 42%). See Phase II TDD at C-4.

EPA's analysis and its conclusion are incorrect. <FN 40> The Agency's analysis is also expressly contradicted by the informed assessment of the NYSDEC, through its consultant, which concluded during its review that "the analysis presented by, the owners of the Hudson River Facilities <FN 41> appears to be both reasonable and complete." See D.B. Grogan Assoc., Hudson River Power Plants Cooling Water System Design Assessment (Oct. 20, 2000) (Appendix 9). If NYSDEC's consultant had any criticism, it was that the cost estimates understated likely retrofit costs. Id.

EPA's and NYSDEC's conclusions are irreconcilable, due to the multiple errors in EPA's analysis. First, EPA merely compares a 1993 cost estimate to a 1999 cost estimate, both of which were obtained on behalf of the Hudson River Stations. <FN 42> Based on our review of EPA's supporting documentation (DCN 4-2537), EPA based its "low" estimate on the average price of three vendor quotations received by the four Hudson River Facilities in 1993. However, EPA provides no rationale as to why the 1993 cost estimate is more appropriate than the more recent estimate which frames the basis for the Hudson River analysis, and wholly ignores the obvious fact that the market price for construction and related services are ordinarily best determined by a recent, as opposed to an outdated, bid.

Similarly incomprehensible is EPA's other criticism of the 1999 DEIS. Based on site-specific concerns, including community concerns, the DEIS selects mechanical wet/dry cooling as the appropriate technology to minimize the water-vapor plume. EPA concludes that plume effects would be an "insignificant concern," and therefore "the mechanical wet (only) cooling towers [are] a viable option." See Phase II TDD at C-2. The DEIS recognizes that mechanical wet cooling towers may be a viable option, if justifiable based on a cost-benefit analysis, and weighs their benefits and costs against those of a mechanical wet/dry cooling tower. Cognizant of the significant community interest and the legal requirement under New York law relating to certain construction and likely applicable to minimize significant adverse environmental impacts, the DEIS selects the appropriate option for the four stations. EPA apparently disagrees. However, what may appear to be a rational choice to EPA is not appropriate at all sites, and EPA's criticism belies not a measured challenge to a methodology, but bias.

Footnotes

40 EPA states that its goal is to examine the "overall veracity" of the estimates prepared by Power Tech Associates. Whatever EPA's goal, its use of the term "veracity" is profoundly inappropriate.

41 The DEIS was prepared by the then owners of the Hudson River facilities: Bowline Point 1 and 2 was then owned by Central Hudson Gas & Electric Corp., and is now owned by Mirant Bowline LLC; Roseton 1 and was then owned by Southern Entergy New York and is now owned by Dynegy Roseton LLC; Indian Point 2 was then owned by Consolidated Edison of New York, Inc. and is now owned by Entergy Indian Point 2, LLC; and Indian Point 3 was then owned by New York Power Authority and is now owned by Entergy Indian Point 3, LLC.

42 In preparation of its 1999 DEIS, the Hudson River facility owners explain that the "current effort included: detailed review of prior studies; revision of designs including different cooling-tower types: new cost estimates and new performance and economic analyses to reflect conditions of 1999." Power Tech Assoc. Economic and Environmental Review of Closed Cooling Water Systems for the Hudson River Power Plants (Nov. 1999) (attachment to the DEIS) at 1 (Appendix 10).

EPA Response

EPA notes that should the proposal and NODA analyses of cooling tower retrofit costs be underestimated, as asserted by the comment, then the outcome would serve to reinforce and support the Agency's decision to not base the requirements of the final rule on this technology.

EPA believes that the commenters assertions of bias are not appropriate or supported. On the matter of plume abatement at Bowline Point, the Agency examined the record of the 1999 DEIS and historical information related to Bowline Point and nearby power plants. The Agency concluded, as did the consultant to the NYSDEC that mechanical draft towers would be a desirable economic alternative for the plant. Further, the Agency learned that the decision to adopt plume abatement may have been based on a historical analysis that examined only natural draft cooling towers, which would give an overstated aesthetic and drift analysis. As such, the Agency contests the commenter's assertions of bias.

Option: Site-specific determination of BTA

In short, as discussed above, EPA has not supported its efforts to offset alleged AEIs with cooling towers as an appropriate legal, scientific or economic response. Accordingly, Entergy requests that EPA reconsider its analysis, abiding the following suggestions. First, facilities and regulators should have flexibility to evaluate all available technologies and select those that comply in a cost-effective manner. This underscores the importance of a site-specific approach, as it is not appropriate to assume that a single technology that works at one facility will work at another. On the contrary, many factors play into whether a technology will be effective and facilities should be able to take them all into consideration. This flexibility will foster an environment of innovation and allow state agencies the flexibility to decide what will work best in their state.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Comment ID 316bEFR.029.039

Subject Matter Code 10.1

General: cost tests

Second, since cost tests will consume substantial time and resources, if required for each possible technology, Entergy requests that, if a technology can be proven "infeasible" through engineering analysis, no cost test should not be necessary. This approach will aid in streamlining an otherwise cumbersome process.

EPA Response

In the final rule, the cost-test will not require comparison of every possible technology for a particular site. Rather, the cost-test will function such that the facility determines the best technology for their site to meet the applicable requirements and then compare a single or limited set of costs to those considered by the Agency. Therefore, the commenter's concerns have been met. See section IX.H of the preamble to the final rule.

Comment ID 316bEFR.029.040

Organization Godwin Proctor Counselors at Law obo Entergy Corporation

Subject Matter Code 7.02

Performance standards

As a corollary, and third, many of the technologies in the Rule have not been extensively used, with the result that there is a potential for them to not produce the required percentage of reductions. If a technology is installed, maintained and monitored properly, and does not produce the percentage of reductions originally expected or required, a facility should not be considered to be out of compliance. Therefore, compliance measurement should be based upon factors that can be monitored and controlled: installation and maintenance. If a technology does not produce the percentage of reductions required, the facility should be permitted an appropriate amount of time to determine where the problem lies and propose a solution.

EPA Response

EPA believes that many technologies have proven performance records documented by almost three decades of study. For discussion of many of these technologies, see Chapter 3 of the Technology Development Document.

However, as the commenter notes, there are occasions where the performance standards cannot be consistently attained (e.g. because of biological variability considerations). For this reason, EPA has authorized the use of a Technology Installation and Operation Plan with the approval of the Director as a mechanism for determining compliance. Among other things, the Technology Installation and Operation Plan requirements incorporate principles of adaptive management, as this commenter suggests. See the preamble of the final rule for a more detailed discussion of the Technology Installation and Operation Plan.

Finally, once a facility has achieved the required percentage of reductions, they should not have to repeat the entire process at every permit renewal. A re-evaluation should be based upon significant changes in the waterbody or facility operations, as identified through periodic monitoring.

EPA Response

EPA agrees that a comprehensive demonstration study may not be required at every permit renewal. Under 125.95(a)(3) of today's final rule, a facility may apply for reduced application requirements if conditions at the facility remain substantially unchanged from the previous permit issuance. Please see response to comment 316bEFR.034.005 for a discussion.

Benefit Estimation Methodology

EPA'S BENEFITS ANALYSIS IS FLAWED.

According to the proposed Rule, a reduction in impingement and entrainment will result in so-called "use benefits," such as an increase in recreational and commercial catch, as well as so-called "nonuse benefits," such as preservation of fish for future generations. See 67 Fed. Reg. at l7189. EPA employed case studies that were source-waterbody specific, then extrapolated nationwide benefits based upon those case studies. Both the case studies and the extrapolation methodology substantially overstate the benefits associated with the proposed Rule.

The case study methodology proceeds in several distinct steps. First, EPA utilizes facility-specific measurements of impingement and entrainment, measured in terms of individual organisms and categorized according to species. Second, EPA normalizes these measurements by calculating the number of equivalent 1-year old fish impinged or entrained. A critique of these steps is presented in UWAG Comments, Review and Methodology Used by EPA to Evaluate Impacts of Entrainment and Impingement Losses on Commercial and Recreational Harvests ("Review and Methodology").

To determine both use and non-use benefits, EPA argues that preventing the loss of the calculated number of age-1 equivalent fish would result in benefits to the commercial and recreational fishery, as well as to non-use notions of benefits (such as bequest and existence value). As discussed herein, the methodology for each measure of benefits is flawed and, in many cases, defies common-sense application of well-known and well-understood biological and economic principles.

One fundamental error in the benefits analysis is that EPA assumes that impingement and entrainment will be completely eliminated by the Rule. Of course, based upon the standards set forth in the Rule, EPA requires reductions of 60-90% for entrainment and 80-95% for impingement. Thus, the calculated benefits should be discounted accordingly.

Moreover, EPA assumes that all affected facilities currently operate under "baseline" conditions and, therefore, that changes in conditions from today's operations to those under the Rule would actually achieve a new benefit in accordance with the performance standards. In fact, many facilities already have installed technologies aimed at reducing impingement and entrainment, with the result that EPA's assumption is incorrect and overstates benefits. For example, if a facility already has installed technologies that reduce entrainment by 50% from baseline figures, the actual benefits of the Rule for that facility will be a net reduction of entrainment by 10-40%, rather than the 60-90% assumed by EPA.

EPA Response

The comment states that EPA's benefit analysis overstates benefits.

The comment criticizes EPA's I&E calculations. EPA used facility-derived data and standard methods to calculate age 1 equivalents, as described in Chapter A5 of Part A of the Phase II Regional Study Document. Therefore, EPA sees no basis for the commenter's criticism of EPA's age 1 equivalent calculations.

The commenter is wrong to state that "EPA assumes that impingement and entrainment will be completely eliminated by the Rule." In fact, EPA's benefits analysis takes into consideration EPA's estimated percent reductions in I&E resulting from the rule.

The commenter is also wrong to state that EPA did not account for technologies that may have been installed to reduce I&E after the time that I&E data were collected. In fact, EPA made considerable effort to adjust I&E rates as appropriate based on such considerations.

EPA disagrees that its methodology for estimating each benefit category is flawed.

For EPA's responses to comments on specific benefit categories please see the following comments. For EPA's response to comments on the commercial fishery method, please see comment # 316bEFR.323.016. For EPA responses to comments on the recreational fishery methods used at proposal, please see responses to comments 316bEFR.041.452, 316bEFR306.320, and 316bEFR337.010.

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values. The Agency, however, did explore several alternative non-use valuation methods to appreciate the potential magnitude of non-use values for this rule, including meta-analysis and the benefit transfer method. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Commercial Fishing Benefits

The Pilgrim Case Study Overstates Benefits to Commercial Fisheries.

In the following paragraphs, Entergy outlines the multiple, significant errors in EPA's benefits analysis, as applied in its case studies to an Entergy-owned facility, Pilgrim Station. See Case Study, Part G: Seabrook and Pilgrim.

The first step in EPA's commercial-fisheries benefits-analysis involves the translation of impingement and entrainment numbers into changes in the number of pounds of a commercial species sold at dockside. See Case Studies Ch. A9. A critique of this translation is presented in UWAG Comments, Review and Methodology. As EPA acknowledges, its approach assumes a linear relationship between changes in fishery stock and changes in landings, i.e., bringing fish to market. See Case Studies at A-9. In other words, EPA assumes that a reduction in overall stock size automatically results in a proportionate reduction in commercial landings. This assumption skews the analysis by linking it to the highest possible measure of commercial benefit, and ignores the fundamental economic principles of supply and demand that regulate the size of the markets for individual fish species.

1. EPA Assumes, Without Justification, That the Markets for All Fish Species Are Supply Limited.

EPA's approach assumes that commercial landings of all species are limited by supply rather than demand. This assumption leads to EPA's conclusion that each theoretical fish lost to the commercial fishery due to impingement or entrainment results in one fewer fish of that species coming to market (i.e., there would have been a demand for the fish had it been supplied to the market). EPA must justify this assumption. Otherwise, it leads to the maximum possible market impact due to entrainment and impingement. <FN 43>

EPA's approach also fails to recognize that demand may be driving the size of the market in a given fish species. If the market is regulated by demand, then the effects of impingement and entrainment are significantly smaller than EPA's projections and may approach zero. For example, assume a demand for one (1) million pounds of a given species of fish. If the sustainable yield of the fish species is five (5) million pounds annually, a small reduction in the number of adults due to impingement and entrainment has very little effect on the ability of the supply to meet the demand and, therefore, has little effect on market price. Indeed, if the gap between demand and sustainable yield is large enough, there would be no effect on market price. In these instances, a reduction in impingement and entrainment would provide no economic benefit. Nonetheless, EPA chooses to forgo any analysis of the fundamental characteristics (i.e., supply and demand) of the fisheries markets. <FN 44>

As an example, a comparison of the pounds of winter flounder theoretically lost to the total commercial harvest is instructive. According to EPA's exaggerated calculations, as set out in the Pilgrim Case Study, impingement and entrainment results in the loss of 19,819 pounds of winter flounder to the commercial fishery, as compared to regional commercial landings of 11,294,198 pounds (or 0.18%). Thus, if the market for winter flounder is not limited by supply, the fisherman likely to and would catch the additional 19,819 pounds of winter flounder and suffer very little or no increase in cost (particularly if this is spread over the fishing season). If this is the case, the appropriate economic impact at the dockside is not the market value of the theoretically missing fish (because demand has been satisfied), but the marginal cost to the fisherman of catching the additional 19,819 pounds, if any. <FN 45> Nat'l Marine Fisheries Serv., Annual Commercial Landing Statistics, at http://www.st.nmfs.gov/st1/ commerciallandings/annual_landings.html (last visited Aug. 5, 2002) (2000 commercial landings for winter flounder in New England).

2. EPA Assumes, Without Justification, that Demand Is Inelastic.

Assuming a modest increase in the marginal cost to the fisherman, there are two probable outcomes for the marketplace as a whole: (1) a nominal increase in the dockside price of winter flounder, to recover the increase in marginal cost; or (2) the sale of fish at the same market price, with the nominal additional costs absorbed. Under scenario (1), the fisherman recovers his or her costs, because they are passed through to the consumer. Since each subsequent market participant (wholesalers, etc.) obtains the equivalent number of fish, they experience no economic impact other than the increase in dockside price and, therefore, the total impact remains the increase in the marginal cost to catch the 19,819 pounds of fish rather than overall market value (including any post-dockside value added) of the theoretically missing fish.

Under scenario (2), the fisherman is forced to sell at the same price, because demand is elastic (i.e., there are substitutes in the market that satisfy subsequent producers and the ultimate consumer). If substitutes exist within a given market, there is no post-dockside impact resulting from impingement and entrainment in the first instance. Just as with scenario (1), the net economic impact is the cost to the fisherman which, again, is the marginal cost to catch the additional fish, rather than the market value of the additional fish. Thus, EPA must consider the elasticity of demand for each commercial species when it analyzes economic impacts, because failing to do so results in substantially overstated economic benefits. <FN 46>

Footnotes

43 For example, there is no a limit on the quantity of winter flounder harvested by commercial fisherman. See Massachusetts Division of Maine Fisheries website (http://www.state.ma.us/dfwele/dmflCommercialFishing/com_index.htm). Thus, the market for winter flounder is not regulated by supply. Even if there were a catch limit, that limit does not necessarily mean that impingement and entrainment losses affect commercial or recreational catches.

44 This market phenomenon is confirmed by a review of NMFS's data on the relationship between commercial harvest and market price for winter flounder. Since 1995, the market price for winter flounder has steadily declined despite year-to-year fluctuation in commercial landings. Thus, supply is not driving market prices. See B. Pollard Rountree et at, Fishery Economic Trends tbl.l at http://www.nefsc.rimfs.gov/sos/econ/ (last revised Apr. 2001) ("Fishery Economic Trends").

45 It may be that supply is so available that there are no marginal increased costs.

46 Again, the steady decline in the dock-side price for winter flounder, despite fluctuations in supply, suggests among other things that, from the perspective of the consumer, winter flounder are fungible commodities.

EPA Response

For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits please see the response to comment 316bEFR.005.029.

Valuation of commercial fishing impacts is based on 0% to 40% of estimated gross revenue changes under the final rule. To recognize uncertainty about assumptions regarding changes in supply under regulated and unregulated fisheries, EPA assumes no market price changes and no change in consumer surplus under the final rule (see Section XII.D of the preamble for the final rule).

Pilgrim

The Pilgrim Case Study Overstates Benefits to Recreational Fisheries.

EPA did not conduct a study of the recreational fishery in the Pilgrim area. See Pilgrim Case Study at G4-7. Instead, EPA used data from a 1994 data set reported in Hicks, et. al (1999) from the Mid-Atlantic coast. The Hicks study attempted to determine a recreational angler's willingness to pay for an increase in catch rate of one (1) fish of a particular fish species for every fishing trip. For obvious reasons, the data is irrelevant to the question that EPA is trying to answer in the Pilgrim Case Study. Namely, what is the willingness of recreational fishermen to pay for the increase in catch rates that would be experienced based upon theoretical reductions in impingement and entrainment at Pilgrim. A proper study is important not only for the accuracy of the Pilgrim Case Study but, because the Pilgrim Case Study is used to extrapolate benefits nationally, the accuracy of national benefits. Moreover, and as explained below, EPA's inappropriate use of the so-called "50% Rule," to determine the value of non-use benefits, compounds the errors inherent in the calculation of benefits to the recreational fishery.

Beyond the substantial concerns over appropriate data, the methodology applying that data overstates benefits substantially. According to EPA's exaggerated calculations of entrainment and impingement losses, as set out in the Pilgrim Case Study, 13,731 winter flounder are lost to the recreational fishery due to entrainment. See Pilgrim Case Study at G4-8. The analysis resulting in that estimate is critiqued in UWAG Comments, Review and Methodology. EPA then applies modified values from the Hicks study, which apparently suggest a willingness to pay between $4.80 and $5.49 to catch one additional winter flounder per fishing trip. EPA multiplies the number of theoretical fish lost by the willingness to pay figures, and arrives at a total impact to the recreational fishery.

The simple flaw in this approach is that it fails to calculate the expected increase in catch rate that would be experienced for winter flounder, based upon even the optimistic benefits of the Rule. EPA has not compared the expected increase in recreational catch rates to the one (1) fish/trip assumption used by Hicks. For example, if the expected increase in recreational catch rate for a given species is less than one (1) fish/trip (say, 0.10 fish/trip), then the Hicks data is entirely useless. The actual question asked in the willingness-to-pay context should be: What is a recreational angler willing to pay to increase catch rates by 0.10 fish/trip? The answer almost certainly is far less than the $4.80 used by EPA.

Again, EPA must correct this significant error, as it leads to a benefit estimate that is substantially overstated.

EPA Response

In the cost-benefit analysis for the final 316(b) Phase II rule, EPA did not use benefits transfer methods to value losses to recreational fishing in the North Atlantic. Instead, EPA used a transfer of benefit function. For all other regions EPA estimated a random utility model (RUM). Please refer to Chapter A11: Estimating Benefits with a Random Utility Model (RUM) of the Regional Analysis Document for the final rule (Docket #6-0003).

In the cost-benefit analyses for the final rule, EPA did not use the 50% rule-of-thumb to estimate non-use benefits. See response to comment 316bEFR.005.034

Pilgrim and Seabrook

The Impacts to Forage Species Are Overstated, Since Impinged and Entrained Organisms Remain in the Food Chain.

EPA utilized two approaches to analyze the benefits associated with reduction in entrainment and impingement of forage species. EPA first relies on the production-forgone method, which assumes that the impinged and entrained organisms are unavailable to the food chain. EPA then estimates the impacts of this loss of food source on higher trophic levels within the food chain.

EPA's assumptions are suspect, if not incorrect. Biomass is not removed from the system by impingement and entrainment, even if one assumes that all impinged and entrained organisms die. The biomass passes through the CWIS and remains available to predator species. In addition, this method assumes that the prey species are food resource limited (i.e., but for a limited food supply, there would be more members of the population). EPA does not substantiate that assumption for the forage species of interest. If a species is food limited, then non-entrained and non-impinged members of the population achieve a competitive advantage due to the reduction in the number of individuals competing for the limiting resource. For these and other reasons, the production forgone figures are overestimates.

EPA also utilizes the replacement cost method by analyzing the costs of operating a hatchery to produce the numbers of fish eggs/larvae entrained or impinged by the Station. Since the site (and cost) of any hatchery must be matched to a proper measure of impact, these costs are vastly overstated.

EPA Response

EPA disagrees with the commentary's assertion that the biomass of I&E fish discharged back to the water body return to the ecosystem and serve as food for predatory species. Although it is possible that dead biomass discharged from facilities might be directly consumed by some predatory species, EPA does not accept that this would be a common occurrence because most predatory species will prey preferentially on live, swimming prey items. Insofar as any discharged biomass is consumed by fishes, EPA maintains that it is far more likely that they will be consumed by scavenger species that are themselves not frequent targets of fisheries. EPA maintains that the mostly likely fate of discharged biomass is slow decomposition and eventual consumption by invertebrate species and microbes. In either case, this represents a major step downward in a food web, so the residual value of the biomass as a harvestable foodstuff is negligible because of inefficiencies in trophic transfer within a food chain that spans from detritus and small detritivores to top predators.

EPA did not use habitat-based replacement costs or hatchery replacement costs in its final Phase II benefits analysis. For additional information, please see the document entitled "Habitat-based Replacement Cost Method" (DCN 6-1003) and EPA's response to Comment #316bEFR.005.035.

Valuing Forage Species (incl non-use and non-landed)

EPA's Approach to Valuation of Non-use Benefits Is Based upon Dated Material and Is Entirely Inappropriate.

EPA relies exclusively on Fisher and Raucher (1984) to value the non-use benefits of the proposed Rule at 50% of the benefits to the recreational fishery. According to EPA's analysis, non-use benefits account for approximately 28% of total benefits. See Pilgrim Case Study tbl. G4-24. Thus, non-use values contribute substantially to EPA's overall estimate of benefits. <FN 47>

EPA's approach is arbitrary. EPA has selected an 18-year-old study to support its adoption of the 50% Rule. Even by EPA's own admission, the Fisher and Raucher study is dated. See Case Studies at A9-10. Moreover, the Fisher and Raucher study examined the issue of non-use benefits associated with improvements in water quality rather than the more narrow issue of reductions in impingement and entrainment. The distinction is important, since the theoretical benefits of improved water quality sweep even more broadly (to include public health, habitat viability, etc.) than the theoretical benefits of a reduction in impingement and entrainment. The proposed Rule is not targeted at improving overall water quality.

The literature reflects substantial disagreement over the application of non-use values in cost benefit analyses. Economists have outlined difficulties defining critical terms such as existence value. See Bruce Madariaga & Kenneth E. McConnell Exploring Existing Value, 23 Water Resources Res. 936 (1987) (Appendix 11); V. Kerry Smith, Uncertainty, Benefit-Cost Analysis, and the Treatment of Option Value, 14 J. Envtl. Econ & Mgmt. 283 (1987) (Appendix 12). Those difficulties have not been overcome. See Jonathan Aldred, Existence Value, Welfare and Altruism, 3 Envtl. Values 381 (1994) (Appendix 13). More recent studies suggest that the concept of existence value is inconsistent with fundamental principles of economics and, in fact, does not exist. See Hans-Peter Weikard, The Existence Value Does Not Exist and Non-Use Values Are Useless, prepared for the European Public Choice Society (2002) (Appendix 14). EPA should undertake an appropriate review of the literature before deciding whether, and how, to value non-use benefits under the proposed Rule.

EPA's arbitrary selection of a single study from the literature also conveniently sidesteps the difficulties of preparing a survey or other measurement tool to accurately quantify non-use benefits, if they exist at all. For example, Professors Diamond and Hausmann conclude that contingent valuation surveys (the predominant means of quantifying non-use benefits) do not measure the economic preferences they attempt to measure. Peter A. Diamond & Jerry A. Hausmann, Contingent Valuation: Is Some Number Better Than No Number?, J. Econ. Perspectives, Fall 1994, at 45 (Appendix 15). It appears that most economists agree that it is very difficult, if not impossible, to craft a survey to measure the non-use value at issue. Diamond and Hausmann recount the substantial concern over the effect of question order, and the impacts of respondents who may not care about the resource but do care about the activity causing a harm to a resource. In the latter instances, the surveys tend to measure overall concern over certain industrial activities rather than a valuation of the resource. These and other well-documented shortcomings of non-use benefits analysis are simply ignored by

EPA.

Even if concepts such as existence value exist, and assuming they can be measured accurately, there is experimental evidence that EPA’s application of existence value under the proposed Rule is misguided. For example, Professor Fredman studied existence value as applied to the health of a population of wildlife. In that study, Fredman discovered that even if a person’s willingness to pay for the continued existence of an endangered species is positive, that same person’s willingness to pay for an increase in population density of a non-threatened species is zero. Peter Fredman, The Existence of Existence Value - A Study of the Economic Benefits of an Endangered Species, 1 J. Forest Econ. 307 (1995) (Appendix 16). The Fredman study applies directly to the Pilgrim Case Study, since none of the species impinged or entrained at Pilgrim is threatened with extinction. Consequently, the willingness to pay for an increase in the population density of species impinged or entrained at Pilgrim may well be zero. <FN 48>

EPA’s approach to non-use benefits is outcome determinative and shows a tremendous reluctance to engage in any serious analysis of the issues. Until EPA tackles the substantial problems inherent in its arbitrary approach, it should eliminate non-use benefits from the analysis.

Footnotes

47 As mentioned above, the “50% Rule” compounds errors inherent in the analysis of benefits to the recreational fishery.

48 It also stands to reason that an individual fish has no existence value, since it would die of natural causes many times over before the next generation could enjoy it. As has been pointed out by Messrs. Barnthouse, Coutani and Van Winkle, Status and Trends of Hudson River Fish (Appendix 3) and others, populations rather than individuals persist through time. Thus, any existence value would and should be tied to the viability of a population rather than an individual or group of individuals. This is supported by the Fredman study.

EPA Response

For EPA's response to comments on the use of the 50% rule-of-thumb to estimate non-use benefits, please refer to EPA's response to comment #316bEFR.005.034.

Please also refer to EPA's response to comments on the HRC methods (316bEFR.005.035) and the SRP methods (316bEFR.005.006); the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003); and to EPA’s Guidelines for Preparing Economic Analyses (EPA 240-R-00-003).

As noted by the commenter, there is debated in the economics profession and other related professions about the challenges of measuring non-use values. For details on EPA's non-use analyses please see Chapters A12, Non-use Meta-analysis Methodology, and A9, Economic Benefit Categories and Valuation Methods of the final Phase II Regional Studies Document (DCN #6-0003). Please also see Chapter D1 of the final Phase II EBA document regarding break-even analysis (DCN #6-0002).

For a discussion on the feasibility and challenges of doing original state preference research please see EPA's response to comment #316bEFR.316.105.

Pilgrim and Seabrook

Ultimately, EPA Could Achieve the Same Ecological Benefit Using More Cost-effective Strategies.

As a point of reference for the benefits analysis, it is useful to note that the reduction in the loss of fish eggs and larvae to the levels demanded by the Rule could also be achieved by a reduction in either commercial or recreational landings. For example, according to the Pilgrim Case Study, the mean annual entrainment of winter flounder at Pilgrim Nuclear Power Station is approximately 31 million organisms. According to the life history data provided by EPA, a female winter flounder produces between 500,000 and 1.5 million eggs annually. Assuming mean of 1 million eggs annually, a reduction in the commercial or recreations catch of 31 female winter flounder achieves the same ecological benefit as eliminating entrainment of winter flounder at Pilgrim. Assuming an adult, female winter flounder weights approximately 2 pounds, and using the 1999 dockside price/pound of Trends, the market price for those 31 fish is approximately $78.74

Thus, the impacts targeted by the Rule, which proposes the expenditure of tens of millions of dollars for each existing facility, could be achieved by the payment of costs several orders of magnitude lower than that proposed by the Rule. EPA should consider alternative solutions to capturing the ecological benefits it seeks in the proposed Rule, before imposing the enormous cost of compliance on each existing facility.

EPA Response

EPA notes that the commenter has not provided an alternative strategy that could achieve the same ecological benefit as today's final rule using more cost-effective strategies. If the commenter is suggesting that EPA reduce commercial or recreational landings, these issues are beyond the scope of 316(b). For explanation for the basis of today's final rule, please see the final rule preamble.

Subject Matter Code 10.02.03

Use of Replacement Costs (HRC and hatchery-based)

EPA's HRC Methodology is Fatally Flawed

In the Rule, EPA proposes to employ the so-called Habitat-Based Replacement Cost ("HRC") methodology to calculate the proposed benefits of the Rule, stating that the HRC method provides "a more comprehensive indication of the benefits of reducing entrainment and impingement on all species, including forage species." See 67 Red. Reg. at 17193. In two case studies (including one for Pilgrim Station), EPA applies the HRC methodology, deriving what the Agency contends are benefits-transfer values. See 67 Fed. Reg. at 17199. While conceding that the HRC analysis represents an "upper bound," EPA nonetheless applies the methodology to Pilgrim Station, producing a theoretical estimated benefit of eliminated entrainment and impingement in excess of $9.0 million in 2001 dollars. Id.

EPA's use of the HRC methodology is irremediably inappropriate. Even if the methodology were not, as it is, wholly at odds with settled economics (as a mechanism for evaluating the purported benefits of reduced entrainment and impingement), the Agency's application of the HRC in the Pilgrim Station Case Study reveals numerous fundamental, if not misleading, assumptions, which compel the irrefutable conclusion that EPA's approach is irrevocably biased.

NERA evaluates EPA's effort to employ the HRC methodology. NERA, Economic Evaluation of the Habitat Replacement Cost Methodology in the U.S. Environmental Protection Agency's 316(b) Benefits Case Study for Pilgrim Station (Aug. 2002) ("HRC Evaluation") (Appendix 17). As NERA notes, EPA's use of the HRC is inconsistent with basic economic principles and therefore fundamentally and conceptually flawed, insomuch as the HRC only can be appropriately employed in conjunction with an assessment of costs, not of benefits as EPA proposes to do in the Rule. See id. Indeed, NERA concludes that EPA's reliance on the HRC methodology, as undertaken in the Rule and Case Study, is so erroneous as to be misleading. See id.; see also UWAG Comments.

NERA also evaluated EPA's application of the HRC methodology to Pilgrim Station, on the assumption that doing so could provide some insight into how EPA intended the methodology to be employed. As NERA concludes, EPA's application of the HRC is as flawed as the methodology and, again, biased toward increasing the purported benefits of the Rule. See HRC Evaluation (Appendix 17). As NERA concludes, based upon its economic expertise EPA's use of the HRC is "fundamentally misleading," in part because it: (1) has cobbled together the model as a substitute for a thoughtful and credible commercial and recreational fisheries assessment; and (2) has created results which exaggerate benefits by at least twenty fold, as calculated by NERA revealing either the wholesale misconception of the benefits analysis and the HRC methodology, or a deliberate bias. See id. Indeed, NERA characterizes as among the HRC's "arbitrary assumptions:" EPA's unexplained and unsupported "preferred habitat" selection process; its improper use of species abundance as a measure of production; its blind failure to accurately identify, explain and correct obvious sampling limitations; and its inexplicable insistence on a one-to-one replacement, even for large projects. See Id.

Again assuming that the HRC were, as it is not, valid, Entergy also retained ENSR to evaluate the biological assumptions in EPA's application of the HRC in the Pilgrim Case Study. See ENSR Comments (Appendix 2). As ENSR's analysis concludes, "[t]he application of the HRC method to [Pilgrim Station] includes several inaccurate and/or inappropriate assumptions as well as a miscalculation of site-specific conditions." See Id. at 6. Among these several errors are the following: (1) EPA's HRC analysis includes costs for species addressed in the commercial/recreation fisheries analyses; (2) EPA's unexplained use of annualized, as distinct from present-value, costs; (3) EPA's use of abundance data as a surrogate for productivity, with the result that EPA has grossly overestimated needed restoration; (4) the absence of site-specific information; (5) the failure to consider relevant, and less costly, mitigation measures, such as fish hatcheries and stocking; (6) the inappropriate use of flawed "baseline" conditions; (7) reliance on inappropriate restoration-cost data from non-analogous circumstances; and (8) unreasonable monitoring costs. See Id. at 6-11.

Each of these is detailed in the ENSR Comments (Appendix 2), the contents of which are not repeated here, except with respect to EPA's use of abundance data as a surrogate for productivity data. More particularly, in the HRC methodology EPA would apply, it expects regulated entities to implement restoration measures adequate to replace perceived entrainment or impingement impacts. <FN 49> In conducting its analysis of Pilgrim Station, for instance, EPA determines the required tidal wetlands acreage necessary to off-set presumed winter flounder impacts in terms of age-1 winter flounder. This approach necessarily underestimates the real contribution of such wetlands, which - among numerous other benefits - operate as a spawning habitat for individuals that migrate beyond its boundaries and go on to produce young elsewhere. Indeed, ENSR concluded that "the majority of eggs, larvae, juveniles, and adult fish produced may not be retained in or use the tidal wetland as a long-term habitat, but will likely enter the larger marine ecosystem." See Id. at 7. As such, EPA's failure to consider this additional production therefore materially understates the benefits of the wetlands in question, creating a false conclusion to a muddled analysis.

In short, there is simply no reasonable basis for employing the HRC analysis, which should be eliminated from the Rule.

Footnotes

49 EPA's calculations of impacts is likewise flawed, as discussed at length by the ENSR Comments (Appendix 2), insomuch as it seriously overestimates impacts. For these reasons, EPA's application of the HRC methodology is doubly flawed.

EPA Response

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule. Please see EPA's response to comment #316bEFR.005.035 and the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method.

Please also see EPA's response to comments on HRC production estimates, comment #316bEFR.029.113.

With respect to comments on the annualized vs. present value costs - when EPA was examining the HRC in the context of specific case studies, it needed to convert present value costs into their annualized equivalent in order to facilitate a suitable comparison to other parts of the economic analysis, because all the other aspects of the analysis were developed in an annualized form (such as annualized compliance costs or annualized benefits).

Subject Matter Code 3.03

Definition: Waters of the U.S.

EPA SHOULD EXCLUDE OPERATIONAL WATERS FROM THE RULE.

Reservoirs constructed as cooling ponds for a specific facility are not properly subject to the Rule. See, e.g., Solid Waste Agency v. U.S. Army Corps of Engineers, 531 U.S. 159 (2001) (clarifying the definition of waters of the United States to exclude certain isolated water bodies). These bodies of water are extensions of facility operations, not naturally occurring waterbodies. For this reason, treatment of them as waters of the United States is inappropriate. Id. As such, these reservoirs and cooling ponds should already be considered closed-systems and, therefore, exempt from § 316(b).

EPA Response

Subject Matter Code 10.1

General: cost tests

EPA'S BENEFITS-COST DISCUSSION FOR THE RULE IS WOEFULLY INADEQUATE.

The United States Office of Management and Budget ("OMB") issued guidelines to assist agencies, such as EPA, in their efforts to estimate the benefits and costs of proposed regulations, such as the Rule. See OMB, Economic Analysis of Federal Regulations under Executive Order 12866 (Jan. 11, 1996). OMB's guidelines compel EPA to assess the relative advantages and disadvantages of alternatives in support of regulatory decisions which will have a significant effect on an industry, as the Rule will, pursuant to Order 12866. See Order 12866. EPA's own guidelines, likewise compel a searching benefits-costs assessment. See EPA, Guidelines for Preparing Economic Analysis, Report No. 240-R-00-003 (Sept. 2000).

The Rule does not meet the letter or spirit of the requirements of Order 12866, OMB's guidelines or EPA's own mandates. Nowhere in the Rule or the administrative record, including in EPA's Eco/Ben Analysis, is the benefits-costs analysis EPA has employed to evaluate its proposed decision making adequately or appropriately set forth. Thus, for instance, EPA does no identify or outline the methodology for evaluating or performing its benefits-costs analysis. Likewise, the underlying technical documents, which should contain the information on which EPA must rely, amount to nothing more than a series of superficial spreadsheets outlining the most perfunctory information about power plants, frequently divided among North American Electric Reliability Council ("NERC") regions, e.g., the percentage of fossil-fuel units, without identifying why the NERC delineation or the information itself is relevant or how it is applied in the benefits-costs analysis.

Further, where EPA does undertake any analysis, its approach is invariably inadequate. Particularly infirm, for example, are EPA's efforts to compare technology costs to gross revenues, and its corresponding conclusion that, based upon this flawed comparison, technology costs are acceptable. See Phase II Eco/Ben Analysis at B2-2 to B203; UWAG Comments, Role of Benefit-Cost Analysis. Indeed, in its Report, TER states that EPA's comparison of compliance costs to revenues, among other financial tests: (1) "have no conceptual basis in economic theory or policy science;" (2) have "no connection" with "accepted economic efficiency or even equity measures;" and (3) "fail to account either for economic benefits provided by CWIS investments or their environmental costs." UWAG Comments, Role of Benefit-Cost Analysis (emphasis supplied).

Likewise, EPA's proposal for uniform "performance standards" ignores the variability in the costs and benefits of any specific location, effectively undermining the stated purpose of the Rule, i.e., appropriate application of § 316(b) in a manner that correlates to measurable benefits. As TER concludes, "BTA cannot be identified on an industry, regional, facility-type or waterbody-type basis, except when a group of sites is truly comparable, both in physical and environmental effects and the value of associated environmental services." Id. at 10.

By way of example, EPA fails to provide sufficient rationale for its decision to distinguish its proposed performance standards by waterbody type. Though EPA purports to recognize that “different waterbody types have different potential for adverse impacts,” 67 Fed. Reg. at 17140, its meager exploration of those differences includes only a theory that estuaries and tidal rivers have a “higher potential for adverse impact because they contain essential habitat and nursery areas” for many commercial and recreational important fish, and thus warrant the highest entrainment measures that have been proven to sustain populations of estuarine fish species in the face of environmental stressors, including impingement and entrainment. See UWAG Comments, Role of Benefit-Cost Analyses. <FN 50>

Likewise, EPA’s failure to distinguish between regulated and unregulated facilities renders the proposed Rule infirm. To survive challenge, in the Rule, EPA must account for the significant relevant distinctions between regulated and unregulated entities. See, e.g., Appalachian Power Co. v. EPA, 249 F.3d 1032, 1061-63 (D.C. Cir. 2001). In Appalachian Power, non-electric generating units (among other entities) challenged EPA’s final rule on NOx emissions, which held cogenerators to the same high (and costly) emissions standard as utilities. Id. In its rulemaking, EPA reasoned that deregulation had a dramatic impact on the industry, obviating the distinction between utilities and non-utilities. Id. at 1062. <FN 51> The D.C. Circuit remanded EPA’s classification of cogenerators as electric generating units (instead of non-electric generating units), on the grounds that EPA’s failure to explain its classification did not allow the Court to adequately assess EPA’s decision making. Id. at 1063. Explicit in the Court’s decision is the noteworthy fact that EPA had failed to demonstrate that cogenerators would be able to achieve the requisite NOx emission reductions at the same costs as other (utility-owned) electric generating units. Id. Implicit in the decision is the importance in such an analysis of how costs may impact different, i.e., regulated versus non-regulated, entities. Id. Indeed, EPA conceded as much by its supplemental rulemaking. Id. at 1062.

The failure to account for the important distinction between how regulated and non-regulated entities experience costs is particularly glaring in the proposed Rule, since EPA, in its Eco/Ben Analysis, maintains “[t]he conceptual basis of... section 316(b) regulation in particular is the need to correct imperfections in the markets that arise from uncompensated environmental externalities.” Phase II Eco/Ben Analysis at A2-8. Even if EPA were, in fact, charged with market correction, which it is not, its efforts to undertake a correction are improper, because of the Agency’s failure to account for the differences between regulated and unregulated entities. In addition, the EPA should consider the distinction between peaking and baseload units, as well as nuclear and fossil-fuel electric-generating stations. In each case, the distinction impacts the costs likely to be incurred as a consequence of the Rule, as well as certain alleged benefits which EPA maintains may result from the Rule.

Footnotes

50 Even if EPA’s proffered rationale for imposing the highest performance standard on estuaries is valid, it fails to explain its decision to hold oceans and the Great Lakes to the same high standards. This failure results in a particularly unreasonable result as the Rule is applied to facilities located on the Great Lakes. There, such factors as the introduction of exotic species (sea lamprey and zebra mussels), resource management programs including restocking, eutrophication, overfishing, pollution, shoreline development, and water level changes control the relative viability of fish fauna of the various lakes. Due to these stresses and manipulations of the Great Lakes ecosystems, heroic efforts to reduce entrainment and impingement losses are unlikely to translate into noticeable improvements in the fish community. Thus, as applied to facilities on the Great Lakes, EPA’s proposed performance standard is meaningless and arbitrary. This particular flaw in the Rule is demonstrative of the disastrous effect of EPA’s overall failure to consider and discuss its distinctions among various types of waterbodies in setting performance standards.

51 Obviously and appropriately unconvinced by its own argument, EPA issued a supplemental notice of proposed rulemaking for the proposition that “there is no relevant physical or technologica1 difference between utilities and other power generators.” Id (quoting 63 Fed. Reg. at 25923). EPA should abide its past practice and do the same here, thereby

ensuring appropriate opportunity for public comment.

EPA Response

The Agency in fact did provide a benefits-cost analysis of the regulatory alternatives in the Section X of NODA (68 FR 13521-13587). See response to comment 316b.EFR.206.047 for further response to comments asserting EPA's benefits analysis was incomplete.

Regarding cost to revenue comparisons, the Agency utilized these comparisons in addition to a much more rigorous approach for analyzing benefits for the NODA and final rule. See the final EBA.

Regarding performance standards, the Agency first notes that the commenter is incorrect in stating that the Agency's proposed standards were "uniform" or that the proposal "ignores the variability in the costs and benefits of any specific location." The Agency first points out that it proposed a range of performance standards, thereby contradicting the commenter's assertion that the standards were "uniform". Next the Agency notes that it published revised cost estimates for the NODA that take into account the variability in costs and performance of a wide range of technologies based and applied these technologies based on site-specific data. The costs adopted by the Agency for the final rule reflect the variability in costs between locations, based on the physical characteristics and the environment of the site. Finally, today's rule authorizes a number of compliance alternatives, including the use of TIOP with the Director's approval, to account for variability and site-specific factors.

The Agency disagrees with the commenter's assertion that the Agency has not provided sufficient rationale to distinguish performance requirements between waterbody types.

Regarding the commenter's assertion that the Agency has failed to distinguish between regulated and unregulated facilities, see 060.060. In addition EPA did examine varying cost between peaking vs. baseload and nuclear vs. non-nuclear.

Option: Site-specific determination of BTA

IMPLEMENTING THE RULE, EPA SHOULD ADOPT A DEFENSIBLE AND EQUITABLE BENEFIT-COST ANALYSIS.

As discussed below, the Rule adopts a novel approach to § 316(b) decision making, rejecting three decades of practice for generic national standards. This approach is not appropriate.

Rather, EPA should select an appropriate mechanism for making site-specific determinations. As discussed below, such an approach should involve a site-specific benefits-cost analysis, not the use of national performance standards which, perhaps inadvertently, foster inequity. To that end, Entergy supports a benefit-cost analysis as the framework for evaluating and comparing costs and benefits of technologies, if any, available for minimizing AEI, if any. More particularly relative to the benefit-cost analysis, Entergy has reviewed and supports EPA's use of the TER's analysis. See UWAG Comments, Role of Benefit-Cost Analyses, see also NERA, Economic Evaluation of EPA's Proposed Rule For Cooling Water Intake Structures for New Facilities, (Nov. 2000), UWAG Comments. Both identify a reasoned framework for an appropriate benefit-cost analysis in the context of the Rule.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b) determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact associated with cooling water intake structures.

Option: Site-specific determination of BTA

EPA Should Adopt a Clear Site-Specific Approach, Instead of the Performance Standards in the Rule.

For several decades, EPA has approached § 316(b) determinations in a site-specific manner. The Agency's early guidance (still in draft form after a quarter century) and even its original, now-suspended § 316(b) regulations contemplated site-specific BTA determinations. EPA's and virtually every state's practice is site-specific yet, without explanation, EPA now proposes a very different approach, that of generic national performance standards.

EPA's new approach is not sound environmental policy and fosters inequity. Indeed, a generic approach creates dissonance with other regulators, in contravention of Executive Order 12866 ("Each agency shall avoid regulations that are inconsistent, incompatible ... with its other regulations or those of other Federal agencies."). More particularly, the NRC, in NUREG-1437, identifies generic categories of environmental issues to be considered in the context of relicensing of nuclear facilities. Many are designated as site-specific issues, i.e., Category 2 issues. Among the enumerated site-specific issues are "Entrainment of Fish and Shellfish" and "Impingement of Fish and Shellfish." Thus, the NRC has concluded, based upon available information, that entrainment and impingement are appropriately addressed as site-specific issues in the context of its nuclear re-licensing proceedings.

Likewise, EPA's efforts to avoid a site-specific approach contravene the very nature of the analysis that § 316(b) requires. The reasons are simple. First, assessing and "minimizing" adverse environmental impacts is an inherently site-specific process. The scope, degree and effects of entrainment and impingement necessarily depends on site-specific factors, e.g., the waterbody, the shape of the shoreline, the location and configuration of the intake, the species present at the site, and other factors. Likewise, the feasibility, effectiveness, environmental impacts and cost of technologies to reduce CWIS impacts vary tremendously from site to site. As discussed throughout those comments, certain technologies (barrier nets, for example) cannot be used at nuclear facilities. Further, even available intake technologies have impacts on navigation or on ecosystems which should be considered in making § 316(b) decisions. For such facilities, a generic approach achieves little, at a high cost. Accordingly, EPA should revise the Rule to focus on assessing site-specific factors that determine the impact of entrainment and impingement. <FN 52>

At the heart of EPA's policy reversal are two implicit motivations, neither of which will support so radical a policy change: (1) the Agency's frustration regarding the theoretical impacts of entrainment and impingement; and (2) purported regulatory ease. EPA's frustration is misplaced. As discussed above, sound science supports the conclusion that CWISs may not create adverse environmental impacts. Likewise, regulatory streamlining, is not apt to result from a generic approach. Rather, facilities that suffer from the inequities of the generalized standards of performance in the Rule will be inclined to take action, including through litigation, a more costly and time-consuming result for regulators and regulated entities. In short, while Entergy appreciates EPA's efforts to achieve consistency, those efforts should be directed to creating a process for consistent implementation, not to creating generic, and therefore necessarily arbitrary, standards of performance.

Footnotes

52 Although Entergy recognizes that EPA's Rule is "site-specific" in some respects, the "significantly greater" test is not enough to respond to the flaws in a generic approach.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b) determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact associated with cooling water intake structures.

The rule does not require a determination of whether an adverse environmental impact is occurring is a preliminary step in implementing 316(b). Please refer to the response to comment 316BEFR.313.001 for more information on EPA's position on minimum impacts at existing facilities.

Subject Matter Code 10.1

General: cost tests

EPA's Approach Fosters Inequity.

Further, EPA's flawed reliance on superficially similar performance standards, including the supposed safeguard of alternative decision making (through the "significantly greater" test), masks important differential impacts on different categories of facilities, e.g., nuclear as compared to fossil-fuel facilities. Careful review reveals what may be serious inequities in the application of the Rule, particularly relative to nuclear facilities, absent clarification from the Agency.

In particular, the Rule allows site-specific decision making in lieu of compliance with applicable "performance standards," an approach Entergy supports subject to its above concerns, as follows:

[Y]ou must demonstrate to the Director that your costs of compliance with the applicable performance standards ... would be significantly greater than the costs considered by the Administrator when establishing performance standards, or that your cost would be significantly greater than the benefits of complying with such performance standards.

67 Fed. Reg. at 17321; proposed 40 C.F.R. § 125.94(c)(1).

The Rule continues by indicating that, where costs are dispositive, EPA will make its BTA determination based upon "less costly design and construction technologies, operational measures, and/or restoration measures to the extent justified by the significantly greater cost." 67 Fed. Reg. at 17321; proposed 40 C.F.R. § 125.94(c)(2). In other words, a facility able to demonstrate that certain technologies are too expensive (as defined by EPA) can undertake alternative measures up to the mysterious baseline created by the "significantly greater" test. <FN 53> Where only a single, but too costly, technology is available to meet EPA's performance standards, as is likely the case for nuclear facilities, voluntary restoration or operational measures become the presumptive "alternative measure."

To answer the question, "What costs must be expended to satisfy, in EPA's estimation, §316(b)," however, EPA provides only an ambiguous measure, namely the costs considered by the Agency when establishing its performance standards. To redress this confusion, Entergy requests that EPA clarify what we understand to be the Agency's position, namely that the appropriate comparison is whether a particular facility's estimated costs of compliance exceed EPA's reasoned estimate of the average costs of compliance for the least-cost alternative actually implemented at facilities with comparable flow, recognizing that the comparable facilities for nuclear facilities generally, if not invariably, will be fossil-fuel facilities. <FN 54> Thus, restoration measurements would need to be comparable to the costs estimated by EPA in Chapter 2 of the TDD, Appendix A, for screening devices. Because the Rule is unclear, Entergy would appreciate the Agency's confirmation that these costs redress entrainment and impingement impacts.

EPA should clarify its intent. Entergy further suggests that EPA do so by defining "significantly greater costs” to be “those costs that exceed, by a significant margin, identified as those costs equal to or excess of 25%, the average costs of least-cost technology actually installed at an existing facility of comparable flow to assure compliance with the Rule. For nuclear facilities, a facility with comparable flows may include fossil-fuel facilities.” Further, because the Rule is unclear, we would appreciate the Agency’s confirmation that these costs redress entrainment and impingement impacts.

Footnotes

53 By way of further detail, there may be no reasonable alternative technologies for certain nuclear facilities. For instance, the Gunderboom and other barrier systems are highly unlikely to be “available” technologies for facilities with existing waterbodies that function as the “ultimate heat sink” or serve a nuclear-safety purpose. Given these factors, nuclear facilities may be particularly apt to use restoration measures.

54 Furthermore, in determining the appropriate level of restoration measures, EPA should recognize and take into account costs of technology previously installed in response to § 316(b) concerns.

EPA Response

See section IX.H of the preamble to the final rule for a discussion of the cost-cost test.

For discussion of the definition of "significantly greater costs", see response to comment 316b.EFR.006.003. The Agency did not accept the recommendation of the commenter regarding the definition of significantly greater.

Regarding the concern of the commenter regarding nuclear facilities and the cost to cost test, the Agency notes that a facility compares its costs to those estimated by the commenter for that facility. Therefore, for a nuclear plant, the costs of comparison are for the costs of that particular nuclear plant, with the option to correct the costs based on particular site- verified factors. This is an equitable basis of a cost to cost test for different types of facilities, as the costs would be reflective of the site-specific costs of the facility to comply with the rule requirements and no inequities would arise.

Implications for nuclear facilities

ENTERGY SUPPORTS EPA'S DEFERENCE TO NRC, BUT EPA MUST CONSIDER ECONOMIC IMPACTS.

In the Rule, EPA indicates that it will defer to NRC regarding matters of nuclear safety. This is appropriate as a matter of federal preemption and, therefore, supported by Entergy.

Even if federal preemption did not guide EPA's conclusion, as it does, EPA's deference to NRC is otherwise warranted by the correlation between nuclear safety and water-supply at many, if not most, nuclear facilities, including the Entergy-owned stations. In particular, water systems represent the "ultimate heat sink," or source of water supply necessary to safely operate, shut down and cool down a facility, for nuclear operations. See Ultimate Heat Sink for Nuclear Power Plants, REG GUIDE 1.27 (Jan. 1, 1976) ("Ultimate Heat Sink Guidance") (defining "ultimate heat sink"). To that end, a nuclear-powered electric-generating station's water supply is carefully regulated by NRC, particularly with respect to the adequacy and suitability of existing and proposed water systems to meet applicable NRC criteria to ensure that its safety objectives can be accomplished. See, e.g., 10 C.F.R. Part 50, App. A, "Licensing of Production and Utilization Facilities," General Design Criteria 44 and 2; see also Ultimate Heat Sink Guidance (discussing General Design Criteria 44 and 2).

As the NRC makes clear in its regulatory guidance on such matters, its approach to confirming the availability, under worst-case scenario conditions, of each facility's ultimate heat sink is highly conservative. See Ultimate Heat Sink Guidance at 3 ("Because of the importance of the sink to safety, these functions [must] be ensured during and following the most severe natural phenomena postulated for the site (e.g., the Safe Shutdown Earthquake, design basis tornado, hurricane, flood, or drought."). Thus, for instance, NRC requires a "high level of assurance" that the water sources of the sink will be available, when needed. See id. at 3.

To meet this standard, the NRC ordinarily requires redundancy in these critical systems, achieved by requiring two water sources, each capable of performing an independent safety function. See id. Further, the systems must be effective for an extended, i.e., thirty-day, period, during which safety-related water must be available, obviously requiring a substantial available water resource. See id. at 2.

Because of the need for independence, in conjunction with the amount of water required, NRC's preferred mechanisms for meeting these requirements are "a large river," "an ocean," and other similar resources. See id. at 4. While NRC will accept cooling towers for this purpose, there must ordinarily be redundancy, either through natural or additional man-made water sources. See id. Thus, for instance, the NRC will accept a "mechanical cooling tower with a basin" (capable of meeting NRC's Seismic Category I standard), only in conjunction with another such tower, a river or a lake. See id. Further, these multiple water sources, including their associated retaining structures, canals, conduits and piping, must be separate, so that failure of one will not alter another's capabilities to function as the ultimate heat sink. See id.

By way of example, if an existing facility that relies on a large river as its ultimate heat sink proposes to install cooling towers, NRC likely would require that both the cooling towers and the river act as ultimate heat sinks. As a result, absent its ability to demonstrate an "extremely low probability" of failure in a single source, the facility would have to construct independent piping between the Station and both the river and the cooling towers, both of which would have to meet NRC's stringent standards. <FN 55>

In short, as is evident from the applicable NRC requirements, the NRC, thus, will carefully scrutinize, and must approve, any reconfiguration or alteration of water sources that meet the ultimate heat sink. Clearly, cooling tower retrofits are more likely than not to alter the existing approved ultimate heat sink for nuclear facilities. As such, any implementation of §316(b) must account for NRC's involvement and its dispositive authority with respect to matters of nuclear safety.

Footnotes

55 As discussed above (in Section III.C), EPA has not accounted for these costs in the Rule, as it relates to nuclear facilities, an omission which renders the Rule's estimated costs of cooling-tower installation grossly inadequate as applied to nuclear facilities.

EPA Response

Today's final rule allows for a site-specific determination of best technology available if requirements conflict with Nuclear Regulatory Commission safety requirements (see § 125.94(f)).

Assumptions about I&E survival

Overestimate of Benefits of Regulation

ENSR is concerned that EPA may have overestimated the stated benefits of the regulation. One of the assumptions used in the benefits analysis is 100% mortality for all entrained organisms. Several studies (discussed in more detail in EPRI/UWAG comments on the proposed regulation) have shown that for many species there is significant survivability associated with entrainment. For example, a survival study of winter flounder eggs at Pilgrim Nuclear Power Station (PNPS) showed a survivability of 73%. In addition, the information presented by EPA in Chapter A7-3 of the Case Study Analysis indicates that previous studies have shown survivability of winter flounder larvae of 36% at Brayton Point Station, 65% at Port Jefferson Generating Station, and 10% - 90% at Oyster Creek Nuclear Generating Station. ENSR believes that these data indicate a level of consistency that clearly shows a significant level of entrainment survivability that should considered in both the development and implementation of the regulation. EPA's discussion on the Brayton Point, Port Jefferson, and Oyster Creek studies points out study limitations and concerns about the resulting data. However, similar limitations and data concerns exist for some of the environmental studies used by EPA for developing the draft regulation.

EPA Response

Please see the response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule. Please see the chapter, Entrainment Survival, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule for more information.

Fish Population Modeling

EPA has also assumed that there is no compensation for entrainment losses of eggs and larvae. Studies have shown (again, discussed in more detail in EPRI/UWAG comments) that natural systems compensate for such losses in order to maintain an adult population that is in dynamic equilibrium. An excellent example of compensation in a natural system is provided by blue mussel at PNPS and Seabrook Station. Blue mussel were sampled in the PNPS entrainment monitoring program during the early 1970's (Table G3-14) and in the Seabrook monitoring program during the 1990's (Table G3-6). Large numbers of blue mussels were entrained by the two facilities (2 trillion to 19 trillion at PNPS and 122 billion to 17 trillion at Seabrook) during these monitoring programs. The entrainment monitoring data indicate variability that is typical of biological systems, however the values in the 1970s at PNPS and the 1990s at Seabrook are generally comparable. The consistently high entrainment rate is indicative of a biological system that is able to compensate for the entrainment losses as well as all of the other stressors in the Gulf of Maine/Cape Cod Bay system. In fact, EPA essentially acknowledges that the benefit analysis method used in the draft regulation does not provide reasonable, realistic values for blue mussel by not including blue mussel in the benefit analysis (Chapter G4-3). EPA states (box on page G4-10) that the reason that blue mussel was not included in the analysis is because it is a nuisance species. The reason that blue mussel is a nuisance species is because it colonizes the intake structures in large numbers. Blue mussel's ability colonize in large numbers is largely due to its high productivity and ability to compensate for entrainment and other losses.

ENSR believes that adequate data currently exists to make reasonable estimates of the level of entrainment survivability and compensation for the benefits analysis in the regulation. Without the inclusion of such estimates, the benefits in EPA's analysis are overstated. In addition, as discussed below, errors in the values used by EPA overstate impingement and entrainment at PNPS, and correspondingly, the benefits of the regulation.

EPA Response

Please see responses to Comment 316bEFR.005.009 on fish population modeling and Comment 316bEFR.025.015 on compensation. The high numbers of blue mussel do not necessarily imply a compensatory response to I&E. Colonization and high productivity could account for the high numbers without needing to invoke compensation as an explanation.

Errors and Inconsistencies in Benefit Analysis.

It should also be noted that there are several apparent errors and inconsistencies in the benefit analysis. For example, as discussed in the comment below, the number of fish and the number, of age 1 equivalent fish impinged at PNPS are overestimated by EPA. In addition, even within the EPA analysis the values reported are inconsistent. Specifically, the value for the number of age 1 equivalent fish impinged at PNPS used by EPA for the benefit analysis was 52,800/year, as shown in Figure G6-5. However, this value is variously reported at other locations in the draft regulation and supporting documentation as 1.8 million/year (Exhibit 21), 52,700/year (Table C2-7), and 52,700 million/year (Table C2-7). Other errors and inconsistencies noted in the benefit analysis for PNPS are discussed below.

EPA Response

This comment refers to several documents prepared for proposal. Figure G6-5 of the Case Study Document (DCN # 4-0003) reports that total impingement losses at Pilgrim are 52,800 age 1 equivalents. Table C2-7 of the EBA (Docket #4-0002) reports that total impingement losses at one in-scope facility (Pilgrim) are greater than 52,700. This discrepancy is just a rounding issue. In Figure G6-5 EPA rounded the value to 52,800. In Table C2-7, EPA reported the value as greater than 52,700. Both are correct and the discrepancy is small.

Information provided to EPA by stakeholders

Errors in Reported Impingement Rate.

In Chapter G3, EPA evaluated the impingement impacts to aquatic organisms resulting from the PNPS CWIS. Data used for this evaluation were reportedly obtained from the estimates reported by PNPS. These estimates were based on impingement monitoring studies conducted weekly and extrapolated to obtain annual impingement numbers. However, review of the values in Chapter 03 (Table G3-10) revealed that a portion of the raw annual impingement values “as estimated by the facility” are not identical to and are generally much higher than those reported by PNPS, as illustrated in the following Table A.

Table A: A comparison of annual impingement rate values for selected species as presented in Chapter G3, Table G3-10 versus the values presented in the PNPS 1998 Semi-annual report

[see hard copy for table]

EPA Response

It is incorrect for the commenter to say that the data presented by EPA are "errors." In fact, as indicated in the footnote on page G3-14, in cases where the facility did not identify impinged organisms at the species level, or life history data were not available for species in the same family, EPA grouped the losses together under a single species.

In the case of Atlantic cod and windowpane flounder, certain species within the same family were grouped together due to a lack of detailed life history parameters.

The discrepancies for Atlantic mackerel and Atlantic herring losses are due to discrepancies within the various facility reports. The annual estimate of 12 for Atlantic mackerel losses in 1994 came from Table 5 in Section III.D of the following reference:

Boston Edison Company. 1995. Marine Ecology Studies Related to Operation of Pilgrim Station. Semi-Annual Report Number 45, January 1994-December 1994. April 30.

The annual estimate of 41,419 for Atlantic herring losses in 1991 came from Table 6 in Section III.D of the following reference:

Boston Edison Company. 1994. Marine Ecology Studies Related to Operation of Pilgrim Station. Semi-Annual Report Number 43, January 1993-December 1993. April 30.

EPA methods: age 1 equiv, yield, prod foregone

Overestimate of Impinged Age-1 Equivalents and Lost Fisheries.

Age-1 equivalents impinged were estimated from impingement losses following the method discussed in Chapter G3 and further detailed in Chapter A5. These values are larger than raw impingement numbers because EPA assumed that the age of impinged individuals was distributed between Age-1 through Age-2 and then losses were normalized back to Age-1 equivalents by accounting for mortality during that period. In general fish typically impinged at PNPS are juveniles of larger fish species and juveniles and adults of smaller fish species. Assuming that the age of impingement is equally distributed across the beginning of Year 1 to the beginning of Year 2 likely overestimates the Age-1 equivalents impinged of larger fish species since larger fish species impinged are usually juveniles.

EPA then extrapolated impinged age-1 equivalents to lost fisheries in pounds as discussed in Chapter G4 and further detailed in Chapter A5. This method to estimate forgone production conservatively assumes that impingement at the PNPS results in 100% mortality. Continuous washings of screens has been implemented at the plant following a study that revealed noticeably higher survival rates, including 50% or greater for the four most dominant species impinged during 1998.

EPA Response

EPA's final analysis does not assume that all impinged fish are age 1. Unfortunately, few facility studies provide information on the age distribution of impinged fish, so the Agency could not provide the public with this information. In EPA's original case studies, EPA assumed that all impinged fish were age 1. Based on comments on this assumption and a review of available information on the ages of impinged fish (e.g., EPRI 1999, DCN #4-4002B) final analysis for the 316(b) Phase II rule assumed that impinged fish range in age from juvenile to age 5 and that the age distribution of impinged fish is species specific and follows a fixed distribution as indicated by the set of stage-specific survival rates for each species. In all cases, this method leads to an assumed age distribution that is dominated by juvenile stages, followed by age 1-age 5 fish, each in decreasing relative abundance. EPA did not assume 100% mortality of impinged fish if data were available to demonstrate otherwise.

In the case of the Pilgrim facility, facility studies only examined survival at 1 hour post-impingement. EPA concluded that this is not a sufficient period of time for determining survival following impingement. Therefore, in this case, 100% impingement mortality was assumed.

Pilgrim

Errors in Entrainment Rate.

EPA evaluated the entrainment impacts to aquatic organisms resulting from the PNPS CWIS in Chapter G3 using entrainment monitoring study data reported by the facility. Review of Table G3-14 indicated that some of the raw annual entrainment values “as estimated by the facility” are not identical to those reported by PNPS. An example is provided in the following Table B.

Table B: A comparison of annual entrainment rates for fourbeard rockling as presented in Chapter G3, Table G3-10 versus the values presented in the PNPS 2000 316 Demonstration

Year	Fourbeard rockling	
	Case Study<1>	PNPS Report<2>
1990	161,001,461	87,189,946
1991	141,180,985	36,386,498
1992	126,361,457	59,249,285
1993	60,326,651	48,285,771
1994	60,933,441	42,364,073
1995	33,524,219	66,734,393
1996	29,396,000	27,287,342
1997	95,461,605	48,893,342
1998	140,083,704	81,559,688

<1> Case study indicates values used in EPA case study Chapter 03, Table 03-14
<2> PNPS Report refers to those values reported in the PNPS 1990-1998 Semi-annual Reports

In addition, mean annual entrainment values for PNPS estimated by EPA from data collected 1974 to 1999 overstate recent and current entrainment rates. Because of the decline in commercial fisheries between 1974 and 1990 due to numerous factors (dominated by overfishing and habitat loss), entrainment rates for commercial fish species during the 1990s and currently are generally lower than those from the pre-1990 period. For example, average annual entrainment values for pollock as estimated by PNPS and used in the EPA case study were only obtained from 1974 through 1976. Estimated values were 104,972,000 (1974), 2,144,710 (1975), and 21,137,710 (1976) (Table G3-14). Current annual entrainment values estimated by PNPS, but not included in the EPA Case Study evaluation did not exceed 260,000 between 1989 and 1998 (Table 5.4-1 2000 316 Demonstration Report). Therefore, the reported mean annual entrainment rate of 42,751,473 in Table G3-14 of Chapter G3 significantly overestimates and does not reflect the current entrainment rate.

Similarly, average annual entrainment values for rainbow smelt used in the EPA case study were only obtained from monitoring years 1974 through 1976. Estimated values were 30,105,000 (1974), 145,400 (1975), and 87,242 (1976) with a mean of 10,112,547. Current annual entrainment values (1989-1998) estimated by PNPS (but not included in the EPA case study) included three years in which no early life stages of rainbow smelt were observed and averaged 126,000/year (Table 5.3-8 2000 316 Demonstration Report). Therefore, the mean annual entrainment rate of 10,112,547 reported in Chapter G3, Table G3-14, significantly overestimates and does not reflect current entrainment values.

EPA Response

It is incorrect for the commenter to say that the data presented by EPA are "errors." In fact, the data were taken from facility reports (see DCN #4-2049). The 2000 report referred to by the commenter apparently includes corrections the facility made to its own estimates, not EPA's. EPA was unaware of these revised estimates at the time of its analysis. EPA wishes to note that not all of the data from the semi-annual reports used by EPA are an overestimate when compared with the revised estimates in the facility's 2000 report. EPA also notes that the 2000 report only contains annualized data by life stage for 4 species (winter flounder, rainbow smelt, cunner, & Atlantic mackerel). Therefore, the report is insufficient, in and of itself, for estimating total entrainment at the Pilgrim facility expressed as age 1 equivalents, foregone fishery yield, and production foregone, the metrics used in EPA's analysis.

Pilgrim and Seabrook

Comparison of Entrainment Data between PNPS and Seabrook.

Other analyses are also questionable and may lead to erroneous conclusions. For example, EPA concludes that entrainment sampling at Seabrook and PNPS indicates that entrainment is lower at Seabrook than PNPS. This is presumed by EPA to be because of Seabrook's offshore intake structure compared to PNPS's shoreline intake structure. However, evaluation of the data indicates that the difference may be attributable to uncertainties associated with the sampling and data analysis, not the location of the intake structures. On Page 52 of Chapter G3, EPA correctly states that entrainment sampling at Seabrook Station only during daylight periods may have led to an underestimate of entrained organisms, while day and night sampling at PNPS likely provides a more realistic entrainment value. However, EPA incorrectly concludes that an underestimate of entrainment at Seabrook would result in an underestimate of the difference in entrainment between the two stations. In reality, this would lead to an overestimate of the difference in entrainment between the stations. This overestimate, plus the overestimate caused by the differences between the two stations in using actual versus full-load flow rates in calculating entrainment (as described on Pages 51-52 of Chapter G3), potentially accounts for the differences in entrainment rate.

In addition to the different methodologies used to derive estimated annual entrainment rates that likely overestimate the differences, mean annual entrainment values for PNPS were estimated from data collected 1974 to 1999. As discussed above, the entrainment rate values EPA used for PNPS are overstated because of the inclusion of data during the 1970s and 1980s. On the other hand, entrainment rates for Seabrook were estimated with data collected from 1990 to 1998 after the decline in commercial fishery stocks, resulting in lower mean annual entrainment rates.

In conclusion, the discussion in Chapter G3 could lead to the conclusion that PNPS's shoreline intake has a higher entrainment rate than Seabrook's submerged offshore intake and that offshore submerged intake structures are generally preferable to shoreline structures. However, assessment of the sampling methods between PNPS and Seabrook indicates that there is likely not any difference in the entrainment rate between the two stations. Also, the type of CWIS (shoreline or offshore submerged) that results in the lowest level of impact may vary and should be determined by site-specific considerations.

EPA Response

EPA stands by its conclusion that the available data indicate that I&E losses at Seabrook are less than those at Pilgrim. The commenter is also referred to a peer reviewed publication that reaches the same conclusion by Saila et al., 1997, "Equivalent adult estimates for losses of fish eggs, larvae, and juveniles at Seabrook Station with use of fuzzy logic to represent parametric uncertainty," North American Journal of Fisheries Management 17:811-825 (DCN #4-1969).

EPA methods: age 1 equiv, yield, prod foregone

Equivalent Adult Model Estimates.

EPA used an Equivalent Adult Model (EAM) for expressing I&E losses as, an equivalent number of individuals at some other life stage (discussed in Chapter G3 and detailed in Chapter A5). ENSR was unable to replicate the age-1 equivalent values following the method described in Chapter A5 of the Case study. For example, in a comparison between the estimated age-1 adult equivalent Atlantic mackerel derived from entrainment data, values presented by MRI (1999) between 1980 and 1997 were approximately 50% lower than the Age-1 adult equivalent Atlantic mackerel presented in Chapter G3, Table G3-15.

EPA Response

The commenter does not provide information on exactly where they had difficulties, so it is unclear from this comment why the commenter was unable to replicate EPA's results. EPA believes the Agency provided sufficient data to replicate the results presented at proposal. However, the Agency reviewed all chapters of the final Regional Analysis Document (DCN #6-0003) to make sure that the discussions were as clear as possible.

Benefit Transfer Analysis.

As discussed above, the PNPS I&E values used in the EPA analysis is overestimated. As a result, the forgone production lost that is based on these numbers is also overestimated. This effect of this overestimate in the benefits transfer analysis is problematic. For example, as discussed above the rainbow smelt losses due to entrainment were substantially overestimated in the EPA analysis and these same losses are the basis for a significant portion of the forgone recreational value (22-36%; as estimated by the EPA in Chapter G4, Table G4-10).

EPA Response

EPA disagrees that its I&E estimates for the Pilgrim facility are incorrect. Please see responses to related comments on the Pilgrim analysis: 316bEFR.029.104 and 316bEFR.029.106. Regarding EPA's production foregone calculation, please see response to Comment 316bEFR.305.003.

Commercial Fishing Benefits

Also, the economic valuation to determine the forgone benefit to society may be artificially inflated as it stands based on potential losses to commercial fisheries since the non-use or passive values are only applied as a cost to the forgone production side of the analysis. Environmental costs stemming from habitat destruction and loss of non-targeted fish species inadvertently collected (bycatch) are not currently reflected into the commercial fishery market.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values. The Agency, however, has explored several methods that indicate the potential for significant non-use values. See Chapters A12, Non-use Meta-analysis Methodology, and A9, Economic Benefit Categories and Valuation Methods of the final Phase II Regional Studies Document (DCN #6-0003).

For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits, please see the response to comment 316bEFR.005.029.

For EPA's response to comments about benefits of nontarget (e.g., forage) fish species, see response to comment 316bEFR.075.502.

Use of Replacement Costs (HRC and hatchery-based)

HRC Method

ENSR is concerned with EPA's conceptualization and application of the HRC method as documented in Chapter G5 of the Case Study Analysis. The application of the HRC method to PNPS includes several inaccurate and/or inappropriate assumptions as well as a misapplication of site-specific conditions. We are concerned that this regulation could set a precedent for the use of the HRC method including the same or similar inappropriate assumptions, and that the specific results of the problematic PNPS analysis could be used as the basis for inappropriate restoration measures for the PNPS. Detailed comments on the HRC application to PNPS are provided below.

Value of the HRC Method versus Recreational/Commercial Value Assessment. EPA, in Chapter G5-9, states that the costs associated with the I&E losses for PNPS are $9.2 million annually using the HRC method as compared to a much lower estimated benefits using the recreational/commercial value method. EPA attributes the difference in these estimates to limitations in the recreational/commercial value methods ". . .because they include only a small subset of species, life stages, and human use services..." while "...the HRC valuation is capable of valuing many more and, in some cases, all species and life stages...". Despite this goal, the actual application of the HRC method ultimately focuses on a single species for each of the restoration measures. For the application to PNPS, nearly all the $9.2 million cost estimate for the HRC method is attributable to restoration measures for two species (tidal wetlands restoration for winter flounder and reef development for cunner). Both of these species are considered in the recreational/commercial valuation. In fact, the recreational valuation considers 14 species (Tables (G4-9 and G4-10), and the commercial valuation considers 18 species (Tables G4-1 3 and (G4-14). In addition a valuation of forage species was performed considering 8 species (Table G4-20). In contrast, the HRC method is limited in the species considered as well as the application method, as outlined in the comments below.

EPA Response

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule.

Please see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method. Please also see EPA's response to comment #316bEFR.005.035.

With respect to annualized versus present value costs, when EPA was examining the HRC in the context of specific case studies, it needed to convert present value costs into their annualized equivalent in order to facilitate a suitable comparison to other parts of the economic analysis, because all the other aspects of the analysis were developed in an annualized form (such as annualized compliance costs or annualized benefits).

Comment ID 316bEFR.029.112

Use of Replacement Costs (HRC and hatchery-based)

Use of Present Value versus Annualized Costs.

Chapter A11 provides a discussion of the evaluation method used by EPA for the HRC analysis. Chapters A11-2.7 and A11-2.8 state that the final step in the analysis is to develop a present value cost estimate for each restoration alternative. As EPA states in Chapter A11-2.7, present value costs are generally appropriate for such analyses because, present value costs “simplify addressing costs that may be incurred over a number of years”. However, in the application of the HRC method for the PNPS, annualized costs, at 7% for 20 years, were developed in Chapter G5-8. Present value costs were not developed. EPA does not explain the rationale for using annualized rather than present value costs in the PNPS analysis in contradiction to the statements and approach presented in Chapters A11-2.7 and A11-2.8.

EPA Response

The Agency is no longer using the HRC method in its assessment of the benefits and costs of the 316b rule. Additional discussion of HRC issues is provided in response to comment 316bEFR.005.035.

With respect to the specific question raised in this comment, when EPA was examining the HRC in the context of specific case studies, it needed to convert present value costs into their annualized equivalent in order to facilitate a suitable comparison to other parts of the economic analysis, because all the other aspects of the analysis were developed in an annualized form (such as annualized compliance costs or annualized benefits).

Author Name Elise N. Zoli

Organization Godwin Proctor Counselors at Law obo Entergy Corporation

Subject Matter Code 10.02.03

Use of Replacement Costs (HRC and hatchery-based)

Development of Estimated Increase in Species Production.

For each of the alternatives considered in the PNPS HRC analysis, including SAV restoration, tidal wetland restoration, artificial reef development, and installed fish passageways, the increase in species production was developed using estimates of abundance not production (Chapter G5-5). For example, in Chapter G5-5.2, the required area of tidal wetlands to be restored was determined primarily by the equivalent number of age 1 winter flounder entrained by PNPS and the density of winter flounder in tidal wetlands reported in previous studies. However, tidal wetlands, though of value as a habitat for age 1 fish, are of even greater value as a spawning and nursery area to produce additional eggs, larvae, juveniles, and adult fish. The majority of the eggs, larvae, juveniles, and adult fish produced may not be retained in or use the tidal wetland as a long-term habitat, but will likely enter the larger marine ecosystem. This is particularly true for marine species such as winter flounder. Therefore, it is inappropriate to determine the necessary size of a restoration (or created) habitat area for a specific species without consideration of any additional production of that species in the restored (or created) habitat.

EPA states that the reason that abundance rather than production data are used for these estimates is that production data are not, while abundance data are, available. First, it is not appropriate to use incorrect data simply because they are available. Second, we believe that existing data are available to make reasonable estimates of production rates. If such data are not available - given the importance of this analysis - studies should be performed to obtain the necessary data before applying the HRC method.

Further, ENSR believes that the use of the appropriate production data, rather than abundance data, would result in a much smaller area required for tidal wetland restoration for PNPS, and therefore much lower associated costs. At the very least, EPA should note that for this application the HRC method has resulted in conservatively high cost estimates.

EPA Response

First, EPA notes that it did not use the Habitat-based Replacement Cost (HRC) method to estimate benefits for the final Section 316(b) Phase II rule. For additional information on the HRC and its uses, please refer to the document entitled “Habitat-based Replacement Cost Method” (Docket #6-1003).

Secondly, EPA notes that species abundance is a reasonable proxy for secondary productivity under the following conditions assumed by EPA in its HRC analyses: the production to biomass ratio is 1; all of the annual production occurs during the time of sampling; and there is no turnover. EPA notes that for scaling purposes it is important to use the same method to convert abundance to productivity in both the loss (I&E) and gain (habitat production) calculations. EPA's HRC analyses converted fish numbers to age 1 equivalents for this purpose.

Subject Matter Code 4.01
Source data used by EPA

Author Name Elise N. Zoli
Organization Godwin Proctor Counselors at Law obo Entergy Corporation

Use of Site-Specific/Local Data.

To the extent possible, site-specific data should be used for biological analyses. This approach has been advocated by EPA Region 1 in past PNPS study discussions in which EPA staff indicated concern over the use of Rhode Island data for fish population modeling. In the HRC analysis, biological data for the tidal wetland restoration alternative (Chapter G5-5.2) was derived only from sites in Rhode Island. Rhode Island data was also used (along with Massachusetts data) for each of the other restoration alternatives (Chapters G5-5.1, G5-5.3 and G5-5.4). This approach is inconsistent with the EPA Region 1 position and is inappropriate for the HRC analysis.

EPA Response

There is nothing inconsistent about EPA's approach to data selection for the purpose of developing HRC case studies for the national rulemaking and the approach that the commenter states has been advocated in the past by Region 1 in discussions regarding the development of fish population modeling studies for the Pilgrim station. Depending on the specific issues involved in the modeling issues being addressed by Region 1, the use of "off-site" data might pose different problems and it might (or might not) be advisable to require the collection of additional, more site-specific data.

However, EPA notes that site specific data are not always available. Nonetheless, EPA made a good faith effort to obtain the best biological data available for its HRC analyses, with an emphasis on local data to the extent possible. The analyses also included consultations with local expert panels. For additional discussion of the HRC method, which EPA did not use for the final rule analysis, please see the document entitled "Habitat-based Replacement Cost Method" (Docket #6-1003).

Role of Restoration

Restoration Alternatives Considered.

The restoration alternatives considered in the PNPS HRC analysis include SAV restoration, tidal wetland restoration, artificial reef development, and installed fish passageways. Another alternative that should be considered, particularly when the restoration requirements and costs are determined by a single species, is stocking.

Several hatchery-reared stock enhancement programs have been successful for many freshwater fisheries. Marine stocking programs have also been successful but are not as easily monitored to assess success given technological and financial constraints for open coastal systems. However, studies of anadromous fish enhancement efforts have indicated that hatchery-reared stocking programs can be successful in marine systems as well. For example, a study initiated in 1985 to investigate the contribution of hatchery-reared fish to wild stocks (e.g. Chesapeake Bay striped bass stocking program). Between 1985 and 1999 more than 9 million tagged hatchery-reared striped bass fingerlings were released into the Chesapeake Bay System. This study revealed that the hatchery fish accounted for close to half the striped bass in some rivers and eventually contributed to the coastal population as evidenced by tagged individuals captured as far north as Canada. As anticipated the hatchery fish alleviated the pressure on local stocks temporarily and wild fish far outnumber hatchery fish in the Chesapeake Bay (USFWS, 2001).

Recently, stock enhancement of hatchery-reared young-of-the-year winter flounder (Pseudopleuroriectes americanus) was implemented in Plymouth Harbor and Duxbury Bay to assess the feasibility of contributing to the local winter flounder stock and mitigating the potential entrainment impacts from Entergy's Pilgrim Nuclear Power Station (PNPS) (MRI, 2001). Approximately 15,300 and 13,950 hatchery-reared, young-of-the-year P. americanus were marked and released during the summer of 2000 and 2001 respectively. Pen studies conducted in combination with recapture surveys following the 2001 release, revealed that hatchery-reared P. americanus do survive, grow, and successfully convert to wild food sources (MRI, 2001).

MRI, 2001. Hatchery Production Study Young-of-Year Winter Flounder Post-Release Collections, July-November 2000, June-September 2001.

U.S. FWS, 2001. Striped Bass (Rockfish) Morone saxatilis online: http://marylandfisheries.fws.gov/stripedbass.htm

EPA Response

Facilities wishing to implement any restoration measure for purposes of compliance with the final rule must first demonstrate to the Director that the measure meets the requirements described in the final rule, including those in sections 125.94 and 125.95.

Performance standards

Use of an Appropriate Baseline Condition.

The costs associated with the artificial reef development alternative are determined primarily by the entrainment losses for cunner and data on the abundance of cunner in reefs. While ENSR has concerns associated with the use of abundance data rather than production data (discussed above); there are additional concerns for this alternative associated with the use of an appropriate baseline condition and lack of consideration of the site-specific reasons for the relatively high entrainment rate for cunner. Construction of the intake at PNPS involved construction of an adjacent breakwater that provides an ideal artificial reef habitat that has been successfully colonized by cunner. The habitat provided by the breakwater adjacent to the station intake has resulted in an artificially high population of cunner in the vicinity of PNPS and consequently an artificially high cunner entrainment rate. Overall, the cunner population of the coastal system near PNPS is greater because of construction of the breakwater and the station. In general, the baseline condition that should be used for such applications should be the pre-station condition without mitigating influences, such as the breakwater. In such an application, the extent of restoration required would consider the mitigation already provided by the site-specific existing condition. In the PNPS situation, the existing breakwater provides mitigation for cunner such that further restoration needs are likely nominal at best.

EPA Response

For discussions on the basis for and implementation of the calculation baseline, please see response to comments 316bEFR.308.014 and 316bEFR.063.022, as well as the preamble to today's rule.

Use of Replacement Costs (HRC and hatchery-based)

Development of Reasonable, Site-Specific Cost Estimates.

The cost estimates for each of the restoration measures (Chapter G5-7.1 for SAV restoration, Chapter (G5-7.2 for tidal wetland restoration, Chapter G5-7.3 for artificial reef development, and Chapter (G5-7.4 for installed fish passageways) are based on previous restoration efforts. If done correctly and the restoration efforts are analogous, this should provide a reasonable cost estimate. However, in some cases this method may result in cost estimates that are considerably in error. For example, the unit costs for tidal wetland restoration were developed based on a range of projects involving construction and elimination of tidal restrictions. Because of the range of site-specific considerations and requirements for these restoration projects, the unit costs ($/acre restored) for the projects range over 5 orders of magnitude (Table G5-35). From these data, EPA developed a frequency distribution of the unit costs and median value for the projects that was used as the basis for the tidal wetland restoration cost estimate. Because of the extremely large range in costs, the potential error associated with the median value is considerable. As a result, EPA's cost estimate for the tidal wetland restoration alternative is likely incorrect, perhaps by as much as several orders of magnitude when applied to a specific facility. Further the analysis did not, but should have, evaluated whether there are any existing potential tidal wetland sites in the vicinity of the power plant. In order to develop a reasonable cost estimate, it would be necessary to evaluate site-specific conditions including the availability of potential restoration sites and restoration measures (e g culvert or tidal gate construction) that would be required for the project. This procedure would eliminate the potential errors associated with EPA's method for developing costs.

EPA Response

First, EPA notes that it did not use the Habitat-based Replacement Cost (HRC) method to estimate benefits for the final Section 316(b) Phase II rule. For further detail, please refer the document entitled "Habitat-based Replacement Cost Method" (Docket #6-1003).

Secondly, with regard to the site-specificity of restoration cost estimates, for the HRC analyses presented at proposal EPA met with and received information from local experts with experience in the types of restoration under consideration. EPA believes that the information it provided was sufficiently site-specific and sufficiently reviewed by local experts to prevent any systematic bias of unit costs.

EPA also notes that the HRC analyses presented at proposal served two primary goals: 1) to calculate realistic but hypothetical cost estimates to allow cost comparisons between technology and restoration; and 2) to determine the general types and amounts of restoration that would be needed to offset I&E that will remain with any given technology. However, the HRC analyses do not attempt to provide detailed implementation plans for executing actual restoration projects.

Use of Replacement Costs (HRC and hatchery-based)

Practicality of Restoration Alternatives.

As indicated above, it is not apparent that construction of the tidal wetlands alternative developed by EPA is practical. Analysis of the artificial reef alternative indicates that it is not practical. The unit costing analysis for this alternative in Chapter G5-7.3 was based on six reefs with a total surface area of 1,024 m2, or 171 m2 per reef. For the reef alternative developed for PNPS (requiring 176,145 m2of reef area; Table G5-42), a total of 1033 of the same size reefs would be required. If instead a single reef that was 5 meters high and 5 meters wide were used in a linear configuration, the reef would need to be 7.3 miles in length. Clearly, both configurations are impractical.

EPA Response

EPA disagrees that reef construction is impractical or that the configurations described by the commenter would necessarily be required. For the Pilgrim HRC referred to by the commenter, EPA met with local experts with experience relevant to I&E species and the restorations likely to increase their numbers. EPA notes that the HRC analyses serve two primary goals: 1) to calculate realistic but hypothetical cost estimates to allow cost comparisons between technology and restoration; and 2) to determine the general types and amounts of restoration that would be needed to offset I&E that will remain with any given technology. However, the HRC analyses do not attempt to provide detailed implementation plans for executing actual restoration projects.

EPA believes that the HRC analyses conducted for proposal were relevant and practical for determining likely costs and scales of necessary restorations to offset I&E, and that details such as exact configurations of individual reefs (or other details for other restoration projects) were unnecessary for the intended level of analyses.

Finally, EPA notes that it did not use the HRC method to estimate benefits for the final 316b Phase 2 rule. For additional information on the method and its uses, please see the document entitled "Habitat-based Replacement Cost Method" (DCN # 6-1003).

Monitoring requirements

Unreasonable Monitoring Cost Estimates.

Monitoring costs (Chapter G5-7) included in the total annualized cost estimates appear to be unreasonable for several alternatives. For example, the annualized unit cost used for monitoring of the artificial reefs was $19.36/m2 (Chapter G5-7.3.2). This value is nearly 80% of the total unit cost value of $24.85 (Chapter G5-7.3.3). Application of EPA's unit monitoring cost for the PNPS artificial reef alternative (with 176,145 m2 of reef area; Table G5-42) results in an annual monitoring cost of $3.4 million. The basis of EPA's unit cost value, as stated in Chapter G5-7.3.2, is a reef monitoring program with a much more reasonable cost of $28,000/year. Clearly, the scaling used to extrapolate this cost to the monitoring of a larger reef has resulted in an unrealistic cost value for the PNPS assessment.

Similarly, as described in Chapter G5-7.2.2, EPA's tidal wetlands monitoring costs are based on a field team of three staff working for five days per year for an estimated annual cost of $1600 for monitoring tidal wetlands of various sizes. From this value, EPA developed a unit annualized cost of $1146/acre. Application of this unit cost for the tidal wetland area (2,429,812 m2 Table G5-42) developed by EPA for PNPS results in an estimated annualized monitoring cost of approximately $680,000. A similar scaling of the staffing requirements would indicate that 1275 workers would be needed for a five day monitoring effort of the PNPS tidal wetland area (using the initial estimate that monitoring of a tidal wetland would be performed in a five day period). Again, clearly the EPA analysis has resulted in an unrealistic estimate.

EPA Response

First, EPA notes that HRC results were not used in its benefits analysis for the final rule. The document entitled "Habitat-based Replacement Cost Method" provides details on the method and its uses.

Secondly, EPA notes that the magnitude of habitat restoration costs for any specific project are sensitive to a number of factors, particularly estimates of species productivity in restored habitats, which are often difficult to obtain and subject to substantial uncertainty, the scaling rule used, and location specific features. Variables such as these will influence both implementation and monitoring costs.

In the case of the Pilgrim HRC, unit costs were developed and scaled linearly to the scale of implementation needed to offset the I&E losses for all species for which a habitat restoration action could be identified and data were available. Note that the scale of restoration required can be quite high when losses are high and productivity in the restored habitats is comparatively low.

Although adjustments to the scaling rule such as allowing "fish trading" can reduce the scale of implementation, the ultimate impact on any costs associated with a specific project will vary depending on site specific factors.

In the HRC analyses presented at proposal, annualized monitoring costs were developed for units of habitat based on available data and then extrapolated linearly to the scale of restoration required to offset total I&E losses. The habitat required to offset the loss is high both because losses are high and productivity in the restored habitats is comparatively low.

For artificial reefs, the commenter finds cause for alarm with the artificial reef monitoring costs representing 80% of the annualized unit cost, but finds the estimate of $28,000 per year in monitoring costs reasonable. Given that the annualized monitoring cost is mathematically equivalent to the yearly monitoring costs when the scale of the project is accounted for there should be no cause for alarm. Monitoring organism production over 10 years on an artificial reef where the use of scuba divers is required becomes relatively expensive compared to installation of the reef when all the costs are annualized.

Reef monitoring costs would be less if the required scale of implementation were smaller or an alternative sampling design were developed that could reduce costs. These opportunities will be very site-specific and sensitive to the required scale of implementation. Based on the information available, linear scaling of costs was used in the Pilgrim HRC analysis.

Similarly, the monitoring costs for tidal wetlands will, in practice, be sensitive to how the scale of restoration is achieved. As with artificial reefs, there may be opportunities to reduce these costs in an actual restoration project depending on the project design (i.e., how the acres are located). However, it can also be argued that the costs associated with the current wetlands monitoring program are conservative.

Although the labor and equipment specifications come from a collaborative document proposing regional standards for tidal wetland monitoring (Neckles and Dionne, 1999, DCN # 4-1808), the protocol focused solely on the field staff, equipment, and desired frequency of sampling. Omitted from this protocol is a discussion of the associated labor and equipment requirements for processing and analyzing the collected data. Incorporating these costs would increase monitoring costs.

Use of Replacement Costs (HRC and hatchery-based)

Use of the HRC Method for 316(b) Evaluations.

In Chapter A11-3 it is stated that the HRC method is currently being applied to PNPS as well as several other power stations. As discussed in the detailed comments above, the application to PNPS is founded on several inappropriate and inaccurate assumptions and has resulted in unrealistic and unreasonable conclusions. Therefore, as presently formulated and used, ENSR concludes that the HRC method is problematic and not applicable to 316(b) evaluations.

EPA Response

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule.

Please see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method. Please also see EPA's response to comment #316bEFR.005.035.

Costs

Estimated Cost of Compliance

ENSR is concerned that EPA's cost estimate for compliance with the proposed regulation underestimates the potential compliance costs. We believe that sufficient data does not exist to estimate the costs for retrofitting existing power plants for technology that can achieve the entrainment reduction requirements in the regulation - 60% to 90% for many water bodies.

EPA Response

EPA disagrees with the commenter's assertion. EPA concludes that the database it developed for support of the entrainment reduction standards supports the conclusion that existing power plants can retrofit their intakes to meet the standards. See the Technical Development Document.

See responses to comments 316b.EFR.034.008, 316b.EFR.060.038, 316b.EFR.077.033, 316bEFR.100.004, and 316bEFR.902.001. Also see comments 316b.EFR.088.008, 316b.EFR.207.009.

Source data used by EPA

Author Name Elise N. Zoli

Organization Godwin Proctor Counselors at Law obo Entergy Corporation

EPA also indicates that such reductions may potentially be achieved by cooling towers, aquatic filter barrier systems, and fine mesh screens. In the proposed regulation (Section Vl.B.1), EPA has identified three facilities that operated as once-through cooling plants and then converted to closed-cycle plants using cooling towers. This is an inadequate database to use for the extrapolation of nationwide costs. Two of the three facilities are located in South Carolina, none are located along the coast, and only one is larger than 500 MW. None of the conversions occurred in the last decade. It is unclear how the availability of water arid cost of a reliable water supply were considered in the cost estimate. This is an increasingly important consideration nationwide with increased competition for water resources in recent years.

The proposed regulation gives only one example each for applications of aquatic filter barrier systems and fine mesh screens (Section VI.A2). It is our understanding that each of these applications has required extensive efforts to achieve some level of reliable operation and the target entrainment reductions. The costs associated with implementing these technologies nationwide cannot be extrapolated from these applications. We understand that several pilot and laboratory studies have been performed that indicate that these technologies can achieve the goals. However, until there are more practical applications in the field, the total costs associated with system installation, fine-tuning, optimization, and maintenance for these technologies cannot be estimated with a great degree of confidence.

EPA Response

In developing national costs for the final rule, EPA evaluated other sources in additional to the information the commenter noted in the comment. See the Economic and Benefits Analysis for the Final Section 316(b) Phase II Existing Facilities Rule for a discussion on the development of the national costs.

It is unclear what the commenter is stating in the sentence, "It is unclear how the availability of water arid cost of a reliable water supply were considered in the cost estimate." Therefore, EPA can provide no response.

EPA evaluated wide range of technologies including aquatic filter barrier systems and fine mesh screens for the final rule. See the cost modules in the Technical Development Document for the Final Section 316(b) Phase II Existing Facilities Rule for a discussion on the technologies evaluated for costing.

Documented facility examples of CWIS impacts

Status and Trends of Hudson River Fish Populations and Communities Since the 1970s: Evaluation of Evidence Concerning Impacts Of Cooling Water Withdrawals

Lawrence W. Banthouse
Charles C. Coutant
Webster Van Winkle

January 2002

Introduction

The purpose of this paper is to summarize our views concerning the status of fish populations and communities of the Hudson River estuary, and whether those populations and communities reasonably can be said to have changed since the mid-1970s as a result of operation of the Bowline Point, Indian Point, and Roseton generating stations ("stations"). Our concern is with impacts as defined by biologists, using established definitions and standards of ecology and resource management. The paper does not address any of the regulatory issues currently being addressed through the SPDES process, and specifically does not address either (1) the regulatory definition of "Adverse Environmental Impact' (AEI) under section 316(b) of the Clean Water Act, or (2) Best Technology Available (BTA) for minimizing AEI. We have not conducted an independent analysis of the supporting data used in the preparation of the generators' Draft Environmental Impact Assessment (DEIS). We have, however, reviewed both the DEIS and the comments on the DEIS prepared by ESSA and Pisces. We requested and received updated abundance indices through 2000. Our conclusions are based on our evaluation of all three reports, as augmented by the updates.

Rationale for focusing on population- and community-level impacts

Our interpretation of the data is premised on a view that populations and communities are the proper focus for evaluating impacts of cooling water withdrawals on the Hudson River estuary. The reason for this is that all individual organisms have finite life spans, only populations and communities persist through time. As long as key populations are relatively stable, the mix of species present remains relatively constant, and important functional relationships continue, the river can be said to be healthy and can continue to persist in spite of the deaths of individuals. There are ample precedents for a focus on populations and communities. For instance, EPA's Guidelines for Ecological Risk Assessment (EPA 1998, section 3.3.1.1.) identify "ecological relevance" as a key criterion for selecting specific entities to be evaluated in risk assessments. Examples of relevant entities discussed by EPA include individual species, functional groups of species, and communities. A focus on populations and communities is also fundamental to natural resource management. The Magnuson-Stevens Fishery Conservation Act, for example, focuses on maintenance of sustainable yields from exploited populations. In fact, even the concept of "sustainable yield" implicitly focuses on populations and communities, because only populations and communities are persistent and therefore “sustainable”

A population and community-based approach is frilly consistent with the approach taken in the studies that supported the 1980 Hudson River Settlement Agreement (HRSA) These studies, which expressly focused on populations and communities, are frilly documented in the peer-reviewed scientific literature (Barnthouse et al 1988) and are widely regarded as a classic study in environmental impact assessment

A population and community-oriented framework for impact assessment made sense in 1980, and from a scientific perspective it still makes sense today. However, the information base to support population and community assessments vastly exceeds the information available at the time of the settlement. Models were the principal technical approach used in 1980 in large part because long-term monitoring data did not exist. An extraordinarily extensive data set is now available, for use in impact assessment. Techniques for modeling impacts of fishing and power plant mortality on fish populations have also advanced greatly since 1980; these models provide additional insights into the potential impacts of cooling water withdrawals.

Hypotheses concerning expected impacts of cooling water withdrawals on fish populations and communities

Estuarine environments are highly variable. Moreover, land use changes, pollution-abatement harvest restrictions, invasions by exotic species, climate change, and many other factors that potentially influence fish populations and communities have occurred in the lower Hudson River valley since the 1970s. Under these circumstances, simply documenting the types and magnitudes of changes that have occurred is insufficient to fully evaluate the presence or absence of changes related to cooling-water withdrawals. Specific hypotheses concerning the expected impacts of cooling-water withdrawals (termed “risk hypotheses” in EPA’s Guidelines for Ecological Risk Assessment) are useful for distinguishing between changes that could have been caused by cooling-water withdrawals and change that are most likely related to other causes.

Entrainment and impingement by once-through cooling systems can result in mortality of early life stages of fish and other aquatic organisms. If the magnitude of this mortality were high enough, and if this mortality persisted over a long period of years, then the following types of adverse changes in populations and communities might be expected:

-Continued, long-term declines in the abundance of susceptible populations. Such declines would result where entrainment and impingement mortality rates exceed the replacement capacity of the affected populations. Such declines would be most likely to occur in species that (1) are highly susceptible to entrainment or impingement (because of their life history and spatial distribution), (2) are also subject to other sources of mortality, especially harvesting, and (3) have an inherently low capacity to sustain additional mortality. Declines related to cooling-water withdrawals should approximately coincide with the startup of the three stations (possibly with a lag time of several years).

-Reduction in species richness or diversity. Species richness (as measured by the number of species present in a community) and species diversity.(as measured by various numerical indices that consider both the number and the relative abundance of species present in a community) are among the most widely accepted indicators of adverse community-level effects (Rapport et al. 1985, Gotelli and Graves 1996). Declines in species richness and diversity can be caused by a wide variety of stressors, through a wide variety of mechanisms. If cooling-water withdrawals were reducing species richness or diversity, then declines in these indicators should be observable over time, although the declines would not necessarily coincide in time with the startup of the stations. Any such declines could be localized within the immediate vicinity of the stations, or could be estuary-wide. Because changes in species richness and diversity are nonspecific indicators of stress, additional information on spatiotemporal patterns of hypothetical causes is usually needed to: interpret any changes that are observed.

-Change in the balance of predator and prey species. If cooling-water withdrawals were reducing the abundance of predator populations (e.g., striped bass) within the estuary, then the abundance of prey populations (e.g., bay anchovy) would be expected to increase. Conversely, if cooling-water withdrawals were reducing the abundance of forage species such as bay anchovy, then the abundance of predators could decline even if those predators are not themselves vulnerable to entrainment or impingement. Because the dominant predator and prey species in the estuary are migratory and widely distributed, any such changes would be expected to be estuary-wide.

Changes consistent with one or more of the above hypotheses could be related to cooling-water withdrawals over the past 25 years of operation of the stations. Changes inconsistent with these hypotheses (e.g., of a type not expected to result from mortality to early life stages of fish, or occurring at times or locations inconsistent with the expected effects of cooling water withdrawals) likely are related to other causes.

Evaluation of impact hypotheses using results from 25 years of monitoring

The data presented in the DEIS indicate that changes that most fisheries biologists would view as “adverse” have not occurred. Further, changes that have occurred appear to be inconsistent with the ‘impact hypotheses discussed above and; therefore, are not reasonably attributable to the’ stations.
Trends in population abundance

It would be laborious and probably not very meaningful to attempt to summarize trends in the abundance of all 17 of the target species evaluated in the DEIS for this brief analysis. For determining whether cooling-water withdrawals have affected fish populations, it should be sufficient to evaluate those for which station-related mortality, measured in terms of the CMR, is the highest These populations are striped bass, white perch, Atlantic tomcod, American shad, blueback herring, alewife, bay anchovy, and spottail shiner.

Striped bass

This species is, among all of the species present in the lower estuary, perhaps the most vulnerable to cooling-water withdrawals. The spawning grounds of Hudson River striped bass are located primarily north of the Hudson Highlands. Striped bass are pelagic spawners, and the early life stages of striped bass are also pelagic. Striped bass eggs, larvae, and juveniles are subject to tidal transport and are susceptible to entrainment at all three stations. Estimated CMRs for striped bass are consistently among the highest of all of the species evaluated in the DEIS. In addition to entrainment and impingement, the Hudson River striped bass population is also affected by harvesting. Moreover, as a top predator, station impacts on lower trophic levels (e.g., bay anchovy and other forage fish) would be expected to translate into reduced striped bass production.

If entrainment and impingement were adversely affecting the Hudson River striped bass population either directly, through reduced abundance of young fish, or indirectly, through a reduction in prey availability, then a decline in the abundance of these fish should be observable over the 27 years of available data. Figure 1 shows trends in four indices of striped bass year-class strength, each derived from a different data set. The four sets of indices are highly consistent and show that there has been no trend in striped bass recruitment since the initiation of the utility and NYSDEC monitoring programs. At the same time, the abundance of adult striped bass and of early striped bass life stages has greatly increased. The increase was, biologists agree, caused by harvest restrictions imposed beginning in the mid 1980s. Reduced fishing mortality increased the annual survival rate of adult striped bass, resulting in a rapid buildup of the adult population after 1980. The increased spawning stock is now producing far more eggs and larvae per year than were produced in the l970s, although the production of young-of-the-year fish has been stable. Meanwhile, cooling-water withdrawals have occurred at a relatively constant rate (as measured by the CMR) throughout a quarter-century.

One might argue that without power plants the population growth would have been even greater. However, the constancy of year-class strength, even as egg production has greatly increased, supports a conclusion that an additional increase in larval abundance (as would have occurred bad there been no entrainment) would not have translated into an increase in abundance of young-of-the-year striped bass.

White perch

White perch are similar to striped bass with respect to life history and vulnerability to cooling-water withdrawals, except that (1) spawning occurs further up-river, (2) white perch juveniles are more evenly dispersed throughout the river than are striped bass, and (3) adult white perch are nonmigratory and much smaller in size, so they remain vulnerable to impingement throughout their life spans. However, in spite of the lifetime vulnerability of white perch to impingement, entrainment is still the prevalent station-related source of mortality to this species (avenge CMR of 17.5% for entrainment, as compared to 2.2% for impingement).

Trends in the abundance of white perch juveniles and yearlings indicate an apparent decline from 1979 through 1996, however, data for the years 1998 through 2000, which were provided to us by the generators, suggest that the white perch population may have stabilized. The abundance of juvenile and one-year-old white perch appears to have increased since 1996, with an especially strong year class being produced in 1999. As noted in the DEIS, the spatial distribution of white perch within the estuary appears to have shifted, with the decline in juvenile and yearling abundance being much greater in the lower estuary (regions 1-5) than in the upper estuary (regions 6-12). The DEIS discusses possible explanations for these changes (predation by striped bass in the lower estuary; changes in submerged aquatic vegetation in the upper estuary). Although no definitive conclusions appear possible at this time, there is no apparent reason why cool- ling-water withdrawals should have affected white perch but not striped bass. Estimated CMRs for these two species are similar. White perch are more widely distributed throughout the estuary and make greater use of tributaries. Thus, they should be less vulnerable to entrainment and impingement than striped bass. White perch are not heavily exploited, so that this species should be less vulnerable to effects of additional mortality due to entrainment and impingement than should striped bass. During the period in which the abundance of juvenile and yearling white perch was declining, the abundance of post yolk-sac larvae (PYSL, Figure 2) did not decline, indicating that the annual reproductive output of the population was never reduced.

Atlantic tomcod

Atlantic tomcod is unique among the fish species of the Hudson River estuary in that it is adapted to cold climates; and the Hudson River population is the southernmost spawning population of this species. Spawning occurs during winter, primarily between West Point and Poughkeepsie. Atlantic tomcod larvae and juveniles are found primarily in the lower estuary, between Yonkers and Cornwall. Because the Hudson River is at the southern end of the range of Atlantic tomcod, this population may be especially sensitive to climatic fluctuations, especially high summer temperatures. Growth rates in juvenile Atlantic tomcod have been shown to decline when water temperatures rise above 55°F and to stop when they exceed 71°F, a temperature that is exceeded annually in the Hudson River.

Data for evaluating trends in the abundance of Atlantic tomcod are available both from the utilities ichthyoplankton survey, which samples larval and juvenile tomcod, and from an Atlantic tomcod mark-recapture program that samples 1-year old and 2-year old fish. Annual abundance values from these three data sets (from Table V-21 of the DEIS) are plotted in Figure 3. As noted in the DEIS, the design of the mark-recapture program changed after 1979 and age-1 and age-2 population estimates for 1979 and earlier may not be fully comparable to estimates for later years. Although correlations between the larval/juvenile index and the mark-recapture indices are low, all three indices show a decline only after 1989.

The Atlantic tomcod is a short-lived species, with a generation time of 1-2 years. If entrainment and impingement were adversely affecting the Hudson River Atlantic tomcod, then a decline in abundance should have been evident within a few years after the startup of the stations. The recent decline in abundance of this species, however, did not begin until about 1990. Changes in cooling water withdrawal rates that could explain such an abrupt decline did not occur during this period. As noted in the DEIS, warmer summer or winter water temperatures, among other factors, could influence Atlantic tomcod populations. However, a detailed evaluation of these factors has not been performed.

American shad

American shad spawn in the uppermost regions of the estuary, and early life stages, of this species are found primarily in the upper estuary above Poughkeepsie. Juvenile American shad are present in the vicinity of the stations primarily in the fall, during emigration from the river. After emigration, American shad remain at sea until they become sexually mature and return to spawn, at an age of 3-6 years.

Juvenile abundance indices for American shad show limited evidence of a downward trend in recent years. Figure 4 shows trends of the two available indices of juvenile abundance, derived from the utility and NYSDEC beach seine data sets (from Table V-25 of the DEIS). Both indices indicate that strong year classes were produced in 1986, 1989, and 1990, and that relatively weak year classes were produced in 1984 and 1995. Data for 1998-2000, available only for the utility index, indicate that the 1998 and 2000 year classes were also weak.

Other information indicates that the decline in abundance of American shad is coastwide, and is likely due to overfishing. According to the Atlantic States Marine Fisheries Commission (ASMFC 1998a) shad abundance has declined greatly since the end of World War II. Although fishing mortality within the Hudson River itself has apparently declined since 1984, this decline has been offset by an increase, in mortality due to the Atlantic coastal intercept fishery.

Blueback herring and alewife

These two species need to be considered together for purposes of evaluating impacts of cooling-water withdrawals, because the early life stages of these species are indistinguishable.

Figure 5 shows abundance trends for both species for the years 1979 through 2000. Figure 5 shows that the two species have tended to vary together, with strong year classes being produced in 1980, 1985, 1987, and 1996, and weak year classes being produced in 1983, 1986 and from 1993 through 1995. The only years when divergent changes in abundances occurred were 1980 and 1999, when strong alewife and weak blueback herring year classes were produced. Year-class abundance in both species appeared to decline from the late 1980s through the mid 1990s. Otherwise no trends are apparent for either species.

Coastwide populations of both: blueback herring and alewife were severely depleted by, overfishing during the l960s and 1970s. Harvesting has been severely restricted, but coastwide populations of both species have remained depressed (ASMFC l998b). Damming of tributaries is believed to have substantially reduced the available spawning and nursery habitat for both, but especially for blueback herring. There is no evidence of a long-term decline in either species that would be consistent with expected impacts of cooling water withdrawals.

Bay anchovy and spottail shiner

Bay anchovy and spottail shiner are both forage species, meaning that they are small fish that serve as prey for larger, predatory fish. Bay anchovy is the principal forage species in the lower estuary. For this reason, impacts on bay anchovy could indirectly affect predators such as striped bass and bluefish. Spottail shiner is abundant primarily in the upper estuary. Impacts on this species could indirectly affect predators such as striped bass and largemouth bass.

Figure 6 plots time trends in juvenile abundance for both species No trend in abundance of spottail shiner is evident, however, the abundance of bay anchovy appears to have declined between 1995 and 2000 This recent, abrupt decline is inconsistent with the expected effects of cooling-water withdrawals and is likely related to other causes

Trends in species richness and diversity

As documented in the DEIS, changes in species richness and diversity have been observed in the Hudson River estuary. Trends in species richness and diversity have varied between life stages, with the number and diversity of ichthyoplankton species increasing slightly and the number and diversity of juvenile and older fish decreasing slightly over the period from 1974 through 1997. The decline in richness and diversity of juvenile and older fish has resulted primarily from a small reduction in the numbers of freshwater species present, especially in the upper estuary (Regions 6-12). These species should be less susceptible to entrainment and impingement than the marine, diadromous and estuarine species (e.g., striped bass, bay anchovy, white perch, and blueback herring) that dominate the lower estuary (Regions 1-5). The causal mechanism through which cooling-water withdrawals could reduce species richness in a component of the community that is not highly susceptible is unclear. It is possible, as stated m the DEIS, that habitat changes, such as regrowth of water-chestnut beds, have reduced the quality of littoral habitat present in the freshwater zone of the estuary, and thus reduced the ability of this habitat to support freshwater species. Regardless of the specific causes, the observed changes are well within the range of natural variability that would be expected in an estuarine environment and are unlikely to be related to cooling-water withdrawals.

Predator-prey balance

If cooling-water withdrawals were substantially depleting prey populations in the estuary, then predators that depend on those prey populations could also decline in abundance. If, on the other hand, cooling water withdrawals were depleting predator populations, then prey populations could increase because of reduced predation These types of changes have not been observed in the Hudson River estuary. Major prey species such as bay anchovy, spottail, shiner, and juvenile blueback herring have been stable over most of this period. The principal predator species, striped bass, has also been stable. Disruption of predator-prey balance in the estuary clearly has not occurred.

Strength of evidence supporting conclusions regarding lack of adverse changes potentially related to cooling-water withdrawals

The data sets on which the above conclusions are based are unprecedented in our experience. Independent data sets, ranging between 10 and 25 years in duration, include:

-Utilities' Longitudinal River Ichthyoplankton survey
-Utilities' Fall Shoals Survey
-Utilities' Beach Seine Survey
-NYSDEC juvenile beach seine survey
-Utilities' mark-recapture surveys of striped bass and Atlantic tomcod

Like all biological data sets, the data provided by each of the above survey programs is subject to a variety of source of unquantifiable uncertainties and potential biases. However, where comparisons are, possible, the results provided by these surveys are consistent. The consistency of these results is a strong indication that the data sets are providing valid information concerning trends in the abundance of Hudson River fish populations.

At least with respect to striped bass, the conclusions evident from our evaluation of the DEIS are supported by coast-wide assessments performed by federal and interstate resource management organizations. Data summarized in the Stock Assessment Review Committee (SARC) report for 1998 (NMFS l998a) show that the total coastwide biomass of spawning Atlantic striped bass in 1996 was more than ten times as high as in 1982 (NMFS 1998a, Figure C11). Although the contribution of Hudson River striped bass to the growth of the coastal population has not been quantified, data summarized in Tables C17 and C18 of the SARC report show that the abundance of juvenile and 1-year-old striped bass in the Hudson River fluctuated without a discernable trend between 1981 and

1996. The SARC report utilized many of the same data (e.g., the utility and NYSDEC beach seine indices) that were used in the DEIS, indicating that the review committee believed these data to be valid indicators of the status of the Hudson River striped bass population. An updated assessment (ASMFC 2000) showed a slight decline in coastal spawning stock size, but continued stability in the abundance of juvenile striped bass produced by the Hudson River population.

The validity of spawner-recruit analyses as supporting lines of evidence

We firmly believe that the extraordinary long-term database on population and community trends in the Hudson River provides the strongest evidence concerning the ecological significance of cooling-water withdrawals by Hudson River power plants. However, the population modeling results discussed in the DEIS provide valuable supporting evidence.

Spawner-recruit analyses such as the striped bass, American shad, and Atlantic tomcod models presented in the DEIS (and critiqued by ESSA and Pisces) have been especially controversial components of impact assessments performed for Hudson River power plants. Such models have been used both in pre-HRSA assessments and in the DEIS to demonstrate the existence of density-dependent population regulation in Hudson River fish populations and to quantify the impacts of power plants on the long-term abundance of those populations. As shown by Christensen and Goodyear (1988) and by Fletcher and Deriso (1988), the data and modeling techniques available at the time of the URSA were clearly insufficient to support credible modeling efforts. However, significant improvements in both data and modeling techniques have occurred over the past 20 years. These advances, which have been recently reviewed by Rose et al. (2001), include measurement techniques for inferring the age, environmental history, and health of individual fish; demonstrations of the operation of specific density-dependent processes in well-studied populations; new methods for modeling fish populations; improved understanding of the relationship between density-dependence and fish life history; comprehensive data bases for the study of spawner-recruit relationships in many fish species; and improved statistical techniques for detecting and quantifing density-dependence from time series of spawner-recruit data. As documented by Rose et al. (2001), detailed studies of individual fish populations and comprehensive analyses of long-term data sets for many fish populations have demonstrated the existence of density-dependence as a general property of fish populations.

Federal and state resource management agencies also recognize, the necessity of considering density-dependence when making resource management decisions. The role of density-dependence in maintaining sustainable fisheries is implicitly acknowledged in the federal regulations implementing the Magnuson-Stevens Fishery Conservation Act (NMFS 1998b). Technical committees of the ASMFC have developed spawner-recruit models for two of the species evaluated in the DEIS: striped bass (NMFS 1998a) and weakflsh. (NMFS 2000). Appendix VI-4-C of the DEIS, which documents a spawner-recruit model for the Hudson River American shad population, was prepared by NYSDEC staff and consultants.

Whether or not there is agreement on the numerical results of the spawner-recruit models used in the DEIS, even the most conservative interpretations of the data (e.g., the “low compensation” fits shown for American shad in Figure 3 of Appendix VI-4-C) provide evidence that density-dependent processes are operating in these populations. These results provide, at a minimum, supporting evidence for the conclusions we have arrived at through examination of population trends: the

Hudson River fish populations most likely to be affected by cooling-water withdrawals have in general maintained stable populations over the past quarter century. The few declining trends that have occurred are inconsistent with the expected effects of the stations and are likely related to other causes.

Reductions in entrainment and impingement mortality are unlikely to result in detectable improvements in populations or communities.

We have not performed a benefits analysis related to the mitigation proposals being discussed by the generators, NYSDEC, and Riverkeeper. However, to the extent that these mitigation proposals are intended to reduce cooling-water withdrawals, our evaluation of the data suggests that the ecological benefits of those reductions is likely to be negligible. If measurable changes attributable to cooling-water withdrawals have not occurred over the past 25 years of operation of the stations, then reductions in those withdrawals would be unlikely to result in measurable improvements such as increases in population abundance or species richness.

[see hard copy for figures, slides, and references]

EPA Response

EPA acknowledges receipt and has reviewed this submission. This is a review of the draft Environmental Impact Statement regarding the cumulative impact of these facilities on the fish populations of the Hudson River. EPA has also received from NYSDEC and has reviewed the Final Environmental Impact Statement. EPA disagrees with the commenter that populations and communities are the proper focus for evaluating impacts of cooling water withdrawals. EPA agrees with NYSDEC in that attempts to measure specific impacts are complicated by interacting variables that can cause fluctuations in fish populations each year, such as flow, temperature, salinity, dissolved oxygen, nutrients and disease, and thus population models cannot determine the impact of impingement and entrainment losses on adult populations with much confidence. Please see section IV of the preamble for the discussion of the environmental impacts of these facilities on the Hudson River. Please see response to comment 316bEFR.207.015 for the discussion regarding impacts of cooling water intake structures at the individual versus population level.

EPA Chapter A7 Entrainment Survival

Overview

In it's §316(b) Existing Facilities Benefits Case Studies, Chapter A7: Entrainment Survival, EPA has reviewed the current state of knowledge about the survival of entrained organisms, primarily fish, and found the existing body of information insufficient to use as a screening tool on a nationwide basis. While this finding is understandable given the relatively small number of studies that have been done nationwide and the site-specific factors that determine survival, EPA has failed to recognize the value of the data that are available at a few selected locations.

EPA's review was primarily of information provided in the 2000 EPRI report "Review of Entrainment Survival Studies: 1970-2000." That report detailed 36 studies conducted at 21 different power stations. While 36 studies nationwide is not a large amount of information, 16 of those studies were conducted at plants in the mid Hudson River estuary: 1 from the Danskammer station, 4 from the Bowline station, 5 from the Roseton station, and 6 from the Indian Point stations. This concentration of information in the Hudson River contrasts with the sparseness of information from the rest of the nation: 4 additional studies in New York; 3 studies in mid-Atlantic states, 7 studies in the mid-West; 4 studies on the west coast, and 1 study in the south (Figure 2-3 in EPRI 2000).

In addition to the 6 Indian Point studies included in EPRI 2000, there were an additional 4 years of in-plant studies at Indian Point not included in the EPRI review (NYU 1974, 1976a, 1977, 1978), and additional studies conducted to examine the mechanisms of entrainment mortality (NYU 1976b, 1979; O'Connor & Poje 1979) that were done with the participation of the Indian Point owners. While these early in-plant studies did not use the specialized sampling gear deployed in later studies, they nevertheless provided valuable information and contributed to the evolution of the sampling gears and protocols.

EPA's recognition of the value of entrainment survival information, but dismissal of all previously collected information as flawed and inadequate is distressing. EPA appears to have forgotten the value its own consultants placed on the entrainment survival data in reaching a settlement of the Hudson River case in 1980 (Klauda et al. 1988; Christensen et al. 1981). EPA consultants participated in some of the in-plant studies, and conducted other experimental work independent of the utilities efforts (Coutant and Kedl 1975; Kedl and Coutant 1976; Suffern 1977; Suffern et al. 1979; Cada et al. 1982) that enhanced the acceptance of the in-plant studies.

There is no logic, given the progress that has been made, in EPA's attempt to turn back the calendar nearly 30 years to the state of knowledge that existed in the early 1970s. EPA should explicitly recognize that some facilities have demonstrated that entrainment mortality is not 100%, and that in certain cases sufficiently rigorous protocols have been followed to allow estimation of the survival rate. Failure to make this recognition will only encourage regional and state permitting activities to ignore the valuable information that exists, and will facilitate incorrect and ill-informed permitting decisions.

Specific Comments

1) In the Introduction to Chapter A7, EPA states "Assessment of ecological and economic consequences of entrainment is based on estimates of the number of fish and shellfish killed as a result of entrainment." Although EPA is correct that estimation of the numbers killed must be part of the assessment process, a realistic assessment of ecological and economic consequences must go well beyond estimation of numbers killed. The assessment should also include information on the subsequent natural mortality processes that would apply to the organisms killed so that the effects of entrainment, mortality can be examined at the population level. To the extent possible with existing information, the population consequences should also be placed in the context of losses to sport and commercial fisheries and effects on other trophic levels should also be part of the assessment. Although there is a trade-off between certainty of consequences and level of biological organization examined, any assessment that attempts to address ecological and economic consequences must proceed beyond mere numbers killed.

However, in the event that EPA follows through with its stated intent to assess compliance without examining population and community levels, it is even more critical that the survival rates of entrained organisms be factored into the assessment. For reasons to be discussed below, an unjustified assumption of 100% mortality of all entrained organisms will be neither correct, nor necessarily protective of the populations subject to entrainment.

2) EPA should revise section A7-1.1 to present a more balanced depiction of the involvement of eggs and larvae with power plant intakes. Eggs and larvae, to be subject to entrainment, must occur in the water column. Many species, for example the catfishes, many sunfishes, and pikes, build nests and/or spawn in the shore zone, and therefore are seldom entrained. Species that are commonly entrained generally, are pelagic spawners or have larval stages that move into the water column. This type of life history is also usually associated with high fecundity, and high mortality rates from the egg stage to adulthood. The high mortality does not necessarily occur within the egg stage, and high natural mortality rates are not necessarily indicative of high entrainment mortality, i.e. high natural mortality could be due to predation. EPA should also recognize that entrainment of a life stage with a high natural mortality rate, or a high natural mortality rate in subsequent life stages, will mean that most of

the entrainment losses would have been removed from the population at a later stage due to natural causes, thus the population effect is not accurately characterized by the number lost to entrainment.

3) In the second paragraph of section A7-1.1, EPA sets a very high standard for demonstrating entrainment survival: “any assertions that survival rates are appreciably greater than zero should be viewed with skepticism, and evidence in favor of that assertion must be quite strong to be convincing.” The studies reviewed by EPA in Section A7-3, although perhaps lacking in many instances as a quantitative estimate of survival rate are sufficient to rebut the presumption that entrainment and passage through a cooling water intake structure would kill most if not all organisms. Even with the problems EPA finds in the prior studies the one underlying message that should come across to an unbiased party is that, in nearly all cases examined, a significant fraction of fish eggs and larvae can survive. The remaining challenge is not to demonstrate that survival can occur, but to determine what sets of circumstances permit survival and to accurately estimate its magnitude.

4) Entrainment survival data can be collected to (1) estimate the realized survival at the subject station and/or (2) provide data with which to develop predictive models of entrainment survival at other plants or in different sets of conditions. EPA needs to understand the difference between these two possible uses for the data, and realize that a complete understanding of the factors affecting survival rates and their potential interactions is not necessary for plant-specific estimates of realized survival.

At any particular time, the ambient water conditions, the numbers and life stages of each species being entrained, and to a large extent the plant operating conditions, are not amenable to experimental manipulation. Therefore, although the data collected will inevitably be a subset of the possible combinations of factors that might potentially be important, the combinations of factors that do occur will generally reflect the relevant combinations for that station. One possible exception would be a limited set of plant operating regimes that might not reflect the range of plant operation typical of that plant.

It would be nearly impossible, in any particular year to collect large samples of all commonly entrained, species and life stages under all potential conditions of ambient temperature, thermal exposure, mechanical stress, and biocide use. In order to obtain a more complete data set, it would be necessary to combine results across years for the same station. This combination can best be done if sampling apparatus and methodology are standardized. Unfortunately, most of the existing survival data were collected during the late 1970s and early 1980s when the sampling gear and protocols were rapidly evolving.

If, as seems necessary, EPA intends to incorporate entrainment survival into its assessment process, it is important that it clearly signals that it recognizes the realities of entrainment survival sampling and will be willing to evaluate entrainment survival studies conducted over a period of years, given that some of the previous shortcomings of design and protocols can be solved.

5) Section A7-1.2 (Thermal stress) lists a large number of temperature-related variables that potentially affect entrainment survival rates. Although these factors may be theoretically relevant, past studies have shown that exposure. temperature (i.e. the temperature measured in the discharge after it exits the condensers) is typically the most important factor. For instance, Jinks et.al. (1978) successfully predicted thermal mortality using a model with exposure temperature (most important),

ambient temperature, and exposure duration as independent variables. It would be impossible to collect real entrainment data sufficient to statistically test the influence, of all the factors, and potential interactions of the factors, that EPA lists.

6) In Section A7-1.2 (Chemical stress) EPA should realize that at many stations, biocides are not "routinely used", and would generally, not be a factor influencing entrainment survival. EPA's characterization of biocide use as routine is particularly surprising because biocide use is far below what it was in the 1970s as a result of EPA's efforts to reduce chlorine discharges. Current. NPDES/SPDES permits incorporate strict limits on chlorine discharges. The SPDES permit issued to the Indian Point units in 1987 is a prime example with a limitations of two hours per day and a maximum of 9 hours per week at both units combined.

Certainly, entrainment survival studies should record when biocides are used and analyze those data separately from data collected when biocides are not used. However, failure to record the data is not likely to result in substantial bias to the entrainment survival estimates, and if any bias exists it would be likely to have a negative effect on the estimated survival.

7) In section A7-2 (Page A7-4), EPA lists deficiencies of previous studies that lessen the applicability of entrainment survival studies. This encyclopedic list includes many factors that have little or limited relevance, but by including them the overall appearance of deficiency of the studies is promoted

-Geographic distribution — The geographic location of an entrainment survival study is not a factor that should carry weight in its evaluation. Although the studies reviewed were highly concentrated with nearly half of the studies being conducted on the Hudson River, their relevance, or lack thereof, to other power plants is independent of geography. Factors that might limit their applicability in other places would be whether the species entrained are similar, whether the life stages occur at the same ambient temperatures, and factors related to thermal exposure and duration and mechanical stress.

-Small sample sizes - in many cases, the sample sizes were not small for the most commonly entrained taxa, and in fact are far larger than is typical in bioassay studies. For instance, the 1977 program at the Indian Point stations collected 806 striped bass post yolk sac larvae (PYSL) at the intake and 518 at the discharge. In 1978, 423 PYSL were collected at the intake and 551 at the discharge. Intake and discharge collections in 1979, 1980, and 1988 were 64 and 114, 142 and 207 and 273 and 2398 respectively.

Naturally, taxa and life stages that are less abundant in the water column will be less abundant in entrainment survival samples. However, in many cases, the common taxa have reasonably large sample sizes.

-Limited species in the studies - Due to the concentration of studies in the Hudson River, a great deal of the available information exists for a relatively few number species, i.e. those that are common in the Hudson However, for plants that entrain these same species, there is a great deal of relevant information

-Variation in sampling procedures - EPA must recognize that most of the existing studies were conducted during a time of rapid evolution in the sampling equipment and protocols. This evolution resulted in substantial improvement in the data collected and in the precision of entrainment survival estimates as the methodology matured (Muessig et al. 1988). EPA should not use the improvements in sampling as a reason to disregard the entrainment survival results, but instead should weight those studies using the improved methods and protocols more heavily.

-Absence of information on chemical stresses - Use of biocides was far less common than EPA suggests, which makes this generally an issue with low relevance. Any bias due to unrecorded biocide stress would be negative.

-Absence of information on mechanical stress - It is not necessary to differentiate the sources of stress in order to describe the empirical entrainment survival at a particular power plant. (See comment 4 above)

-Limited data on latent physiological effects on species - EPA must recognize the trade-off that exists between handling large numbers of larvae and the ability to collect detailed information on individuals. EPA criticizes sample sizes as too small and also criticizes the studies for not collecting detailed information on latent physiological effects, information that could only be obtained by devoting substantially more time and laboratory resources to each collected organism. Requirements for detailed physiological analysis would only make survival studies far more difficult and expensive to conduct.

Even if such studies were attempted they would be severely limited by the artificiality of the laboratory environment. Most past studies were limited to 96 hours or less of post-entrainment observation in order to avoid starvation, cannibalism, and behavioral interactions that could cloud the interpretation of the data. Any attempt to examine longer-term latent effects would be subject to laboratory-induced confounding due to the artificial holding environment, food items and densities provided to the larvae, and behavioral effects.

-Effects from entrainment on growth rates - Information on the effects of entrainment on growth rates could be provided if EPA is willing to compare growth of entrained fish to unentrained control specimens held in the same post-sampling conditions. Comparison of entrained fish to wild unentrained fish would not be a valid exercise due to the unnatural conditions in the laboratory environment.

-Increased vulnerability to natural mortality, maturation, and fertility/fecundity - Aside from a possible increased vulnerability to predation immediately after entrainment, it is difficult to postulate how a short-term (on the order of 30 minutes) exposure to entrainment stresses while sub-lethal, could have life-long effects on the maturation, fertility and fecundity of entrained organisms. Even if EPA could reasonably hypothesize how such effects would occur, it must realize that collection of data demonstrating the magnitude would be impossible in most cases.

8) In section A7-3 (Braidwood Nuclear and elsewhere), EPA embraces the design concept of lagging the discharge sample behind the intake sample so that both samples are drawing from the same pool of organisms. Although this seems logical in practice the conceptual advantage is overridden by the need to ensure that both samples are exposed to the same degree of sampling stress. This consideration is best satisfied when intake and discharge samples are collected and processes simultaneously so that handling stress can be assured to be identical.

9) In A7-3 (Braidwood Nuclear), EPA recommends that dead-opaque larvae should be included with dead in order to calculate entrainment survival. The translucent character of live fish eggs and larvae, and the change in opacity that occurs after death is a useful indicator of prior physiological state. Since opacity generally takes some time to develop, opaque larvae can be considered to have been dead at the time they were initially sampled, and not to have died during or after sampling.

10) In section A7-3 (Braidwood Nuclear at top of page A7-5) EPA suggests Abbott's formula not be used to adjust the discharge survival proportion for sampling-related mortality "the percent survival of all individuals sampled from the discharge without correcting for sampling equipment related mortality be used to ensure a fair accurate and conservative estimate of entrainment survival." If implemented, the "conservative" estimate EPA desires would actually be biased by the severity of sampling mortality and/or the proportion of already dead organisms in the samples This suggestion should not be implemented.

11) In A7-3 (Brayton Point [last paragraph on page A7-5] and Port Jefferson [2nd paragraph on page A7-10]) EPA suggests that discharge survival rates higher than intake survival rates indicate erroneous results. Actually, if entrainment mortality is low there is a distinct possibility that due to chance, discharge survival will at times exceed intake survival. When this occurs, survival obviously is only 100%. Rather than throwing out the data as EPA suggests, researchers should calculate a lower confidence bound for survival using appropriate statistical techniques.

The possibility of control mortality exceeding test mortality also exists in bioassay testing EPA s Methods for Measuring the Acute Toxicity of Effluents and Receiving Waters to Freshwater and Marine Organisms", which also uses Abbot's formula to adjust for control mortality, does not routinely exclude results when control mortality exceeds toxicant mortality.

12) In Section A7-3 (Cayuga and Indian Point) EPA feels the handling and latent effects studies "may not accurately simulate the actual conditions to which organisms are exposed after discharge from the facility." If EPA is concerned over the immediate post-entrainment environment, then the gradual cooling back to ambient temperatures that occurs during sampling should approximate the mixing of the discharge plume with ambient temperature water. Of course, the actual post-entrainment thermal experience of the unsampled organisms will vary greatly in the field.

For the longer term, e.g. 2 to 96 hours after entrainment, it is not possible to hold test organisms in a natural setting and continue to monitor the health and status of individuals. If EPA is criticizing this aspect of the latent effects studies they are setting an impossibly high standard for the studies. The critical factor is that the entrained and control organisms are both held in the same conditions so holding effects can be removed by applying Abbott's formula.

It should be noted that EPA's sanctioned Whole Effluent Toxicity testing protocols also holds organism under unnatural conditions. But because test and control organisms are held in the same conditions, the effects of the subject effluent can be estimated.

13) EPA takes an inconsistent position on adjustment of discharge survival rates in section A7-3. For the Cayuga studies EPA claims that adjustment of discharge survival for intake survival give "falsely high survival rates." In its review of the Quad Cities studies, EPA argued for adjustment as a means to eliminate the bias of the already-dead larvae in the samples. As previously discussed in comment 10,

the adjustment of the discharge sample for sampling mortality is necessary to produce an unbiased estimate of entrainment survival.

14) EPA infers in A7-3 (Port Jefferson Page A7-10, paragraph 3 and elsewhere) that unequal sample sizes at intake and discharge are a problem. There is no statistical requirement for equal sample sizes for the intake and discharge samples. However, substantial inequalities could indicate non-random sampling at one or both locations. Therefore, it should be recommended that researchers examine the organism densities, survival rates, species compositions and length frequencies at the two stations to assist in detecting non-randomness. For instance, differing length frequency distributions at intake and discharge locations might indicate avoidance by live organisms, extrusion of small organisms, or possibly destruction during plant passage. Sample size differences can also be generated by differing sample volumes at the two locations and by stratification, particularly at the intake. The large differences in sample sizes in the 1988 Indian Point studies were the result of using two samplers at the discharge and only one at the intake and probable stratification of larvae at the intake in depths away from the sample intake point.

15) In A7-4 EPA correctly states that “accurate quantification of biological impacts should include entrainment survival in cases where entrainment survival rates have been estimated by valid means. However, the entire chapter promotes the view that there are no instances where valid entrainment survival estimates currently exist. EPA should make explicit distinctions between situations where data are sparse and collection methods are suspect and situations where data are abundant and have been collected by state-of-the-art techniques (e.g. Indian Point, Bowline, and Roseton plants).

16) In A7-4.1, paragraph 2, EPA incorrectly indicates that no attempts to calculate entrainment survival should be made when control survival is less than discharge survival. As discussed, in comment 11, discharge survival rates higher than intake survival rates are not necessarily an indication of invalid data or violated assumptions.

17) In A7-4.1 (Paragraph 3), EPA recommends studies throughout the year. Entrainment abundance studies at many plants have demonstrated that, entrainment is typically highly seasonal, corresponding to the spawning period of the dominant taxa in the fish community, therefore a year-round entrainment survival study be a significant misallocation of resources. Instead of year-round sampling, information from previous entrainment abundance studies or knowledge of the spawning seasons of the dominant taxa should be used to target the survival sampling to their periods of abundance.

18) EPA recommends ends that 24-hour sampling should be done to capture diet changes in survival Unless plant operating conditions change on a diel basis, there is no reason to expect any diel differences in survival. Therefore, it might be useful to incorporate diet sampling into peaking stations whose generation levels change dramatically between peak and off-peak periods, but at baseload stations, such as most nuclear plants, diel sampling would not be necessary.

19) In Section A7-4.1, paragraph 4, EPA requests information that is for the most part superfluous to measuring entrainment survival at a particular plant, such as impacts caused by speed and pressure changes within the condenser, the occurrence of abrasive surfaces, turbulences within the condenser. This information, if available, could be used to develop predictive models of entrainment survival however it is not necessary to characterize empirical entrainment survival at a particular station.

If predictive models for application to other power plants are desired, a better way to collect the relevant data would be through simulation studies (e g O'Connor and Poje 1979; Coutant and Kedl 1975; Kedl and Coutant 1976; Suffern 1977). In a simulation study, conditions can be closely controlled and sample sizes can be fixed sufficiently high to conduct the necessary statistical analysis to understand the effects of different factors and their interactions.

20) In A7-4.1, paragraph 5 EPA recommends that studies be done under worst-case conditions. Worst-case conditions, generally maximum ambient temperatures and maximum generation levels, often occur over only a relatively brief period of time. This period might not correspond with periods of significant entrainment. In the United States, many fish species subject to entrainment, spawn during the spring, generally before peak ambient temperatures and, for many stations, peak generating loads occur. Usually only a small fraction of entrainment would ever occur under worst-case conditions. Depending on the station an attempt to collect data under worst-case conditions would likely result in small sample sizes for a very limited number of species.

21) EPA states in A7-4.4 that adequate precision of estimates and parameters is required, but correctly provides no standards for determining when precision is adequate. As is typical in statistical analysis, the precision of estimates should be calculated and the estimates should be evaluated based on the precision achieved. Thresholds for precision should not be established.

EPA should also realize that while entrainment survival studies are conceptually similar to bioassays, they will be inherently more variable than bioassays. Thus standards that might be applicable to bioassay studies are not applicable in entrainment survival. The additional variability arises from the differences in test organisms, and the lack of ability to control test conditions. In bioassays, the test species are selected for their ability to provide a reliable test of toxicant effects. The organisms will be relatively uniform in age condition and genetic lineage. In entrainment survival studies, the species collected will be those that are subject to entrainment (whether or not they survive well), and will be very heterogeneous in age, condition, and genetic lineage. In addition, many of the factors that might affect entrainment survival are not subject to experimental control (e g ambient temperature, delta-T, exposure duration, mechanical stress, organism size). These organismic and experimental factors add considerably to the variability of results observed in entrainment survival studies.

22) EPA's statement in the last paragraph of A7-5 that previous studies provide only a "provocative set of anecdotes" is incorrect. Despite the design and analytical problems that occurred in past studies while sampling gear and protocols evolved, the studies have conclusively disproven the presumption of 100% mortality for some species.

23) EPA is incorrect in its view that retaining the 100% mortality presumption is a universally prudent stance for the agency in its precautionary approach. If a 100% mortality presumption is used as the default assumption, then facilities will have only two options to reduce their entrainment mortality: either screen out entrainable life stages or reduce cooling water flow. For species that actually do have substantial entrainment survival, as those on the Hudson River have demonstrated, either option may actually increase the numbers killed and produce a result opposite of the EPA's intention.

Screening out entrainable life stages through the use of fine-mesh screens may well increase the actual number of fatalities for taxa and life stages that currently exhibit non-trivial survival rates. If flow reduction is chosen as the mitigation method, care must be taken that lower flows do not increase the exposure temperature to the point that all entrained organisms are killed by the thermal stress. If that occurs, the actual number killed might be higher at lower flow rates.

Regulatory agencies can properly use entrainment survival data to achieve a correct §316(b) determination only by examining the existing data on a case-by-case basis. Where little or no applicable data exist, an agency may be justified in assuming 100% mortality as a baseline condition. The burden is then on the applicant to collect information to justify an alternative value for survival and to propose mitigation strategies that use that information. However, when data sufficient to demonstrate significant entrainment survival already exist, as they do at Indian Point and other Hudson River plants, agencies should not cling blindly to the 100% mortality assumption and risk implementing mitigation measures that result in increased numbers of fish lost.

EXECUTIVE SUMMARY

This report reviews and critiques the U.S. Environmental Protection Agency's ("EPA") use of the Habitat Replacement Cost ("HRC") methodology as a means for valuing the benefits of reducing impingement and entrainment ("I&E") by cooling water intake structures ("CWIS") at facilities within the scope of EPA's proposed rule for existing facilities under Section 316(b) of the Clean Water Act ("316(b) Phase II Proposed Rule). We focus on the use of the HRC to calculate benefits at Pilgrim Station ("Pilgrim"), as reported in EPA's Seabrook and Pilgrim Facilities Case Study (U.S. EPA 2002, hereafter "Case Study").

Summary of Findings

The principal finding of this report is that HRC is an invalid method for estimating the benefits of proposed regulatory alternatives for implementing Section 316(b). Although this conclusion is sufficient to disqualify the use of the HRC methodology for benefits analysis, we also evaluate EPA's application of this method in the case of Pilgrim, and find several concerns about the implementation of this flawed methodology. We summarize our findings below.

1. HRC is not a valid method for measuring the benefits of prospective 316(b) policies.
HRC cannot and does not provide a measure of the benefits of a prospective policy designed to reduce I&E by CWIS. HRC is a method that, if implemented properly, can provide a measure of the cost of a specific policy alternative - namely, compensating for I&E losses by developing new habitat that may generate equivalent fish populations and ecosystem services.

2. There is no basis in the economics literature or EPA guidelines for using HRC as a benefits estimation tool.

The economics literature, as well as the recent EPA Guidelines (U.S. EPA 2000), provides examples of methods that may legitimately be used to estimate ecosystem benefits. HRC is not among them. Although HRC superficially resembles some other economic valuation methodologies that are cited by EPA as support, it differs from these methodologies in critically important ways and, therefore, cannot and should not be treated as analogous. None of these other valuation approaches are appropriate precedents that would support the use of HRC to estimate the benefits of reducing I&E losses at Pilgrim or other electric generating facilities.

3. The application of the HRC method to the estimate of habitat replacement costs for the Pilgrim Facility is flawed in implementation (apart from its lack of a sound conceptual basis as a benefit-estimation method).

EPA's application relies on several arbitrary assumptions that are poorly supported in the Case Study. Moreover, EPA provides no conceptual basis for the choice of replacement habitats in the Case Study. Finally, the approach used by EPA exhibits a significant upward bias.

4. The inappropriate application of HRC results in a dramatically higher estimate of the benefits of reducing I&E at the Pilgrim facility than the estimate developed using conventional methods.

Using HRC to estimate the benefits associated with eliminating I&E losses at Pilgrim yields a much higher estimate of benefits than derived by EPA using conventional methods supported in the economics literature and in EPA's guidelines for conducting economic analyses. As illustrated in Table ES-l, the benefit estimates in EPA's Case Study derived using HRC are more than 20 times greater than those derived using conventional methods. <FN 1>

Table ES-1 Summary of EPA Estimation Methods for Damages Due to Impingement and Entrainment at Pilgrim Station.
[see hard copy for table]

Conclusion

The use of the HRC method to develop benefits estimates is completely unsupported in EPA guidelines and in the economics literature. In light of this fundamental and inescapable problem, EPA should eliminate the HRC as a method for benefit estimation in revising the Pilgrim Case Study as part of its analysis of the final rule. Instead, EPA should rely on acceptable economic approaches to measure benefits for Pilgrim in the Case Study.

I. INTRODUCTION

This report evaluates the use of EPA's "habitat replacement cost" ("HRC") methodology, as set out in EPA's proposed rule for existing facilities under the Clean Air Act (67 FR 17121, the "316(b) Phase II Proposed Rule") to estimate the benefits of a potential project - in this case a project that would reduce impingement and entrainment (“I&E”) <FN 2> of fish and other organisms by cooling water intake structures (“CWIS”) at certain existing power plants. We address the fundamental question of whether the HRC method is an appropriate economic methodology as it is used m the case study of the Pilgrim Nuclear Station (“Pilgrim”).

A. Background

EPA’s proposed rule would establish performance standards commensurate with closed-cycle cooling for CWIS at existing power producing facilities with a cooling water intake flow of 50 million gallons per day or more from rivers, streams, estuaries, and other U.S. waters. Under the Rule, where there is an adverse environmental impact (which EPA has presumed), facilities would be required to implement “best technology available” (“BTA”) for CWIS to minimize that impact.

As part of its development of the proposed rule and pursuant to the requirements of Executive Order 12866 (“Regulatory Planning and Review”) and relevant statutes, EPA must perform an analysis of the benefits and costs of the proposed rule and alternatives. To inform this exercise, EPA has prepared a number of ease studies examining the potential benefits of reducing I&E at CWIS in various ecosystems around the U.S. This report examines EPA’s estimation of the value of losses at Pilgrim Nuclear Station (“Pilgrim”) as part of EPA’s Seabrook and Pilgrim Facilities Case Study (“Case Study”). The Case Study evaluates the effect of I&E by CWIS at the Seabrook and Pilgrim facilities; both of which are on the New England Coast and within the scope of the 316(b) Phase II Proposed rule.

The case studies are important for at least two reasons. First, EPA uses the results of the case studies to extrapolate national benefits of the 316(b) Phase II Proposed Regulation and various regulatory alternatives. Second, various permit writers, will undoubtedly use the case study methodologies as guidance for the implementation of benefit-cost analyses to evaluate options for individual permits.

The remainder of this chapter provides an overview of the Case Study results for Pilgrim, a discussion of the specific objectives of this report, and an outline of the other chapters.

B. Overview of EPA Case Study Benefit Results for Pilgrim

EPA’s Seabrook and Pilgrim Facility Case Study presents results for the Seabrook and Pilgrim Nuclear stations on the New England Coast. In this report, we focus on the results for Pilgrim Table 1 summarizes EPA’s Case Study results reported for Pilgrim. The values are annualized, based on the midpoints of the ranges estimated in the case study. According to the Case Study, total annual damages due to impingement and entrainment at. Pilgrim are calculated at about $13.1 million per year (2000 dollars), using the HRC method. The vast majority of the losses are due to entrainment rather than impingement; of the $13.1 million, entrainment accounts for $12.3 million, or 93.6 percent of the total. Note that these values are annualized. Using a discount rate of seven percent and an initial license termination date of 2012 for Pilgrim, subject to extension for an additional 20 years, implies that the present value of losses through 2032 due to I&E at Pilgrim would be approximately $150 million (in 2000 dollars), based on the results of the Case Study.

Table 1. Summary of EPA Estimation Methods for Damages Due to Impingement and Entrainment at Pilgrim Facility.

Method	Impingement	Entrainment	Total
Loss to Fishery:			
Commercial	$1,300	$77,000	$78,300
Recreational	$1,800	$348,600	$350,400
Forage	$90	$29,300	$29,390
Nonuse	$900	$174,300	$175,200
Total Loss to Fishery	$4,090	$629,200	$633,290
Habitat Replacement Cost:			
Total HRC	$840,000	$12,300,000	$13,140,000

Ratio of EEC Estimate to 205:1-20:1Loss of Fishery Estimate 21:1
Source: EPA (2002), Figure G6-4, and NERA calculations.

As Table 1 shows, the estimate of losses obtained with the HRC method are dramatically higher than those obtained using conventional methods for estimating benefits - $13.14 million per year, as compared to $633,000 per year, a difference of a factor of 21. This gross disparity in the value obtained using HRC versus that obtained using the conventional approach suggests the need to reconsider the validity of the approach. Accordingly, this report focuses on examining the conceptual validity of the HRC method and the values developed for the Pilgrim Case Study.

C. Objectives of This Report

The major objective of this report is to evaluate the HRC method used by EPA for Pilgrim. In particular, we consider whether the HRC analyses are based on sound conceptual and empirical methodologies. The criteria for our judgments are based on the economic literature, as well as on current guidelines for regulatory analyses developed by EPA (U.S. EPA 2000) and the Office of Management and Budget (1996).

D. Outline of the Report

The report is organized as follows. Chapter II provides an overview of EPA's HRC methodology and its application to Pilgrim. Chapter III evaluates this methodology and application. Chapter IV concludes the report.

II. OVERVIEW OF EPA'S HRC METHODOLOGY AND ITS APPLICATION TO BENEFIT ESTIMATES FOR PILGRIM STATION

This chapter describes EPA's HRC methodology and its calculation of HRC for Pilgrim.

A. Description of EPA Habitat Replacement Cost Methodology

Chapter A11 of EPA's case study document (U.S. EPA 2002) provides an overview of EPA's HRC method for valuing losses of fish and other organisms resulting from I&E by CWIS. EPA argues that conventional techniques may underestimate: true values for losses sustained as a result of I&E,

because they allegedly fail to account for the impact of losses in early-stage fish and shellfish populations (i.e. eggs and larvae). EPA also implies that conventional means of estimating losses do not account for nonuse value.

Chapter A11 of the EPA ease study document describes the basic approach of the HRC method:

The HRC method values natural resource losses based on the costs of ecological habitat-based restoration activities, as opposed to approaches not based on habitat such as fish stocking, that are scaled to increase natural production as an offset to the I&E losses. Thus, HRC uses resource replacement costs as a proxy for the value of resources lost to I&E. (U.S. EPA 2002, p. Al1-3)

In short, the HRC approach develops an estimate of costs for undertaking an activity that would be intended to have an equivalent result to ceasing or reducing I&E at the affected facility. Under the HRC method, EPA presumes these costs to be a measure of benefits.

B. Application of HRC Methodology to Estimate Value of Fish Losses at Pilgrim Station

Chapter G5 of EPA's case study document (U.S. EPA 2002) presents a step-by-step discussion of its method for valuing I&E losses at Pilgrim. EPA outlines what is essentially a five-step process:

1. Measure I&E Losses

2. Identify a "Preferred" Habitat Restoration Alternative for I&E Species

3. Quantify Expected Increases in Species Production

4, Scale I&E Losses Using Expected Increases in Species Production

5. Calculate Unit and Total Costs

We discuss these steps in detail below.

1. Measure I&E Losses

Pilgrim has been monitoring impingement three times per week since 1974. Screens are washed over once in the morning, once in the afternoon, and once in the evening during a single 24-hour period. The number of organisms obtained is then converted to an hourly impingement rate by dividing by the number of hours between catches. This number is then multiplied by 24 and then by 365 to generate the annual impingement rate. These values are averaged over the course of the year. Pilgrim has also recorded entrainment since 1974. Pilgrim uses a mesh net - which varies depending on time of year - to sample entrained fish.

In its analysis, EPA included only those fish that had losses greater than 0.1 percent of the total I&E losses at Pilgrim EPA converted all values to average annual age-one equivalents.

We understand that EPA's calculations of I&E costs are disputed.. We have undertaken no independent assessment, but have simply assumed EPA's calculations of I&E losses are acceptable for purposes of this discussion. <FN 3>

2. Identify a “Preferred” Habitat Restoration Alternative for I&E Species

EPA identified the habitat requirements of I&E species and generated a list of possible habitat restoration alternatives. In this case, EPA identified six alternatives: submerged aquatic vegetation (SAV), tidal wetlands, artificial reefs, improved anadromous fish passages, improved water quality, and reduced fishing pressures. After identifying feasible restoration alternatives, EPA convened a committee of officials from EPA, National Marine Fisheries Service, and various Massachusetts protection agencies to designate “a preferred restoration alternative for each species” (U.S. EPA 2002, p. Al1-2.4 and G5-4). As discussed below in Chapter III, it is unclear exactly what criterion EPA uses to judge the “preferred” alternative, or how these alternatives were selected.

3. Quantify Expected Increases in Species Production

Because fish species populations living in restored habitats are likely to grow significantly after restoration, EPA calculated the expected increases in species population as a way of quantifying the benefit of the restoration. Given the limited data available, however, EPA used a proxy to estimate this restoration effect:

Unfortunately, available quantitative data is not sufficient to estimate reliably the increase in fish production that is expected to result from the habitat restoration actions ... There is also limited data available on the production of these species in natural habitats that could be used to estimate production in restored habitats. Therefore, in this analysis EPA relied on quantitative information on fish species abundance. in the habitats to be restored as a proxy for the increase in production expected through habitat restoration (U.S. EPA 2002, p.G5-9)

EPA used several techniques to estimate species abundances in the various habitats being considered. As an example, EPA used otter trawls to estimate fish species abundances in SAV habitats. Because fish tend to avoid trapping equipment, EPA adjusted the results using a sampling efficiency - the estimated percentage of fish caught in a given area compared to the real population in that area. EPA estimated sampling efficiency at 40 to 60 percent. Ultimately, EPA adjusted the results by multiplying by a factor of 2.5 (i.e., using the 40 percent figure).

EPA then converted these values to age-one equivalents using survival rates. That is, EPA’s estimated number of juveniles was summed and then multiplied by the estimated survival rate to obtain EPA’s estimate of the equivalent number of age-one individuals that would be expected from this number of juveniles. When survival rates for juveniles were unavailable, EPA estimated the rate using the value for larvae survival averaged with 1.0 (which is, by definition, the percentage of age-one individuals who survive until age one).

4. Scale I&E Losses Using Expected Increases in Species Production

EPA used the estimated abundance (as a proxy for production) values for each species’ preferred habitat to estimate how much restored habitat would be necessary to restore I&E losses. That is, EPA divided I&E losses for each species by the increased production, as calculated above. For each habitat, EPA then took the maximum value - the species that needs the most of that habitat to recoup

I&E losses - and used that as the "assumed units of implementation required to offset I&E losses" (U.S. EPA 2002, p. G5-29) for all of the species with a given preferred habitat.

We understand that EPA's calculations of restored habitats are disputed. We have undertaken no independent assessment, but have simply assumed EPA's calculations of restored habitats are acceptable for purposes of this discussion.

5. Calculate Unit and Total Costs

Using values from organizations with experience in rebuilding habitats, EPA estimated the cost to restore one square meter of each type of habitat (e.g. submerged aquatic vegetation, tidal wetlands, etc.). Because increased fish production units were estimated per 100 square meters, EPA scaled the unit cost to 100 square meters by multiplying by 100.

For each habitat, EPA multiplied this unit cost by the "assumed units of implementation required to offset I&E losses," as determined above, producing a cost for each type of habitat. EPA then summed these values to generate a total cost figure for habitat replacement.

III. EVALUATION OF EPA'S HABITAT REPLACEMENT COST METHODOLOGY AND APPLICATION TO PILGRIM STATION

This chapter evaluates the use of the HRC approach from a methodological standpoint and considers EPA's estimate of habitat replacement costs for Pilgrim.

A. HRC Is a Profoundly Flawed Methodology and Does Not Provide a Measure of the Willingness to Pay for Losses.

This section explains why EPA's use of the HRC approach to measure the benefits of reducing fish losses through I&E is conceptually incorrect and inconsistent with relevant EPA guidelines for benefit estimates.

1. General Principles for Benefit Estimation

Benefit-cost analysis is an established methodology for providing information to decision makers faced with the task of determining whether a project should be undertaken, and if so, at what scale of activity (see, e.g., Stokey and Zeckhauser 1978, Nas 1996). The approach involves systematic enumeration of benefits and costs that would accrue to members of society if a particular project were undertaken. Benefit-cost analysis provides an ex ante perspective; a project is evaluated in advance to aid in deciding in what form it should be undertaken and, indeed, whether the project should be undertaken at all.

The rationale for undertaking a benefit-cost analysis of a particular decision is to allow society's resources to be put to their most economically valuable use. In choosing among alternatives, the basic benefit-cost principle is to select the alternative that produces the greatest net benefits (i.e., benefits minus costs). It is possible that all project alternatives produce net benefits that are negative. In that case, the higher value alternative is to "do nothing," which at least produces a net benefit of $0.

Assuming an adverse environmental impact, benefit-cost analyses of the choice of BTA require the careful enumeration of the monetary value of different impacts resulting from various alternatives. These impacts are typically separated into costs (negative impacts) and benefits (positive effects), although the two categories are closely related.

The benefits included in benefit-cost assessments should reflect benefits to society. Estimates of benefits associated with environmental improvements reflect social benefits when they are based on the willingness to pay ("WTP") of individuals who receive the increased environmental services (e.g., commercial fishing services). WTP represents the value of a good or service in monetary tents (i.e., the amount the individual is "willing to pay' in dollar terms). The current EPA Guidelines for preparing economic analyses explain this concept as follows

The willingness to trade off compensation for goods Or services can be measured either as willingness to pay (WTP) or willingness to accept (WTA). Economists generally express WTP and WTA in monetary terms. In the case of an environmental policy, willingness to pay is the maximum amount of money an individual would voluntarily exchange to obtain an improvement (or avoid a decrement) in the environmental effects of concern. Conversely, willingness to accept compensation is the least amount, of money an individual would accept to forego the improvement (or endure the decrement) (U.S. EPA 2000, p. 60, emphasis in original).

EPA notes that: "In practice, WTP is generally used to value benefits because it is often easier to measure and estimate" (2000, p. 61). As discussed below, HRC does not measure WTP.

2. HRC Does Not Conform Basic Economic Principles

In this section, we first explain the logical flaw in using HRC as a measure of benefits and then discuss its lack of support in the economics literature. Finally, we compare HRC to other superficially similar methodologies that could at first glance - but mistakenly so - appear to provide support for using HRC as a benefits estimation method and conclude that HRC cannot reasonably be used as a benefits-estimation method, particularly in the context of 316(b).

a. The Logical Flaw in the Use of HRC as a Measure of Benefits

HRC is designed to measure costs rather than benefits. Therefore, HRC is not, and cannot be used as, a measure of the benefits of that policy or of any other policy. <FN 4>

HRC provides an estimate of the costs of undertaking an activity - creation of new fish habitat - that theoretically would be intended to have an equivalent result (i.e., increasing the population of certain fish species and other aquatic organisms) to ceasing or reducing I&E at the affected facility. 'But the costs do not provide' a measure of the benefits associated with undertaking such a policy.

Indeed, the purpose of benefit-cost analysis in the context of a regulatory policy decision is to determine whether the additional benefits of particular alternatives exceed the additional costs of undertaking them. <FN 5> To use HRC as a measure of benefits is to assume, without any explicit basis, that the benefits of a potential policy alternative (in this case, habitat replacement) are precisely equal in all cases to their costs. In short; using HRC as a measure of benefits begs the very question that is at issue - what are the benefits of each policy alternative?

EPA may be confusing HRC with a revealed-preference approach, such as a market transaction. The difference is that, in the case of HRC, there is no demonstrable revealed preference for replacing the habitat - no habitat replacement has taken place in a private market transaction. Individuals might, in theory, value the replacement of this habitat at some level equal to or greater than its cost; but the HRC analysis gives us no basis for knowing whether the social value of the habitat replacement is greater or less than the cost of undertaking it.

b. The Lack of Support for HRC in the Economics Literature

Not surprisingly, there is no support in the economics literature for using costs to measure benefits. Indeed, EPA effectively concedes as much by admitting that HRC is a “new approach” (U.S. EPA 2002, p. A11-3).

The reader of the Case Study document should not be misled, therefore, by the fact that EPA cites a number of economic sources in the section of the document describing HRC. These references discuss many useful economic concepts that are tangentially related to HRC, but they say nothing that would validate HRC as a method.

3. EPA Guidelines for Benefit Estimation Do Not Identify HRC as an Appropriate Methodology for Benefits Estimation

EPA’s Guidelines for Preparing Economic Analyses (2000) identify a number of specific techniques that can be used to estimate the benefits of improvements in environmental quality (or conversely, damages associated with environmental degradation). Table 2 provides EPA’s summary of benefits categories with examples of appropriate valuation methodologies. As is evident from Table 2, EPA has recognized several approaches to valuing goods and services, in this case lost early life stages of certain fish and other aquatic organisms, and any associated environmental amenities.

EPA’s Guidelines provide a comprehensive description of methodologies that can be used to estimate benefits of regulatory alternatives. The chapter on analyzing benefits (U.S. EPA 2000, Chapter 7) is extensive and detailed, referencing approximately 200 sources within the economics literature. The EPA Guidelines, and therefore the methods they discuss, were reviewed by a distinguished panel of thirteen environmental economists from the Environmental Economics Advisory Committee of EPA’s Science Advisory Board. Thus, they represent consensus within the field of economics on acceptable methodologies.

HRC is not mentioned or referenced anywhere within the Guidelines as a legitimate method for benefits estimation. As discussed above, this is not surprising, because the fundamental premise of the HRC approach - that the costs of a hypothetical activity can be used as a measure of the benefits of another activity - is completely incompatible with the basic principles of economics, as reflected in EPA’s Guidelines (2000).

[see hard copy for table]
Table 2. Examples of Benefit Categories. Service Flows, and Commonly Used Valuation Methods
Source: U.S. EPA (2000), p. 67.

4. Comparison of HRC to Other Superficially Similar Methodologies

As a further exploration of the misapplication of HRC, it is useful to examine superficially similar methodologies that EPA incorrectly and inappropriately cites as support for use of HRC to estimate benefits.

a. Habitat Equivalency Analysis

In Chapter A11 of the case study document, EPA argues that the HRC is “consistent with and related to lost resource valuation techniques such as habitat equivalency analysis (HEA)” (U.S. EPA 2002, p. A11-3). While HRC is superficially similar to the HEA method, there are important differences that make the analogy faulty, and, therefore, misleading.

The most important, and effectively dispositive, distinction between the two methodologies is the context in which they are used. HEA has been considered an appropriate methodology for estimating the replacement cost of a lost resource in penalty cases. In these cases, because of an applicable requirement, the U.S. is entitled to recover costs or collect compensatory damages under the National Marine Sanctuaries Act (“NMSA”) and related statutes. Further, the cost of acquiring an equivalent resource is appropriate, because the original resource cannot otherwise be restored or replaced. <FN 6> In these circumstances, NMSA provides that damages be compensated and that the National Oceanic and Atmospheric Administration undertake remedial action to preserve or replace the damaged site. <FN 7> Thus, HEA has been used as a means to estimate the costs of an activity that must be undertaken by law so that those costs can be reimbursed to the U.S. Government by the party that caused the damage necessitating the restoration.

HEA, therefore, has been used as a means of estimating costs, rather than benefits, as embodied in the NMSA and other statutes. HEA differs from HRC precisely for this reason. HRC, as it is presently used in EPA’s economic analysis for the 316(b) rulemaking, is intended to inform a decision that has not yet been made about what policy should be undertaken. In contrast, HEA plays no role in the overarching decision about whether restoration should occur - that decision is already embodied in the statute. HEA merely estimates how much cost should be collected in order to finance the implementation of that decision.

b. The Cost Replacement Method

The cost replacement method involves using cost to develop an upper bound on the potential benefits that could derive from undertaking a potential project. In this approach; the cost of an available alternative that achieves the same objectives as the potential project can be used to determine whether the project under, consideration should be undertaken. The key relationship is that the project has the same benefits as the known alternative—even if these benefits are not precisely known. If the alternative is less costly than the potential project, then the project—which has the same benefits - will have fewer net benefits than the alternative, and therefore would have a lower ranking in terms of economic efficiency. This approach can be used as a screening method to eliminate projects from consideration without the need to undertake a potentially benefit-cost analysis. <FN 8>

This method differs from RRC in that the known costs of an available alternative are interpreted as a maximum value—a limit on the cost that should be incurred to undertake any project that achieves the same benefits as the available alternative—rather than an estimate of the actual WTP for the project. Thus, the cost replacement method does not provide information about the actual benefits of undertaking a project, but only informs us as to whether the project is inferior to another alternative means of achieving the same objective.

c. Defensive-Expenditure and Averting-Behavior Methods

Another class of methods that appear superficially similar to HRC, but are distinct and better founded, includes defensive-expenditure and averting-behavior methods. These methods use empirical evidence about costs that have already been incurred to avoid environmental harm. Examples include expenditures on bottled water to avoid contaminated drinking water or expenditures on sunglasses to avoid UV radiation (including any additional time or other resources expended beyond the price. Abdalla et al. (1992) review the literature on this issue, which concludes that averting expenditures will define a lower bound to consumers' WTP. Thus, averting expenditures can legitimately be used to measure benefits, although Freeman (1993, pp. 359-360) notes that it may be difficult to measure benefits this way in practice, because averting behaviors may be motivated by other factors.

The key difference between the legitimate averting behavior approach and the inappropriate HRC method is that the former relies on activities that have already been undertaken by individuals. Thus, individuals' WTP is inherently revealed by their expenditures on certain goods or services. This is not the case for HRC. HRC uses highly speculative projects, which have not been undertaken privately or publicly, to estimate benefits.

5. Other Spurious Claims for HRC

EPA also argues that the HRC method has a broader scope than the methodologies EPA uses to develop benefits associated with commercial and recreational fishing:

The HRC method differs fundamentally from the commercial and recreational impact valuation method because the latter accounts for only those species and life stages that can be valued directly, such as those species targeted by recreational or commercial anglers (U.S. EPA 2002, p. A11-2).

This argument is fundamentally misleading for several reasons. First, to the extent that EPA is using an appropriate biological model to estimate the effects of I&E, that model should reflect the implications of losses of life stages other than age-one populations. In other words, the use values assigned to age-one populations, if properly developed, should reflect the entire life cycle of the population. Similarly, if the commercial and recreational impact valuation method does not value an appropriate range of species, it is because EPA has not used it appropriately. If any species have been omitted from the estimation procedure, that reflects a flaw in the application rather than in the methodology. Third, if there are ecological services provided by the habitat that cannot be properly valued in the commercial and recreational impact estimates, they presumably reflect nonuse values. But methods exist within the economics literature for measuring nonuse values. Finally, the quotation above suggests that the application of the HRC would account precisely for all species and life stages. But EPA's application of the HRC to Pilgrim exhibits a flaw that would cause benefits to be overestimated. Specifically, by selecting an amount of habitat corresponding to the maximum needed by the most habitat-intensive species, EPA guarantees that the habitat will produce species, and individuals beyond the number that have been impinged or entrained, i.e., effectively compelling substantial overcompensation by regulated entities

B. In Addition to Overwhelming Conceptual Problems, EPA's Impletnentation of the HRC Method Has Many Failings as a Cost-Estimation Method

EPA's use of the HRC method to measure benefits, at Pilgrim is fundamentally and conceptually flawed. However, even ignoring this, EPA's implementation of this approach has a number of shortcomings even as a cost-estimation tool, which we discuss below.

1. The "Preferred" Habitat Restoration Alternative

In order to estimate the HRC for the Pilgrim Station, EPA first convened a committee of officials from EPA, National Marine Fisheries Service, and various Massachusetts, protection agencies to discuss what habitat is "preferred" by each species affected by I&E. EPA then assigned a specific "preferred" habitat to each species and calculated posts based on this. Despite EPA's frequent assertion that it has made many cost-reducing assumptions, as discussed below, this methodology seems both vague and cost-inflating.

a. Lack of Selection Criteria

The Pilgrim Case Study provides no explanation of the criterion used to determine the habitat for each species except, that it is "preferred." Without an understanding of the steps undertaken to determine the "preferred" habitats, it is impossible to know whether EPA's selection process was valid. Absent specific criteria or a selection methodology, EPA's selection of the "preferred" habitats for the Pilgrim Case Study appears quite arbitrary.

b. Effects on Species from Habitats Other than the "Preferred"

In order to determine total costs, EPA summed the costs from each of the four "preferred" habitats. However, this takes no account of the effects on a species derived from habitats other than the "preferred." As an example, EPA's analysis assumed that the estimated. 242,981,200 square meters of tidal wetlands restoration would have no positive effect on any species except those for which tidal wetlands is the "preferred" habitat. It seems unlikely - if not impossible - that there would be no positive effects whatsoever on other species.
A more reasoned approach would be to select the habitats that are most cost-effective overall. However, it is impossible to know whether EPA selected those, habitats that would be most effective in reducing total cost. Even if EPA chose the habitat that is most cost effective for a given species, it may not have selected the option that would keep total cost the lowest. At the very least, EPA should have considered multiple alternatives for each species.

2. Using Current Species Abundance to Measure Increases in Fish Production

Due to data limitations, EPA could not calculate the effect of restoration on fish production in various habitats. As a result, EPA used a measure of the current species abundance in the relevant habitats as a proxy for fish production. Like the HRC method itself, this presents both a fundamental conceptual flaw and implementation-specific issues.

a. Confusing Stock as Flow: Abundance as a Proxy for Production

EPA's use of abundance as a measure of production in the Pilgrim case study is fundamentally flawed. Instead of measuring the potential growth in fish production (the "flow"), EPA measures the current "stock" of fish. As discussed in ENSR (2002), EPA's approach can lead to an overestimate of the amount of habitat, that would be needed to "compensate" for I&E losses at Pilgrim. Specifically, ENSR notes that tidal wetlands serve as spawning and nursery areas for fish that migrate to the larger marine ecosystem at adulthood. Thus, the production of these areas may well exceed the abundance of fish that would be measured there.

b. Correcting for Sampling Inefficiencies

In order to estimate current species abundances in various habitats, EPA used nets to collect specimens in each habitat and counted' the number of species caught, then calculated fish production per square meter. However, because many fish can sense the equipment, these catches do not accurately reflect the population of the region. The Case Study for Pilgrim uses a sampling inefficiency number to correct for this.

As an example, in the case of submerged aquatic vegetation habitats, EPA, used offer trawls to estimate fish species abundances. There, EPA assumed sampling efficiency to be approximately 40 to 60 percent. Ultimately, EPA adjusted the results by multiplying by a factor of 2.5 (i.e., using the 40 percent figure). The case study document provides no rationale for this. Indeed, the use of this number appears arbitrary. In addition, EPA uses a single sampling efficiency for all species and ages. Presumably, the probability of a fish getting caught varies by species and age. EPA's methodology appears not to take account of any of these differences.

3. Scaling Up Costs

EPA's Pilgrim analysis estimated habitat restoration costs on a per square meter basis and then scaled up to the project size. This methodology fails to take account of a common economic phenomenon - increasing returns to scale or declining average total cost. It is often very costly to produce the first unit of a good, but costs tend to decline, often significantly, as production is scaled up. In this case, larger-scale wetlands restorations would probably generate savings on both labor—because workers would become more efficient for longer projects—and materials, This suggests that EPA's estimates of the total restoration cost may be significantly overstated, particularly for the larger projects. <FN 9>

4. Requiring One-for-One Replacement

In implementing the HRC methodology, EPA estimated costs based on replacing each fish with a fish of the same species. In many cases, it might be far more cost effective to substitute species that are more affordable in relation to their value. For example, if species A were worth $5 and cost $20 to produce, and species B were worth $5 and cost $5 to produce, producing species B would be far more cost effective than producing species A. However, the EPA analysis of Pilgrim does not take this consideration into account. By ignoring this important consideration, EPA further overstates its valuation of consumers' willingness to pay.

IV. CONCLUSION

EPA's use of the HRC method to measure the benefits of alternative approaches to reducing I&E losses at CWIS is fatally flawed and appears to overstate the benefits of reducing I&E by at least 20 times their actual value.

A. Fundamental Flaws in the Use and Application of HRC

The use of HRC as a measure of benefits is inconsistent with the theoretical foundations of benefit estimation. It purports to replace long-established methods with a new method that is utterly lacking in foundation in the economics literature and in EPA's own guidance. Superficial similarities between the HRC method and other methods that have been used in other contexts are not sustained upon a closer evaluation.

Even if one were to set aside the lack of a theoretical basis for the use of HRC, EPA's implementation of this inappropriate method fails on several fronts:

-First, EPA's selection of each species' "preferred" habitat appears arbitrary and lacking in any methodological basis. This approach fails to consider the possibility that species could successfully thrive in alternative non-"preferred" habitats.

-Second, EPA's calculations of potential increases in fish production from habitat restoration appear to adjust for errors in an inaccurate and arbitrary way.

-Third, EPA fails to take account of potentially increasing returns to scale in habitat restoration.

-Finally, EPA does not consider the production of alternative species as a cost-saving measure.

As a result, EPA's implementation of the inappropriate HRC method overestimates the costs of habitat replacement.

B. Recommendations for Future Action

EPA's use of the HRC method is irreparably flawed. But this, does not mean that satisfactory methods for benefit estimation do not exist. Indeed, EPA's Case Study already presents benefits estimates developed with conventional methods of valuing commercial and recreational fisheries. Although we do not evaluate them here, in principle the other methods can provide estimates of the benefits of fish protection that will be consistent with the EPA guidelines and with the well-established economic literature on benefits estimation.

Indeed, this problem is an indication of the general flaw of confusing costs and benefits (WTP for reduced I&E of various species).

C. Summary

HRC is a deeply flawed methodology, lacking in foundation within economic theory or acceptable applied economic analysis. Moreover, its application to estimate the costs, of implementing habitat replacement to “compensate” for I&E at Pilgrim suffers from numerous flaws and arbitrary. assumptions that tend to bias the estimates upwards.

Footnotes

1 We do not consider whether the other benefit assessments in the Case Study are consistent with sound economic methodology.

2 Impingement is defined as the trapping of fish and other aquatic life on equipment at the entrance to CWIS. Entrainment occurs when aquatic organisms, eggs, and larvae are taken into the cooling system, passed through the, heat exchanger, and then discharged back into the source water body.

3 ENSR (2002) provides a technical assessment of EPA’s I&E estimates at Pilgrim. The ENSR comments identify a number of sources of error in EPA’s estimates of I&E at Pilgrim. These errors result in EPA overstating the true effect of I&E at Pilgrim on fish populations.

4 This same conclusion is reached in other economic reviews of EPA’s HRC methodology. See Stavins (2002) and Desvouges et al (2002).

5 Benefit-cost analysis also can identify which alternative provides the greatest net benefits (benefits minus costs).

6 See US. v. Fisher (1997) and US. v. Great Lakes Dredge & Dock Co. (1999, 2001).

7 As distinct from the Clean Water Act, NMSA specifically requires that damages (defined at 16 U.S.C. 1432(6), excerpted below) be reflected in terms of compensation for the lost resource and various costs likely to be incurred by the government:

(A) compensation for:

(i) the cost of replacing, restoring, or acquiring the equivalent of a sanctuary resource; and

(ii) the value of the lost use of a sanctuary resource pending its restoration or replacement or the acquisition of an equivalent sanctuary resource; or

(iii) the value of a sanctuary resource if the sanctuary resource cannot be restored or replaced or if the equivalent of such resource cannot be acquired;

(B) the cost of damage assessments under section 1443(b)(2) of this title;

(C) the reasonable cost of monitoring appropriate to the injured, restored, or replaced resources;

(D) the cost of curation and conservation of archeological, historical, and cultural sanctuary resources; and

(E) the cost of enforcement actions undertaken by the Secretary of Commerce in response to the destruction or loss of, or injury to, a sanctuary resource;

8 As an example, if the cost of supplying bottled water to a neighborhood is less expensive than cleaning up a water supply that is ‘valued solely for supplying drinking water, this method would suggest that remediation of the water supply should not be undertaken. (Note that this example abstracts from other values that may be associated with remediation of the water supply — that is not to say that such values should not be considered, but only to simplify the example.)

9 See ENSR (2002) for a related observation—that EPA overstates monitoring costs by assuming that they would scale linearly.

EPA Response

EPA agrees that the cost replacement method, the defensive expenditure, and averting behavior methods can be useful tools in the decision making process.

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule. Please see EPA's response to comment #316bEFR.005.035. Please also see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method.

Please also comment #316bEFR.306.105 for EPA's response to comments on the feasibility of doing original stated preference work.

Costs

Economic Considerations

It's pretty amazing how consistently regulators under-estimate the costs of their initiatives and over-estimate the benefits…just like business tends to over-estimate those same costs. But you guys really get the prize this time. How can you honestly say that the sum total, industry-wide compliance cost will be $182 million? With 420 affected utility facilities, you can not honestly believe the costs of studies, engineering, installation, O&M, energy losses and monitoring…for EVERYONE…will be this low. If I ran a power plant, I wish I could use your figures for my facility and give you what you say it would cost…then hold you to achieving the results you would demand from me…on that amount. Fat chance.

EPA Response

The comment provides an opinion unsupported by factual evidence. For the record, the Agency believes that the costs of compliance with the final rule will approach $389 million (year $2004 dollars). This is for all facilities within the scope of the rule, specifically 543 facilities.

More Stringent Requirements

Is this rule really more flexible?

EPA has loaded this regulation with so many provisions and angles to make compliance with the [alleged] flexible parts so difficult…then they throw in a threat of even worse regulation because more stringent requirements could be imposed based on water quality standard issues or T&E species or habitat protection laws. The agency suggests that these requirements could be imposed under other laws like the Wild & Scenic Rivers Act [When was the last time we had a power plant operating on a designated Wild &/or Scenic River?] This about getting everyone to throw up their hands and build cooling towers [which would be a wonderful addition to a Wild & Scenic River, no?]. Your rule should acknowledge not just the cost but also the other economic and environmental impacts of cooling towers. Especially in this time where water availability is looking like the major domestic water issue of the new century, I would not want to advocate widespread use of such a consumptive technology unless the site watershed could accommodate the impact.

EPA Response

EPA believes today's final rule maintains the desired flexibility for both the permitting authority and the permitted facility to determine the most cost-effective means to reduce impingement mortality and entrainment losses. EPA recognizes that there will always be considerations raised by obligations to other regulatory programs; nothing in today's rule forecloses the implementation of applicable state or tribal law, or other federal law.

EPA is not requiring the installation of cooling towers in today's rule. See response to comment 316bEFR.206.022 for a further discussion on why EPA is not requiring closed-cycle cooling in today's' rule.

EPA agrees with the commenter's concerns over cumulative stressors on a waterbody or within a watershed and believes that such stressors should be considered during the decision-making process. Because of the potentially numerous variables that interact in various waterbodies and watersheds, EPA believes the Director will be best suited to make a determination of an appropriate watershed boundary for his or her constituency.

More Stringent Requirements

EPA should acknowledge the other causes of stress to fish populations

Also, you suggest that there may need to be an explicit provision to establish criteria for when more stringent requirements could be imposed. Examples would be “if the rule by itself” would result in unacceptable effects on sport of commercial fisheries or would not adequately address multiple impacts or multiple stressors. This seems to be going too far and loading this one regulatory consideration with justifications or responsibilities to fix everything that is wrong with aquatic populations.

EPA Response

Please see response to comment 316bEFR.002.016 and 316bEFR.030.002.

Subject Matter Code 6.0

Environmental Impacts

Commercial and sport fisheries are stressed by over fishing, invasive species and habitat degradation. SHUTTING DOWN power plants entirely will not change the status of many stressed populations. The agencies responsible for managing and regulating the fisheries resources need to do their part to bring back the numbers. To put this all on the power plants is folly. Don't acknowledge the environmentalists' assertion that power plants are the root of all evil. Use your scientific sense. You're supposed to be the experts in this area.

EPA Response

Many anthropogenic activities work concurrently on the environment. It is extremely difficult to separate the effects of any one factor. The intention of section 316(b) of the Clean Water Act is to minimize the adverse environmental impact of cooling water intake structures specifically and does not seek to eliminate stress on fisheries due to overfishing, invasive species, habitat degradation or any other factor. EPA did not receive any comments asserting that power plants are "the root of all evil". EPA has received data, however, which indicate that billions of fish are killed by cooling water intake structures yearly. This situation hinders improvements to the nation's fisheries made by fishery resource agencies. Today's final rule to minimize the effects on the fisheries from cooling water intake structures is just one step in aiding stressed fisheries. Fishery management plans, water quality improvements and habitat restoration will also help reduce stress, but those solutions are outside the scope of section 316(b) of the Clean Water Act.

Fish Population Modeling

This should be about SCIENCE, not politics – You are supposed to be the environmental experts

COMPENSATION is an accepted cornerstone of fisheries management science. The NMFS and every state natural resource agency could not get to first base in its resource planning without programs based on compensation…you know it and I know it. You guys are supposed to be the experts. The political pressures are over-riding your common sense and understanding of how nature works.

EPA Response

Contrary to the commenter's characterization, EPA's analysis is based on sound science. Reasons for not considering compensation are provided in EPA's response to Comment 316bEFR.025.015.

RFC: Entrainment vs. entrainment mortality

Entrainment survival is real. You know it happens. You should make the standard one of mortality as you have proposed for impingement…or acknowledge that microscopic/planktonic biomass returned to the system does not reduce its ultimate function or purpose in the aquatic environment. To instead deflect the issue of entrainment survival by questioning utility data and the methods employed is stonewalling. To cast suspicions on the reliability of the studies and draw the line on how future studies might be approved is intimidating. I see no similar considerations applied to the studies EPA cites that support the proposed regulation.

EPA Response

Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis. Please see the response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule. The return of "microscopic/planktonic biomass" to the ecosystem from a cooling water system does change its function. Eggs and larvae are available for consumption by juvenile and adult fish (organisms at a higher trophic level), whereas disintegrated eggs and larvae "biomass" are typically available for consumption by detritivores (organisms at a lower trophic level).

Option 3--Site-specific determination

As our environmental regulators, you are supposed to understand environmental science. You are not supposed to ignore everything that does not support the underlying objective – that's what the environmentalists do. You can't deny that a significant number of organisms survive entrainment. You can't deny the existence of compensatory actions in aquatic populations. You can't ignore all the information out there that does not fit your thesis. The people who want to close down Millstone say it has nearly destroyed the winter flounder population in the area yet, when it was down for nearly three years, there was no recovery. Over-fishing is the culprit. If you can't regulate that, find someone who can. The Connecticut River was studied exhaustively to determine if the Connecticut Yankee plant was harmful in any way. Even the state's regulators had to admit it was not. Now the plant is closed and there has been no rebound in any population…because there was no problem to begin with. This is not to absolve all power plants as benign. It is to encourage a site-specific approach that honestly assesses impacts and takes steps to control them when they are adverse.

EPA Response

EPA acknowledges that other factors such as overfishing or declining water quality may also affect fish populations. However, these factors do not diminish the increased potential for adverse environmental impact from cooling water intake structures in tidal rivers and estuaries.

For information on entrainment survival, please refer to the entrainment survival chapter in the Regional Studies document (DCN 6-0003 in OW-2002-0049, the docket for the final rule).

For information on compensation in fish populations, please refer to the response to comment 316bEFR.025.015.

General Statement of Opposition

Write a rule that gets to the heart of the issue…and it will work

This looks like another example of an agency trying to be comprehensive at the expense of actual success. The rule demonstrates scant awareness of the potential consequences. There seems to be little sense of how to craft a rule that will actually get us a net environmental benefit…after the true costs are objectively considered.

EPA Response

EPA disagrees. Please refer to the preamble and the supporting documents for more information.

Comment ID 316bEFR.030.009

Subject Matter Code 21.01.04

Comprehensive demonstration study (7 parts)

Author Name T.G. Ringger

Organization T.G. Ringger

While some plants may need to re-do their demonstrations, I would suggest that the bigger problem is that some plants have not made these assessments at all. As one who has worked in a state that has taken it's charge seriously and made its power plants address its §316 impacts, I resent that certain regions have been allowed to slide all these years. I am certain that this lack of attention to this issue by some facilities has contributed towards the drive to litigate and develop new regulations. However, it is frustrating that a new round of requirements are being laid on every plant, many of which have spent millions to study their impacts, install improvements and demonstrate, to the satisfaction of their regulators, that their cooling water intakes do not have an adverse environment impact. These plants should not have to pay again because EPA has failed to address its regional consistency problems. Make the plants that have not done the work do the work.

EPA Response

EPA acknowledges that many States have made rigorous efforts to implement 316(b) programs. As such, EPA is allowing the use of alternative State programs to be used in lieu of today's final rule, as long as the State NPDES requirements will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment that would otherwise be achieved under § 125.94 (see § 125.90(c)). EPA disagrees, however, that certain facilities should be allowed exemptions from today's final rule based on historical assessments. Many 316(b) studies were conducted 20 years ago or more, and may not be reflective of current conditions. In order to ensure that today's final rule is both protective and consistently applied, all facilities will be required to submit a minimum of information to demonstrate whether additional protective technologies are required. In cases where facilities have recently studied their impacts and/ or installed protective technologies or implemented operational or restoration measures, all of those elements will be considered by the Director. Historical biological studies may also fulfill certain Comprehensive Demonstration Study requirements. See final rule preamble and EPA's response to comment 316bEFR.034.005. Finally, a facility that wishes to comply through Compliance Option 2, may demonstrate to the Director that the facility's existing design and construction technologies, operational measures, and/or restoration measures meet the performance standards (see § 125.94(b)(2)). For all of the reasons described, EPA believes that States and facilities that have made efforts to implement 316(b) programs will most likely have reduced burden relative to those States and facilities that have not been proactive in already establishing such programs.

Comment ID 316bEFR.030.010

Author Name T.G. Ringger

Organization T.G. Ringger

Subject Matter Code OPP

General Statement of Opposition

I believe that many plants are actually ready to do something. They are grateful that the rule does not mandate cooling towers. I suggest this rule can present a fine opportunity to make significant environmental improvements in a number of areas. However, the rule also tries to be all-inclusive and totally comprehensive and the result could easily be that much less is actually accomplished because you demanded too much…and focused on process and ancillary issues more than results…and minutiae more than the big picture…and the insignificant more than the important…and the politics more than the science.

EPA Response

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to the preamble for more information on why EPA rejected this alternative.

Comment ID 316bEFR.030.011

Author Name T.G. Ringger

Organization T.G. Ringger

Subject Matter Code 21.04

Determination of compliance

The proposed rule lacks critical information on implementation and compliance

Compliance with the requirements is another issue that needs clarification.

What if a plant does not meet the standard after two years? Is it a violation? Will the plant have to add more technologies or mitigation or will it be required to modify/refine the approved approach in place.

[Even if some regulators don't want to make many decisions and want some clear-cut guidance that shows them the way, it won't be like that. They are going to have to work with utilities and be a party to negotiating some acceptable approach. However, after that, both parties are going to be involved to see IF it works. And, if it doesn't, both parties are going to have to decide why and what needs to be done next…and NONE of that is covered in this proposed regulation.] – This is NOT how to make it easier on understaffed, resource-strapped agencies.

EPA Response

The permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see the preamble to the final rule and EPA's responses to comments 316bEFR.017.003 and 316bEFR.063.005. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. EPA disagrees that regulators and facilities will not have to work together. On the contrary, EPA has designed the rule to facilitate a great deal of feedback and consultation among State and local agencies and the regulated community. For details on this please refer to EPA's response to comment 316bEFR.034.066.

Comment ID 316bEFR.030.012

Author Name T.G. Ringger

Organization T.G. Ringger

Subject Matter Code 21.01.04

Comprehensive demonstration study (7 parts)

EPA suggests that a "comprehensive reevaluation" of the 316(b) demonstration might be necessary every time the NPDES permit is renewed [CITE]

With all due respect, this goes beyond burdensome. It is ridiculous and seems like one of those extreme positions you throw in just to negotiate away and settle on something more reasonable [and then complain about how much you are giving away]. Here, you have a chance to make significant environmental improvements in intake impacts and you put in things like this. It can scare off a community that is largely ready to do something. It makes it seem like the real intent is to keep revisiting the issue and ratchet the impact down to zero. Biological populations are not like toxics or carcinogens where the [also mistaken] view is "any quantity, no matter how small, must be bad and must be eliminated". Absent a definition of 'adverse environmental impact', this provision suggests there are still some interest in the 'one-dead-fish' viewpoint.

Please don't go overboard. Concentrate on the plants that need to assess their impacts, get them to make the necessary changes, ensure they comply and declare victory.

EPA Response

In today's final rule, EPA has provided facilities with the opportunity to reduce their permit application requirements, so that they may avoid conducting a thorough Comprehensive Demonstration Study following the first permit term. Please refer to EPA's response to comment 316bEFR.034.005 for details on how facilities may request reduced submittal requirements following the first permit term. Regarding the definition of adverse environmental impact, EPA has not chosen to not define this term for the purpose of today's final rule. A facility's capacity to cause adverse environmental impact is dependent upon a multitude of site-specific factors, including the structural and operational characteristics of the facility's intake, the volume and velocity of the intake, and the physical, biological and chemical conditions of the waterbody itself. Because each facility will have unique attributes, EPA chose to not establish a "one-size-fits-all" definition of adverse environmental impact. Instead, EPA has left the determination of a facility's impact to the individual permitting Directors, who know the facilities in their jurisdiction and will be best able to make these decisions.

Subject Matter Code 21.09
Permit applications/implementation schedule

Timing – You ask a simple question @ p. 17173 – “When does the proposed rule become effective?” Why do I feel like I need a lawyer to make sure the answer is clear? Proposed §125.92 [in too many words] says one must comply when the new NPDES permit is issued. This would clarify and support a compliance schedule that BEGINS with the new permit instead of having applicants, absent any final regulation or guidance, try to put together the Comprehensive Demonstration Study and all the other components that are needed for the permit renewal application. If you want something that WORKS, recognize the need for final guidance and time to do what will be required. Make the compliance schedule a permit condition and give the plants, the states and EPA staff the time to do it right.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion. See also the preamble to the final rule for a discussion of how compliance with the rule will be determined.

Performance standards

Author Name Chuck Wemple

Organization Reliant Resources Inc.

A Flexible Site-Specific Approach is Essential

While Reliant recognizes that a generalized approach might reduce the potential burden on State agencies in implementing the proposed rule, Reliant believes that uniformly applying specific national performance standards to highly variable and complex site settings is technically flawed and runs the risk of unfairly penalizing facilities that have operated in compliance with the CWA 316(b) for decades. The collective experience of the industry, states, and EPA regions is that adverse environmental impact and the successful deployment of cooling water intake structure (CWIS) technologies is highly site specific.

EPA Response

Today's rule provides the desired flexibility for facilities to determine the most cost-effective combination of design and construction technologies, operational measures, or restoration measures best suited to each individual facility.

Performance standards

Reliant requests that EPA abandon the proposed national performance based standards, i.e. specific reduction standards, and implement a flexible site-specific approach which considers local ecological settings and living resource population dynamics when defining adverse environmental impact and identifying best technology available options. To truly gage adverse environmental impact (AEI), EPA should ensure that the permittees and implementing entities have the flexibility to define and evaluate it at the community and population level as they have done as part of resource management programs for 30 or more years.

EPA Response

Please see response to comment 316bEFR.311.002 and the preamble to today's rule.

Comment ID 316bEFR.032.006

Author Name Chuck Wemple

Organization Reliant Resources Inc.

Subject Matter Code 10.01.02.02

Fish Population Modeling

Consistent with the findings of the Electric Power Research Institute, Reliant believes that EPA's equating sensitivity to density in developing national performance standards has essentially no basis in biological science and is therefore substantially flawed. This flaw is of particular significance within estuarine systems, where salinity fluctuations and high pre-adult mortality rates have driven the evolution of sophisticated density dependent survival mechanisms such as reproductive compensation (producing enormous numbers of eggs, larvae, and juveniles to overcome naturally high mortality rates). Entrainment of egg and larval stage organisms and impingement of juveniles in these rich and productive systems are unlikely to have an adverse environmental impact to local communities and populations. If EPA is determined to base performance goals on sensitivity, EPA should base the goals on species diversity and community dynamics rather than population density.

EPA Response

Please see responses to Comment 316bEFR.005.009 on fish population modeling and Comment 316bEFR.025.015 on compensation. Population- and community-level assessment was not a goal of EPA's analysis.

Discussion of Site-Specific Approaches

The case for a flexible site-specific approach can be illustrated by example of Galveston Bay, a Gulf of Mexico estuary located along the upper Texas Coast. It should be noted that the unique biological and physical nature of Gulf of Mexico estuaries has not been adequately considered under EPA's proposed rule. EPA's only example from the Gulf of Mexico is a facility located in Tampa Bay, Florida, an area unaffected by the extensive riverine silt and detrital plumes that feed the estuaries of the upper and western Gulf. Estuaries in Louisiana and along the upper Texas coast, including Galveston Bay, experience very high suspended-sediment loads and have extremely high levels of particular organic matter that form the basis of a complex and extremely productive detrital food web.

The very high aquatic productivity levels seen in the Galveston Bay estuary result from long growing seasons, an abundant food supply, freshwater inflows, and prolific intertidal marsh and reef habitats. This intense productivity, although seasonally and diurnally variable, is seen virtually year-round with a myriad of phytoplankton and zooplankton assemblages, abundant nekton species, as well as invertebrate and mollusk species.

Although impingement and entrainment of organisms in this setting is unavoidable, previous 316(b) studies conducted at the five Reliant facilities located along the tidal rivers and side bays of the Galveston Bay estuary indicated that CWIS impingement was insignificant relative to other anthropogenic sources of potential AEI. (HL&P, 1979 and 1980). However, under the proposed rule and despite nearly three decades of operating in compliance with the CWA, the above-referenced facilities would be assumed to be causing adverse environmental impact and be subject to national technology based performance standards for impingement and entrainment, and CWIS best technology available (BTA) retrofits.

EPA Response

EPA disagrees that some waterbodies are under-represented. Please refer to the response to comment 316bEFR.333.002 for more information.

With respect to the use of previous studies, a goal of today's rule is to set national minimum performance standards that reflect the best technology available for minimizing adverse environmental impacts. Given that previous determinations of best technology available were not made in reference to the national performance standards, EPA believes that the Director should not rely entirely on historical determinations. EPA believes that these national requirements will promote more effective and consistent implementation of section 316(b) requirements, and ultimately minimize adverse environmental impacts associated with the use of cooling water intake structures by Phase II existing facilities. Today's rule also provides for site-specific determinations based on cost-cost and cost-benefit considerations.

Subject Matter Code 7.03.01

Sample facilities/technologies

EPA's proposed rule for applying section 316(b) of the Clean Water Act to existing facilities asserts that certain intake technologies, including wedgewire screens, fine mesh screens, and aquatic fabric filter barriers, represent BTA for reducing impingement mortality and entrainment. With over 30 years of operating and maintaining CWIS in Galveston Bay, Reliant believes that the very high aquatic productivity, heavy sediment loading in the water column, intense biofouling communities (i.e., oysters, barnacles, mussels, and colonial hydroids), shallow waters, and dead-end intake canals, will clearly limit the application of the proposed BTA in this system. The problems posed by this example, specifically a lack of demonstrated AEI and unworkable BTA alternatives, further support our earlier comments regarding the need for a flexible site-specific approach and reinforce UWAG's proposal for a simpler alternative for facilities that have already proven they are not harming the aquatic community.

EPA Response

EPA recognizes the variability between waterbody conditions, species densities, and intake configurations and has adopted performance ranges in today's rule. EPA does not state, nor does it expect, that any given design and construction technology will necessarily achieve identical performance rates at different facilities.

Today's rule allows for a facility to demonstrate to the Director that its current design and construction technologies, operational measures, and/or restoration measures are already meeting the performance standards, thereby not triggering the requirement for additional or alternative measures.

Cooling system costs (e.g., dry, wet, recirculating)

Cooling Tower Retrofits Cannot Be Required To Meet BTA

If mandated in the final rule, cooling tower retrofits and operating measures would result in increased fuel usage, increased air emissions, energy penalties associated with reduced efficiency, and retrofit construction downtime, and potential decommissioning of existing facilities that are currently in compliance with the provisions of the Clean Water Act. As indicated by EPA, facilities located on oceans, estuaries, and tidal rivers would incur huge capital and operating and maintenance costs for conversions of their cooling water systems. Furthermore, since impacted facilities would be concentrated in coastal regions, there would be significant unanalyzed short-term energy impacts and potential supply constraints in these areas. The short and long-term national impacts associated with mandated cooling tower retrofits would be staggering and totally unsupported by the rulemaking record.

EPA Response

EPA thanks the commenter for these comments. EPA has decided that it would not base the requirements of the final rule on cooling tower technology.

RFC: EPA rationale to not require closed-cycle

Reliant supports EPA's decision not to base BTA for any Phase II existing facilities on cooling tower retrofits. To remain within the intended scope of §316(b), proposed BTA alternatives must be limited to the plant intake structures. Cooling towers are used to dissipate heat produced during the generation process and are not intake structures. As a result, cooling towers are beyond the scope of §316(b).

EPA Response

EPA disagrees that forming the basis of a 316(b) rule on cooling towers would be beyond the scope of the intention of the Clean Water Act. As a matter of fact, there exists a regulation for new facilities that contradicts the commenter's assertion. Simply stated, cooling towers utilize cooling water and affect the design of the cooling water intake structure. They are within the scope of Section 316(b).

Regardless of this issue, the Agency does not base the requirements of the final rule on cooling towers and the commenter's point is not directly applicable to the final rule.

Author Name Chuck Wemple
Organization Reliant Resources Inc.

Subject Matter Code 11.01
RFC: Proposed use of restoration measures

Habitat Enhancement/Restoration Should Be A Flexible and Voluntary Alternative

Reliant applauds EPA's proposal to include voluntary habitat enhancement and restoration as an alternative approach to addressing potential adverse environmental impacts associated with impingement and entrainment. The habitat enhancement/restoration approach to achieving compliance compliments the concept of assessing potential adverse environmental impacts at the community level.

Habitat restoration options include benefits that extend far beyond fishery population dynamics. In addition to extensive wildlife benefits discussed by UWAG, non-fisheries benefits include, but are not limited to, water quality improvements, flood control, erosion control, increased recreational and educational opportunities, and improved economic values that accompany all of these benefits. These added-value benefits should be recognized in the crediting process.

Once preserved, habitat will be unavailable for development and subsequently will have ensured productivity essentially in perpetuity - well beyond the operating life cycle of the generating facility. The long-term benefits of preserving existing productive habitats should also be considered during the crediting process.

Site-specific restoration approaches are essential because ecological benefits can have a much greater overall impact than implementation of BTA for impingement and entrainment compensation. Eligible site-specific restoration approaches should include Estuary Program Prioritized Conservation Plans, as well as other State or local habitat management initiatives.

As stated earlier, flexibility and the consideration of site-specific conditions are critical to achieving compliance under the proposed rule. To that end, Reliant believes that EPA should consider working with State and Federal agencies, industries, and the scientific community to develop a reasonable and consistent approach to determining spatial scale, units, monitoring requirements, and values of restoration projects.

EPA Response

For a discussion of the extent to which restoration measures are voluntary, see EPA's response to comment 316RFR.060.022.

The goal of restoration measures in the final rule is not to reduce impingement mortality and entrainment of individual fish, but to minimize, or help to minimize, through production and increase of fish and shellfish in the impacted waterbody or watershed, the adverse environmental impacts that derive from impingement and entrainment of individual aquatic organisms.

The commenter cites a number of benefits (such as habitat preservation in perpetuity) potentially associated with successful restoration measure implementation. EPA notes that the ecological benefits required from restoration measures are described in section 125.94 of the final rule. Compliance with the rule will be determined based on whether the ecological benefits have been realized, i.e., whether fish, shellfish, and community structure and function in the relevant waterbody or watershed is maintained at a level that is substantially similar to the level you would achieve through compliance with the applicable impingement mortality and/or entrainment requirements. While there could be other types of benefits from restoration measures, those benefits would not be relevant to compliance determinations.

For discussion of the use of existing restoration measures, see EPA's response to comment 316bEFR.034.032.

Because restoration measures are to be used specifically in place of or as a supplement to installing design and construction technologies and/or operational measures that reduce impingement mortality and entrainment under section 316(b), facilities may not claim credit for a restoration measure's fish and shellfish production when that production is already required under other applicable law (e.g., wetland creation to satisfy CWA 404 requirements).

EPA believes the restoration requirements in the final rule provide state permitting agencies and permit applicants with a significant amount of flexibility. In the final rule, EPA has given some specific requirements for determining spatial scale, monitoring, and other aspects of restoration measures, but has left flexibility for permitting authorities to determine additional requirements on a statewide or case-by-case basis.

General: cost tests

The Cost-Cost and Cost-Benefit Tests Are Essential to the Rule

Reliant supports UWAG's belief that, without an alternative for excessive cost situations, the proposed rule would be insufficient as a matter of law. Reliant believes that both tests must be flexible, site-specific, and are necessary alternatives to the nationwide performance standards.

EPA Response

The final rule includes cost-cost and cost-benefit tests that are flexible, site-specific alternatives to the national performance requirements.

Author Name Chuck Wemple

Organization Reliant Resources Inc.

Subject Matter Code 16.01

RFC: Regulating limited capacity facilities

Exemptions Based on Operational Thresholds Must Provide Flexibility

EPA proposals to include exemptions from portions of the proposed rule based on operational thresholds are sound. Our comments regarding freshwater river withdrawal and generating capacity utilization thresholds are presented below.

Reliant proposes that EPA adopt a flexible approach to determining the fresh water river withdrawal threshold for triggering the requirement for entrainment controls. Recognizing that the alternative approaches, other than the 5% of median annual flow, contained within the proposed rule could require detailed studies and monitoring, Reliant suggests that the 5% of median annual flow be used as a default value. Providing a suite of options and a default value would allow facilities greater flexibility in selecting the flow measurement method that best fits their needs.

Reliant's facilities operate across a broad range of capacity factors to meet base load and peak supply demands in a wide variety of markets. Reliant is concerned that the proposed 15% Generating Capacity Utilization Rate Threshold calculated over "several years" does not provide sufficient flexibility for peaking plants. To that end, Reliant proposes that the utilization threshold be set at 20%, corresponding to the low end of the entrainment goal and allowing greater flexibility for peaking plants. In addition, Reliant suggests that "several years" be defined as the number of years covered by the permit, rather than a subjective, un-quantified number between one and many.

EPA Response

The Agency invited comment on the following alternative withdrawal thresholds for triggering the requirement for entrainment controls: (1) 5% of the mean flow measured during the spawning season (to be determined by the average of flows during the spawning season, but remaining applicable to non-spawning time periods); (2) 10% or 15% of the mean annual or spawning season flow; (3) 25% of the 7Q10; and (4) a species-specific flow threshold that would use minimum flow requirements of a representative species to determine allowable withdrawals from the waterbody.

The commenter states that it "suggests that the 5 % median annual flow be used as a default value." The commenter does not give reason or evidence as to why the "median" should be used, as opposed to the "mean." The Agency continues to consider the "mean" annual flow definition to be the most reasonable decision, and point out that the "mean" will be more flexible to facilities than "median" in typical cases. The commenter suggests that EPA provide a "suite" of options and a default value, but does not suggest or cite any of the "options" he refers to. In addition, the commenter states that the other alternatives suggested by the Agency (as noted above) require "detailed studies and monitoring." The Agency interprets this to mean that the alternative approaches were not favorable to the commenter. As such, the Agency continues to consider the approach adopted for the proposal, NODA, and final rule of 5% of mean annual flow to be the best suited for this national rule.

EPA disagrees that the capacity utilization rate cutoff be raised to 20 %. The commenter does not provide a rationale for why plants require more flexibility than the 15 % already provides. However, the Agency agrees that a less subjective measure than "several years" be defined. As such, the Agency has provided clear requirements for the calculation of the capacity utilization rate. See the preamble to the final rule.

Proposed standards for oceans

States Should Have Discretion Not to Apply Entrainment Standards to Ocean Intakes

The proposal to subject all ocean intakes to entrainment standards is scientifically unjustified. Ocean habitats, are disproportionally inhabited by the adult stages of fishes and invertebrates, and do not sustain the intense populations of eggs, larvae and juveniles life stages so common to the coastal estuary. For these reasons, it appears unsupported to require facilities with ocean CWISs located offshore and away from the mouths of estuaries to meet the proposed performance standards for entrainment. The absence of organisms near ocean intakes in life stages susceptible to entrainment and the costs associated with technology installation and maintenance clearly do not justify the implementation of proposed performance standards for entrainment at ocean CWISs.

EPA Response

EPA disagrees. Facilities located on oceans (and having a capacity utilization rate greater than 15%) are subject to additional requirements, as these waterbodies are similar to estuaries in that they have areas of high productivity and sensitive habitat.

EPA continues to believe that oceans are a unique system that deserve additional protection from the impact of cooling water intake structures. Oceans are large waterbodies with a variety of habitats. While EPA recognizes that not all habitats in the oceans may be as sensitive as others, there are many areas that are similar to an estuary in terms of productivity, and therefore of similar sensitivity. EPA also notes that the more sensitive areas are often located in the nearshore areas of larger waterbodies, which is also a common location for cooling water intake structures. Facilities may also be located in close proximity to migratory pathways.

Special definitions

Cooling Reservoirs Represent Closed Cycle Cooling

Cooling reservoirs function as closed cycle recirculating systems, and in many cases have been constructed specifically to support the operation of generating facilities. The reservoirs are often stocked for recreational fishing and have maintained (or more correctly, introduced) a highly valued perennial habitat where historically there may have been an intermittent streambed. These are artificial systems and it makes little practical sense to consider such reservoirs in the same manner as the other waterbodies in EPA's proposal. In man-made reservoirs, the hypothetical shoreline intake won't exist independent of the reservoir. In a practical sense the reservoir is an extension of the plant intake that was installed for multiple uses including cooling and water storage/reuse. Reliant requests that EPA define cooling reservoirs as closed cycle cooling.

EPA Response

EPA agrees that in some cases, cooling reservoirs are part of a closed-cycle cooling system, though the final determination will be left to the Director. The final rule defines "cooling water intake structure" to mean the total physical structure and any associated constructed waterways used to withdraw cooling water from waters of the U.S. The cooling water intake structure extends from the point at which water is withdrawn from the surface water source up to, and including, the intake pumps. EPA has not defined the phrase an "associated constructed waterway." Whether or not a waterway is considered part of the cooling water intake structure can vary depending on the location, type of facility, and other factors. EPA has left this determination up to the permit writer, who will evaluate each situation on a case-by-case basis.

In general, how the definition of "cooling water intake structure" is applied to a particular facility should be based on consultation between the permittee and the permitting authority. In determining whether an irrigation ditch or other water conveyance system is part of the cooling water intake structure, the permitting authority is to consider whether the structure or constructed water way is used to withdraw water from the source waterbody (which must be a "water of the U.S.") into the cooling water.

This final rule does not define the term "cooling ponds" (or cooling lakes) or change the status of cooling ponds under the Clean Water Act. The final rule recognizes that cooling lakes can be part of a closed-cycle recirculating system, which EPA agrees conserves water resources. However, in certain circumstances cooling ponds (or cooling lakes) can be "waters of the U.S." See 40 CFR 122.2. This determination is made on a case-by-case basis. The applicability of this rule to any new facility, and in particular the cooling lake at that new facility, must be determined by the permitting authority.

EPA has not categorically excluded facilities that withdraw water from cooling ponds from the final rule. In certain circumstances, cooling ponds can be "waters of the U.S." (See 40 CFR 122.2). Given that the Clean Water Act applies to and seeks to protect "waters of the U.S.," a categorical exclusion is not appropriate. The determination of whether a cooling pond is a "water of the U.S." is made on a case-by-case basis by the permitting authority through application of 40 CFR 122.2.

Subject Matter Code 17.03.02

RFC: EPA rationale to not require closed-cycle

Existing power plants, even the largest water users, are not required under the proposed regulations to install proven technology that will greatly reduce the kill rates for these intake structures. The OEC disagrees with the proposed language and supports the requirement that was in the USEPA's original draft regulation--to require the largest plants to install "closed-cycle cooling technology". This technology would be of great benefit to aquatic life, yet this requirement has been dropped, reportedly at the demand of the Office of Management and Budget. The OEC is requesting that closed-cycle cooling technology be a required "best technology" for all existing plants.

EPA Response

The Agency refers the commenter to the preamble to the final rule, which explains the reasons the Agency did not adopt closed-cycle cooling for any existing plants. The Agency disagrees that the rule will not greatly reduce entrainment mortality, especially for the largest water users. The Agency estimates that entrainment rates will decrease substantially upon implementation of this rule. The fact that the requirements are not based on closed-cycle cooling is not paramount for entrainment reduction. The Agency has taken a more practical approach to the requirements of the final rule than requiring closed-cycle technology retrofits in situations that may not warrant or allow their adoption. See response to comment 316b.EFR.404.058.

Comment ID 316bEFR.033.003

Author Name Keith Dimoff

Organization Ohio Environmental Council

Subject Matter Code 10.07.04

RFC: Appropriateness of and tests for variance

Power plant companies will be allowed, under the proposed regulations, to say that special economic circumstances should let them off the hook for meeting the minimum technology or performance standards. The OEC disagrees with the proposed regulation. We believe that these facilities have already had the benefit of decades of inaction on their first round of NPDES permits, many of which were inadequate, and that no further delays or “special economic circumstances” should be allowed. If this weakened provision remains in the final regulations in some form, we believe it should be written so that the corporation must provide a significant burden of proof, including engineering and cost studies by independent third parties. The applicant should be required to provide substantial funding to the USEPA which the USEPA can use to hire an independent assessment of the cooling water intake structure.

EPA Response

EPA disagrees. The final rule does not let facilities that seek a site-specific determination of BTA "off the hook," but includes the site-specific alternatives to ensure that the costs of the rule remain economically practicable and that there is a reasonable relationship between the costs of cooling water intake structure technology and the benefits associated with its use. See section VII of the preamble to the final rule. Under the final rule, cost and benefit studies, as well as a technology plan and a monitoring plan are required under these compliance alternatives. In addition, the Director must review these documents, so independent review is not necessary. EPA has not required the applicant to fund an independent review, again, because the Director will review these documents. The Director will use all available resources, including in-house expertise and possibly other experts and resources as appropriate, in assessing this information.

Comment ID 316bEFR.033.004

Author Name Keith Dimoff

Organization Ohio Environmental Council

Subject Matter Code 10.07.04

RFC: Appropriateness of and tests for variance

Power plants, under the proposed regulations, would be able to avoid the technology standard by pleading special economic circumstances or by claiming that the local ecosystem does not merit protection. The OEC disagrees with this provision for site specific determinations, believing that they would greatly undervalue aquatic ecosystems.

EPA Response

See response to 316bEFR.033.003. Facilities that seek a site-specific determination of BTA are not avoiding the technology standard; rather, they are to required to demonstrate that they qualify for a site-specific determination of best technology available. In addition, the rule requires a facility seeking a site-specific determination of BTA based on significantly greater costs compared to benefits to develop a benefits valuation study that fully values both impacts and the benefits of compliance. (See § 125.95).

Comment ID 316bEFR.033.005

Author Name Keith Dimoff

Organization Ohio Environmental Council

Subject Matter Code 11.01

RFC: Proposed use of restoration measures

Additionally, restoration measures should not be used in lieu of technology measures to meet performance standards. These measures remain vague and unproven, and are rarely intended the replace the number or variety of aquatic life killed during the water intake process.

EPA Response

EPA disagrees somewhat with the commenter's statement that restoration measures should not be used in lieu of technology measures to meet performance standards. EPA is instead providing permit applicants and permitting authorities with significant flexibility in how they comply with the requirements of the final rule. The requirements for restoration measures described in the final rule, including those under sections 125.94 and 125.95, allow facilities to use restoration measures wholly in lieu of design and control technologies and operational measures.

However, under the final rule, permit applicants must demonstrate to the permitting authority that they have considered the use of design and control technologies and operational measures. EPA requires this demonstration to ensure that permit applicants and permitting authorities examine the variety of compliance alternatives available to them. Also, EPA is concerned about the uncertainties associated with restoration measures (see EPA's response to comment 316bEFR.206.055). EPA agrees with the commenter that there are uncertainties associated with the use of restoration measures.

EPA also agrees with the commenter that for some facilities, it will be difficult to create restoration measures that address all of the types and number of fish and shellfish impacted by a cooling water intake structure.

Comment ID 316bEFR.033.006

Author Name Keith Dimoff

Organization Ohio Environmental Council

Subject Matter Code 21.01

Submittal of required information

The proposed regulations do not require that engineering or scientific studies need to be done at the maximum withdrawal capacity of the power plant. Rather, we believe that this should be required in order to ensure that the information on environmental and ecosystem impacts is adequate at any possible level of withdrawal. Such a requirement will avoid the problem of a power plant being permitted to withdraw more water than studies have shown that the ecosystem will support. These studies should also take into consideration the physical nature of the intake and outfall.

EPA Response

EPA disagrees that studies should be conducted exclusively at the maximum withdrawal capacity of the facility; in general, EPA believes that studies should reflect typical conditions and take into consideration other variables such as seasonal fluctuations and periods when additional capacity may be necessary. However, the Director has the final determination on specific study parameters.

Comment ID 316bEFR.033.007

Subject Matter Code 21.09

Permit applications/implementation schedule

Author Name Keith Dimoff

Organization Ohio Environmental Council

The proposed regulations do not contain strict enforcement and renewal provisions. The OEC believes that these permits should be required to be renewed annually and that the power plant corporation should not be eligible to receive a renewal if they have failed to comply with their permit.

EPA Response

Permits have a five year term and applications will be reviewed by the Director and new conditions will be provided, as necessary, in a renewed permit. If a facility is not complying with its permit conditions, the facility is subject to enforcement action.

Comment ID 316bEFR.033.008

Author Name Keith Dimoff

Organization Ohio Environmental Council

Subject Matter Code 21.09

Permit applications/implementation schedule

Finally, the application, the permit and all supporting documentation need to be public and should be provided to all local governments and to any citizens that request them in a timely manner.

The OEC is basing our comments on our experience with cooling intake structures in Ohio. We believe that the NPDES permits in place today are not adequately protective for several reasons, including:

-Changes in the physical structures have taken place without any study of the effect of the changes on the kill rates for aquatic life.
-Power plants have withdrawn quantities of water well beyond the quantities that were used in the original applications and associated studies.
-The quantities of water being withdrawn are often a significant percentage of the source waterbody's flow, yet no modeling or biosurveys have been conducted to determine if the reduced flow is harming aquatic life.

Two examples of plants in Ohio that exhibit these problems are the Edison Bay Shore power plant in Oregon, Ohio, and several of the Dayton Power and Light facilities.

EPA Response

NPDES permits and supporting administrative records are public documents and copies may be requested directly from the State or EPA Regional office. However, portions of the record that are identified as confidential business information will not be released.

Through provisions of today's final rule, EPA hopes to curtail the actions that the commenter has cited above.

Option 3--Site-specific determination

Section 316(b) requires that the "location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact." 33 U.S.C. § 1326(b). Through this rulemaking process, EPA is attempting to implement this statutory provision with technology-based performance requirements. Under the proposed rule, the facility's owner or operator gets to choose the technology (or combination of technologies and other measures) the owner/operator believes will meet the performance standards. Georgia Power supports leaving it up to the facility owner or operator to determine what technology is most appropriate for its facility and believes the Clean Water Act intends for the facility owner or operator to make that decision.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Comment ID 316bEFR.034.004

Author Name Michael E. Wilder

Organization Georgia Power

Subject Matter Code 7.02

Performance standards

The proposed rule establishes performance standards for each type of waterbody in which a cooling water intake structure may be located. The proposed rule addresses oceans, estuaries, tidal rivers, freshwater rivers and streams, lakes, and reservoirs. Each standard calls for owners or operators to minimize their impacts to aquatic life by reducing, by a certain percentage, the number of organisms entrained or killed by impingement. Georgia Power believes that to the extent EPA continues to choose this regulatory approach, these standards and their implementation can be vastly improved over EPA's current approach.

EPA Response

Please see the preamble to the final rule for a discussion of the performance standards and their applicability in today's final rule.

Comment ID 316bEFR.034.005

Author Name Michael E. Wilder

Organization Georgia Power

Subject Matter Code 21.01

Submittal of required information

To begin the process of complying with the new performance standards, each facility submitting a permit renewal application will need to include a possibly overwhelming amount of information in its application, including: waterbody characterization data for the waterbody in the vicinity of the cooling water intake structure and data characterizing the design and operation of the structure itself. Proposed 40 CFR § 122.21(r)(2)-(3), (5). Each facility must also submit a Comprehensive Demonstration Study, unless it has or will implement controls which have or will reduce its intake flows to a level commensurate with the use of a closed-cycle, recirculating cooling system. Proposed 40 CFR § 125.95(a), (b).

EPA Response

EPA has added many efficiencies to today's final rule since the proposal and NODA to provide options for streamlining application requirements. First, the final rule offers five compliance alternatives including a site-specific determination of best technology available. Under compliance alternative 1(i) (see 125.94(a)(1)(i)), facilities with design intake flows commensurate with closed-cycle recirculating systems are exempt entirely from the Comprehensive Demonstration Study requirements and are deemed to have met the performance standards; and, if a facility has reduced its design intake velocity to less than or equal to 0.5 feet per second, the facility is only required to submit studies relating to entrainment reductions. In addition, compliance alternative 4 (125.94(b)(4)) allows a facility to install a pre-approved technology with minimal Comprehensive Demonstration Study requirements. For facilities that select this alternative, only the verification monitoring plan and design and construction technology plan are required. Director burden is also reduced for facilities that select compliance alternative 4 since only minimal studies are required.

EPA is also allowing the use of historical data as long as it is reflective of current conditions. EPA believes that some historical data may be appropriate for determining the calculation baseline and for characterizing the nature of impingement and entrainment at the site, and therefore has given the Director the discretion to determine whether historical data are applicable to current conditions. If the facility uses historical data, it must show that the data is representative of current conditions and that the data was collected using appropriate quality assurance/quality control procedures (see 125.95(b)(1)(ii)).

Additional flexibility is provided through both the Technology Installation and Operation Plan and the Restoration Plan, which reduce the facility's burden by eliminating the requirement to comply with performance standards during the first permit term (and subsequent permit terms, see preamble section 9 for a full discussion).

An opportunity for reduced Comprehensive Demonstration Study requirements is also offered at each permit renewal cycle. EPA has included a provision in today's final rule whereby the facility may receive reduced information collection requirements if conditions (such as biological, chemical, or physical) at the cooling water intake structure and waterbody have not substantially changed since the last permit issuance (see 125.95(a)(3)). The facility must request the reduced information requirements at least one year prior to the expiration of the existing permit and provide justification for each information requirement in 122.21(r) and 125.95 that they believe has not changed. EPA believes that over time, natural and anthropogenic changes that occur in a waterbody may affect a facility's ability to meet performance standards. Thus, EPA believes that it is important to ensure that the in-place design and construction technologies, operational measures, and/ or restoration measures are still appropriate for conditions at the facility. If conditions have changed, facilities will be required to submit all of the relevant Comprehensive Demonstration Study studies when they submit the application for permit renewal. If conditions have not changed, the facility may be granted reduced Comprehensive Demonstration Study requirements at the discretion of the Director.

General Statement of Opposition

Georgia Power believes that EPA needs to properly address these comments in order to improve the Rule's enforceability, make the rule more effective and consistent with the overall NPDES regulatory program, and maximize the overall use of resources. Furthermore, by failing to address these comments, EPA runs a significant risk of having the rule, if finalized as proposed, be held arbitrary and capricious and, for certain aspects, beyond the scope of EPA's delegated authority.

EPA Response

No response is required, as this comment summarizes the author's comments. Each issue is addressed individually in subsequent responses.

Performance standards

The Proposed Percent Reductions from the Calculation Baseline are too High.

Under the proposed rule, applicability of the performance standards vary, depending primarily on the source waterbody. If a facility withdraws water from a freshwater river or stream and that facility withdraws five percent or less of the river or stream's mean annual flow, then the facility must reduce fish and shellfish impingement mortality by 80 to 95 percent from the baseline. If the facility's design intake flow is more than five percent of the mean annual flow, the facility must lower impingement mortality by 80 to 95 percent and lower entrainment by 60 to 90 percent.

For an entity whose cooling water <FN 2> intake structure withdraws water from a lake or reservoir, the facility must reduce impingement mortality by 80 to 95 percent from the baseline. For entities whose cooling water intake structures withdraw water from the Great Lakes system, tidal rivers, estuaries, or oceans, those facilities must lower impingement mortality by 80 to 95 percent and lower entrainment by 60 to 90 percent. Regardless of the waterbody, however, the entrainment reduction component does not apply if the facility has a capacity utilization rate that is less than 15%.

EPA states that the performance ranges "reflect the uncertainty inherent in predicting the efficacy of a technology on a site-specific basis." In essence, EPA recognizes the inherently variable nature of aquatic environments. 67 Fed. Reg. 17141, Col. 3. The low end of the range indicates the minimum level of impingement or entrainment reduction that EPA believes all facilities -- even those operating in the most sensitive environments -- could achieve with the existing technologies on which EPA's assumptions are based. The high end of the range reflects EPA's belief that in some environments the same technology (technology upon which EPA based its proposed performance standards) will be more effective.

While the overall structure of the rule is not the ideal approach, <FN 3> Georgia Power believes it is workable. However, in addition to other deficiencies, the percent reductions from the calculation baseline are too high and not justified by the record.

Footnotes

2 EPA defines "cooling water" to mean "water used for contact or noncontact cooling, including water used for equipment cooling, evaporative cooling tower make up, and dilution of effluent heat content." Proposed 40 CFR § 125.83. Georgia Power requests that EPA make it clear that the water is no longer "cooling water" after it has performed its intended cooling function.

3 Georgia Power agrees with UWAG that the site-specific approach is better.

EPA Response

For a discussion of the basis for the performance standards ranges selected by EPA, see the preamble to the final rule.

Subject Matter Code 7.03
Available I&E technologies

EPA's Places Too Much Confidence in Existing Technology For Which Only Limited Information is Available.

The impact reduction levels were set based on limited experiences with certain technologies, which EPA implicitly expects facilities will opt to use. EPA based its impingement mortality reduction performance standards on design and construction technologies like wedge wire screens and aquatic filter barrier systems (which EPA believes can achieve a 99% impingement mortality reduction); barrier nets (EPA believes barrier nets are capable of 80-90% mortality reduction); and modified screens and fish return systems, diversion systems, fine mesh traveling screens, and fish return systems. 67 Fed. Reg. 17142, Col. 1.

For reducing entrainment, EPA acknowledges that the performance that can be expected from available technologies is less clear than with impingement mortality reduction. 67 Fed. Reg. 17142. The situation is further complicated by the fact that some of the entrainment reduction technologies cause problems by increasing impingement. Still, EPA believes technologies such as aquatic filter barrier systems, fine mesh wedge wire screens, and fine mesh traveling screens with fish returns should reduce entrainment by 80 to 90 percent from the baseline.

Notwithstanding EPA's admission that the support for its entrainment reduction technologies is less than ideal, EPA proposes using these impact reduction benchmarks anyway. Georgia Power believes EPA is being hasty in its approach and needs to re-examine the performance standards and make appropriate adjustments so that the standards will be more consistent with the practical realities of the numerous uncertainties that are associated with the regulation of cooling water intake structures and their very site-specific environments.

EPA Response

EPA does not expect nor does it require any facility to use a specific technology (except those facilities opting for compliance alternative 4) to meet the requirements of today's rule. EPA evaluated technology performance data published over the last three decades, and consulted with industry stakeholders, technology vendors, laboratory analysts, environmental organizations, academics and the public to determine the practicability of the performance standards presented in today's rule. EPA believes that the performance standards it has selected in today's rule represent the optimal ranges that facilities can be expected to achieve without incurring unreasonable costs.

EPA disagrees with the assertion that "[t]he impact reduction levels were set based on limited experiences with certain technologies." While some technologies are relatively new to the market and have not been evaluated at many facilities (e.g. aquatic filter barriers), other technologies have enjoyed wide use and have been continuously evaluated under a variety of circumstances over the past three decades (e.g. fish handling and return systems). In response to comments received at proposal, EPA expanded the scope of data used to support the performance standards (see Chapter 3 of the Technology Development Document) and compiled a database containing basic information about technologies and their performance (see Technology Efficacy Database in the Docket). EPA attempted to include as much data as it could collect in these documents but acknowledges that additional data may still be available.

EPA agrees with the commenter that some entrainment technologies can interfere with desired impingement mortality reduction goals. EPA does not, however, believe that such conflicts, as uncommon as they may be, are insurmountable and maintains that the requirements for entrainment can be reasonably achieved at all Phase II facilities.

Subject Matter Code 7.02

Performance standards

EPA Needs to Modify its Proposed Performance Standards to Reflect the Uncertainties Related to the Operation and Impact of Cooling Water Intake Structures.

For several reasons, EPA needs to adjust down the ranges of the performance standards. First, the technologies that EPA relies on have not been broadly tested to guarantee the kinds of results EPA identified. Indeed, perhaps with the exception of fine mesh screens, which have their own shortcomings, there is very little reliable data on the technologies EPA identifies.

Second, EPA itself recognizes the inherent variability of aquatic environments. Adding to the complexity of this problem is the fact that the limited evaluation data that is available does not reflect the diversity of aquatic environments in which EPA expects that these technologies will be applied. Accordingly, EPA should create more room in the standards to accommodate the uncertainties and variabilities.

EPA Response

Please see response to comment 316bEFR.029.040.

Subject Matter Code 15.0
State or Tribal Alternative Requirements

Third, such substantial percentage reductions assume that this issue has been completely overlooked by state agencies. This is simply not the case. Many of the facilities have been around for decades with not only significant and proper regulatory oversight, but also noteworthy public scrutiny. With volumes of NPDES-related data generated regarding water bodies and studies conducted under the various state programs, including assessments done by state wildlife resources departments, significant entrainment and impingement would not have gone unnoticed. Moreover, in certain areas, general knowledge about recreational fishing would have helped to identify facilities that are having significant impacts as a result of entrainment or impingement.

EPA Response

EPA recognizes that several states and agencies have made great strides in reducing impingement mortality and entrainment losses resulting from cooling water intakes and notes that significant impacts are not necessarily occurring at all sites. With public input and regulatory oversight, many facilities have addressed the concerns associated with cooling water impacts by installing new technologies, modifying facility operations to reduce cooling flow, or developing habitat restoration measures to restore and maintain impacted aquatic communities. EPA notes, however, that cooling water operations at many facilities do result in adverse environmental impacts and warrant further oversight to minimize these impacts.

EPA agrees with the commenter that an understanding of recreational fishing, along with commercial fishing and other waterbody uses, helps to identify the impacts resulting from impingement and entrainment. Several of the compliance alternatives in today's rule require the collection and analysis of these types of data when determining the most efficient means of meeting the rule's requirements.

Organization Georgia Power

Subject Matter Code 7.02

Performance standards

A Possible Improvement to the Rule is to Broaden the Range.

There are several approaches EPA should consider to establish more reasonable standards that are workable within EPA's current structure. One option is to broaden the ranges and allow permit writers to establish the percent reduction for individual facilities based on characteristics of the waterbody, existing aquatic communities, and other site-specific data. Georgia Power recommends using 50-70% range for impingement reductions and 40-60% range for entrainment reduction. These ranges are much more reasonable in light of the numerous uncertainties associated with the water bodies, the individual intake structures, the water quality of the various waterbodies, the extent of existing aquatic species, the types of aquatic species, the abundance or lack of nuisance species, the potential for endangered species, and the limited information available regarding the technologies identified by EPA.

EPA Response

Please see response to comment 316bEFR.040.

In addition, today's rule also authorizes site-specific determinations of Best Technology Available (BTA) for minimizing adverse environmental impacts, for example, to account for cost-benefit considerations or for special needs of the affected waterbody in accordance with state, tribal, or other federal laws (e.g. Endangered Species Act).

Organization Georgia Power

EPA Could Establish Interim Limits Until More Is Understood About Available Technology.

Another option that Georgia Power would support is the establishment of interim standards (e.g., for the next five years, reduce impingement by 40% and entrainment by 30% compared to the calculation baseline, where applicable). Then, at the end of that five year period, when assessments of both the waterbodies and technologies have been conducted, a permanent, more stringent standard can become effective.

EPA Response

EPA does not see the benefit of interim standards and in fact believes that such an approach would add unwarranted cost to facilities during the compliance process. For a discussion of the Technology Installation and Operation Plan provisions of the rule, see response to comment 316bEFR.029.040.

Author Name Michael E. Wilder
Organization Georgia Power

Subject Matter Code 21.01.04
Comprehensive demonstration study (7 parts)

EPA Needs to Establish Clear Definitions of the Objectives of an Acceptable Impingement and Entrainment Study, Including Some Guidance Regarding the Calculation Baseline Impingement and Entrainment Rates.

Under the proposed rule, the permittees of those facilities not employing, and not planning to employ, closed-cycle recirculating cooling systems (or their equivalent) will be required to submit an Impingement Mortality and Entrainment Characterization Study. Proposed 40 CFR § 125.95(b)(3); 67 Fed. Reg. at 17175, Col. 3. This Study is one of several steps to be undertaken as part of the Comprehensive Demonstration Study. This is arguably the heart of a 316(b) Comprehensive Demonstration Study, yet EPA provides very little meaningful guidance as to how to accomplish this component of the demonstration. Because clear objectives and guidelines are not established, the permittee is left with very little information as to how, as a practical matter, to scope the Study and how to extrapolate to a "calculation baseline." Compounding the problem is the absence of a definition of adverse environmental impact. Establishing clear guidelines for impingement and entrainment studies is important not only in the context of individual facilities that will be subject to the proposed rule, but also for the overall, long-term goal to reduce the effects of impingement and entrainment and improve the effectiveness of protective technologies. There is a great deal of information available from previous 316(b) studies. However, the scope, objectives, methods, estimation and reporting of these individual studies vary greatly. The variability in the studies themselves is one of the largest obstacles to creating a useful 316(b) database that could be used to help predict impingement and entrainment effects, or help predict the potential effectiveness of various protective technologies for a given set of environmental and operational conditions. Requiring facilities to conduct characterization and demonstration studies, without providing clear guidance to standardize those studies, is short-sighted and only promotes additional variability.

EPA Response

In today's final rule, EPA has provided an explanation of what facilities must submit for the Impingement and Entrainment Characterization Study (see § 125.95(b)(3)). EPA intends to develop implementation guidance for owners and operators that will address how to comply with information submission requirements, the sampling and monitoring requirements, and the record keeping and reporting requirements in these final regulations. In addition, when the applicant submits a this information, he or she will have ample opportunity to receive feedback from his or her permitting Director, who will be able to assess whether the proposed Impingement and Entrainment Characterization Study is sufficient.

Regarding EPA's definition of calculation baseline, it should be noted that in the NODA, EPA requested comments on the proposed definition of calculation baseline (see 68 FR 13580). The amended definition in today's final rule is found at § 125.93. The calculation baseline may be estimated using the facility's historical impingement mortality and entrainment data, or that of another facility with comparable design, operational, and environmental conditions. A facility may also use current impingement mortality and entrainment data that is reflective of the facility’s actual impingement mortality and entrainment rates.

The calculation baseline provides a standard intake configuration by which facilities can determine relative reductions in impingement and entrainment. EPA recognizes that this definition cannot address the variety of intake configurations and other conditions at all facilities and therefore cannot define the calculation baseline in all settings. In these instances, however, EPA believes that the calculation baseline in the final rule is clear and straightforward to implement, and allows for proactive facilities (i.e., those with control technologies, operational procedures, or restoration measures already in place) to take credit for existing measures. For additional explanation of the calculation baseline, refer to the final rule at § 125.93, and the following sections of the preamble: Section VI, VII and VIII, as well as the Phase II NODA, 68 FR 13580.

Finally, EPA disagrees that it should define adverse environmental impact. For an explanation of EPA’s decision to not define this term, please see the preamble to the final rule and EPA’s response to comment 316bEFR.030.012.

Ecological Risk Assessment

Employing EPA's Ecological Risk Assessment methodology in this context could provide structure for characterizing the potential ecological risk due to impingement and entrainment at cooling water intake structures. Georgia Power encourages EPA to consider using its own guidelines (US EPA, 1998 Guidelines for Ecological Risk Assessments, EPA/630/R-95/002F) in this context.

EPA Response

EPA agrees that its Ecological Risk Assessment Framework provides a useful structure for characterizing impingement and entrainment impacts. See Chapter A1 of EPA's Phase II Regional Study Document (DCN #6-0003)for a discussion of the Ecological Risk Assessment Framework as it applies to section 316b.

Organization Georgia Power

Subject Matter Code 21.01.04

Comprehensive demonstration study (7 parts)

Elements of an Impingement Mortality and Entrainment Characterization Study Needs to be Clarified.

The preamble identifies three elements of an Impingement Mortality and Entrainment Characterization Study. First, the preamble states that the characterization would include "taxonomic identifications of those species of fish and shellfish and their life stages that are in the vicinity of the cooling water intake structure and are most susceptible to impingement and entrainment." 67 Fed. Reg. at 17175, Col. 3. EPA needs to elaborate further and provide more clarity as to what it means with respect to this first element. For example, with respect to "taxonomic identifications" of species in the vicinity of the cooling water intake structure, to what extent can facilities rely on existing data generated by State natural resource and wildlife agencies or others? We understand from EPA's language that not every specie needs to be evaluated, just the ones that are "most susceptible" to impingement and entrainment. But what does EPA mean by "most susceptible?" One possible interpretation of this term is to focus on those species that are noticeably higher than the rest with respect to the frequency and abundance of the extent of entrainment or impingement. Another concern is to what extent can the permittee select representative species when the species that are being impacted are similar?

The second element EPA mentions is no clearer than the first. EPA expects a "characterization of these species of fish and shellfish and life stages, including a description of the abundance and temporal/spatial characteristics in the vicinity of the cooling water intake structure." Id. What does EPA mean by "characterization of these species?"

The third element is the "documentation of the current impingement mortality and entrainment and an estimation of the calculation baseline." Id. EPA does not explain the extent of the documentation that may be needed. Nor does EPA provide any useful guidance regarding the establishment of the theoretical baseline. As a practical matter, if the facility is once-through cooling with no existing technology, Georgia Power is concerned that EPA may take the position that the facility is itself equal to the baseline. However, there might be other considerations that may have already lowered the extent of any impingement or entrainment that may not be limited to technology. For example, certain operational controls or the location/angle of the cooling water intake structure may operate to limit the extent of entrainment or impingement. EPA should, therefore, provide facilities with the opportunity to take into account other considerations beyond technology for purposes of determining the calculation baseline.

EPA Response

EPA disagrees that it needs to further clarify "taxonomic identifications of those species of fish and shellfish and their life stages
that are in the vicinity of the cooling water intake structure and are most susceptible to impingement and entrainment." In today's final rule, EPA has provided a clear explanation of what facilities must submit for the Impingement and Entrainment Characterization Study (see § 125.95(b)(3)). In

addition, EPA believes that any questions a facility may have will be answered through dialogue with their State permitting authority. A facility must submit to the Director a Proposal for Information Collection, which is a description of the information the facility will use to support the various components of its Comprehensive Demonstration Study. The Director will review the Proposal and provide feedback to the facilities. Therefore, facilities will be informed by their State permitting agency if their proposed data collection efforts are not sufficient. The Director will be most familiar with the site and waterbody conditions in his or her jurisdictions and will be able to comment on lists of species of concern proposed by the facilities. In answer to the question regarding the use of existing data, EPA does permit the use of such existing or historical data so long as it is reflective of current conditions. For information on the circumstances under which existing data is accepted, please see the final rule preamble section VIII.E.2.c. Other means of determining compliance, section VIII.E.4. a. Requirements and burden, and EPA's response to comment 316bEFR.034.005. Furthermore, EPA has specified in today's final rule what is meant by "characterization of these species." Please see § 125.95(b)(3)(ii). Finally, EPA has clarified its definition of calculation baseline in today's final rule (see EPA's definition at § 125.93). For additional detail on determining a facility's calculation baseline, see EPA's response to comment 316bEFR.034.013.

Organization Georgia Power

Subject Matter Code 10.03

Case Study Specific Comments

EPA's Case Studies Are of Limited Value.

Georgia Power has some concerns about the case studies that EPA provided. Because of variabilities in the way the studies were conducted and reported, there is little information that can be transferred in a meaningful way to other facilities. Those case studies, therefore, have limited use. In addition, the case studies are repeatedly qualified as out of date and likely to underestimate impingement and entrainment, suggesting that EPA would like some as yet undefined but better process. Finally, Georgia Power is concerned that a calculated baseline scaled to design MGD is not a defined measure if the underlying impingement and entrainment studies are open to significant criticism. In real operations, actual pumping rates are often significantly less than design MGD, which might put some facilities in a position of trying to reduce a "calculation baseline" that is greatly overestimated.

EPA Response

EPA disagrees with the commenter's assertion that I&E estimates cannot be extrapolated. Please see EPA's response to Comment 316bEFR.041.041 on EPA's extrapolation approach.

Author Name Michael E. Wilder
Organization Georgia Power

Subject Matter Code 21.04
Determination of compliance

Allowances for Unavoidable Episodic Impingement and/or Entrainment Events.

In development of the Final 316(b) Rule for existing facilities, EPA should acknowledge and make allowances for the occurrence of unavoidable episodic impingement and entrainment events that are beyond the control of the cooling water intake structure facility operator. For example: Threadfin shad (Dorosoma petenense) are a temperate freshwater forage fish species that occurs throughout the southern and southwestern United States. (Lee, D.S., C.R. Gilbert, C.H. Hocutt, R.E. Jenkins, D.E. McAllister, and J.R. Stauffer, Jr. 1980 et seq., Atlas of North American Freshwater Fishes. N.C. State Mus. Nat. Hist., Raleigh. i - x + 854 pp.)

Threadfin shad are very sensitive to water temperatures with significant mortality of young and adults occurring below 7 C (44.6 F), with 5 C (41 F) reported as the lower lethal temperature for the species. Threadfin shad experiencing decreased swimming ability and/or mortality due to cold stress/shock are subject to impingement, and possibly entrainment, as they enter the cooling water intake structure hydraulic Zone of Influence. Winter stress or kill of threadfin shad commonly occurs in the northern portion of the species range and large die-offs have been known to result in excessive cooling water intake structure impingement rates to the point of intake screen collapse and, consequently, facility power curtailment and/or shutdown. King, R.G., GeoSyntec Consultants, personal communication re: Gentleman Station, Nebraska Public Power District (2002).

Similar phenomena can occur in marine environments involving a variety of thermally (cold) sensitive fish (e.g., snook, Centropomidae, and mullet, Mugilidae). Marine invertebrates are also susceptible candidates for unavoidable episodic impingement and entrainment, particularly planktonic species whose movement is subject to the wind, tides, and currents, and whose populations undergo cyclical expansions or "blooms" (e.g., jellyfish, a group that includes Scyphomedusae, Hydromedusae, Siphonophores, and Ctenophores).

The occurrence of such an unavoidable episodic event during the conduct of the Impingement Mortality and Entrainment Characterization Study, as currently required by the proposed rule, would unfairly bias the results of the study whose objectives are to provide representative data to support development of the Baseline Calculation for evaluating reductions in impingement mortality and entrainment; document current impingement mortality and entrainment; and provide the basis for evaluating the performance of potential technologies, operational measures, and/or restoration measures. Additionally, in the absence of provisions acknowledging unavoidable impingement and/or entrainment, should such an event occur during Compliance Monitoring a facility could face possible regulatory actions ranging from enforcement penalties to unnecessary implementation of more stringent and costly technological controls and/or restoration measures to meet a required reduction in impingement and/or entrainment mortality from the facility Calculation Baseline; a baseline value that, at the time determined, may not have experienced a similar episodic event.

Therefore, the Final 316(b) Rule for existing facilities should: 1) include language defining and recognizing the occurrence of unavoidable episodic impingement and/or entrainment events; 2) allow exclusion of such events during the conduct of the Impingement Mortality and Entrainment Characterization Study and associated Calculation Baseline determination; and 3) provide exemption from any regulatory actions, including enforcement actions, arising from an unavoidable impingement and/or entrainment event that might occur during Compliance Monitoring or otherwise during the life of the facility NPDES permit.

EPA Response

EPA agrees that provisions for unavoidable episodic impingement and entrainment events and emergency intakes should be considered. However, EPA believes that it is incumbent upon the facility to build protective measures into their technology selection and operation to accommodate these potential events. In other words, it is EPA's position that a facility needs to install a technology that is protective enough to account for periods of variability. Furthermore, EPA has designed the rule so that a Director has tremendous flexibility in establishing how compliance with performance standard will be determined, including approving averaging periods proposed by the applicant for determining compliance. EPA envisions that most episodic events will be "averaged out" over a longer interval of time, as deemed acceptable by the Director. In this way, facilities that are generally in compliance, but experience an unusual peak of impingement mortality and/ or entrainment, may be considered to still be in compliance due to past good performance. Therefore, EPA respectfully disagrees that it should 1) include language defining and recognizing the occurrence of unavoidable episodic impingement and/or entrainment events; 2) allow exclusion of such events during the conduct of the Impingement Mortality and Entrainment Characterization Study and associated Calculation Baseline determination; and 3) provide exemption from any regulatory actions, including enforcement actions, arising from an unavoidable impingement and/or entrainment event that might occur during compliance monitoring or otherwise during the life of the facility NPDES permit. See also the preamble for additional discussion of compliance issues.

Organization Georgia Power

Subject Matter Code 17.02

Option: Reduce capacity comm. with closed-cycle

The Use of Off-Stream Lakes or Ponds Should be Viewed in the Context of the Overall Reduction of Water Withdrawn.

Under the proposed rule, existing facilities with intake flow levels “commensurate with” that which can be attained by a closed-cycle recirculating cooling system using minimized makeup and blowdown flows are deemed to be in compliance with the rule as proposed. Georgia Power believes that certain aspects of this section of the rule is arbitrary, legally unsupported, and in need of clarification. Because of EPA’s unclear definition of “closed-cycle recirculating cooling system,” Georgia Power is concerned about the regulatory status of several of its power plants with cooling towers and off-stream ponds or reservoirs.

EPA Response

Please refer to the response to comment 316bEFR.063.011.

Comment ID 316bEFR.034.019

Author Name Michael E. Wilder

Organization Georgia Power

Subject Matter Code 3.02

Definition: Cooling Water Intake Structure

Georgia Power recommends a more practical definition of closed-cycle recirculating cooling system as follows: "A system that minimizes the extent of its overall water withdrawal rate and/or use by recirculating its cooling water through any one of several mechanisms that does not involve once-through use of a significant percentage of the cooling water. Such systems can involve the use of a cooling tower, with a source of make-up water such as an off-stream lake or a cooling pond."

EPA Response

The comment does not explain the shortcomings of the proposed definition of closed-cycle recirculating system (which referenced the Phase I definition in 40 CFR 125.83) or why the commenter's suggested definition is more practical than the proposed definition. The definition in the final rule (see, § 125.93) is the same as the one discussed in the proposal and included in the Phase I rule (40 CFR 125.83). EPA believes this definition is sufficiently clear and provides adequate flexibility for practical application on a case-by-case basis.

Organization Georgia Power

Subject Matter Code 3.07

Special definitions

Use of Off-Stream Ponds is a Practical Component of a Closed-Cycle System.

In Georgia Power's case, off-stream ponds were created to ensure compliance with Georgia's water withdrawal regulatory scheme and to provide a reliable, easily accessible source of water for cooling tower make-up. <FN 4> Essentially, an off-stream pond adds a step to the water withdrawal process while at the same time providing a buffer to the original source waterbody. Water is pumped from the original source waterbody into the off-stream pond. The pumps at the original source waterbody operate on a limited basis to maintain the off-stream pond at a certain level. Water is then pumped from the off-stream pond to serve various plant functions. The pond's primary function, however, is to serve to make-up the cooling tower water when it is reduced, mostly as a result of evaporation or blowdown. Because Georgia's water withdrawal law implemented through water withdrawal permits imposes certain pumping restrictions, off-stream ponds enable Georgia Power to meet the plants' water needs without overburdening the source waterbody or otherwise violate the water withdrawal regulatory scheme.

Georgia Power believes that a determination of whether a system is "commensurate with" a closed-cycle recirculating system should be based on the overall reduction of water use based primarily on the reduction in water withdrawn from the original source waterbody. Whatever definition EPA ultimately uses, however, Georgia Power's sole concern is that the definition does not inadvertently exclude facilities with off-stream ponds.

Footnotes

4 Georgia Power does not believe that off-stream ponds are waters of the U.S.

EPA Response

EPA disagrees that in the example provided by the commenter, the off-stream ponds represent part of a closed-cycle cooling system. Rather, the off-stream ponds could be functioning as part of the cooling water intake structure. They may constitute "waters of the U.S," depending upon the facts presented. For additional explanation, please refer to the response to comment 316bEFR.032.015.

Special definitions

At the Very Least, EPA Needs to Change or Clarify Certain Terms Used in the Current Definition of Closed-Cycle, Recirculating System.

EPA does not explain the meaning of certain key terms included in the proposed rule. EPA's failure to define some of these terms and certain related concepts will make the preliminary determination regarding whether the facility's system is "commensurate with" a closed cycle, recirculating system difficult. First, EPA does not define "commensurate with." Webster's dictionary definition of "commensurate" is "equal in measure or extent, corresponding in size, extent, amount, or degree." This being the case, we assume EPA to mean "equal to" or "same as" when it uses the term "commensurate with."

We believe "commensurate with" is too inflexible for situations where a variety of factors can affect the need for make-up water or the extent and frequency of blowdown. These factors include climate differences, the need for certain water quality within cooling towers, differences in water quality standards applicable to the receiving waterbodies, and evaporation. For these reasons, Georgia Power recommends using "similar to" instead of "commensurate with".

Second, EPA does not explain what is meant by "minimized make-up and blowdown flows." Configurations of closed-cycle, recirculating systems vary. As mentioned, some systems, such as Georgia Power's, use reservoirs or off-stream ponds to provide make-up water. Depending on the configuration of the system, the amount of make-up water needed may vary, due largely to evaporation. A system should be considered minimized provided that the majority of the water used does not serve a once-through cooling function.

Also, the frequency of blowdown varies depending, in part, on applicable water quality standards and the quality of the intake water. The quality of the water in the cooling tower must be maintained at a certain level to preserve the system. A system's blowdown should be considered minimized when blowdown is not performed more than is reasonably necessary.

EPA Response

EPA disagrees that it should change the definition of "commensurate with" to "similar to." The language used in the definition of closed-cycle cooling has been used historically (see the Phase I rule), and thus far EPA's choice to not define the term has in no way hampered the ability of facilities to implement the rule. EPA also disagrees that it should quantify "minimized make-up and blowdown flows." Because each facility has unique intake configurations and surface waterbody conditions, EPA has decided to leave the determination of how much a facility should minimize its make-up and blowdown to the Director's discretion. EPA therefore believes that it is sufficient to state that facilities are required to minimize make-up and blowdown flows, thereby minimizing the impacts associated with those flows and increasing the efficiency of the facility.

Proposed standards for FW rivers and streams

EPA Should Increase the Water Withdrawal Threshold Relating to Rivers and Streams.

Under the proposed rule, facilities located on freshwater rivers or streams do not need to address entrainment, provided that the facilities' design intake flow is 5% or less than the source river's mean annual flow. EPA explains that the 5% withdrawal threshold is based on the concept that, "absent any other controls, withdrawal of a unit volume of water from a waterbody will result in the entrainment of an equivalent unit of aquatic life…suspended in that volume of the water column." 67 Fed. Reg. 17151, Col. 2.

Accordingly, EPA concludes that "if 5% of the mean annual flow is withdrawn, it would generally result in the entrainment of 5% of the aquatic life within the area of hydraulic influence of the intake." Id. Because EPA believes that it is unacceptable to impact more than 5% of the organisms within the area of an intake structure, EPA is choosing to require those facilities that withdraw more than 5% of the mean annual flow of a fresh water river to reduce entrainment by 60-90%. For several reasons, Georgia Power believes that EPA's approach is arbitrary.

First, the 5% criterion uses design intake pumping rate and annual average flow. Operational measures which may be implemented because of the hydrologic regime are ignored but may minimize entrainment and impingement. Also, consideration should be given to use of actual volume pumped and river flow for periods during critical life stages when fish and shellfish would be impacted.

Second, the 5% criterion assumes a uniform distribution of entrainable organisms to derive a conservative estimate of the potential for adverse impact. See EPA 2002, EPA -821-R-02-002, page A1-5. Examination of the case study data EPA provided shows no relationship between design intake pumping rate and total entrainment or impingement. See The Ohio River Watershed Case Study, EPA 2002, EPA-821-R-02-002, Part C. This can be seen qualitatively by noting that the facility with the greatest capacity to withdraw water from the Ohio River, the W. H. Sammis facility, with design intake capacity of 7.46% of annual river discharge, reports lower annual entrainment rates than four other facilities with design intake capacities ranging from 0.36% to 4.75% of mean annual flow. Possible reasons for this include: different habitat preferences for various fish species; orientation of the intake in relation to the source water body; differences in life history including differences in reproductive strategies. As far as Georgia Power can tell, EPA has provided no supporting data for the proposition that entrainment is proportional to design pumping capacity as a percent of average annual river flow.

Third, the existing intake structure may be located in a waterbody segment that supports minimal valuable aquatic life. In certain cases, potential impingement or entrainment may be reduced because of the location of the structure relative to the channel, migratory pathways or other desirable microhabitats. The 5% threshold makes no allowance, for example, for situations where nuisance species may be the primary species being entrained or impinged.

EPA's broad-brush approach to the 5% withdrawal threshold ignores these factors that could justify a higher threshold.

Given various considerations that could affect the potential relationship between aquatic organisms present in the water body and the percentage that is likely to be entrained, we recommend a higher threshold with the opportunity for the permit writer to be more stringent if the situation requires it. EPA should use a threshold flow equal to 15% of the spawning season flow.

Regardless of the ultimate threshold EPA decides to apply, Georgia Power believes that at any such threshold, the risk of entrainment and the relative significance of impingement should be sufficiently low to warrant an avoidance of both impingement and entrainment requirements below the threshold.

EPA Response

Facilities withdrawing greater than 5% of the mean annual flow from freshwater rivers and streams (and having a capacity utilization rate greater than 15%) are required to meet both impingement and entrainment requirements. The withdrawal threshold is based on the concept that absent any other controls, withdrawal of a unit volume of water from a waterbody will result in the entrainment of an equivalent unit of aquatic life (such as eggs and larval organisms) suspended in that volume of the water column. EPA discussed these concepts in more detail and invited comment on the use of this threshold and supporting documents in its NODA for the New Facility Rule (66 FR 28863). EPA believes that a 5% mean annual flow requirement for freshwater rivers and streams achieves an acceptable level of protection for the source water while remaining economically and practicably reasonable for existing facilities.

With respect to the use of design intake flow, this standard is not applicable to the daily operation of a facility's cooling water intake structure (i.e., actual intake flow). That is, a facility is not expected to constantly monitor the instream flow of the source water and adjust its water intake accordingly. EPA believes the design intake flow standard for riverine facilities affords a level of protection for the source water body acceptable under most, if not all, stream conditions.

EPA continues to believe that the 5% mean annual flow requirement for freshwater rivers and streams is appropriate with respect to the distribution of organisms. EPA recognizes that, in some cases, organisms may not be uniformly distributed in the water column. However, EPA believes that assuming a uniform distribution is a conservative and appropriate approach to estimating impingement and entrainment rates.

With respect to nuisance species, today's final rule requires that monitoring be conducted in accordance with the verification monitoring plan (125.95(b)(7)), the Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5). The Director may consider additional monitoring requirements as well. Specific study parameters may be proposed by the applicant for review and approval by the Director.

With respect to increasing the withdrawal threshold and using the spawning season flow, EPA disagrees with the commenter. As stated earlier in this response, EPA believes that a 5% mean annual flow requirement for freshwater rivers and streams achieves an acceptable level of protection for the source water while remaining economically and practicably reasonable for existing facilities. Also, as stated earlier in this response, EPA believes the design intake flow standard for riverine facilities affords a level of protection for the source water body acceptable under most, if not all, stream conditions.

With respect to facilities withdrawing less than the withdrawal threshold, EPA disagrees that said facilities should have no impingement or entrainment requirements. These facilities continue to withdraw from the waterbody and may continue to impinge or entrain organisms, and are therefore potentially subject to applicable requirements. However, such a facility could elect to demonstrate that its current intake configuration meets the applicable performance standards, as described under § 125.94(a)(2) or could opt to seek a site-specific determination of best technology available, as described under § 125.94(a)(5).

RFC: Regulating limited capacity facilities

Author Name Michael E. Wilder

Organization Georgia Power

The Utilization Rate Needs to be Increased.

EPA proposes to exempt facilities from entrainment reduction requirements when a facility operates less than 15% of the available operating time (based on historical data). Proposed Rule 40 CFR § 125.94(b)(2); 67 Fed. Reg. 17153, Col. 3. EPA explains that "because these facilities operate only a fraction of the time compared to other facilities, such as base-load plants, the peaking plants achieve sizable flow reductions over their maximum design annual intake flows." 67 Fed. Reg. 17153, Col. 3. EPA also explains that the reduced standard is further justified on the basis that these peaking facilities operate during the peak of winter and summer, which are not the most crucial periods for aquatic organisms. Georgia Power agrees that low capacity utilization facilities should be granted certain exemptions. However, EPA's threshold is too low.

EPA needs to increase the utilization rate that triggers entrainment reductions and give permit writers the flexibility to agree to permit conditions regarding the facility's utilization rate that may depart from the facility's historical operation with or without supporting data, provided that the facility can demonstrate future compliance with the utilization rate it chooses.

Georgia Power believes that a 30% utilization threshold is justified on the basis that, compared to 100% utilization, there is an overall reduction in flow of about 70% which puts the facility within range of the proposed reduction in entrainment (60-90%). In addition, Georgia Power believes the impingement requirement should not apply to facilities with capacity utilization rates up to 20%. This would also be in line with the performance standard (80-95% reduction) for facilities that have 100% utilization.

EPA Response

Correlating the utilization rate directly and solely to the performance targets for entrainment or impingement reduction is an incomplete justification of the capacity utilization threshold. The Agency cannot adopt the suggestions for the final rule. The commenter does not clarify which side of the range would the commenter have the Agency adopt. If the Agency were to adopt the upper bound of the ranges referenced by the commenter, then the capacity utilization rate threshold would be lowered by 5 % for entrainment requirements. The commenter provides no justification as to why the rate should be lower. The commenter's desires for a lessening of the requirements is not sufficient basis for said lessening.

The Agency explains its rationale for selecting the 15 % capacity utilization rate at DCN 6-3586.

Apply 316(b) before a det. of impact/AEI

Adverse Environmental Impact Cannot be Presumed.

To the extent that EPA is using 316(b) to regulate cooling water intake structures that are not having an adverse impact on the environment, EPA is acting beyond the scope of its authority. Consistent with the Clean Water Act, EPA must allow a two step process that enables a utility to show whether there is any adverse environmental impact in the first place. Section 316(b) of the Clean Water Act requires the location, design, construction, and capacity of cooling water intake structures to "reflect best technology available for minimizing adverse environmental impact." 33 U.S.C. § 1326(b). On the basis of strict statutory interpretation, if adverse environmental impact is absent, then the question whether the facility has best technology available becomes largely irrelevant.

Under the rule as proposed, EPA assumes that there is adverse environmental impact by virtue of the operation of a cooling water intake structure. Georgia Power disagrees with this position and finds it to be not only arbitrary, but completely at odds with the Clean Water Act. EPA is without delegated authority to require facilities to undertake activities with respect to their cooling water intake structures where there is an absence of adverse environmental impacts.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Subject Matter Code 18.01.01

UWAG definition of "adverse environmental impact"

Georgia Power supports the UWAG definition of "adverse environmental impact" as stated in the proposed rule. See 67 Fed. Reg. at 17163. EPA appears to take the position that a definition for "adverse environmental impact" is relevant only if the Agency adopts a site-specific approach. See 67 Fed. Reg. at 17164. Georgia Power disagrees with EPA's approach. Consistent with the Clean Water Act, a determination of adverse environmental impact is a necessary first step.

EPA Response

Please see the response to comment 316bEFR.002.019 for the discussion on the definitions EPA rejected for adverse environmental impact in this rulemaking. In addition, EPA disagrees that it is required to define adverse environmental impact. In this case, EPA has reasonably exercised its discretion not to codify a definition.

Comment ID 316bEFR.034.026

RFC: Definition of “adverse environmental impact”

There are many considerations that may factor into the presence or absence of adverse environmental impact. At the very least, those considerations should include the following factors: (1) whether species compensate for or accommodate the impact to an extent that the overall impact is “not adverse” (e.g., the nuisance species are minimized or the impacted species would have otherwise died or that the species otherwise make up for the loss); (2) if the facility is impacting the waterbody to an extent that is less than 75% of the calculation baseline then the facility should be exempt under the theory that a 25% impact relative to the baseline is acceptable unless endangered or threatened species are involved.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

Subject Matter Code 20.0

Role of Trading

Expansive Trading Should be Allowed.

Georgia Power believes that the rule should be modified to specifically allow trading. To ensure maximum flexibility and to encourage some experimentation among the states, EPA should let individual states develop their own trading programs. States should be allowed to pursue interstate trading if they desire. States should be given the flexibility to have their programs include the potential for source-based controls, receptor-based mitigation, and compensation based mitigation.

A trading program would be especially useful in this area because of the variety of methodologies that can be employed. As examples, a program can be structured to augment current water quality standards schemes or to meet broad biodiversity goals.

One possible way for a state to design a program would be to conduct a survey of facilities located in the state (perhaps on a per watershed basis) and identify a series of mitigation measures each facility can undertake in order to achieve certain biodiversity goals, achievement of water quality standards or some other measurable outcome. The state can then assign a certain value to these measures and relate these measures to units that can be applied toward reduction in impingement and entrainment as compared to the calculation baseline. Ultimately, fashioning the program should be up to the states. However, EPA should provide the regulatory basis and encourage states to develop such programs

EPA Response

Trading in the context of section 316(b) raises many complex issues. Due to the complex issues relating to trading, EPA has elected not to specify how a trading program in the context of section 316(b) should be implemented but rather has left it to the discretion of a permit director to decide whether a trading program is a beneficial use of State resources. Should a State choose to propose a trading program under § 125.90(c), EPA will evaluate the State's proposal on a case-by-case basis to ensure the program complies with the regulatory requirement – that it will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment that would otherwise be achieved under the requirements established at §125.94. To this end, EPA foresees potentially approving only those trading programs which allow trades within individual watersheds and trade for numbers of the same species.

Role of Restoration

Voluntary Restoration Should Not Be Limited to a Supplementary Role.

Under the proposed rule, restoration measures are allowed in lieu of or in combination with reductions in impingement mortality and entrainment. 67 Fed. Reg. at 17146. Georgia Power strongly supports the use of restoration and does not believe that the role of restoration should be limited to supplementing technology or operational measures.

EPA Response

Under the final rule, facilities may use restoration measures either in lieu of or in combination with technologies that reduce impingement mortality and entrainment.

Comment ID 316bEFR.034.029

Author Name Michael E. Wilder
Organization Georgia Power

Subject Matter Code 2.04.06
Restoration measures in place of technologies

Voluntary Restoration is Consistent with the Clean Water Act.

Georgia Power can find no regulatory or legal reason to limit the use of restoration. In fact, one of the key premises of the Clean Water Act is restoration. 33 U.S.C. § 1251. To the extent that EPA is concerned about over-reliance on restoration measures or that industry may avoid practical technological fixes, this reflects a failure on EPA's part to allow permit writers to fulfill their roles. The permit writer is positioned on the ground and can recognize when an owner or operator is proposing deficient restoration measures. In any event, the permit writer will eventually be able to identify if the restoration project is a failure and will be able to require additional compliance measures.

EPA Response

For information on EPA's authority to allow restoration under today's rule, see the preamble to the final rule. EPA agrees that its restoration provision is consistent with the goals of the Clean Water Act (CWA) as expressed in CWA section 101(a).

Under the final rule, it is the responsibility of the permitting authority to review a permitee's application and decide whether or not restoration measures are an appropriate means for the permittee to comply with the requirements of the final rule. As described in section 125.95, the rule requires permittees to develop a Restoration Plan and submit several pieces of information to the permitting authority in order to aid both the permittee and the permitting authority in their consideration of the feasibility of restoration measures. Once permittees obtain the permitting authority's approval and implement restoration measures, it is their responsibility to ensure and demonstrate to the permitting authority that the measures meet the requirements of the final rule.

Comment ID 316bEFR.034.030

Organization Georgia Power

Subject Matter Code 11.01

RFC: Proposed use of restoration measures

Voluntary Restoration Ensures Flexibility and the Best Use of Resources.

Under EPA's preferred regulatory approach, EPA has opted not to pursue the site-specific approach. In order to add some level of flexibility to EPA's approach, it is imperative that EPA make restoration completely voluntary. While Georgia Power does not believe that voluntary restoration will provide a complete fix for the proposed rule, it will certainly translate to a significant improvement. Because owners and operators are best positioned to determine how to maximize their resources, they will be able to identify the optimum approach (or combination of approaches) to comply with the rules. There might be situations where restoration is simply not cost effective. On the other hand, physical limitations may make employment of technical improvements unattractive or impracticable. Giving the owner or operator the regulatory freedom to determine which approach or combination of approaches would be most efficient and effective would produce the best result. Indeed, it may enable the employment of more creative, environmentally beneficial solutions.

EPA Response

EPA believes the inclusion of the option to use restoration measures in the final rule provides permitting authorities and permit applicants with additional compliance flexibility.

For a discussion of the extent to which restoration measures are voluntary, see EPA's response to comment 316bEFR.060.022.

For a discussion of the responsibilities of the permitting authority and the permit applicant in the assessment and application of restoration measures, see EPA's response to comment 316bEFR.034.029.

For a discussion of the requirement to consider design and construction technologies and operational measures before choosing restoration measures, see EPA's response to comment 316bEFR.033.005.

RFC: Appropriate spatial scale for restoration

While Georgia Power supports broad flexibility to engage in restoration projects, Georgia Power would support limiting restoration to the watershed that serves the facility's intake, at least for initial projects. Georgia Power believes restoration projects should not be located elsewhere until opportunities for reasonable restoration within the source watershed are not available.

EPA Response

For a discussion of the appropriate scale on which to conduct restoration measures, see EPA's response to comment 316bEFR.212.001.

Comment ID 316bEFR.034.032

Author Name Michael E. Wilder

Organization Georgia Power

Subject Matter Code 11.0

Role of Restoration

Credit for Past Environmentally Beneficial Projects or other Activities that Limit the Extent of Impingement or Entrainment.

Under the proposed rule, facilities that have certain technologies in place that reduce entrainment and impingement will be credited for such technologies when calculating the "calculation baseline." While it is not clear how such projects should be taken into account in determining the "calculation baseline," Georgia Power believes the same treatment should be granted to past projects that may not have involved the employment of technology or technological improvements, but yet served whether directly or indirectly to minimize entrainment or impingement. Credit should be expanded to include, among other things, historical operational measures, regardless of whether such measures were put in place to address entrainment or impingement. Similar credit should be given to projects that improved the quality of the aquatic environment.

EPA Response

EPA believes that facilities should be given credit for existing restoration measures undertaken for the purposes of mitigating adverse environmental impacts from cooling water intake structures. Under section 125.94 of the final rule, facilities may request credit for existing design and control technologies, operational measures, and restoration measures. Existing restoration projects must meet the requirements described under sections 125.94 and 125.95. Facilities may claim credit for the ongoing fish and shellfish production from the restoration measures. They may not claim mitigation of cooling water intake structure impacts by restoration measures that have been implemented in order to fulfill some other environmental requirement (e.g., wetland creation in order to satisfy CWA 404 requirements).

Comprehensive demonstration study (7 parts)

Streamlined Demonstration, Monitoring, and Implementation.

Because a significant amount of the costs to electric utilities that could result from this rule will be associated with the 316(b) demonstration studies, verifying the effectiveness of the selected compliance methods, and post-permit issuance monitoring, Georgia Power believes that these costs can be substantially reduced, without jeopardizing EPA's objectives, if EPA were to streamline the process.

EPA Response

Please see EPA's response to comment 316bEFR.034.005 for details on measures EPA has taken to streamline the information collection requirements and implementation of today's final rule.

Comment ID 316bEFR.034.034

Author Name Michael E. Wilder
Organization Georgia Power

Subject Matter Code 18.02
RFC: Use of previous demonstration studies

Streamline the Demonstration Study.

First, a 316(b) demonstration should never have to be repeated unless circumstances have so changed to make the original demonstration unreliable. If a utility holds a NPDES permit with an accepted 316(b) demonstration, a re-evaluation of entrainment and impingement should only be required under specific circumstances such as: (1) when there has been material change in the operation of the facility that would increase the extent of impingement or entrainment; (2) when technological improvements are determined to be ineffective; (3) when restoration projects have failed; and (4) when significant changes are made to the cooling water intake structure. New and significant information should be evaluated through consultation with state and federal natural resource agencies to determine whether species of concern (threatened and endangered species) may be present or changes in the fishery have occurred which may significantly increase the rate of impingement and entrainment at a facility.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule; however, existing data that is reflective of current conditions may be used to support the required studies. Please see response to comment 316bEFR.040.001 for details.

Organization Georgia Power

Subject Matter Code 21.09
Permit applications/implementation schedule

Streamline the Implementation.

EPA is concerned about the potential burden on permitting agencies associated with the implementation of the proposed rule. Georgia Power believes that one of the best opportunities to minimize the impact of the proposed rule on both the responsible agencies and the regulated community is through the permit implementation process. The implementation process needs to be streamlined. Too much information is being required at the permit re-issuance application first step. The responsible agencies are likely to be overwhelmed and the permitees are likely to struggle with having to address so many issues at one time.

Under the proposed rule, owners or operators must submit the following information when applying for a re-issued NPDES Permit: (1) physical data to characterize the source waterbody in the vicinity where the cooling water intake structures are located (proposed 40 CFR § 122.21 (r) (2)); (2) data to characterize the design and operation of the cooling water intake structures (proposed 40 CFR 122.21 (r) (3)) which is to be provided in two components, the first being the cooling water intake structure data and, the second being the existing facility cooling water system description; and (3) a Comprehensive Demonstration Study (proposed § 125.95(b)). Only facilities with closed-cycle, recirculating systems (or their equivalent) are not required to provide the Demonstration Study. Georgia Power believes that this amount of information will be overwhelming to the agencies and may have numerous negative results. Georgia Power recommends a more streamlined/orderly approach as follows:

-All permittees with permits that will expire within two years after the date the rule becomes final shall submit information to the responsible agencies in two steps. In step one, the permittee shall submit: the source water physical data; the cooling water intake structure data; and the existing facility cooling water system description to the director within 60 days of the permit expiration date. These permittees should be required to follow the normal permit renewal process (i.e., new permit conditions related to the 316(b) rule will not be imposed in the first renewal process for permits that will expire within the first two years after the date the rule becomes final). This information gathering stage merely gives the agency the ability to determine (1) whether the facility has a closed-cycle recirculating system and is therefore in compliance with the rule, or (2) what performance standard the facility would need to comply with absent a request for a site-specific determination.

-In step two, facilities with permits that will expire within two years after the date the rule becomes final and that do not have closed-cycle recirculating cooling systems (or their equivalent) should be required to submit a Comprehensive Demonstration Study within two years from the day the permit expires. The permitting agency will review the results of the Study and other factors, and shall request any necessary additional information. The permitting agency shall impose all 316(b) related permit conditions when the permit is renewed in the next renewal cycle.

-For those permits with expiration dates beyond the two years after the date of the final rule, steps one and two above are consolidated. The permittee shall submit (1) the physical data to characterize the source waterbody; (2) data to characterize the design and operation of the cooling water intake structure; and (3) a Comprehensive Demonstration Study along with the normal permit renewal application.

EPA Response

EPA has added many efficiencies to today’s final rule since the proposal and NODA to provide options for streamlining application requirements. Please see response to comment 316bEFR.034.005 and the preamble to the final rule.

Subject Matter Code 3.07

Special definitions

EPA Should Provide a Definition of "Significantly Greater."

Under the proposed rule, the owner or operator of an existing facility may demonstrate to the Director that a site-specific determination of best technology available is appropriate for its facility if the owner or operator can meet one of the two cost tests. 67 Fed. Reg. at 17145. To obtain a site-specific determination, the facility must first demonstrate (1) that its costs of compliance with the applicable performance standards specified in proposed § 125.94(b) would be significantly greater than the costs considered by the Administrator in establishing such performance standards, or (2) that its cost of complying with such standards would be significantly greater than the environmental benefits at the site.

EPA has not provided any meaningful guidance concerning the term "significantly greater." To begin with, it is not clear why "significantly" is even part of the analysis. From an economic standpoint, Georgia Power believes that it should be enough that the costs of compliance are "greater" than the EPA costs or that the costs are greater than the benefits to be able to qualify for a site-specific determination. We fail to see any reason, whether legal or purely economic, to oppose a site-specific determination when the costs outweigh the benefits under the performance standards approach. To the extent EPA's primary concern and, the reason for its insertion of "greater," is because of potential administrative costs associated with reviewing the appropriate documentation in support of a site-specific determination, EPA could encourage permit writers and agency experts to consult with the owner or operator as much as needed to make the permit writer's work as easy as possible. In other words, Georgia Power, and probably most, if not all of industry, would be happy to do as much as possible to ease the permit writer/agency workload.

One thing is for sure, it would certainly ease the burden on both EPA and the regulated community if EPA were to provide clear and precise guidance on the meaning of "significantly greater." One way to do this is to identify a cap, beyond which a presumption of "significantly greater" would be established (e.g., 25% more than EPA's estimated compliance costs or if the costs exceed the benefits by more than 25%).

EPA Response

EPA has not defined the term "significantly greater" in today's final rule. It is EPA's position that the determination of what constitutes "significantly greater" should be determined on a case-by-case basis, based upon the cost tests presented by the applicant. Please refer to comment 316bEFR.006.003 for more details.

RFC: Entrainment vs. entrainment mortality

Entrainment Survival Has Been Documented.

The proposed rule would establish a performance standard for reducing entrainment, not entrainment mortality. In fact, the proposed rule does not account for entrainment survival. EPA does not provide a credible basis for not recognizing entrainment survival. In particular, EPA states that it chose to regulate entrainment because it does not have sufficient data to establish performance standards based on entrainment mortality. Limited data or the absence of data should not preclude a facility from justifying compliance with the performance standard, at least in part, on the basis of credible scientific data that species survive.

EPA Response

RFC: Directors set performance levels for a facility?

Should EPA require the greatest achievable reduction (within the proposed ranges), or leave it to the Director to determine appropriate performance levels? 67 Fed. Reg. at 17142, Col. 1.

EPA should leave it up to the Director (or the states) to determine appropriate performance levels. <FN 5> Further, leaving this determination up to the Director or the states will enable more flexible use of each facility's uniqueness while still within the performance range. In addition, if a trading program is put in place, the market will entice facilities to achieve the greatest possible reduction where they will gain a marketable commodity from doing so. Also, mandating the greatest achievable reduction increases the burden, possibly in a very uneven way, on facilities.

Footnotes

5 As stated earlier in Part II.A. of this document, EPA should go even further and lower the performance ranges.

EPA Response

EPA has adopted national performance standards for today's rule but notes that in considering a permit application, the Director must review the performance of the technologies implemented and require additional or different design and construction technologies, operational measures, and/or restoration measures, if needed, to meet the impingement mortality and entrainment reduction, or production, requirements for all life stages of fish and shellfish. In addition, the Director may consider any other factors including chemical, water quality, and other anthropogenic stresses on the source waterbody and other factors in determining whether to impose more stringent conditions to comply with the requirements of the applicable State and Tribal law or other Federal law (see § 125.94(f)).

Performance standards

Author Name Michael E. Wilder

Organization Georgia Power

Should EPA require compliance with the performance standards, or should the rule specify that proper design, installation, operation and maintenance would satisfy the permit terms until it is reissued? 67 Fed. Reg. at 17143, Col. 3.

The rule should specify that proper design, installation, operation and maintenance will satisfy the permit terms until the permit is re-issued. To the extent that the permitting authority requires specific information for a determination of compliance, such information can be requested when the permit is being renewed. In any event, Georgia Power believes that if any compliance monitoring is required, it must be streamlined.

EPA Response

RFC: Appropriateness of "significantly greater"

Should EPA grant exception for an entity whose costs are "significantly greater" rather than "wholly disproportionate to the costs in EPA's record"? 67 Fed. Reg. 17146, 17166.

"Significantly greater" is a more appropriate standard. Georgia Power agrees with EPA's effort to make the site-specific determinations more available to Phase II facilities, for which complying with new technological standards may be more complicated than for Phase I facilities. Also, site-specific determinations in general are an appropriate way to allocate the burdens of compliance, and the "significantly greater" standard in particular is a more reasonable means for allowing that option to be pursued where merited. Note, however, as discussed in Part II, Georgia Power believes "significantly" should be dropped so that site-specific determinations can be pursued where the cost to the facility is "greater" than EPA's costs.

EPA Response

Comment supports rule. Regarding "significantly greater" versus "greater," see response to 316bEFR.018.009.

RFC: Restoration measures as supplement only?

Should restoration measures be allowed only as a supplement to installing control technologies or operational measures? 67 Fed. Reg. 17146, Col. 3.

No, as discussed in Part II, restoration should be allowed as a 100% substitute, where it will achieve similar or better results as installing the proposed technologies. The purpose of the rule is to reduce impact; EPA should explore all ways to do so. Furthermore, the more restoration is allowed, the greater the possibility facilities will have credits to sell and trade; the more efficiently facilities can allocate resources to meet the standard, the better the results.

EPA Response

Facilities may use restoration measures under the final rule either in lieu of or in combination with technologies that reduce impingement mortality and entrainment. All restoration measures must satisfy the requirements in the final rule, including those described in sections 125.94 and 125.95.

Under the final rule, permitting agencies may develop trading programs. For additional discussion of trading programs, see the preamble to the final rule.

RFC: Proposed use of restoration measures

Should voluntary restoration measures be considered in determining what counts toward compliance? What criteria should be included for measuring effectiveness? 67 Fed. Reg. 17166, Col. 3.

Any restoration effort should be considered toward compliance. Restoration is an excellent way to give industry the flexibility it needs in trying to achieve meaningful reductions in impact. EPA should focus on the overall goal of building and maintaining sustainable communities of the species involved. Restoration is another way of achieving that goal, and may significantly improve the cost-effectiveness of reducing adverse environmental impact.

The appropriate criteria to determine effectiveness will vary and should be left up to the Director and the state's natural resources expertise.

EPA Response

For a discussion of the general role of restoration measures in the final rule, see EPA's response to comment 316bEFR.056.006.

Restoration measures must meet the requirements described in the final rule, including those in sections 125.94 and 125.95.

EPA believes the inclusion of the option to use restoration measures in the final rule provides permitting authorities and permittees with additional compliance flexibility.

For a discussion of the roles and responsibilities of the permitting authority, see EPA's response to comment 316bEFR.060.026.

RFC: Discretionary restoration approach

Author Name Michael E. Wilder

Organization Georgia Power

Which, if any, restoration approach makes the most sense: discretionary, mandatory or restoration banking? 67 Fed. Reg. 17169 - 17170.

Discretionary restoration with the option of restoration banking. Each situation is too different, and facilities and permitting agencies need the discretion to employ appropriate restoration where they make the most sense. As a practical matter, mandatory restoration is unwise as it ignores cost benefit considerations, especially in situations where a technological fix will not only be less costly, but can also be implemented much more rapidly with almost instant results. As a legal matter, the Clean Water Act does not authorize nor give EPA authority to require restoration in the NPDES permitting context. Still, restoration should be strongly encouraged and made broadly available as an option. Same with restoration banking -- this should be made available, but not mandatory. It is a means for bringing market forces to bear on allocating resources, so the market forces should be left to decide how it works.

What should be the spatial scale on which restoration can take place and be attributable to a facility? Water body, watershed, state…? 67 Fed. Reg. 17146, Col. 3.

The largest possible scale on which restoration will, as a biological matter, adequately displace impacts. This may be complicated, but EPA should strive to broaden the availability of restoration if the program is to work.

How do you measure "substantially similar performance" of restoration measures? What can be done to reduce the uncertainty? How do you measure success or failure? Should a facility be required to restore more individual species than are being impinged/entrained? 67 Fed. Reg. 17147, Col. 2.

Restoration is imprecise, and its success or failure should be measured in terms of whether, over the term of the permit, and beyond, as appropriate, the restoration measure provided a similar level of stability to the overall population of the species in question that other technologies meeting the standards would have provided.

A facility should not be required to restore more species than are impacted. However, for purposes of trading or other state or local reasons, a facility should be allowed to restore more than are impacted. One way to continue to emphasize the need for the broadest parameters for restoration and credit trading is that if restoration is encouraged on a larger scale, we will have better and better information about it, and future restoration efforts may not be so uncertain.

EPA Response

For a discussion of the extent to which restoration is voluntary under the final rule, see EPA's response to comment 316bEFR.060.022.

For a discussion of trading programs, see EPA's response to comment 316bEFR.074.020.

For a discussion of the appropriate spatial scale on which to implement restoration measures, see EPA's responses to comments 316bEFR.212.001 and 316bEFR.059.008.

For a discussion of the role of the permitting authority in determining the appropriate For a discussion of the extent to which restoration is voluntary under the final rule, see EPA's response to comment 316bEFR.060.022.

For a discussion of the requirement to consider design and construction technologies and operational measures before choosing to implement restoration measures, see EPA's response to comment 316bEFR.033.005.

RFC: Restoration above BTA level

Author Name Michael E. Wilder

Organization Georgia Power

Who is the appropriate authority for establishing margins of safety and measures to ensure safety of restoration activities? What is an appropriate basis on which to add safety margins (e.g. project uncertainty, nature of species, etc.)? 67 Fed. Reg. 17147-8.

EPA should establish some guidance in the final rule on restoration ratios, with some flexibility. However, this is an area where the permit writer must rely on the State Water Resources and Fisheries expertise. A "one-size-fits-all" approach to this issue would only discourage practical and highly beneficial uses of restoration.

EPA Response

For a discussion of the roles and responsibilities of the permitting authority in determining the appropriate level of performance to satisfy the requirements of the final rule, see EPA's responses to comments 316bEFR.060.026 and 316bEFR.212.001.

RFC: Consideration of additional env. Benefits

Should additional (incidental) environmental benefits be considered besides impingement and entrainment in determining proper restoration measures? (e.g., habitat conservation). If so, how? [key: restoring water quality may benefit species more than reducing direct impacts] 67 Fed. Reg. 17148.

Absolutely. EPA’s goal should be focused on preservation of the aquatic environment, however that preservation is efficiently assured. If, for example, some action improves water quality in a way that contributes to the health of the population, by all means, credit should be given to the owner/operator.

EPA Response

Any restoration measure must meet all the requirements described in the final rule.

For a discussion of the ancillary benefits associated with restoration measures, see EPA's response to comment 316bEFR.032.011.

Comment ID 316bEFR.034.048

RFC: Consultation with wildlife agencies

Should fish & wildlife agencies be consulted or involved in restoration measures? If so, what information should be submitted to state, tribal or federal fish & wildlife agency? What should be the role of fish & wildlife agencies in any site-specific approach? 67 Fed. Reg. 17146-7, 17167

Fish & wildlife agencies should be involved in restoration issues, particularly state agencies, since it is not only largely their jurisdiction, but also because they are far more familiar with the particular issues of the individual water bodies. All relevant information already prepared for the application should be made available, as needed, to the fish & wildlife agencies. EPA should recommend that facilities consult with the fish & wildlife agencies in designing a site-specific approach.

EPA Response

For a discussion of the role of authorities other than the permitting authority, see EPA's response to comment 316bEFR.320.007.

Comprehensive demonstration study (7 parts)

Are the narrative criteria at proposed 40 CFR § 125.95(b)(1) sufficiently comprehensive and specific to ensure adequate data is used to determine best available technology? 67 Fed. Reg. 17148.

In general, narrative criteria are difficult to implement and present opportunities for abuse. To improve this provision, EPA should specify with more clarity, exactly what is required. Further, EPA should use quantitative requirements whenever appropriate.

EPA Response

EPA agrees that the narrative criteria at § 125.95(b)(1) of the proposed rule alone will not be sufficient for basing a best technology available (BTA) determination. For this reason, EPA has required that facilities conduct quantitative studies or present existing data that is reflective of current conditions before state permitting Directors may make determinations as to which compliance option will be appropriate. Please refer to EPA's response to comment 316bEFR.034.066 for more details.

Author Name Michael E. Wilder

Organization Georgia Power

Subject Matter Code 12.02

RFC: Monitoring frequencies

Should EPA set specific, minimum monitoring frequency requirements to deal with uncertainty? One suggestion: once a month over 24 hour period for at least 2 years following permit issuance. Would more frequent sampling be needed to accurately assess diel, seasonal and annual variations in impacts? 67 Fed. Reg. 17149.

EPA should not set minimum monitoring frequency, except to state that monitoring data should be generated as long as necessary to provide representative data. The Director should determine what frequency of monitoring would be appropriate, taking into consideration the circumstances unique to the situation. Some facilities will be dealing with very predictable outcomes, and should not be held to the same level of monitoring as a facility dealing with unique problems and stresses on the biotic population.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7) for review and approval by the Director. EPA has included a two-year monitoring minimum for facilities that must meet the specifications of a Verification Monitoring Plan. EPA feels that this is a reasonable, and not overly burdensome, means of verifying that the design and control technology or operational measures are meeting the performance requirements. The Director may consider additional monitoring requirements as well. For an explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. RFC: State or Tribal alts. achieve comparable perf.

Author Name Michael E. Wilder

Organization Georgia Power

Should EPA allow states and tribes to suggest an alternate regulatory requirement at the watershed level which would achieve comparable reductions in impacts? If so, what should definition of watershed be? Should states be allowed to demonstrate comparable performance at the state level instead? 67 Fed. Reg. 17152.

This is a good idea. This is one potential mechanism for allowing states and tribes to continue with pre-existing, successful state programs.

EPA Response

Please see response to comment 316bEFR.099.020.

Comment ID 316bEFR.034.054

Author Name Michael E. Wilder
Organization Georgia Power

Subject Matter Code 21.05
Role of States and Tribes (alt./equiv. programs)

What criteria should EPA use to determine whether an alternate state or tribal program to reduce impingement and entrainment mortality is "functionally equivalent"? Should restoration and habitat enhancement be part of a functionally equivalent program? 67 Fed. Reg. 17180.

Restoration and enhancements should certainly be part of a functionally equivalent program. The overall goal is protecting populations. Relying on "functionally equivalent" further emphasizes this point. EPA is right to focus on the bottom line of population protection, and all the features EPA has proposed -- trading, restoration, habitat enhancement, etc. -- help focus everyone on the primary purpose of reducing overall adverse impacts.

EPA Response

EPA believes that a State or Tribal program is functionally equivalent if the program will result in environmental performance within each relevant watershed that is comparable to the reductions in impingement mortality and entrainment that will be achieved under 125.94 under today's final rule. The State or Tribe may use any methodology that it deems appropriate to achieve these levels.

RFC: Watershed boundaries within political?

Author Name Michael E. Wilder

Organization Georgia Power

At what scale should a watershed be defined to reflect the variability of the receptors? Should watershed boundaries lie within political boundaries of a tribe or state? 67 Fed. Reg. 17152.

The watershed should be defined in the broadest possible terms which make sense as a biological matter. If the watershed goes beyond the jurisdiction of the state or Tribe, the state or Tribe should seek cooperation from the neighboring jurisdiction. If that cooperation can be established, comparable performance should go forward. Although this sounds complicated administratively, we believe in the long haul states and Tribes will successfully establish these relationships, and that industry will be able to allocate its resources toward their most effective use.

EPA Response

In the proposal, EPA requested comment on the appropriate definition for watershed with regard to achieving comparable environmental performance through alternative regulatory requirements in a State (§ 125.90(c)). In today's final rule, EPA has deferred the decision on the appropriate definition of watershed to the permit director. With regard to watersheds that cross political boundaries of a Tribe or State, the permit directors involved should consult each other.

Author Name Michael E. Wilder
Organization Georgia Power

Subject Matter Code 7.01.03
Option 3--Site-specific determination

Should EPA use minimum standards for comprehensive cost evaluation studies (to qualify for the site-specific option)? EPA also invites comment on the burden reviewing these studies places on permitting agencies. 67 Fed. Reg. 17153.

Only if such minimum standards do not exclude any significant number of facilities from having a fair opportunity to present their case. It is reasonable to ask a facility for the information the Director needs, but it is not reasonable to exclude a facility that would otherwise qualify for a site-specific determination from seeking one because it has no way to get the information EPA is looking for. Any minimum standard should allow for exceptions. The important thing is that the standards be designed so no facility that would qualify for a site-specific determination is arbitrarily forced to comply with the proposed standard, and to absorb particularly high costs.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

For more information on the cost-cost test and the cost-benefit test, please refer to the responses to comments 316bEFR.410.001 and 316bEFR.005.020, respectively.

Subject Matter Code 21.08
Burden on permitting agencies (general)

What are the burdens of a site-specific option on permitting agencies? Have the resource requirements created a disincentive for revisiting permit conditions every 5 years? 67 Fed. Reg. 17167.

Georgia Power does not believe that site-specific determinations are necessarily more burdensome on the agency.

EPA Response

In today's final rule, EPA has preserved the site-specific determination of BTA option for facilities whose costs of compliance with the final rule may be significantly greater than the costs estimated by EPA, or whose costs may be significantly greater than the benefits of complying with the national performance requirements in 125.94(a). In addition, EPA has added several other compliance alternatives to provide flexibility for streamlining the permitting process (e.g., the pre-approved technology alternative at 125.94(b)(4) and compliance using a Technology Installation and Operation Plan at 125.94(e)). EPA believes that this approach will provide the combined benefit of addressing site-specific concerns and ensuring that permits are finalized in a timely manner.

RFC: Harmonize of permit reissuance with trading

When should permits be reissued to trading partners? Should timing be harmonized among partners in a trading area? 67 Fed. Reg. 17173-75.

Harmonizing trading could cause more problems than it solves. If a facility has a credit to sell, it should be able to hang on to that credit until it finds a trading partner, even after it receives its permit. The timing issue should be made an issue for purchasers of credits only, since these facilities will need to procure credits to show that they meet the standard. If the system can be designed so that the sellers are under no time pressure to sell their credits, but still have plenty of incentive to create saleable credits even in the absence of an immediate buyer, then there should not be a major timing issue.

EPA Response

Please see response to comment 316bEFR.034.027 regarding the role of trading in today's final rule.

Subject Matter Code 21.01

Submittal of required information

Should EPA establish a specific time frame for submitting the information collecton proposal required as part of the Comprehensive Demonstration Study? Should the Director's approval of the info collection be required? 67 Fed. Reg. 17175

There is no reason to mandate a timing. Facilities should know that submitting the information collection in advance is in their interest. Approval of the director is not necessary, either, although the director should be required to respond if any additional information is needed within 60 days of receiving the information collection, so that facilities will have time to follow up.

EPA Response

As outlined in the preamble to today's rule, EPA has clarified the timeframe for the required studies. The timeframe is based on the amount of data gathering and research activities required by the final rule. For a typical facility that will install technology, EPA expects section 316(b) activities to commence prior to reissuance of the permit with submission of the Proposal for Information Collection. The Director would then review the Proposal for Information Collection and provide comments to the facility. The facility may begin the required studies prior to receipt of comments from the Director at its discretion. As stated in the preamble, it is expected that a facility may need about one year to complete the necessary studies. For facilities not having to install a technology, the timeframe for information collection activities may be shorter. Facilities currently holding a permit must submit the majority of application information and data 180 days prior to the end of the current permit term, including all information required under 40 CFR 122.21(r)(2), (3), and (5) and all sections of § 125.95. EPA has revised the regulation to account for facilities whose permits expire four years from the publication of the rule. In these situations, the facility would submit the required information according to a schedule determined by the Director after submission of its permit application. The Director will review the application materials and prepare a draft permit for public review and comment. This provides the applicant and other interested parties an opportunity to review the draft conditions and provide feedback to the Director. Following the comment period, the Director will address all comments and prepare the final permit.

If the permit is reissued prior to the completion (or consideration) of the studies, section 316(b) requirements would need to be included in the permit on a best professional judgment (BPJ) basis.

EPA believes that this schedule is reasonable and will not force facilities into noncompliance. The Agency has built a tremendous amount of flexibility into the rule, including in particular, the facility's choice to comply using a Technology Installation and Operation Plan and/or Restoration Plan (see preamble for further discussion).

RFC: Application to "unique" facilities

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Clarify that storm water permits do not subject an otherwise non-applicable facility to coverage under the Phase II rule.

EPA proposes to apply the Phase II rules to existing power generation facilities that (1) are point sources subject to an NPDES permit, and (2) use a cooling water intake structure (CWIS) to withdraw certain amounts of cooling water from waters of the United States. Indeed, the preamble discusses a hypothetical facility that discharges wastewater, storm water, and cooling water, or some combination thereof, and suggests that the permitting agency would include CWIS requirements in the NPDES permit. The preamble then goes on to state:

In the event that a Phase II existing facility's only NPDES permit is a general permit for storm water discharges, the Agency anticipates that the Director would write an individual NPDES permit containing requirements for the facility's cooling water intake structure. The Agency invites comments on this approach for applying cooling water intake structure requirements to the facility. 67 Fed. Reg. 17129.

The Coalition disagrees with EPA's assertion of jurisdiction over facilities that have NPDES permits only for storm water. There are both legal and practical arguments against such an approach. First, Section 316(b) of the Clean Water Act (CWA) does not grant EPA comprehensive authority to address all cooling water intake structures. Instead, EPA is directed to develop Best Technology Available (BTA) requirements in connection with "any standard established under section 301 or section 306 and applicable to a point source." The special provisions addressing storm water discharges
in CWA section 402(p) were enacted subsequent to that directive in section 316(b), and in any case they do not constitute a "standard established under section 301 or section 306." There is thus no indication that Congress intended that a facility subject only to a storm water permit would have to comply with section 316(b) standards.

In addition to the absence of CWA statutory authority for applying the proposed rule to storm water permits, there are a number of practical reasons why it would be inappropriate for EPA to do, especially considering the potential impacts that such an action would have if similarly applied in Phase III. If EPA were to subject to section 316(b) those facilities whose only direct discharge is storm water, most of which are subject to an NPDES general permit, EPA would be imposing a significant administrative burden on both the regulated community and on state and EPA permit writers. Permitting authorities would have to somehow identify such facilities and then develop, following procedural requirements that apply to NPDES permitting, individual NPDES permits for such facilities for the first time. EPA should avoid imposing this burden, in light of its lack of statutory authority and the questionable environmental benefit to be obtained from such an action.

EPA Response

The final rule applies to Phase II existing facilities that meet the requirements in § 125.91. These provisions include a requirement that such facilities constitute a point source (i.e., they discharge or might discharge pollutants from a point source to waters of the Unites States and thus have an NPDES permit or may be required to obtain one). As noted in section II of the preamble to the final rule, the requirement that a facility is a point source that has or is required to have an NPDES permit includes being subject to a storm water permit. Facilities subject to storm water permits are addressed under this rule because section 316(b) requirements apply to all point sources subject to standards under CWA §§ 301 or 306 (i.e., 316(b) does not exclude any categories of NPDES-permitted facilities from its requirements).

With regard to EPA authority for this approach, the requirements of section 301 establish, in conjunction with section 402, the basic framework for the NPDES permitting program, including permitting of storm water discharges. Section 402(p) of the CWA is a component of this permitting authority but does not provide stand-alone authority for storm water permitting. Rather, it addresses when storm water permits can be issued and to whom, as well as specifies certain permit and permit application requirements. In fact, EPA has permitted storm water discharges well before the enactment of section 402(p). In addition, section 402(p)(3)(A) itself specifies that permits for discharges associated with industrial activity must meet all applicable provisions of section 301. Thus, storm water NPDES permit requirements are sufficiently among the requirements and standards established pursuant to section 301 and 306 to justify application of section 316(b) to permitted storm water discharges.

EPA does not agree that it would be highly impractical to implement 316(b) requirements at facilities with storm water permits. Given the applicability requirements in § 125.91, which includes a requirement that the design intake flow at a Phase II existing facility must be 50 MGD or greater, available data regarding in-scope facilities with only storm water permits does not suggest that a significant number of Phase II existing facilities possess only storm water permits, and will be required to comply with this rule. Thus, any burden associated with this aspect of the Phase II rule is expected to be limited.

RFC: Cooling water withdrawal thresholds of 25%

The definition of a cooling water intake structure, and the applicability threshold for the rule, should be based on a minimum of 50% of the intake water used for cooling purposes. EPA should not require monthly determinations of the applicability of the Phase II rule on the basis of water use.

The proposed rule states, in effect, that it applies to an existing facility if the facility is a point source with a water intake structure, and the facility uses for cooling purposes at least 25% of the water drawn through that intake structure. As Coalition members stated in comments on the Phase I rule, there is no logical reason for asserting that an intake structure constitutes a "cooling water intake structure" where the primary purpose of the intake structure is to withdraw water for non-cooling purposes. A cooling water intake structure should be one that withdraws water where more than 50% of the water is used as cooling water, i.e., where the primary purpose for the structure is to withdraw cooling water.

Regardless of whether the applicability threshold is 50% or 25%, or some number in between, though, EPA needs to provide clearer and more practical guidance on how to determine if the threshold is met. Section 125.91(d) of the proposed rule discusses how one calculates whether 25% or more of water withdrawn is used for cooling water.
Unfortunately, the language of the proposed rule would create serious implementation problems.

The proposed rule states that the 25% threshold "is met if any monthly average of cooling water over any 12 month period is 25 percent or more of the total water withdrawn." Besides the ambiguous language used, the primary problem with this approach is that it seems to suggest that a facility make a determination every month as to whether or not it is within the scope of the rule. Applicability of the Phase II rule is a very important determination with significant financial and other resource consequences. It is both unreasonable and impractical for the regulated entity, as well as the permitting authority,
to be expected to make this determination every month. Moreover, withdrawal rates may vary from month to month due to seasonal or process variables, and facilities should not be subject to the rule simply because cooling water use percentages may marginally exceed 25% (or other applicability threshold) in a given month.

We suggest instead that the rule require that the calculation be made once at the time the facility submits its application for renewal of its NPDES permit. At that time, the facility should review the previous 12 months of flow data or, alternatively, a representative 12-month period between permit renewals. If the total amount of cooling water used during
that period is 25% or more of the total flow for that period, then the facility would be subject to the Phase II rule. If not, the facility is not subject to the rule. This determination would be revisited each time a permit is renewed and would be based on the previous five years' worth of data.

This approach provides a high degree of certainty for both the facility and the permitting agency as to the basic question of whether a facility is subject to the rule. It also is comparable to the approach

EPA has taken for applying production-based effluent limitations guidelines, where application of the guidelines and calculation of mass effluent limitations based on production occurs at the time a permit is issued or renewed, not on an ongoing basis.

EPA Response

The 25% threshold in today's rule is to be measured on an annual average basis, for reasons set forth in the preamble.

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 3.06.01

Withdrawal threshold of 50 MGD

Permittees should have the option of meeting an actual flow threshold in lieu of the 50 MGD design flow threshold.

The proposed rule lists a design intake flow of 50 million gallons per day (MGD) as one of the criteria for applicability of the proposed Phase II regulations. In many cases, however, actual intake flow is below the design capacity. If a permittee is willing to accept permit limitations that restrict its actual water use to some level below 50 MGD, and thereby not be subject to the Phase II regulations, EPA should encourage such actions as a means of reducing the potential for entrainment and impingement, which the rule seeks to avoid.

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 3.06.01

Withdrawal threshold of 50 MGD

EPA should exempt emergency intakes.

The Coalition suggests that EPA exempt "emergency" intakes from the coverage of the Phase II rule. Due to drought conditions in some areas of the U.S., facilities may need to install emergency pipes and intakes upstream of the facility to avoid saltwater intrusion in the water intake zone. In some cases these intakes would be only temporary. In other cases, they might be permanent, but with use on an infrequent basis. EPA should exempt these temporary intakes or permanent intakes if or when operated a small percentage of the time. EPA could justify such an exemption on the de minimis nature of the amount of time of operation.

EPA Response

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 2.04.02

Apply 316(b) before a det. of impact/AEI

In developing the Phase III regulations, EPA should assess whether minimal adverse environmental impact already exists.

The Coalition notes that section 316(b) of the CWA imposes requirements for "minimizing adverse environmental impact." Thus, if there are levels of entrainment or impingement below which there is no environmental significance, i.e., where there is no "adverse environmental impact," then no additional BTA requirements for CWIS are authorized or necessary under that provision. For this reason, if EPA decides to regulate CWIS for Phase II facilities under an approach similar to that required when promulgating effluent guidelines, EPA is not bound to use a similar approach in its Phase III rulemaking. In Phase III, which is applicable to manufacturing facilities and certain electric power facilities, EPA would be well within its statutory authority to find that requirements are not applicable to a facility's CWIS if the agency is unable in the first instance to determine that there is an adverse environmental impact from the operation of that intake. Indeed, EPA should make such a finding before imposing additional restrictions on a facility's CWIS under section 316(b).

The Coalition believes EPA should make a determination of adverse environmental impact the first inquiry before imposing particular technology requirements on Phase II facilities, as well. But even if EPA declines to do so here, that should not prevent EPA from making a determination of adverse environmental impact the first step in considering technology requirements for the smaller Phase III facilities.

EPA Response

The commenters remarks regarding the Phase II rule are beyond the scope of this rulemaking. In response to the commenter's remarks on Phase II of the rulemaking, see the preamble, particularly sections III, VII, and VIII, and supporting documents.

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 3.05

Facilities not covered by today's proposal

Remove the proposed imposition of Best Professional Judgment requirements.

The proposed Phase II rule contains a provision that is certain to cause confusion and is potentially the source of regulatory uncertainty, controversy, and litigation. Proposed 40 C.F.R. § 125.90(c) states that: "Existing facilities that are not subject to this subpart [the Phase II rule] must meet requirements under section 316(b) of the CWA determined by
the Director on a case-by-case, best professional judgment (BPJ) basis." The apparent effect of this provision would be to subject any facility with an NPDES permit and withdrawal of any amount of surface water for cooling purposes to case-by-case section 316(b) BPJ determinations.

This provision unnecessarily blurs the distinction between Phase II and Phase III facilities. EPA appears to be directing permit writers to impose BPJ section 316(b) conditions on Phase III facilities (and even facilities with de minimis impacts or falling below the applicability thresholds in an eventual Phase III rule) before EPA promulgates the Phase III rule. The benefits and objectives of the phased rulemaking addressing different types of facilities in different rules would be contravened by including a provision in the Phase II rules that sweeps in all of the Phase III facilities as well.

The language in proposed section 125.90(c) is unnecessary. Although EPA claims that the authority for applying BPJ interpretations for purposes of section 316(b) requirements already exists, it has never included such a requirement in its regulations, including the 40 C.F.R. Part 125 Subpart A regulations on establishing BPJ permit limits. If EPA believes that its rules have always allowed imposition of case-by-case requirements for cooling water intake structures, then there is no need to modify the regulations now. By including express BPJ language in section 125.90(c) of the proposed Phase II rule, EPA seems to imply a greater need for BPJ requirements for Phase III intake structures now, when in fact the opposite is true: Phase III facilities will be addressed shortly in a new rulemaking, so it would be particularly inefficient and problematic to direct permit writers to begin issuing BPJ requirements for Phase III facilities that have been operating without any BPJ intake structure requirements for many years.

EPA Response

See response to 316bEFR.063.021.

Comment ID 316bEFR.035.007

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 3.0

Scope and Applicability of Proposed Rule

Moreover the proposed Phase II regulations give no guidance as to when BPJ permit conditions are required. In fact, proposed 40 C.F.R. § 125.90(c) could be interpreted to require that BPJ requirements under section 316(b) be included in every NPDES permit for any facility with a surface water intake structure where any portion of the water is used for cooling purposes. Likewise, EPA provides no guidance in the regulations or preamble as to how the permit writer should establish BPJ section 316(b) permit conditions. The absence of details or specific interpretive guidance on the applicability of BPJ requirements makes it impossible for industry to comment comprehensively or specifically on this proposal. Even more importantly, the lack of specificity would leave permit writers and permittees with the difficult and resource-intensive task of trying to develop and negotiate permit conditions in a regulatory vacuum.

EPA Response

See response to 316bEFR.063.021. In addition, EPA acknowledges that BPJ-based permits may potentially be more resource intensive than permits developed under nationally applicable standards, such as those established in the final rule, but notes that all past 316(b) permits were developed in this case-by-case manner.

Comment ID 316bEFR.035.008

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 3.0

Scope and Applicability of Proposed Rule

Industry has both legal and practical concerns about the concept of BPJ limitations on intake structures in general. We have previously communicated some of those concerns to EPA and plan to do so in greater detail in the Phase III rulemaking. Apart from these specific concerns with BPJ, however, there is no justification for EPA implying consideration of BPJ limits for Phase III facilities in the Phase II rule.

If a state permitting authority believes that an intake structure at a Phase III facility needs to be regulated before EPA promulgates the Phase III rule, and if that state has a state law that authorizes imposition of requirements on cooling water intake structures, then under Clean Water Act section 510 the state would be able to impose those more stringent requirements. States do not, however, have any authority to come up with their own case-by-case interpretation of the regulations EPA is developing under section 316(b). The BPJ language of the Phase II proposal incorrectly implies that they do.

Another aspect of BPJ authority provided by proposed 40 C.F.R. §125.94(e) is the provision to authorize the permit writer to: "establish more stringent requirements as best technology available (BTA) for minimizing adverse environmental impact" if the permit writer determines that compliance with the technology requirements of the Phase II rule "would not meet the requirements of other applicable Federal, State, or Tribal law." Again, this provision is both confusing and unnecessary. It makes no sense to suggest that a given set of technologies for minimizing adverse environmental impact from a cooling water intake structure constitutes BTA unless use of that technology would not meet the requirements of some other applicable law. While there may be some other law that requires imposition of more stringent conditions on a particular cooling water intake structure, those more stringent conditions would not be determinative of BTA; rather, they would be imposed by the other law as a requirement in addition to the BTA requirement of CWA section 316.

At a minimum, EPA should delete language suggesting that BTA may be dictated by other statutes, rather than the requirements of section 316(b) and EPA's implementing regulations. It would be preferable, however, to remove this provision altogether, which raises more questions than it answers and is not necessary for proper operation of the Phase II regulations.

EPA Response

See response to 316bEFR.063.021. In addition, EPA notes that this rule does not alter the existing State NPDES program authorization requirements. Under these requirements, with the promulgation of this rule, states authorized to administer the NPDES program must have or put in place sufficient authority and program requirements to ensure their State programs are at least as stringent as the federal program. Such authority includes the ability to develop BPJ-based permit conditions as provided in 125.90(b). Thus, States should have sufficient authority to implement this rule.

Finally, EPA has included 125.94(e) in the final rule, which allows a Director to require more stringent requirements as BTA if compliance with the rule's BTA requirements would not meet the requirements of applicable State and Tribal law or other Federal law. As discussed in the proposed rule at 67 FR 17150-17151, this provision has been included in part because, although States already have authority to include more stringent provisions based on State law, such is not the case where EPA is the permitting authority.

Facilities not covered by today's proposal

COGENERATION DEFINITION AND EXCLUSION

EPA should specify in the Phase II regulations that the rule does not apply to facilities whose primary business activity is not power generation.

The proposed Phase II regulation includes criteria for applicability if the facility "both generates and transmits electric power, or generates electric power but sells it to another entity for transmission." Section IV of the preamble clarifies the above applicability criteria by stating, "Today's rule does not apply to facilities whose primary business activity is not power generation, such as manufacturing facilities that produce electricity by co-generation." The Coalition supports this statement and recommends that EPA include this in the regulations to provide more clarity on the applicability of the Phase II Rule.

EPA Response

See response to 316bEFR.050.002. Also see 125.91(b).

Comment ID 316bEFR.035.010

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 3.06.02

Cogeneration facilities

In addition, the discussion in proposed 40 CFR § 125.91(b), concerning the determination of whether an electricity-generating facility that shares an intake structure with another facility meets the 50 MGD threshold, should not be limited to cogeneration facilities. There may be situations where an electric-generating facility that is not a cogenerator nevertheless shares an intake structure with a manufacturing facility. In that case, only the portion of the water that is withdrawn for the electric-generating facility, and not that used for the manufacturing process, should apply toward the 50 MGD threshold.

EPA Response

The Agency agrees with the comment. The Agency has removed the reference to cogeneration facilities from the cited definition.

Comment ID 316bEFR.035.011

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 3.06.02

Cogeneration facilities

The definition of cogeneration should not include the phrase "from the same fuel source."

Section 125.93 of the proposed rule includes the following definition for a cogeneration facility: "Cogeneration facility means a facility that operates equipment used to produce, from the same fuel source: electric energy used for industrial, commercial, and/or institutional purposes at one or more host facilities and/or for sale to another entity for transmission..." (Emphasis added). It is not clear what the phrase "from the same fuel source" means and what it adds to the definition. No clarification can be found in the preamble. Our concern is that the phrase could be interpreted to exclude legitimate
cogeneration units from the "cogeneration" classification and therefore subject them (and the host facility) to Phase II applicability as independent power generators. It is important to note the statement in the preamble that "Today's rule does not apply to facilities whose primary business activity is not power generation, such a manufacturing facilities that produce electricity by cogeneration." 67 Fed. Reg. 17135.

The definition also has implications for Phase III. A host facility and associated cogeneration facility typically have access to a variety of fuel sources, e.g., natural gas purchased from public and private suppliers, natural gas produced as part of host facility operations such as petroleum exploration/production, as well as fuel gases and fuel oils produced during host manufacturing operations such as petroleum refining. For example, a host facility might use internally generated fuel gas to produce some electricity for the facility, while the associated cogeneration facility might generate electricity by buying
natural gas for gas turbines. This practice could be considered to constitute using different "fuel sources" under the proposed definition even though the cogeneration facility is clearly integrated with the host facility. The accuracy of the definition is not diminished if the words "from the same fuel source" are deleted, and such deletion would in fact eliminate the possibility of unintended restrictions on the type of facilities defined as cogeneration units.

EPA Response

The Agency notes the comment and has removed the definition of "cogeneration" from the final rule.

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 3.03

Definition: Waters of the U.S.

THE RULE'S TREATMENT OF COOLING PONDS AND LAKES NEEDS TO BE CLARIFIED

Ponds created specifically for cooling are treatment systems and are excluded from the definition of "waters of the U.S."
Existing 40 C.F.R. § 122.2, exempts "waste treatment systems" from the definition of "waters of the United States" for NPDES purposes. The definition reads, in part, as follows:

Waters of the United States means:
(a)All waters which are currently used, were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters which are subject to the ebb and flow of the tide…Waste treatment systems, including treatment ponds or lagoons designed to meet the requirements of CWA (other than cooling ponds as defined in 40 CFR 423.11(m) which also meet the criteria of this definition) are not waters of the United States... <FN 1>

Thus, thermal treatment systems, including ponds and lagoons designed to meet CWA requirements (which clearly includes cooling ponds), are specifically exempted from the NPDES permit requirement. <FN 2> Because a cooling pond is a part of a plant's treatment system, the make-up water intake point should be considered the jurisdictional intake for the purposes of section 316(b).

Footnotes

(1) This definition contains a clerical error, in that 40 CFR §423.11(m), which used to define "cooling pond" now defines "coal pile runoff."

(2) Such systems, if created in waters of the United States, were at one time brought back within the application of the other criteria in the definition by the restrictive provision at the end of the treatment system exemption; however, that restriction was suspended in 1980 and no longer has any legal effect. Cooling ponds "as defined in 40 CFR 423.11" also fall outside the treatment system exemption. But the rule containing
the definition of "cooling ponds" cited in that parenthetical, which served as the basis for that restriction, was set aside by the Court of Appeals in Appalachian Power Co. vs. Train, 566 F. 2d 451 (4th Cir. 1977). Thus, as a matter of law, the cooling pond exclusion from the treatment system exemption no longer has any force or effect.

EPA Response

See responses to 316bEFR.006.001 and 015.002.

Comment ID 316bEFR.035.013

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 3.07

Special definitions

Disturbingly, EPA's proposed definition of "once-through cooling water system," section 125.93, says that such systems sometimes use "ponds." This definition may give the wrong impression, since cooling "ponds" are clearly "treatment systems" instead of "waters of the United States."

In the preamble, EPA says that it "interprets 40 C.F.R. §122.2 to give permit writers discretion to regulate cooling ponds as 'waters of the United States' where cooling ponds meet the definition of 'waters of the United States.'" To the best of our knowledge, EPA has never issued any such interpretation on a national basis, and the only EPA memorandum on point of which we are aware says that the reference to cooling ponds in section 122.2 may be interpreted as having no legal force or effect, thereby taking cooling ponds wholly outside the ambit of the definition. Letter from Robert Perciasepe, Assistant Administrator of EPA's Office of Water, to W. Ray Cunningham, Director, Water Management Division (EPA Region IV)(December 13, 1993). In any case, for purposes of implementing section 316(b), we believe strongly that EPA should find that cooling ponds (and, as discussed below, other man-made impoundments created solely or primarily for supplying cooling water) are closed-cycle cooling systems and are not waters of the United States subject to section 316(b).

EPA Response

Whether source water is a "water of the United States" will be determined on a case-by-case basis. Please refer to EPA’s response to comment 316bEFR.032.015.

Comment ID 316bEFR.035.014

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 3.07

Special definitions

EPA should consider cooling lakes and reservoirs to be closed-cycle cooling systems.

As explained above, cooling "ponds" should be excluded from "waters of the U.S." Cooling "lakes," formed by damming rivers or streams that are waters of the U.S., should be treated the same way for section 316(b) purposes. EPA has long asserted broad authority to define waters of the U.S. and to include and exclude waters from the definition of "waters of the U.S." where necessary to achieve the purposes of the Clean Water Act, although this claimed authority has been narrowed in some ways by Solid Waste Agency of Northern Cook Co. v. U.S. Army Corps of Engineers, 531 U.S. 159 (2001). As a matter of public policy, EPA should treat both cooling ponds and cooling lakes, built in whole or in part to supply cooling water, as closed-cycle cooling systems that achieve the requirements of section 316(b). <FN 3>

Footnotes

(3) The same can be said of some reservoirs, which typically are man-made, highly engineered systems that in some cases were constructed primarily to supply cooling water and heat treatment. For example, many reservoirs in Texas and other parts of the Southwest were built primarily or solely for this purpose. Thus, states should have the authority to deal with reservoirs just as they do cooling lakes or ponds and treat them as part of a closed-cycle system where the reservoir is constructed primarily for cooling water supply and thermal treatment.

EPA Response

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 8.02

Proposed standards for lakes and reservoirs

It makes no sense to expose existing facilities to the possibility that they will have to construct additional fish protection technologies on impoundments designed and constructed to provide cooling water.Furthermore, EPA does not appear to have made any attempt to identify the number of facilities with cooling lakes or thermal treatment reservoirs that would be required to retrofit additional technologies or the costs and benefits of such additional controls. In fact, a review of information EPA provides suggests that EPA assumed that all or most of these facilities would not be required to retrofit any additional technologies or do any additional studies.

EPA Response

With respect to cooling ponds as waters of the U.S., please refer to the response to comment 316bEFR.006.001.

Permit applications/implementation schedule

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

PERMIT REQUIREMENTS MUST ALLOW FOR THE TIME NEEDED TO COLLECT DATA, ANALYZE IT, AND DESIGN, INSTALL, AND TEST INTAKE TECHNOLOGY

Because of the unusual nature of section 316(b), it should be construed as a one-time only requirement – that is, that once "best technology available" is determined for a plant, installing and operating that technology ought to relieve the plant of further section 316(b) obligations for life. The "location, design, construction, and capacity" of the cooling water intake structures are matters of design and construction, not operation, and Congress could not have intended that power plants be in the business of redesigning, demolishing, and reconstructing key components of their physical plant every five or ten
years.

Taking into account section 316(b)'s uniqueness in the CWA scheme, the most appropriate way to apply it would be as the National Environmental Policy Act (NEPA) is applied to, for example, a construction permit: a one-time review designed to achieve minimal "adverse environmental impact" at a reasonable cost.

If, on the other hand, EPA holds to its proposal to implement the section 316(b) rule by requirements in NPDES permits (which have to be renewed every five years), then two important questions arise. First, how are new requirements of the rule to be implemented for the first time? Second, what effect is the new rule to have on subsequent permit renewals that must take place every five years over the 40- or 50-year life of a facility?

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to 316bEFR 041.126 for a discussion.

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

Permit applications/implementation schedule

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

The application process requires certain steps to be completed, some of them time-consuming.

A permit application addressing section 316(b) will presumably have to be submitted 180 days before an existing permit expires. The 180 days is the time provided in the current permitting regulations between permit application and expiration of the permit to allow for agency review.

EPA's Information Collection Request (ICR) (DCN 4-0001) raises puzzling questions about EPA's intentions as to the initial implementation schedule. For example, on page 47, the ICR says that 350 of the 539 facilities are scheduled to have permits issued during the first three-year ICR period (9/2000-8/2004). It adds that:

These facilities [i.e., the 350] will be on an accelerated schedule and thus will receive their permits as scheduled. Since these are existing facilities, it is assumed that they will be able to draw on some existing data. In addition, EPA assumes that these facilities will have reopener clauses included in their permits to allow for the results for the Impingement Mortality and Entrainment Characterization Studies to be submitted after permit issuance and for the permits to be modified based on the results of these studies, if necessary. The remaining 189 facilities will not receive their initial permit renewals until after the ICR approval period, and thus will have the full three years to perform their Impingement Mortality and Entrainment Characterization Studies prior to receiving their initial permit renewals.

Although the above passage is not entirely clear, it does recognize the need to consider where a permittee is in the application process when the section 316(b) rule becomes final. For example, a permittee who has already submitted an application for permit renewal when the new rule comes out in the Federal Register should not have to go back and rewrite the application to satisfy the new rule. Likewise, a permittee who has only a few days or weeks remaining before the deadline for application cannot be expected to comply with the new regulation on the old permitting schedule.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a complete discussion.

See also response to comment 316bEFR.034.005 for a discussion of the many streamlining efficiencies added to reduce burden in today's final rule. See also the preamble to the final rule.

Subject Matter Code 21.09

Permit applications/implementation schedule

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Moreover, EPA needs to evaluate the different amounts of time that will be required to determine under the new rule BTA for different sites. A best-case situation would be where a facility already has performed a section 316(b) demonstration, where the data are still representative of current conditions in the waterbody, and where no additional construction or modification of the intake structure or installation of screens will be required. Even then, a permittee still might require six months to analyze existing data to demonstrate compliance with the 80-95% impingement mortality reduction and 60-90% entrainment reduction and then to write up a permit application.

A different facility might need far more time. It could easily require two, three, or even more years of biological monitoring to collect the data needed to calculate the impingement mortality and entrainment for the baseline, determine what technology might be required, calculate the impingement mortality and entrainment reduction to be accomplished by the new technology, and write up all this information in a permit application. If part of the solution was to create or improve a wetland, even more time would be needed to find a suitable wetland site and prepare a plan for improving it, let alone for doing the work and monitoring its success.

EPA Response

EPA recognizes that preparing the required studies could take several years. EPA has attempted to accommodate this in today's rule. EPA also recognizes that a determination of BTA may take several years depending upon the site conditions and design and construction technology and/or restoration measure(s) selected. In today's final rule, EPA offers five compliance alternatives, including a site-specific determination of BTA, to provide maximum flexibility to the facility and Director and to speed permitting. See response to comment 316bEFR.034.005 for a discussion.

Permit applications/implementation schedule

The best way to implement the BTA requirements would be to impose a permit condition setting out a process for choosing BTA.

The best way to implement the section 316(b) rule would be to have the permittee, as part of its permit application package, propose a schedule for developing the data collection plan, getting approval from the Director, collecting and analyzing the data, using the data to assess technologies, and preparing the BTA recommendation. This process, once
approved by the permitting agency, would be written into the permit as a permit condition, as would be the physical implementation or installation of the BTA once it was selected.

The permit could require that once the technology was finally selected, it would be installed within a certain amount of time (which time limit would have to be chosen carefully, since at the time the permit was written the choice of technology would not yet be known). Alternatively, once the technology was chosen, the permit could be modified to require that it be installed and operated. This would allow permits to be issued faster and eliminate most of the timing problems.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a complete discussion. For a discussion of compliance issues, see the preamble to the final rule.

Permit applications/implementation schedule

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Time must be built in for agency review.

In the schedule described above for gathering data and choosing BTA, time also must be allowed for the permitting agency (the Director) to review and approve the key steps. For example, the Director will need to approve the data collection program and also, later, the permittee's choice of technology. The section 316(b) rule should make clear that time for agency review must be built into any schedule either prescribed by the rule itself or required by an NPDES permit condition.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies, Director review time, and permit compliance issues in today's final rule. See response to comment 316bEFR.034.066.

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 21.09

Permit applications/implementation schedule

A "grandfather" period is needed for permittees who are very near the application deadline.

If EPA does not adopt the above-suggested reasonable approach of prescribing a data collection and analysis schedule in the permit, it will have to be much more careful about thinking through the timing of the section 316(b) requirements in the future. For permittees who have applied already for a permit renewal when the section 316(b) rule becomes final, and are thus in the period of agency review of the application, the permittee should not have to redo its application because of the new rule. In such a case, the succeeding five-year permit term should be the time in which the permittee complies with the new rule.

Similarly, if the new rule becomes final when a permittee is very near the time when its renewal application is due (for example, between 365 and 180 days before his permit expires), it would be almost as unreasonable to require the permittee to adjust its application process to the new rule. The practical difficulties in preparing a permit application, especially if biological monitoring is needed, suggest that the new rule should not apply, until the succeeding permit term, to any permittee which has one year or less until its permit expires when the section 316(b) rule becomes final.

EPA Response

EPA agrees with this comment. EPA has clarified timing requirements for the submittal of required studies. See response to comment 316bEFR.034.066.

Comment ID 316bEFR.035.023

Author Name Roger Claff
Organization Cooling Water Intake Structures Coalition

Permit applications/implementation schedule

Time is needed to collect data and prepare the application.

Assuming a permittee is more than one year away from having its permit expire (that is, more than six months away from having to file a renewal application), then it might be reasonable to expect it to complete an application to comply with the new rule during the present permit term. But whether this is in fact possible depends on the permittee's situation. How section 316(b) applies is site-specific, and this is as true of scheduling as of biology.

If the permitting authority expects to approve a permit requirement for new section 316(b) technology, then it will have to have a good deal of information. Assuming that some change, such as new fine mesh or wedgewire screens, will be required to meet the 80-95% and 60-90% reduction criteria, then the applicant will have to provide, and the agency will have to review, several things. First, the permittee may have to collect biological data. In particular, if its present configuration is not a shoreline intake with no impingement or entrainment reduction controls, then the permittee may have to sample the density of entrainable eggs and larvae at the place where such a baseline intake structure would have been placed. It may have to collect these data at certain times of the year when eggs or larvae are present, such as the spawning season, and this monitoring may have to be done for several different species. Then the egg and larvae density data will be used, along with information about the volume or flow of the waterbody and the intake flow, to model the number of eggs and larvae entrained for the baseline, for the existing intake technology, and for any new intake technology that may be required. An analysis will have to be done for impingement as well. <FN 5>

The permittee then will have to calculate the impingement mortality and entrainment at the plant as it is now configured to determine whether the 80-95% and 60-90% criteria are met by the plant "as is." If not, the permittee must explore new technologies, such as installing wedgewire screens, fine mesh screens, or an aquatic filter barrier. The permittee then has to do an analysis to show that one or more new technologies would reduce impingement mortality by 80-95% and (except for lakes and a few other waterbodies) entrainment by 60-90%. This analysis might have to be done for a variety of technologies and combinations of technologies, and the permittee might choose to analyze restoration measures or operating restrictions as well. If the costs are too high, the permittee may opt to do a site-specific cost- or cost-benefit analysis of available technologies. The results then would have to be written into a permit application and the data presented in a format that allows the permit writer to review them.

Depending on the complexities of the site and the amount of data already available, preparing an application could take more than two years – at least two years to collect data and half a year to analyze the data and write a permit application. Even this 2½-year period might not be enough to compare alternative intake technologies and design a new set of screens, let alone plan a wetland restoration. For a facility that required all this work before an adequate application could be completed, it would be unreasonable to require a completed application less than 2½ years after the rule became final.

One solution would be to require a complete application in compliance with the new rule only for permittees whose permits are due to expire more than three years after the rule becomes final (thus allowing 2½ years to prepare the application before it is due). A shorter period could be provided if the application was not required to have the final
answer of what BTA to install, but rather to have a conceptual plan for gathering the biological data and designing the intake technology.

Thus, EPA could require a full-fledged application with proposed technology for permittees whose permits expired more than three years after the rule becomes final; require a more abbreviated, conceptual application with a plan for data collection and analysis for those with less than three years before their permit expires (that is, less than 2½ years before the application is due); and require no compliance with the new rule (until the following permit term) for those with only one year or less left to prepare an application for renewal (one year before expiration) when the rule becomes final. Thus:

Time Before Permit Expiration When Section 316(b) Rule Becomes Final

```
    1 year        1 year       1 year        6 months
|           |           |           |           |
|           |           |           |           |

                                 Application      Permit
                                     due          Expires

|---------|------------------------|---------------------------------|

Full           Abbreviated permit              No permit
application     application                  application due
due by          required, with               until next permit
"application    data collection                   term
due" date       plan
```

If a less ambitious, conceptual application was allowed for permittees in the middle group, they would have to satisfy the permit writer that they had an adequate plan for collecting data. The permit, when issued, would need to allow a reasonable compliance schedule for collecting the data, designing new screens or procuring an aquatic fabric filter barrier, installing the equipment, and testing it. This compliance schedule should take into account the seasons of the year in which the data might have to be collected, and should provide for doing construction, installation, and testing during planned outages so as to minimize the impact on electric power supply.

Footnotes

(5) There is a current shortage of trained larval taxonomists, especially those capable of identifying freshwater larvae. We believe there may be only 12-15 freshwater larval experts nationwide. Therefore, if many facilities need to perform studies requiring larval identification within a short period of years, there will be an extreme shortage of experts capable of performing this work.

EPA Response

For the reasons set forth in this comment, EPA is providing additional time for facilities to submit the required studies. See response to comment 316bEFR.034.066.

Permit applications/implementation schedule

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Despite the need for a grandfather period, EPA should allow a facility to choose to comply with the new rule early.

Notwithstanding the timing requirements outlined above, some facility operators may prefer to meet the requirements of the new section 316(b) rule even though they are already well into the application process when the rule becomes final. EPA should permit such operators to choose to comply with the new rule earlier than required, rather than take advantage of any grandfather period that might be allowed. Although a grandfather period is definitely necessary, the rule should not require anyone to use it.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066. Facilities are free, however, to choose to submit the required information faster than the timeframes specified in the rule.

Organization Cooling Water Intake Structures Coalition

Time is needed to install and test new equipment.

Even a permittee who has time to prepare a complete application by 180 days before its permit expires will need a compliance schedule after the permit is issued, if changes in the intake are needed to satisfy the new rule. It will need this in order to install and test the new screens or filter or fish return system. A compliance schedule should provide for
installing the new equipment during a regularly planned outage. If part of the solution is restoring a wetland or building a fish hatchery, of course, more time might be required. The rule should allow for this contingency.

EPA Response

For a discussion of the compliance alternatives authorized by today's rule, including the availability of a Technology Installation and Operation Plan with the Director's approval, see the preamble to today's rule.

Subject Matter Code 21.09

Permit applications/implementation schedule

It would not be reasonable to make the new rule immediately effective and rely on administrative consent orders while new technology is being installed.

Because so much time has passed since section 316(b) was originally enacted by Congress, there may be some inclination by EPA to make the technology requirements of the new rule immediately effective. Since this could put some facilities overnight in violation of the law, it could raise due process concerns. EPA might choose to use administrative orders as a stopgap measure; however, it would not be appropriate to make the requirement for BTA immediately effective and then use administrative consent orders to suspend enforcement until the technology could actually be installed. Nor is it necessary to do this. EPA has the authority to define "compliance" as an approved program or plan for collecting the necessary data and choosing and installing appropriate technology.

Section 316(b) says that "[a]ny standard established pursuant to section 301 or section 306 of this Act and applicable to a point source shall require that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact." In this sense, section 316(b) is tied to the "standards" of section 301. (Since the present rulemaking is for "existing" facilities, the reference to "standards of performance for new sources" in section 306(b)(1)(B) does not apply.)

Section 301(b)(1)(A) provides that "best practicable control technology" and water quality standards-based limitations should have been achieved by July 1, 1977. "Best available technology" requirements for toxic pollutants are to have been achieved no later than 1981. Section 301(b)(2)(C), (D). Finally, sections 301(b)(2)(E) and (F) provide for compliance in no case later than March 31, 1989. Thus, the requirements of section 301 for "existing" facilities, according to Congress' original intent, are supposed to have been achieved by March 31, 1989.

Nevertheless, this cannot mean that the section 316(b) rule for existing facilities must be effective by that date, for the following reasons:

1. The statute does not say that the section 301 deadlines apply to section 316(b). The statute is (at best) ambiguous on the deadline for section 316(b), and EPA is entitled to interpret it in a reasonable way.

2. It is impossible to have immediate compliance with a rule that will require in many cases biological studies, analysis, design, and construction. Congress could not have intended that existing facilities comply with a complex new section 316(b) rule instantaneously.

3. It would be a denial of due process of law to require immediate compliance with a new rule that requires expensive and time-consuming construction.

Although linked to section 301, section 316(b) contains separate and distinct requirements and does not itself contain a deadline. "Best technology" under section 316(b) is different and distinct from, for example, "BAT" under section 301. The section 301 standards apply to the discharge of pollutants; section 316(b) regulates features of intake structures. All section 301 says is that section 301 standards "shall require" that section 316(b) be met; it does not say when.

Moreover, section 316(b) clearly requires, at least in some cases, significant construction. It is not possible to comply with regulations that require construction instantly upon promulgation of the regulations. It would be irrational to suppose that Congress intended instantaneous compliance, especially since in other sections of the Act, Congress painstakingly laid out schedules for phasing in new requirements.

Finally, it would violate due process to require instant compliance with a new rule that requires extensive analysis and construction. Due process requires that regulated entities have reasonable notice of legal requirements to which they will be subject. There can be no reasonable notice when a new requirement is made to apply instantly.

Throwing many facilities into noncompliance by imposing an immediate effective date, and addressing the problem by consent orders, would be highly inappropriate. Consent orders may carry the stigma of breaking the law and may not prevent citizen suits by third parties. EPA would do better simply to write a reasonable compliance schedule into the
rule and provide for compliance schedules in NPDES permits.

EPA Response

EPA agrees that section 316(b) leaves to EPA's discretion decisions regarding how compliance with the final rule will be determined and when. For a discussion of the five compliance alternatives authorized by today's rule and other compliance issues, see the preamble.

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 21.09

Permit applications/implementation schedule

Reasonable compliance schedules are necessary to avoid disruption of the permitting process.

The above scheduling concerns are important because of fairness to permittees, but they are important also for practicality. If EPA were to make the new section 316(b) rule immediately applicable, it would lead to more rather than less delay in the NPDES permitting process. For one thing, the available consultants who can help with biological
monitoring and design of intake technology would undoubtedly be overworked and would have to put many permittees on waiting lists. Moreover, negotiations over consent orders might well bog down the permit process in some states. Undoubtedly the backlog of unprocessed NPDES permit applications would grow worse. Reasonable compliance schedules are a matter of administrative necessity as well as of fairness to permittees.

EPA Response

See response to comment 316bEFR.035.026.

Comment ID 316bEFR.035.028

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 21.03

Monitoring requirements

The time needed for compliance monitoring differs from site to site.

Since section 316(b) is different from either the water quality-based requirements of section 303 or the technology-based requirements of sections 301 and 306, and since EPA's performance standards are based on certain specific intake technologies that EPA has found to be effective (wedgewire screens, etc.), the most appropriate way to ensure compliance would be to require the permittee to install one of the selected technologies and then monitor simply to be sure that it was being maintained and operated correctly.

EPA Response

EPA has included in today's final rule several alternatives for achieving compliance, including demonstrating compliance with a Technology Installation and Operation Plan in place of numeric performance requirements. Please see the preamble and EPA's responses to comments 316bEFR.017.003 and 316bEFR.063.005 for an explanation of what constitutes compliance with today's performance requirements. Also please see the final rule preamble section IX for a discussion of the Technology Installation and Operation Plan.

Comment ID 316bEFR.035.029

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 21.02

Director's role in determining requirements

As EPA has constructed the rule, facilities may need to do impingement/entrainment compliance monitoring, but only as specified by their permitting authority. Proposed 40 C.F.R. § 125.96. This flexibility makes sense, since many facilities have been thoroughly studied and their regulators have adequate existing data regarding the performance of impingement/entrainment reduction equipment. Yet EPA also would require facilities subject to the rule to design and submit a two-year plan for compliance monitoring. Proposed 40 C.F.R. § 125.95(b)(7). This provision will, for all practical purposes, remove the flexibility provided in section 125.96, because most regulators will simply require that the submitted two-year plan be carried out, without considering whether such a plan is necessary in light of existing data or adequate to accurately assess the efficacy of the installed technologies.

EPA Response

EPA disagrees that the 2-year monitoring requirement removes flexibility set forth in § 125.96. However, the 2-year monitoring minimum may not be the case for all facilities (please see response to comment 316bEFR.307.007). As written, today's rule gives the Directors tremendous flexibility in setting monitoring requirements for their facilities, including which species and life stages to monitor, the total number of species, whether the organisms should be counted or weighed, whether taxonomic identification is required, and what the averaging period should be for determining compliance (for details please see EPA's response to comment 316bEFR.307.007). EPA has learned that the long-term success of a particular technology is determined by the monitoring, maintenance and adjustments made during the course of its deployment. Simply installing a technology or operational or restoration measure does not guarantee compliance with the performance standards, because the efficacy of a given technology or operational measure will be affected by ambient conditions and by operational adjustments made as part of the technology's ongoing use. EPA therefore believes at least two years of monitoring is needed to verify the full-scale performance of the proposed or already implemented design and construction technologies and of any operational and restoration measures. EPA therefore believes that it is necessary and appropriate for all facilities to demonstrate, during the federally mandated minimum time period set forth by today's rule, that the approved technologies or operational or restorative measures do in fact achieve the required reductions in impingement mortality and entrainment. The Director will use the verification monitoring to confirm that the facility is meeting the level of impingement mortality and entrainment reduction expected and that fish and shellfish are being maintained at the level expected (as required in § 125.94(b)). Technology Installation and Operation Plans are also available as mechanisms to demonstrate compliance, subject to the approval of the Director.

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 21.03

Monitoring requirements

To take another example, on larger river systems such as the Mississippi River and the Illinois River, it may take as many as ten years to effectively demonstrate that new technology has achieved reductions consistent with EPA's performance standards. This may indicate a need to perform source water sampling after the monitoring phase. This monitoring is costly and is subject to seasonal river variations. Monitoring may have to go on for years until such time that an improvement in impingement or entrainment can be demonstrated. In Midwest river systems that are subject to river flooding in the spring and summer, flooding may coincide with typical fish spawning periods. At such time environmental conditions would have more impact on entrainment than intake technology. It would be difficult to compare a reduction in entrainment or impingement numbers and take credit for doing so when environmental conditions, not newly installed technology, would be determinative.

By contrast, at some facilities, much less than two years of monitoring will be required. This would be the case, for example, if a plant had collected copious data already and if no change to the plant was required by the new rule. On the other hand, two to five years of monitoring might be required at some estuarine sites where fish populations vary widely from year to year.

EPA Response

EPA agrees that some facilities may need more extensive monitoring than others. Please see EPA's response to comment 316bEFR.074.023.

Comment ID 316bEFR.035.031

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 21.04

Determination of compliance

We recommend that after a verification monitoring period, the data should be analyzed to determine whether the newly installed technology is indeed achieving 80-95% reduction in impingement mortality and 60-90% reduction in entrainment. As long as the data showed performance within these ranges, the technology should be deemed to comply
with the rule. For example, if the entrainment reduction technology was predicted to reduce entrainment by 85% but in fact achieved only 80%, that should be sufficient.

Assuming the data showed performance within the ranges, then no further biological monitoring should be required. Instead, the permittee should be required thereafter simply to monitor and document that it continued to operate and maintain the technology.

If the initial monitoring showed that the technology was not achieving reductions with the performance standards, on the other hand, then there seems to be no fair alternative but to provide for a period of additional study to determine what went wrong and what should be done to fix it, including the replacement of the technology with something different, if necessary and if the cost is not excessive.

EPA Response

EPA agrees that any performance within specified ranges (80-95%; 60-90%) should count as compliance. EPA opted for performance ranges instead of specific compliance thresholds to allow both the permittee and the permitting authority a certain degree of flexibility in meeting the obligations under the final Phase II rule.□□

In response to the commenter's suggestion that once a facility demonstrates reduction in impingement mortality and entrainment rates to satisfy the performance standards it should not be required to conduct further biological monitoring, EPA disagrees. Please see EPA's response to comment 316bEFR.307.027 for a discussion of monitoring requirements.

EPA agrees that a facility that does not achieve the reductions specified by the performance standards may be required to optimize performance by installing additional design and construction technologies or implementing operational or restoration measures. The extent of these additional measures will be determined by a permitting Director, who will take all factors, including costs, into account.

Comment ID 316bEFR.035.032

Subject Matter Code 21.04

Determination of compliance

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

Permit terms should use appropriate averaging times.

As already noted, the best solution to the compliance issue would be to require in the NPDES permit that the appropriately selected intake technology be installed and then maintained and operated properly. The alternative of requiring a permittee to prove periodically that it is entraining or impinging a specified percentage of fish would be highly variable, very expensive, technically unsound, and unfair.

If EPA retains its numeric performance standards, however, and a permittee has chosen a technology (wedgewire screen, fine mesh screen, or aquatic filter barrier) that it predicts will reduce entrainment (compared to the baseline) by 75%, thus meeting the entrainment performance standard, how should the permit requirement be written to implement its commitment to install and operate this technology?

Because of the variability of biological systems and the lack of control that a permittee has over fish and shellfish in the water, it would be unfair to write a permit term requiring the permittee to reduce entrainment by 75%, or, for that matter, to achieve any fixed numerical limit on the biomass or number of organisms entrained. Any performance within the specified ranges of 80-95% and 60-95% should count as compliance.

EPA Response

EPA agrees that today's final rule should include a "streamlining" alternative, and has therefore included the approved technology alternative, which is detailed at § 125.99. EPA disagrees, however, that it should not require any verification that a facility is meeting the applicable performance requirements or standards. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027.

EPA agrees that any performance within the specified ranges of 80-95% and 60-95% should count as compliance. EPA opted for performance ranges instead of specific compliance thresholds to allow both the permittee and the permitting authority a certain degree of flexibility in meeting the obligations under the final Phase II rule. For a discussion of how compliance is to be determined, please see the preamble to the final rule and EPA's responses to comments 316bEFR.017.003 and 316bEFR.063.005.

Subject Matter Code 21.09

Permit applications/implementation schedule

Over what period of time should the percentage reductions be calculated? As suggested above, the permittee would be required to monitor for a period of time, which would be two years or less for most plants and possibly up to 5 years for some estuarine plants. The averaging time for determining compliance should be the period of monitoring it, usually two to five years. Thus, if a plant were required to monitor for two years after installation of new technology and calculated that the technology reduced entrainment by 50% the first year and 70% the second year, for a two-year average of 60%, then it should be considered in compliance with section 316(b). Because of the natural fluctuation of aquatic populations, a short averaging time would be unfair.

But a longer averaging time can be unfair as well, in the following way. If the plant has monitored for two years and discovered only at the end of that time that it has not achieved the 60-90% reduction in entrainment, then it might, in theory, face two years' worth of penalties for "noncompliance." For the same reasons as cited above (the natural
variability of aquatic populations and the lack of control of the permittee), failure to meet the performance standards after several years of monitoring should not be considered a "violation." It should be a signal that additional study is needed, with a suitable compliance schedule for improving performance.

EPA Response

Today's final rule requires that monitoring be conducted in accordance with the verification monitoring plan (125.95(b)(7), the Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5). The Director may consider additional monitoring requirements as well. Specific study parameters may be proposed by the applicant for review and approval by the Director.

Comprehensive demonstration study (7 parts)

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

The above recommendation means that, once the permittee has demonstrated that its technology performed within the performance standard ranges, it would have only to maintain and operate the same technology for the life of the plant and would not have to make repeated demonstrations. This is a fairer proposal, given that section 316(b) is a construction-type requirement, that fish populations are highly variable and subject to many stresses besides cooling water intakes, and that the permittee has limited control over what animals approach its intake.

EPA Response

EPA disagrees that no monitoring should be required once the permit achieves the performance standards. Please see EPA's response to comment 316bEFR.307.027 and 316bEFR.021.007 for an explanation of EPA's monitoring requirements.

RFC: Use of previous demonstration studies

Author Name Roger Claff

Organization Cooling Water Intake Structures Coalition

There is no need to perform a new section 316(b) analysis every five years

The Coalition takes strong exception to EPA's proposed rule suggesting that a "comprehensive reevaluation" of the section 316(b) demonstration be conducted every time a permit is renewed. Once a successful section 316(b) demonstration is made, maintaining and operating the technology for the life of the plant should be enough. At, a minimum, there should be no reconsideration for at least ten years, absent evidence that conditions have so changed that the aquatic community is threatened. After a successful demonstration of compliance with EPA's performance standards, at each later permit
renewal the permit writer should accept the initial demonstration, unless there have been significant changes in plant operations or adverse changes to the aquatic populations. A permittee could also certify that there have been no changes in the design or operation of the intake structure.

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to 316bEFR 041.126 for a discussion.

Performance standards

CALCULATION BASELINE

The proposed rule should be revised so the "calculation baseline" is not the only surrogate measure for the threshold of adverse environmental impact; the rule should provide for use of alternative performance standards [e.g., expanding section 125.94 (c) beyond just cost considerations] that allow demonstrating that the existing intake structure is not adversely impacting populations of aquatic life in the area.

The "calculation baseline" is used in the proposed rule essentially as a threshold for determining when adverse environmental impact begins.   It calls for an "estimate of impingement mortality and entrainment that would occur at your site assuming you had a shoreline cooling water intake structure with an intake capacity commensurate with a once-though cooling water system and with no impingement and/or entrainment reduction controls." (proposed section 125.93). We are not aware of any scientifically supportable way to make this estimate, particularly at an existing facility site where the populations and ecosystem have acclimated to the presence of the existing intake structure. Performance standards based on the calculation baseline are essentially making the performance standard a volume reduction requirement based on reducing intake capacity to that of a cooling tower system.

Organization Cooling Water Intake Structures Coalition

Subject Matter Code 21.04

Determination of compliance

EPA SHOULD INCLUDE BYPASS AND UPSET PROVISIONS IN THE 316(b) RULES

EPA should include bypass and upset provisions in all three phases of the section 316(b) regulations, comparable to the bypass and upset provisions in 40 C.F.R. § 122.41(m) and (n). The problem is that those provisions address diversion "of waste streams from any portion of a treatment facility" and "noncompliance with technology based permit effluent limitations because of factors beyond the reasonable control of the permittee," respectively. Because of this wording, it is not clear that the bypass and upset defenses will be available for section 316(b)-based NPDES permit conditions.

The rationale for including bypass and upset provisions in the section 316(b) regulations is very similar to the reasons for which those provisions are included in the NPDES regulations with respect to wastewater discharges and wastewater treatment technology. Technology-based standards should recognize that the technology is not capable of performing flawlessly, regardless of how well-designed and -operated the system is. At least two federal courts of appeals have recognized that technology-based effluent limitations that fail to account for this reality are not in accordance with law. Marathon Oil Co. v. EPA, 564 F.2d 1253, 1272-74 (9th Cir. 1977); FMC Corp. v Train, 539 F.2d 973 (4th Cir. 1976). Promulgation of cooling water intake structure technology requirements without providing that bypass and upset situations will not be violations would likewise render the section 316(b) regulations unlawful.

For example, if the screens are fouled so as to jeopardize plant operation, the permittee should be allowed to bypass them until they can be cleaned. Similarly, if, due to emergency conditions, water levels in a reservoir are reduced to the point where technologies are inoperative, bypassing to permit continued operation should be allowed. Such exceptional bypasses should be allowed only for short periods of time, until the emergency has passed and the permittee has had time to restore the intake technology to proper operation.

Proposed standards for Great Lakes

GREAT LAKES

The Great Lakes should not be included in proposed section 125.94 (b) (3). The Great Lakes are proposed to be included in the most stringent performance standard. The preamble says that this is done because "EPA believes the Great Lakes are a unique system that should be protected to a greater extent than other lakes and reservoirs." (Preamble Page 17141). EPA has failed to define the unique aspects and justify what aspects require more protection than for other lakes and reservoirs, especially with regard to CWIS. The size, volume, aquatic life population sizes and variety, and opportunity for fish to avoid intake structures seem to make the Great Lakes candidates for less concern than other water bodies regarding impact of impingement and entrainment from cooling water intake systems, not more.

EPA Response

Please refer to the response to comment 316bEFR.025.013 for a discussion of the Great Lakes as sensitive waterbodies.

RFC: Use of previous demonstration studies

There are many electric generating facilities that have already proven to their state regulatory agencies that they are not creating adverse environmental impact (AEI) or that they have already installed the appropriate level of technology (BTA). Exelon strongly supports the position that, where a facility already has performed a Section 316(b) demonstration before the new 316(b) Rule is promulgated and has shown to the satisfaction of its regulatory agency that the facility complies with Section 316(b), or where the agency has confidence that fish populations are not being harmed by the impingement and entrainment impacts of a facility, the state regulatory agency should be given the flexibility to conclude, after a new review of existing information, that no further changes to the facility's intake activities are required.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule; however, existing data that is reflective of current conditions may be used to support the required studies. Please see response to comment 316bEFR.040.001 for details.

Comment ID 316bEFR.036.003

Author Name Sharon Neal

Organization Exelon Corporation

Subject Matter Code 18.01.01

UWAG definition of "adverse environmental impact"

As part of an appropriate site-specific approach, USEPA should adopt a definition of AEI, the requirement for which flows directly from the language of the Clean Water Act's Section 316(b). This definition should provide that the loss of a single fish, a single egg, or even a large number of them, need not be AEI. Instead, AEI occurs when the loss of fish or other organisms is felt at the population or community level, when the loss is so great that it adversely affects the structure or function of the aquatic community. Exelon strongly concurs with UWAG's detailed discussion of this point in Comment III, B, 1.

EPA Response

Please see the response to comment 316bEFR.002.019 for the discussion on the definitions EPA rejected for adverse environmental impact in this rulemaking.

Comment ID 316bEFR.036.004

Author Name Sharon Neal

Organization Exelon Corporation

Subject Matter Code 3.03

Definition: Waters of the U.S.

USEPA's regulation, 40 C.F.R. 122.2, exempts waste treatment systems from the definition of waters of the United States. This regulation provides that [w]aste treatment systems, including treatment ponds or lagoons designed to meet the requirements of CWA (other than cooling ponds as defined in 40 CFR 423.11(m) which also meet the criteria of this definition) are not waters of the United States. The parenthetical was set aside by the Court of Appeals in Appalachian Power Co. v. Train, 566 F.2d 451 (4th Cir. 1977). Thus, as a matter of law, waste treatment systems are not waters of the United States, and the cooling pond exclusion from the waste treatment system exemption no longer has any force or effect.

A cooling pond is a waste treatment system, made part of a plant's closed cycle cooling system, designed to allow the plant to comply with the CWA's thermal requirements. Pursuant to the above quoted regulatory language, such a cooling pond is carved out from the defined "waters of the United States." USEPA's 316(b) rule, as finalized, should not contradict or blur this point.

EPA Response

See response to 316bEFR.006.001.

Author Name Sharon Neal
Organization Exelon Corporation

Subject Matter Code 11.01
RFC: Proposed use of restoration measures

Exelon is a strong advocate of restoration as a feasible, reasonable, and an environmentally correct alternative that can significantly contribute to the enhancement of a fishery and other aquatic life. Restorations should be offered as means for Section 316(b) compliance. States should be given ample flexibility in their treatment and recognition of the environmental benefits of such projects. Restorations can demonstrate measurable results and are also well received by the general public and regulatory agencies. By example, fish stocking as a restorative effort is currently practiced by Exelon's Quad Cities Station as a means to offset fish impingement. Biological monitoring and trending of standing crop estimates in the Mississippi River pools, which are stocked by Exelon, have demonstrated a 30% recruitment in certain game species resulting from these stocking efforts. The Illinois Department of Natural Resources and Iowa Department of Natural Resources have acknowledged this remarkable accomplishment and continue to be strong supporters of the fish-stocking program on the Mississippi River.

Exelon's Shad Restoration Project currently under way on the Susquehanna River is another example of a successful restoration project. During the 2001 International Shad Conference, Pennsylvania's Susquehanna River was recognized as the site that had demonstrated the most dramatic restoration of American shad, the largest member of the herring family. The same year, a record number of American shad had safely passed through the fish-lift facilities at Exelon Power's Conowingo Hydroelectric Station on their annual migratory run, the most in the history of the restoration program.

EPA Response

In the final rule, EPA allows use of restoration measures to minimize or help to minimize the adverse environmental impacts that derive from impingement and entrainment of aquatic organisms. All restoration measures must meet the requirements described in the final rule, including those in sections 125.95 and 125.95. For a discussion of EPA's authority to include restoration measures as a compliance option in the final rule, see the preamble to the final rule.

For a discussion of the role of the permitting authority, see EPA's response to comment 316bEFR.060.026.

Subject Matter Code 9.0

Costs

USEPA justifies one of its central assumptions (that new facility capital costs are adequate surrogates for existing facility costs) based on several assumptions. USEPA's assumptions, as applied to nuclear power plant operations and the suggested utilization of "significant portions of conduit systems," presumably while the plant remains in operation, are inconsistent with nuclear power plant operations. They are also inconsistent with the utilities' out-of-service and modification design process, which would govern the installation of upgraded intakes, traveling screens and the like. Anything that would alter or impact the flow of safety related service water or non-essential service water systems would require an equipment outage and would possibly have to be completed during a unit outage. Since unit outages are now mostly scheduled on an 18-month or 24-month frequency, extension of these scheduled outage timelines would result in serious financial impacts to a utility, which are not recognized by USEPA. Although USEPA does acknowledge that piping modifications could be significant, it does not appropriately address the significant costs of additional unit downtime to perform the modifications.

EPA Response

Although the commenter may have been correct in referring to cooling tower costs for the proposal and NODA, for the final rule analysis, the technologies and costs of their installation were developed specifically for existing facility implementation. Secondly, the assumption about utilization of existing conduit systems is most applicable to the case of cooling towers and generally does not apply to the technologies forming the basis of the final rule.

On the matter of construction downtimes, the Agency has accounted for unscheduled outages in the economic analysis of the final rule when they would apply. The commenter is incorrect in stating the opposite case.

Permit applications/implementation schedule

USEPA's 316(b) Rules should appropriately recognize and accommodate the substantial time and resources required to implement the numerous proposed 316(b) requirements. Specifically, ample time should be allowed for utilities to design, seek and obtain agency approval for, test and conduct baseline source water studies and entrainment and impingement characterization studies. Subsequently, adequate compliance schedules should allow time for all of the involved entities, e.g., utilities, regulatory agencies, environmental consultants, and engineering design and construction companies, to coordinate and perform their necessary activities for 316(b) implementation. In order to accomplish these numerous steps, two full NPDES permit renewal periods may be required: the first for designing and conducting the threshold studies; and the second for responding to the studies results and providing a timeline for implementation of any new intake technologies or procedures.

EPA Response

For a discussion of the timing for submitting the required studies and other issues relating to demonstrating compliance, please see the preamble to the final rule.

Organization Lansing Board of Water & Light

Subject Matter Code 7.01.03

Option 3--Site-specific determination

EPA should be complimented for considering a variety of alternative approaches to the regulation. The Lansing Board of Water & Light is encouraged that the EPA proposal explicitly recognizes that alternative technology selection may be warranted based on site-specific factors that may affect the technical practicability of meeting the proposed standards. Specifically, the EPA recognizes that there may be situations where the costs of meeting the proposed standards at a specific facility may be significantly higher than the costs considered by the EPA in establishing these standards. In those instances the proposal provides the facility with the opportunity to justify an alternative technology election.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Comment ID 316bEFR.037.004

Author Name Jack Hill

Organization Lansing Board of Water & Light

Subject Matter Code 10.07.03

RFC: Test: benefits should justify the costs

The EPA proposal explicitly recognizes that alternative technology selection may be warranted based on site-specific-factors that indicate that the costs of meeting the performance standards are not warranted by the projected benefits at that facility. This is potentially very good. The proposed rule allows facilities to select an alternative level of compliance where the costs of compliance with the EPA's performance levels would be significantly greater than the expected benefits of achieving these levels. This explicitly recognizes the site-specific variations in the water bodies (with varying ecological conditions) and can help account for controls already in place at many facilities.

EPA Response

The final 316(b) regulation also allows a site-specific determination of best technology available for minimizing adverse environmental impact on the grounds that costs are significantly greater than the benefits of complying with the otherwise applicable requirements. For detail see the preamble to the final 316(b) Phase II regulation. See also EPA's response to comment #316bEFR.005.020 on application of the cost-benefit test to assessing the value of alternative CWIS technologies.

Comment ID 316bEFR.037.005

Author Name Jack Hill

Organization Lansing Board of Water & Light

Subject Matter Code 7.01.03

Option 3--Site-specific determination

The EPA has chosen a flexible approach to compliance that allows facilities to meet the performance standards through a number of options, including creation or voluntary restoration of habitats and other non-traditional approaches. This approach allows for continued innovation in addressing the potential adverse environmental impacts associated with impingement and entrainment at power generating facilities. This also leaves significant discretion in determining how best to comply with the standards to state permitting authorities and facilities managers who have developed a great deal of expertise on these issues over the past 25 years. The Lansing Board of Water & Light has a good working relationship with the state and believes in deferring, where possible, to the state regulators.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule. This rule preserves an important role to be played by the State Directors.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

For information on the role of restoration, please refer to sections VII and VIII in the preamble to the final rule.

Comment ID 316bEFR.037.006

Author Name Jack Hill

Organization Lansing Board of Water & Light

Subject Matter Code 22.06

UMRA/Impacts on local governments

However, the EPA has underestimated the impact of these proposed regulations on public power systems. The Lansing Board of Water & Light believes that the EPA should consider these impacts on local government. (See section titled Assessment of Unfunded Mandates Analysis on Public Power in the Comments submitted by the American Public Power Association).

One aspect of these regulations that will fall disproportionately on public power systems is the geographic location of their facilities. By their very nature, public power systems are located within the geographic bounds of the local government they serve. This causes a number of public power facilities to be virtually landlocked and unable to obtain any of the additional land that may be required to install the required control systems. On the other hand, IOUs are not limited as to where they can locate a facility and often have hundreds of acres available for construction of additional control facilities.

The Lansing Board of Water & Light agrees with the APPA that the EPA should encourage states to implement the new 316(b) requirements in coordination with the utilities to ensure reliable grid operations.

The Lansing Board of Water & Light is very concerned with the unintended consequences of downtime in the utility industry when 316(b) requirements are implemented. If the EPA and states attempt to do these too quickly or at the same time, there may be electricity price spikes as public power generators purchase power from IOUs or other public power entities during a one to three month down time. The final rule should encourage state flexibility in setting sensible deadlines for 316(b) retrofits when the utility would have scheduled outage, maintenance or have lower demand. The EPA's proposed rule ignored this potential consequence that could be serious in a region (or watershed) where several utilities face NPDES permit renewal, imposition of 316(b) requirements, and planned outages in the same year. If not timed wisely, the region's customers could face unexpected utility bill increases-particularly during a peak use time such as mid summer or mid winter.

The EPA and states should take a common sense approach to new 316(b) requirements. This common sense approach would minimize potential cost spikes and energy disruptions and would avoid placing too high a demand on the few dozen consulting engineering firms that have considerable expertise in biological studies and the various intake technologies.

EPA Response

For a response to comments on potential impacts on public power systems, please refer to comment 316bEFR.028.008 in subject matter code 22.03.

EPA disagrees with the commenter the space constraints might cause disproportionate impacts on public power systems. The technologies upon which EPA based the requirements of the final rule will not require acquisition or use of additional land for facilities complying with the rule. Unlike the potential case of cooling tower construction at existing power facilities, the addition and/or retrofit of screening, design, and control technologies does not involve large land footprints for the technology nor its construction. In the case that some technologies may have a significant footprint, these are generally aquatic in nature (such as barrier net systems).

Subject Matter Code 17.05

Option: I&E reduction without regard to WB type

New York's Preferred Alternative - We prefer your "Impingement Mortality and Entrainment Controls Everywhere" (as presented on pages 17158-17159 in Section VI(B)(4)) alternative to EPA's Preferred Alternative. We strongly recommend that EPA adopt this alternative because it "levels the playing field" for all generating companies and because it offers flexibility. The generators would be fully aware of what is required to meet the performance requirements of proposed Section 125.94(b)(3). EPA would establish the required level of performance but generators would be free to select any or a combination of techniques to achieve the performance level. This is the simplest alternative to implement and your analysis found that it provides the highest benefit to cost ratio (3.74:1). An additional advantage is that companies and regulators could put their staff and monetary resources into reducing impacts instead of into studies and rebuttals. This alternative also responds to what EPA has asked comment on: the 'extreme burden' on State agencies which cost/benefit and site specific determinations have imposed, over these past years on state agencies. Finally, we agree with EPA's statement that "This alternative would establish clear performance-based requirements that are simpler and easier to implement than those proposed and are based on the use of available technologies to reduce adverse environmental impact. Such an alternative would be consistent with the focus on use of best technology required under Section 316(b)."

EPA Response

EPA disagrees that the "Impingement Mortality and Entrainment Controls Everywhere" is a better alternative than today's final rule. For EPA's rationale for rejecting that option, please refer to the final rule preamble in the section entitled Impingement Mortality and Entrainment Controls Everywhere.

Subject Matter Code 7.01

RFC: Three-option framework for determining BTA

EPA's Preferred Alternative - While parts of "EPA's Preferred Alternative"have very positive elements, we see a number of potentially serious problems. As proposed, a facility would select one of three different Methods to establish the best technology available (BTA) for minimizing adverse environmental impact:

Method 1. The facility owner demonstrates compliance with the new rules.

Method 2. The facility owner implements additional technologies, and operational or restoration measures.

Method 3. The facility owner demonstrates that the cost of compliance would be significantly greater than either the EPA estimate of costs, or the site-specific value of the benefits.

EPA Response

The commenter has characterized the proposed rule; no response is necessary for that portion of the comment. Please refer to the preamble for a discussion of the framework of the final rule.

Comment ID 316bEFR.038.008

Author Name Peter Duncan

Organization NY State Dept of Environmental Conservation, Office of Natural Resources

Subject Matter Code 7.01.01

Option 1--Demonstrate existing BTA

Method 1 is straightforward and we support it. Closed-cycle recirculating facilities would be deemed in compliance. For purposes of regulatory and scientific certainty, a demonstration of compliance at other facilities should require at least one year of impingement and entrainment study in order to document compliance. We recommend that additional studies be conducted at least one year in each five year permit term (except for facilities equipped with closed cycle systems) to verify compliance.

EPA Response

EPA agrees that facilities with closed-cycle recirculating cooling systems are considered to be in compliance with the performance standards. Please refer to § 124.94(a)(1) for further information.

With regard to monitoring requirements, please refer to the preamble and other responses in this comment response document.

Option 2--Implement performance requirements

We support the concept in Method 2 of reducing impacts by adding technology and measuring the results against the standard. We believe, though, that the sampling proposed is insufficient and would yield erroneous or incomplete results. We recommend that collections for impingement should be performed for a 24-hour period at lease once per week for 52 consecutive weeks. Collections for entrainment should be performed at intervals no greater than 6 hours apart over a 24-hour period at least once per week though periods when spawning occurs in the affected water body. Method 2 appears to require that, at a minimum, an impingement and entrainment monitoring program be conducted “before” and “after” mitigative measures have been implemented to determine levels of impact. We support the proposed components of a “Comprehensive Demonstration Study” to be conducted for existing facilities. Finally, as with Method 1, we suggest that facilities be required to reevaluate impingement and entrainment impacts during one year of each five-year permit period.

EPA Response

Please refer to preamble for a discussion of the framework of today's rule. EPA appreciates the commenter's support of the regulatory approach in the proposal, and notes that the final rule uses a similar approach.

With respect to the monitoring requirements, please see the preamble to the final rule, and EPA's responses to comments 316bEFR.017.003 and 316bEFR.063.005.

Subject Matter Code 7.02

Performance standards

We support the different thresholds of protection for different water bodies, as EPA has proposed, and the flexibility for a Director to select a level of protection within a finite range. We agree with the proposed target ranges of reducing impingement mortality by 80 to 95 per cent, and entrainment by 60 to 90 per cent; this approach recognizes that levels achievable from closed cycle cooling vary depending on the salinity of the waterbody.

EPA Response

EPA appreciates the comment.

Subject Matter Code 10.07.02

RFC: Appropriateness of "significantly greater"

Lowering the standard from "costs wholly disproportionate to benefits" to the much less stringent "costs significantly greater than site specific benefits" is unacceptably problematic. The former criterion has been applied to these Phase II and all other facilities since the 1970's and is supported by a substantial body of case law, permit decisions and legal opinions.

EPA Response

See response to 316bEFR.006.003. EPA expects that a similar body of decisions and precedents can be developed for the standard in this rule.

Comment ID 316bEFR.038.013

Author Name Peter Duncan

Organization NY State Dept of Environmental Conservation, Office of Natural Resources

Subject Matter Code 10.07.02

RFC: Appropriateness of "significantly greater"

State fish and wildlife resources would be at risk if the lower standard were used; in New York, the aquatic organisms impacted by plant intakes belong to the State (Environmental Conservation Law §11-0105). Rather than the widely-accepted "polluter pays" approach, the EPA-proposed rule weighs a polluter's cost against a monetized value of fish and wildlife resources it does not own and to which it has no entitlement.

EPA Response

EPA explains its basis for the site-specific BTA determination provisions in the rule in section VII of the preamble to the final rule. As indicated in 125.90(d) and 125.94(e), States remain free to impose more stringent requirements as they deem appropriate.

Comment ID 316bEFR.038.014

Author Name Peter Duncan

Organization NY State Dept of Environmental Conservation, Office of Natural Resources

Subject Matter Code 10.07

RFC: Cost: benefit ratio for site-specific BTA?

The value or "benefit" of State fish and wildlife resources is difficult to quantify. Whereas the costs of mitigative measures are easy to quantify using familiar accounting techniques, the task of placing an accurate dollar value on aquatic resource impacts is rife with ecological and economic challenges; there is no widely-accepted methodology. In contrast, by maintaining the conventional "costs wholly disproportionate to benefits" analysis, generators would have to look at the incremental cost of controls in light of the dollars they make selling electricity.

EPA Response

EPA agrees with the commenter that the value or "benefit" of State fish and wildlife resources is difficult to quantify, and that the cost of mitigative measures is easy to quantify in comparison to valuing the benefits to aquatic resources.

The commenter defines the "costs wholly disproportionate to benefits" as comparing the incremental cost of controls to the revenue or profits received from electricity sales. Traditionally, however, the wholly disproportionate cost test is based on comparing the costs of implementing a regulation or option with the ecological benefits associated with stopping the losses. EPA analyzed a cost to revenue measure for all facilities as part of the cost impact analysis in Part B of the final EBA (DCN #6-0002).

Subject Matter Code 21.08

Burden on permitting agencies (general)

Author Name Peter Duncan

Organization NY State Dept of Environmental Conservation, Office of Natural Resources

Method 3 would generate numerous studies which could impose a substantial review burden on state agencies. As cited in your discussion, Salem Nuclear Generating Station's permit application comprised 36 volumes supported by 137 additional volumes of technical and reference materials. Clearly, a significant effort would be required to meaningfully scrutinize so much information. Furthermore, state water quality and natural resource agencies would frequently need to retain the specialized expertise needed for review of the more arcane studies. Once again, EPA recognizes this extreme burden and we agree.

EPA Response

EPA agrees that a site-specific alternative may be burdensome on Directors and has added several efficiencies in today's final rule to speed permitting and reduce burden. Please see response to comment 316bEFR.034.005 for a full discussion.

Comment ID 316bEFR.038.016

Author Name Peter Duncan

Organization NY State Dept of Environmental Conservation, Office of Natural Resources

Subject Matter Code 7.01.03

Option 3--Site-specific determination

Method 3 appears to provide an unfair competitive advantage to old, inefficient, high impact facilities. In the competitive wholesale electric power market if a biased cost/benefit analysis would enable a facility avoid or reduce the costs needed to achieve standards, it could sell its electricity more cheaply than newer, more efficient, compliant facilities that have internalized the cost of impingement and entrainment protection. This market advantage could be a strong disincentive to comply under Method 1 or Method 2, and would penalize new power plants regulated under the Phase I rule. Such an outcome would not serve the purposes of the Clean Water Act, nor would it serve the interests of cleaner air and more efficient use of fossil fuels. Plants that cannot satisfy Method 1 or Method 2 should be: 1) repowered to modern technology; 2) decommissioned as having outlived their usefulness; or 3) operated at less than EPA's proposed 15 per cent capacity to qualify for that exemption.

EPA Response

EPA recognizes that existing facilities are subject to less stringent requirements than new facilities. This is justified by the record in this case and is consistent with Congress' decision--in connection with effluent limitations guidelines and standards--to allow EPA to treat new and existing facilities differently.

EPA disagrees that an older facility selecting the site-specific alternative will have an economic advantage over a newer existing facility. If both facilities demonstrate that they meet the performance standards, then both will have approximately the same compliance costs. If a newer existing facility is truly more efficient, then it is more likely to meet the performance standards and be subject to fewer requirements, and therefore have lower costs.

EPA disagrees that the Phase II regulations should dictate operational or market-level decisions such as plant closures or levels of operation. Today's final rule establishes national requirements and does not attempt to make facility-specific determinations. EPA does note, however, that a State may choose to impose more stringent standards.

RFC: Proposed use of restoration measures

Author Name Peter Duncan

Organization NY State Dept of Environmental Conservation, Office of Natural Resources

We are also concerned about the provision in EPA's Preferred Alternative (described in Method 2, as well) that would allow for restoration in lieu of controls to avoid and minimize impingement and entrainment impacts. We believe that restoration is appropriate only within the widely-used stepwise approach whereby every effort is made to first avoid and then minimize impacts through technology-based measures on intake design, location, construction, and capacity. Restoration should be used only to address truly unavoidable impacts.

EPA Response

For a discussion of the requirement to consider design and construction technologies and operational measures before choosing restoration measures, see EPA's response to comment 316bEFR.033.005.

Comment ID 316bEFR.038.018

Author Name Peter Duncan

Organization NY State Dept of Environmental Conservation, Office of Natural Resources

Subject Matter Code 11.01

RFC: Proposed use of restoration measures

"Restoration" includes habitat creation, habitat restoration, or stocking organisms. Any approved restoration plan should be designed to promote natural propagation and survival of indigenous species which have been impacted by plant operations. In addition, restoration should be viewed as a temporary measure to allow the facility to continue to operate until suitable in-plant solutions can be devised or the facility is decommissioned.

Stocking to replace organisms killed or injured should be avoided. First, the aquatic resource diversity is high. In the case of New York's Hudson River, for example, more than 100 species are at risk to power plant intakes. Also, artificial propagation is difficult. Our experience with a striped bass hatchery on the Hudson River is that it never reached its target level of production, and the target was still a small fraction of the striped bass killed by plant intakes. Further confounding issues are genetics, disease, and intraspecific competition with naturally-spawned fish.

Finally, there are practical limitations to restoration, too. In many systems, the space and/or hydrology are unavailable for meaningful restoration. Creating another Hudson River or another Great Lake would be impracticable.

EPA Response

EPA agrees that promotion of natural propagation and survival of indigenous species that have been impacted by a cooling water intake structure is a worthy trait to include in a restoration measure.

For a discussion of the requirement to consider design and construction technologies and operational measures before choosing restoration measures, see EPA's response to comment 316bEFR.033.005.

Permit applicants and permitting authorities should carefully consider the true effectiveness of a proposed restoration measure. Some restoration measures may be effective for some locations and not for others. For a discussion of the roles and responsibilities of the permitting authorities and the permit applicants in the choice of restoration measures, see EPA's response to comment 316bEFR.060.026.

EPA acknowledges that space or hydrological limitations may limit the feasibility of restoration measures for some locations.

Option: UWAG's recommended approach

Site-Specific Alternative - We do not endorse "site-specific alternative" approaches as defined in the proposed rule, especially the one proposed by UWAG (the Utility Water Act Group). We believe it would cancel the benefit of having a national standard; it appears to offer less protection than the 1977 draft guidance in current use. The intensity of sampling and study necessary to detect a 1 per cent or 5 per cent population change with certainty, and to be able to attribute that impact to an individual plant, would be exceedingly costly and perhaps technically impossible in most instances.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

UWAG definition of "adverse environmental impact"

We also disagree with the definition of "adverse environmental impact" as proposed by UWAG. We consider any impingement or entrainment to constitute an adverse environmental impact. Considering impacts only when they can be observed on a population level could allow irreversible damages to fish stocks.

EPA Response

EPA agrees with this commenter that adverse environmental impact can be considered at the individual level, and not limited to just community and population level effects. Please see the response to comment 316bEFR.002.019 for the discussion on the definitions EPA rejected for adverse environmental impact in this rulemaking.

Dry Cooling

Dry Cooling - Although dry cooling may be the best technology at some facilities, we agree that retrofitting all existing plants with dry cooling should not be the standard because of 1) the massive cost and loss of efficiency in converting water-cooled plants to dry cooling, and 2) the other non-aquatic environmental impacts that dry cooling technology can impose.

EPA Response

The Agency does not consider dry cooling to be a viable technology in the context of the existing facility rule. See response to comment 316b.022.002.

Comment ID 316bEFR.038.023

Subject Matter Code 17.02

Option: Reduce capacity comm. with closed-cycle

Author Name Peter Duncan

Organization NY State Dept of Environmental Conservation, Office of Natural Resources

Performance Level - We agree that the equivalent of "closed-cycle cooling everywhere" as defined in the proposed rule should not be the standard. The levels of performance are comparable to those we impose. The range of levels permits a wider variety of systems to be used, and would have a lesser impact on electric generation, especially in tidal rivers, estuaries, bays, and oceans.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161). Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to section VII.E of the preamble for more information on why EPA rejected this alternative.

Comment ID 316bEFR.038.024

Author Name Peter Duncan

Organization NY State Dept of Environmental Conservation, Office of Natural Resources

Subject Matter Code 16.01

RFC: Regulating limited capacity facilities

Capacity Factor - We support EPA's proposed exemption for facilities with low capacity but have two reservations; we are concerned that the 15 per cent capacity (55 days per year) factor exemption threshold is too high . First, the time of year the plant is running could coincide with a peak impingement or entrainment period. For example, in New York City, peak capacity is usually needed during the summer; this is when bay anchovy, an important forage species, spawns. Data suggest that 55 days of operation in July or August could entrain very significant proportions of larval and juvenile anchovy populations.

We have a similar concern at facilities with multiple generating units. Since each unit can operate independently, there is a potential for significant impacts resulting from this exemption. A facility with several obsolete units that seldom run and one efficient, newer unit that runs a high percentage of the time could qualify for this 15 per cent capacity factor exemption. As above, this circumstance would pose a problem if the high-use unit were operating during the peak impingement/entrainment season. In any case, the total capacity for a facility should only be based upon those units that have valid air emission permits and valid NPDES or SPDES permits.

EPA Response

For discussion of the level of the threshold see response to comment 316b.EFR.330.032, 316b.EFR.041.238, and DCN 6-3586.

Regarding the commenter's concern over facility-wide versus intake/unit specific definitions of capacity utilization rate, the Agency notes that it has adopted the definition for the final rule that bases the calculation of capacity utilization rate on the generating unit to intake basis (that is, if a generating unit and intake can be directly linked, then the capacity factor threshold applies to that intake only). Hence, the commenter's concerns have been met.

Comment ID 316bEFR.038.025

Author Name Peter Duncan

Organization NY State Dept of Environmental Conservation, Office of Natural Resources

Subject Matter Code 14.01

RFC: 5% threshold and supporting documents

Freshwater Rivers - We support EPA's proposal that on fresh water rivers, facilities that use 5 per cent or less of the mean annual flow would have to reduce impingement mortality, but not entrainment, and those using more than 5 per cent would have to reduce both. We feel that this criterion should not be any larger than 5 per cent for the exclusion from entrainment protection. On one New York river we examined, 5 per cent of mean annual flow equated to approximately 25 per cent of median August flow, with August being our average low-flow month. Thus, this level is still a substantial proportion of the river's flow in low flow months, and would be an even higher proportion in dry years. In such dry years a facility with coarse screens would entrain a greater percentage of small fish.

EPA Response

EPA notes the comment. The Agency has maintained this provision in the final rule.

Comment ID 316bEFR.038.026

Author Name Peter Duncan

Organization NY State Dept of Environmental Conservation, Office of Natural Resources

Subject Matter Code 20.01

RFC: Should EPA include impingement trading?

Mortality Credits - We have concerns about the concept of trading fish and wildlife mortality credits among facilities. First, we do not support trading mortality credits on a national basis. Such a system would appear to violate state sovereign rights over fish and wildlife resources and would compromise our capacity to manage these resources. Also, we do not support trading based on the biomass of the organisms killed. For example, the loss of a two-pound common bullhead cannot be compared in any meaningful way to the loss of two pounds of endangered short-nosed sturgeon eggs or fry. In addition to the huge difference in the number of organisms per unit of weight, these species vary markedly with respect to survival rates, mean age of reproduction, narrowness of habitat requirements, abundance, and susceptibility to extirpation.

EPA Response

Also, see response to 316bEFR.077.052 for the discussion on the appropriate unit for trading.

Subject Matter Code 7.01.03

Option 3--Site-specific determination

EPA should be complimented for considering a variety of alternative approaches to the regulation. Fort Pierce Utilities Authority is encouraged that the EPA proposal explicitly recognizes that alternative technology selection may be warranted based on site-specific factors that affect the technical practicability of meeting the proposed standards. Specifically, the EPA recognizes that there may be situations where the costs of meeting the proposed standards at a specific facility may be significantly higher than the costs considered by the EPA in establishing these standards. In those instances the proposal provides the facility with the opportunity to justify an alternative technology selection.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Subject Matter Code 10.07.03

RFC: Test: benefits should justify the costs

The EPA proposal explicitly recognizes that alternative technology selection may be warranted based on site-specific-factors that indicate that the costs of meeting the performance standards are not warranted bythe projected benefits at that facility. This is potentially very good. The proposed rule allows facilities to select an alternative level of compliance where the costs of compliance with the EPA's performance levels would be significantly greater than the expected benefits of achieving these levels. This explicitly recognizes the site-specific variations in the water bodies (with varying ecological conditions) and can help account for controls already in place at many facilities.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Author Name Thomas W. Richards
Organization Fort Pierce Utilities Authority

Subject Matter Code 7.01.03
Option 3--Site-specific determination

The EPA has chosen a flexible approach to compliance that allows facilities to meet the performance standards through a number of options, including creation or voluntary restoration of habitats and other non-traditional approaches. This approach allows for continued innovation in addressing the potential adverse environmental impacts associated with impingement and entrainment at power generating facilities. This also leaves significant discretion in determining how best to comply with the standards to state permitting authorities and facilities managers who have developed a great deal of expertise on these issues over the past 25 years. Name of utility has a good working relationship with the state and believes in deferring, where possible, to the state regulators.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Subject Matter Code 22.06

UMRA/Impacts on local governments

Criticism: the EPA has underestimated the impact on public powersystems. FPUA believes that the EPA should consider these impacts on local government. (See section titled Assessment of Unfunded Mandates Analysis on Public Power in the Comments submitted by the American Public Power Association).

FPUA agrees with the APPA that the EPA should encourage states to implement the new 316(b) requirements with coordination with states to ensure reliable grid operations.

FPUA is very concerned with the unintended consequences of downtime in the utility industry when 316(b) requirements are implemented. If the EPA and states attempt to do these too quickly or at the same time, there may be electricity price spikes as public power generators purchase power from IOUs or other public power entities during a one to three month down time. The final rule should encourage state flexibility in setting sensible deadlines for 316(b) retrofits when the utility would have scheduled outage, maintenance or have lower demand. The EPA's proposed rule ignored this potential consequence that could be serious in a region (or watershed) where several utilities face NPDES permit renewal, imposition of 316(b) requirements, and planned outages in the same year.

If not timed wisely, the region's customers could face unexpected utility bill increases-particularly during a peak use time such as mid summer or mid winter.

The EPA and states should take a common sense approach to new 316(b) requirements. This common sense approach would minimize potential cost spikes and energy disruptions and would avoid placing too high a demand on the few dozen consulting engineering firms that have considerable expertise in biological studies and the various intake technologies.

EPA Response

For a response to comments on potential impacts on public power systems, please refer to comment 316bEFR.028.008 in subject matter code 22.03.

Comment ID 316bEFR.040.001

Author Name Joyce Livingstone

Organization Dominion Environmental

Subject Matter Code 21.05

Role of States and Tribes (alt./equiv. programs)

Dominion strongly supports the concept that 316(b) approval authority should remain with the state permitting agencies. State agencies are best equipped from prior 316(b) activity to effectively implement the program. In addition, Dominion urges EPA to expand the rule to allow continued reliance on technically sound 316(b) decisions (and 316(b) State programs) that were made in the past.

EPA Response

In today's final rule, EPA has allowed approval of State programs that meet rule requirements at 125.90(d). See response to 316bEFR.023.001 for additional detail on State program approval.

As stated in the preamble to today's final rule, EPA recognizes the intensive effort that many facilities may have conducted in preparing studies for BTA determinations. However, EPA disagrees that existing BTA determinations should remain valid under today's final rule. Historical BTA decisions may be based on physical, chemical or biological conditions which are no longer relevant at the site, or be less stringent than the performance standards set forth by today's final rule. A goal of today's rule is to establish requirements for the best technology available for minimizing adverse environmental impacts. EPA believes that these national requirements will promote more effective and consistent implementation of section 316(b) requirements, and ultimately minimize adverse environmental impacts associated with the use of cooling water intake structures by Phase II existing facilities. Data from existing BTA determinations may be used to support the development of required studies in preparation of the permit application if they are reflective of current conditions at the facility. It is incumbent upon the facility to provide the rationale for using such data.

Subject Matter Code 17.06.01

Sample site-specific rule (p.17159-61)

Encourage the use of existing data to minimize rule's cost impact.

Regulatory Reference: Preamble VI. Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities
C. Site-Specific Based Options Under Consideration
1. Sample Site-Specific Rule (p. 17159-17160)

EPA also invites comment on site-specific approaches for determining the best technology available for minimizing adverse environmental impact at existing facilities.

125.94 (a) (2) A previously conducted section 316(b) demonstration may be used to determine whether the location, design, construction and capacity of the facility's cooling water intake structure reflect best technology available for minimizing adverse environmental impact if it reflects current biological conditions in the water body and the current location and design of the cooling water intake structure. A previously conducted section 316(b) demonstration generally would reflect current conditions or circumstances if:

(i) The previous section 316(b) demonstration used data collection and analytical methods consistent with guidance or requirements of the permitting agency and/or the Administrator;

(ii) The available evidence shows that there have been no significant changes in the populations of critical aquatic species; and

(iii) The owner or operator can show there have been no significant changes in the location, design, construction, and capacity of the facility's cooling water intake structure that would lead to a greater adverse environmental impact.

DOMINION COMMENTS: If a facility has data showing that there is: (1) minimal entrainment and impingement and no discernable harm to the aquatic community, or (2) the environmental impact of entrainment and impingement is of so little economic and environmental significance that the costs of a comprehensive 316(b) study would be significantly greater than its likely benefits, then there should be no need for either further intake evaluation or installation of additional intake technology. A provision should be added to the rule to allow a facility to make a justification that one of the conditions has been met and thus a 316(b) study is not required.

EPA Response

EPA did not adopt the sample site-specific rule language in the proposed rule. While EPA rejected a purely site-specific approach, EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

The rule does not require a determination of whether an adverse environmental impact is occurring is a preliminary step in implementing 316(b). Please refer to the response to comment 316BEFR.313.001 for more information on EPA's position on minimum impacts at existing facilities.

Role of States and Tribes (alt./equiv. programs)

Successful state 316(b) programs should be continued.

Regulatory Reference: Preamble VI. Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities

C. Site-Specific Based Options Under Consideration

Section 125.96 Will Alternative State Requirements and Methodologies for Determining the Best Technology Available for Minimizing Adverse Environmental Impact Be Recognized? (p.17160)

Notwithstanding any other provisions of this subpart, if a State demonstrates to the Administrator that it has adopted alternative regulatory requirements that will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment that would otherwise be achieved under this subpart, the Administrator shall approve such alternative regulatory requirements.

DOMINION COMMENTS: In the proposed rule, EPA proposes to allow States to continue to use "alternative regulatory requirements" they have adopted, if they can show these requirements are functionally equivalent to the new federal rule - that is, if within each relevant watershed they would result in environmental performance that is comparable to the reductions in impingement mortality and entrainment that would be achieved under EPA's proposed 125.94 (67 Fed. Reg. 17,180 col. 1-2).

EPA's proposal appears to require that a State show that its program achieves the same percentage reductions in entrainment and impingement mortality as EPA's performance standards (60-90% and 80-95% respectively). But a successful State program may have focused on larger-scale effects, such as impacts on fish populations or the aquatic community, and the State may know that its program has successfully protected local aquatic communities but not necessarily be able to demonstrate that, for example, entrainment has been reduced by 60-90 percent. EPA should allow States to retain proven successful programs without having to force-fit them into EPA's new performance standards.

Many States have incorporated 316(b) into their water permit programs by adopting the federal 316(b) language and then writing regulations or guidance that references EPA's 1977 draft 316(b) guidance. If a State has complied with its administrative laws and procedure in developing and implementing its 316(b) program, the program should be eligible for consideration as functionally equivalent to proposed 125.94.

Option 3--Site-specific determination

Site specific determination of Best Technology Available is preferred.

Regulatory Reference: Preamble VI. Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities

A. What Is the Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities?

4. Site-Specific Determination of Best Technology Available (p. 17145)

Under today's proposed rule, the owner or operator of an Phase II existing facility may demonstrate to the Director that a site-specific determination of best technology available is appropriate for the cooling water intake structures at that facility if the owner or operator can meet one of the two cost tests specified under. 125.94(c)(1).

DOMINION COMMENTS: Dominion strongly supports EPA's recognition that a site-specific alternative approach is needed to establish intake requirements at sites where the costs of intake technologies are excessive, or where meeting the performance standards with the technologies is not practicable.

The process of designing impingement and entrainment monitoring programs and selecting impact assessment methodologies is inherently site-specific. Site-specific factors are very important in determining the best approach to minimize adverse CWIS effects. Technologies that work at one location are frequently found not to work at another. The only way to accurately and appropriately select best technology available is on a site-specific basis. Site-specificity maximizes the ability to achieve the most environmentally effective and cost-effective reductions in adverse environmental impact.

EPA Response

RFC: Incorp. costs/benefits without burden on Dir.

Streamline the workload for evaluating site-specific applications.

Regulatory Reference: Preamble VI. Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities

A. What Is the Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities?

13. Cost Benefit Test (p. 17153)

EPA is also concerned about the potential for members of the public who object to the authority's site-specific determinations to raise challenges that must be resolved in administrative appeals that can be very lengthy and burdensome, followed in some cases by judicial challenges. An ongoing State study of permitting workloads estimates that appeals of NPDES permits issued to major facilities require 40 hours to resolve in a simple case and up to 240 hours for a very complex permit. EPA Region 1 estimates that one year is required to resolve a complex administrative appeal, involving significant amounts of technical and legal resources. Should the permit appeal be followed by a judicial challenge, EPA Region 1 estimates an additional two years or more of significant investment of technical and legal resources in one decision, with additional time and resources needed if the initial judicial decision is appealed. Again, however, EPA notes that these burdens may be small compared to the potential costs of complying with presumptive performance standards. EPA invites comments on ways to incorporate site-specific consideration of costs and benefits without undue burden on the Director. In particular, EPA invites comment on decision factors and criteria for weighing and balancing these factors that could be included in regulation or guidance that would streamline the workload for evaluating site-specific applications and minimize the potential for legal challenges.

B. Other Technology-Based Options Under Consideration

3. The Utility Water Act Group (UWAG) Approach (p. 17162)

The Utility Water Act Group (UWAG), an association of more than 100 individual electric utility companies and three national trade associations of electric utilities, provided EPA with a recommended site-specific regulatory framework, entitled "316(b) Decision Principles for Existing Facilities." UWAG's recommended approach for decision-making under section 316(b) includes the following components:

A definition of Adverse Environmental Impact;

Use of Representative Indicator Species (RIS) for the assessment of adverse environmental impact;

Making decisions under section 316(b) that complement, but do not duplicate, other Federal, state, and local regulatory programs;

Use of de minimis criteria to exempt small cooling water users that pose no appreciable risk of causing adverse environmental impact because only a small amount of cooling water is withdrawn from a water body at a location that does not require special protection;

Determination of adverse environmental impact or its absence using the facility's choice of three methods, either alone or in combination: (1) Use of previously conducted section 316(b) demonstrations that are still valid in light of current circumstances; (2) use of ecological risk assessment by means of demonstration of no appreciable risk of adverse environmental impact using conservative decision criteria; or (3) assessment of risk using a structured decision making process consistent with EPA's Ecological Risk Assessment Guidelines;

A maximize net benefits approach for selecting the best technology available for minimizing adverse environmental impact;

At the option of the permittee, recognition of voluntary enhancements such as fish stocking or habitat improvements; and

Providing data or information with NPDES permit renewal applications if new information shows that previously conducted section 316(b) demonstrations are no longer scientifically valid.

DOMINION COMMENTS: Dominion supports UWAG's 316(b) Decision Principles, because it will provide technical, legal and policy tools that will ultimately streamline the workload for evaluating site-specific applications.

EPA is concerned that site-specific decisions on environmental impact will require burdensome time and effort by permitting agencies and therefore proposes to simplify the 316(b) decision process by setting a numerical criterion. However EPA's criterion merely prescribes a reduction in the number of individual animals lost and thus fails to address the complexities of aquatic communities.

Without question, State and federal regulators face resource constraints. EPA's proposal makes the goal (60-90% reduction, for example) more numerically precise, to be sure. But proving that the goal is met will require permit writers to consider the effects of the same site-specific factors that have always been considered. Most of the burden of implementing a site-specific approach, conducted in accordance with a clear and consistent decision-making process like that described in UWAG's 316(b) Decision Principles, would fall on regulated facilities, not regulators. Dominion is prepared to perform studies reasonably necessary to allow scientifically and environmentally sound 316(b) decisions. A streamlined process will provide the technical, legal, and policy tools for decision-making that were lacking in the past and as a result minimize the burden on EPA and states.

EPA Response

EPA did not adopt the UWAG’s 316(b) Decision Principles for Existing Facilities or the other similar site-specific approaches considered in the proposed rule. EPA believes that each of these site-specific options would have resulted in higher administrative burdens being imposed on applicants and permit writers relative to the final rule. See section VII of the preamble to the final rule for discussion on why EPA is not adopting these site-specific alternatives.

EPA agrees aquatic communities are complex. See Comment ID 316EFR.025.018 for additional information. EPA has determined that reducing impacts by cooling water intake structures by reducing the numbers of organisms impinged and entrained is appropriate. These reductions will reduce stress on fish populations which EPA believes is the intention of section 316(b). See preamble today's rule for a discussion regarding why EPA chose impingement and entrainment. This approach provides certainty about permitting requirements and streamlines, and thus speeds, the issuance of permits. Focusing this rule’s performance standards on reducing impingement mortality and entrainment is also consistent with NPDES programmatic goals.

Subject Matter Code 18.01.01
UWAG definition of "adverse environmental impact"

EPA should adequately define adverse environmental impact.

Regulatory Reference: Preamble VI. Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities

C. Site-Specific Based Options Under Consideration

5. Discussion of Site-Specific Approach Issues and Associated Questions for Comment

a. Determination of Adverse Environmental Impact

(3) Discussion of UWAG Recommendation for Determining Adverse Environmental Impact

(p. 17163)

UWAG offers the following definition: Adverse environmental impact is a reduction in one or more representative indicator species (RIS) 61 that (1) creates an unacceptable risk to a population's ability to sustain itself, to support reasonably anticipated commercial or recreational harvests, or to perform its normal ecological function and (2) is attributable to operation of the cooling water intake structure.

DOMINION COMMENTS: Section 316(b) cannot be implemented effectively unless there is a definition of "adverse environmental impact." "Adverse environmental impact" cannot mean harm to a single fish or a single egg; it must mean harm at the population or community level. Dominion supports UWAG's recommended definition of adverse environmental impact: Adverse environmental impact is a reduction in one or more representative indicator species that (1) creates an unacceptable risk to the population's ability to sustain itself, to support reasonably anticipated commercial or recreational harvests, or to perform its normal ecological function and (2) this negative impact is attributable to the operation of the cooling water intake structure.

At many electric generating facilities, there is already a high degree of confidence that the facility is not creating adverse environmental impact or has already installed BTA. Examples would include (1) where a facility already has performed a 316(b) demonstration before the new 316(b) rule is promulgated and has shown to the satisfaction of its regulatory agency that the facility complies with 316(b), or (2) where operating experience and knowledge of the local fishery provide regulatory authorities with confidence that fish populations are not being harmed by impingement and/or entrainment.

The statute calls for minimizing environmental impact, not eliminating entrainment and impingement mortality, so technologies should be evaluated accordingly. Fisheries should be viewed as a resource that can be managed and sustained. EPA should recognize that some losses of individual fish are not harmful to the fishery resource as a whole and that there is no reason to view losses caused by cooling water intake structures as fundamentally different from losses caused by any other human activity or natural occurrence. Great losses occur as a result of commercial fishing industry, and a rebound of striped bass populations has been witnessed upon initiation of a fishing moratorium.

EPA's 316(b) rule should use the lessons of fisheries management science. If the impact of a facility's CWIS is in the range of impacts known by fisheries managers to be within normal variation or not of concern to the viability of the fishery, the facility is not creating adverse environmental impact

EPA Response

Please see the response to comment 316bEFR.002.019 for the discussion on the definitions EPA rejected for adverse environmental impact in this rulemaking.

Subject Matter Code 18.01

RFC: Definition of "adverse environmental impact"

EPA should define the term minimal as it pertains to entrainment and impingement losses and adverse environmental impact.

Regulatory Reference: Preamble V. Environmental Impacts Associated With Cooling Water Intake Structures

A. Facility Examples (p. 17137)

In some cases, the number of organisms impinged and entrained by a facility can be substantial and in other examples impingement and entrainment may be minimal due to historical impacts from anthropogenic activities such as stream or river channelization.

A. Facility Examples (p. 17138)

At this facility, fish impingement and entrainment by cooling water intakes were found to be minimal.

VI. Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities

C. Site-Specific Based Options Under Consideration

13. Cost Benefit Test (p. 17153)

EPA notes that at some sites, impingement and entrainment losses are minimal.

DOMINION COMMENTS: Dominion proposes that the rule include a definition for the term "minimal" since the term is often used in discussions of environmental impacts, entrainment and impingement losses (mortality) and adverse environmental impact (this is consistent with the previous comment - EPA should adequately define adverse environmental impact).

Minimal = SMALL = Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource, i.e. population structure.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

Comment ID 316bEFR.040.010

Permit applications/implementation schedule

The rule should be implemented through permit requirements.

Regulatory Reference: Preamble VII. Implementation

B. What Information Must I Submit to the Director When I Apply for My Reissued NPDES Permit?

4. Comprehensive Demonstration Study

a. Proposal for Information Collection (p.17175)

The proposed rule does not specify particular timing requirements for your information collection proposal, but does require review and approval of the proposal by the Director. In general, EPA expects that it would be submitted well in advance of the other permit application materials, so that if the Director determined that additional information was needed to support the application, the facility would have time to collect this information, including additional monitoring as appropriate.

DOMINION COMMENTS: The permittee, as part of its permit application package, should be allowed to propose a schedule for developing the data collection plan, to get the plan approved by the state's permitting authority, to collect and analyze the data, to use the data to assess technologies, and to prepare the BTA recommendation. After being reviewed and approved by the state's permitting agency, this process would be written as a permit condition.

Once the data are collected and the BTA selection has been made, the permit would be modified. The 316(b) rule should make it clear that reasonable time for state agency review must be built into any schedule either prescribed by the rule itself or required by an NPDES permit condition

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066.

Comment ID 316bEFR.040.011

Subject Matter Code 21.09

Permit applications/implementation schedule

Author Name Joyce Livingstone

Organization Dominion Environmental

Reasonable compliance schedules are necessary.

Regulatory Reference: Preamble VII. Implementation

C. How Would the Director Determine the Appropriate Cooling Water Intake Structure Requirements? (p. 17178)

If the Director determines that the Comprehensive Demonstration Study submitted does not demonstrate that the technologies, operational measures, and supplemental restoration measures employed would achieve compliance with the applicable performance standards, the Director may issue a permit requiring such compliance. If such studies are approved and a permit is issued but the Director later determines, based on the results of subsequent monitoring, that the technologies, operational measures, and supplemental restoration measures did not meet the rule standards, the Director could require the existing facility to implement additional technologies and operational measures as necessary to meet the rule requirements. In general, this would occur at the next renewal of the permit. The Director would also review the facility's Technology Verification Plan for post-operational monitoring to demonstrate that the technologies are performing as predicted.

DOMINION COMMENTS: If EPA were to make the new 316(b) rule immediately applicable, it would lead to even more delay in the NPDES permitting process than currently exists. The available consultants skilled in biological monitoring and intake technology design undoubtedly would be overwhelmed with work and would have to put many licensees on waiting lists. Negotiations over consent orders might bog down the permit process in some States, and the backlog of unprocessed NPDES permit applications would grow worse. Reasonable compliance schedules are a matter of administrative necessity as well as of fairness to state regulators and permittees.

The permittee, as part of its permit application package, should be allowed to propose a schedule for developing the data collection plan, to get the plan approved by the state's permitting authority, to collect and analyze the data, to use the data to assess technologies, and to prepare the BTA recommendation. After being reviewed and approved by the state's permitting agency, this process would be written as a permit condition.

EPA Response

For several reasons, including those identified in this and other comments, EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066. In today's final rule, EPA has provided tremendous flexibility to facilities and Directors by offering five compliance alternatives, including a site-specific determination of BTA, which will assist in offsetting any permit backlog issues.

Comment ID 316bEFR.040.012

Author Name Joyce Livingstone
Organization Dominion Environmental

Subject Matter Code 21.09
Permit applications/implementation schedule

Permits should have technology upset and bypass provisions.

Regulatory Reference: Preamble VII. Implementation

E. How Would Compliance Be Determined? (p. 17180)

This proposed rule would be implemented by the Director placing conditions consistent with this proposed rule in NPDES permits. To demonstrate compliance, the proposed rule would require that the following information be submitted to the Director:

Data submitted with the NPDES permit application to show that the facility is in compliance with location, design, construction, and capacity requirements;

Compliance monitoring data and records as prescribed by the Director. Proposed 125.97 would require existing facilities to keep records and report compliance monitoring data in a yearly status report. In addition, Directors may perform their own compliance inspections as deemed appropriate (see CFR 122.41).

DOMINION COMMENTS: The permit should have a provision analogous to EPA's upset and bypass provisions in the NPDES permit regulations to allow an intake technology to be temporarily bypassed if necessary for plant operation. For example, if the screens are fouled so as to jeopardize plant operation, the permittee should be allowed to bypass them until they can be cleared. Similarly, if because of emergency conditions water levels in a reservoir are reduced to the point where technologies are inoperative, bypassing to allow continued operation should be allowed. Such exceptional bypasses should be allowed only for short periods of time, until the emergency has passed and the permittee has had time to restore the intake technology to proper operation. As for any exceptional event, the permittee would be required to report the circumstances of the upset or bypass to the state permitting authority in a timely manner.

EPA Response

Subject Matter Code 21.09

Permit applications/implementation schedule

Permits should be grandfathered if they are due to expire very near the application deadline.

Regulatory Reference: Preamble VII. Implementation

A. When Does the Proposed Rule Become Effective? (p. 17173)

Phase II existing facilities subject to today's proposed rule would need to comply with the Subpart J requirements when an NPDES permit containing requirements consistent with Subpart J is issued to the facility. See proposed 125.92. Under existing NPDES program regulations, this would occur when an existing NPDES permit is reissued or, when an existing permit is modified or revoked and reissued.

DOMINION COMMENTS: For a facility whose permit renewal application is undergoing agency review when the 316(b) rule becomes effective, the permittee should not have to resubmit its application. In such a case, the subsequent permit renewal process should trigger the permittee's compliance with the new rule requirements.

Similarly, if the new rule becomes effective when a permittee is very near the time when its renewal application is due (for example, between 365 and 180 days before the permit expires), it would be almost as unreasonable to require the permittee to adjust its application process in midstream. The practical difficulties in preparing a permit application, especially if biological monitoring is needed, suggest that the new rule should not apply until the succeeding permit term, to any permittee that has one year or less until its permit expires when the rule takes effect.

EPA Response

Subject Matter Code 11.01
RFC: Proposed use of restoration measures

Restoration measures could be employed in lieu of, or in combination with other measures.

Regulatory Reference: Subpart J Requirements Applicable to Cooling Water Intake Structures for "Phase II Existing Facilities" Under Section 316(b) of the Act

125.94 How will requirements reflecting best technology available for minimizing adverse environmental impact be established for my Phase II existing facility?

(d) Restoration Measures. (p. 17221-17222)

In lieu of, or in combination with, reducing impingement mortality and entrainment by implementing design and construction technologies or operational measures to comply with the performance standards specified in paragraph (b) of this section or the Director's determination pursuant to paragraph (c) of this section, you may, with the Director's approval, employ restoration measures that will result in increases in fish and shellfish in the watershed. You must demonstrate to the Director that you are maintaining the fish and shellfish within the waterbody, including community structure and function, to a level comparable to those that would result if you were to employ design and construction technologies or operational measures to meet that portion of the requirements of paragraphs (b) or (c) of this section that you are meeting through restoration. Your demonstration must address species that the Director, in consultation with Federal, State, and Tribal fish and wildlife management agencies with responsibility for fisheries and wildlife potentially affected by your cooling water intake structure, identifies as species of concern.

DOMINION COMMENTS: Dominion supports allowing permittees, on a voluntary basis, to employ restoration measures in lieu of, or in combination with other technologies or operational measures that will result in increases in fish and shellfish species of concern in the watershed. We support the idea of providing improvements to populations using proven technologies and/or strategies, if they are warranted.

EPA Response

For a discussion of the use of restoration measures in lieu of design and construction technologies and operational measures, see EPA's response to comment 316bEFR.041.209.

For a discussion of the extent to which restoration measures are voluntary, see EPA's response to comment 316bEFR.060.022.

Subject Matter Code 11.03

RFC: Appropriate spatial scale for restoration

Regulatory Reference: Preamble VI. Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities

A. What Is the Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities?

5. What Is the Role of Restoration Under Today's Preferred Option? (p. 17146)

EPA also seeks comment on the most appropriate spatial scale under which restoration efforts should be allowed should restoration measures be limited to the waterbody at which a facility's intakes are sited, or should they be implemented on a broader scale, such as at the watershed or State boundary level.

DOMINION COMMENTS: Dominion supports expanded state-wide and even interstate watershed spatial boundaries for restoration projects. This approach appropriately provides the flexibility to locate a restoration project in an area that may provide greater overall environmental benefit and/or enhance an ecosystem that may benefit more than the area in the near proximity of a facility's intakes.

EPA Response

No provision in the final rule prevents implementation of restoration measures in a state other than the one in which a cooling water intake structure is located so long as the restoration measures meet all requirements as described in the final rule. For a discussion of the appropriate scale on which to conduct restoration measures, see EPA's response to comment 316bEFR.212.001.

Subject Matter Code 11.07

RFC: Restoration above BTA level

Regulatory Reference: Preamble VI. Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities

A. What Is the Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities?

5. What Is the Role of Restoration Under Today's Preferred Option? (p. 17147)

EPA recognizes that substantial information exists regarding wetlands mitigation and restoration. For example, tools and procedures exist to assess wetlands in the context of section 404 of the Clean Water Act. However, restoration of other aquatic systems such as estuaries is complex and continues to evolve. EPA seeks comment on how it may measure the success or failure of restoration activities given the high degree of uncertainty associated with many areas of this developing science and that many of these activities do not produce measurable results for many months or years after they are implemented. For these reasons, EPA requests comment on whether to require that a facility using restoration measures restore more fish and shellfish than the number subjected to impingement mortality or entrainment. EPA believes that restoring or mitigating above the level that reflects best technology available for minimizing adverse environmental impact (e.g., restocking higher numbers of fish than those impinged or entrained by facility intakes or restoring aquatic system acreages at ratios greater than one-to-one) would help build a margin of safety, particularly when the uncertainties associated with a particular restoration activity are known to be high.

The concept of compensatory mitigation ratios being greater than one-to-one is found in other programs. For example, under the CWA section 404 program no set mitigation ratio exists, however, current policies require no net loss of aquatic resources on a programmatic basis. The permitting authority often requires permit applicants to provide more than one-to-one mitigation on an acreage basis to address the time lapse between when the permitted destruction of wetlands takes place and when the newly restored or created wetlands are in place and ecologically functioning. The permit may also require more than one-to-one replacement to reflect the fact that mitigation is often only partially successful. Alternatively, in circumstances where there is a high confidence that the mitigation will be ecologically successful, the restoration/ creation has already been completed prior to permitted impacts, or when the replacement wetlands will be of greater ecological value than those they are replacing, the permitting authority may require less than one-to-one replacement.

DOMINION COMMENTS: Dominion does not support a requirement to restore populations above the level of BTA. However, a facility should receive credit if the restoration effort achieves this status during the verification monitoring period and should become eligible to negotiate for reduced monitoring.

EPA Response

For a discussion of the roles and responsibilities of the permitting authority in determining the appropriate level of performance to satisfy the requirements of the final rule, see EPA's responses to comments 316bEFR.060.026 and 316bEFR.212.001.

Organization Dominion Environmental

Subject Matter Code 21.05
Role of States and Tribes (alt./equiv. programs)

Approval authority should remain with the state permitting agencies.

Regulatory Reference: Preamble VI. Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities

A. What Is the Best Technology Available for Minimizing Adverse Environmental Impact at Phase II Existing Facilities?

11. State or Tribal Alternative Requirements That Achieve Comparable Environmental Performance to the Regulatory Standards Within a Watershed (p.17151-17152)

In 125.90, today's proposal includes an alternative where an authorized State or Tribe may choose to demonstrate to the Administrator that it has adopted alternative regulatory requirements that will result in environmental performance within a watershed that is comparable to the reductions in impingement mortality and entrainment that would otherwise be achieved under 125.94. If a State or Tribe can successfully make this demonstration, the Administrator is to approve the State or Tribe's alternative regulatory requirements. EPA is proposing that such alternative requirements achieve comparable performance at the watershed level, rather than at larger geographic scales or at the individual facility-level, to allow States and Tribes greater flexibility and, potentially, greater efficiency in efforts to prevent or compensate for impingement mortality and entrainment losses, while still coordinating those efforts within defined ecological boundaries where the increased impacts are directly offset by controls or restoration efforts. Requiring performance level assessment to take place at the watershed level ensures that facility mitigation efforts take the overall health of the waterbody in the target watershed into account. The Agency requests comment on all aspects of this approach, including the appropriate definition of watershed.

EPA also recognizes that States sometimes assign higher priority to protecting some waters over others. This may be due to the exceptional environmental, historic, or cultural value of some waters, or conversely to a concern with multiple stresses already occurring in a watershed. It could also be based on the presence of individual species of particular commercial, recreational, or ecological importance. For these reasons, States with alternative requirements might choose to provide more protection that would be achieved under 125.94 in some watersheds and less protection in others. Under current language in proposed 125.90, States could not use such an approach because they would not be able to demonstrate comparable environmental performance within each watershed. EPA requests comment on whether it should instead allow States to demonstrate comparable environmental performance at the State level, thus allowing States the flexibility to focus protection on priority watersheds. The standard provided in proposed 125.90 for evaluating alternate State requirements is "environmental performance that is comparable to the reductions that would otherwise be achieved under 125.94." EPA recognizes that it may not always be possible to determine precisely the reductions in impingement and entrainment associated with either 125.94 or the alternate State requirements, particularly at the watershed level or State-wide. Furthermore, alternate State requirements may provide additional environmental benefits, beyond impingement and entrainment reductions, that the State may wish to factor into its comparability demonstration. However, in making this demonstration, the State should make a reasonable effort to estimate impingement and entrainment reductions that would occur under 125.94 and under its alternate requirements, and should clearly identify any other environmental benefits it is taking into account and explain how their comparability to impingement and entrainment reduction under 125.94 is being evaluated. EPA invites comment on the most appropriate scale at which to define a watershed to reflect the variability of the nature of the ecosystems impacted by cooling water intake structures within a State or Tribal area and on methods for ensuring ecological comparability within watershed-level assessments. EPA also invites comment on whether defined watershed boundaries for the purpose of section 316(b) programs should lie entirely within the political boundaries of a Tribe or State unless adjoining States and/or Tribes jointly propose to establish alternative regulatory requirements for shared watersheds.

DOMINION COMMENTS: Dominion supports giving state agencies the flexibility to focus their protection effort on priority watersheds. States also should be allowed to demonstrate overall comparable environmental performance at the State level instead of at the watershed level.

Streamlined decision-making is inextricably linked with preserving state authority. Where a state has already made a careful determination of the best technology available for a particular intake, a change in the state's decision is warranted only if there has been a significant change in circumstance since the determination was made.

EPA Response

Please see response to comment 316bEFR.025.017 for a discussion of State program approval rationale and response to comment 316bEFR.040.001 for a discussion on the use of historical BTA determinations.

EPA believes that the watershed level is a manageable unit of study; the watershed level was selected to ensure protection of ecological resources within a hydrologic unit and for consistency with NPDES permitting efforts that place controls at the watershed level. EPA believes that measuring at a State level may not accurately reflect impingement and entrainment impacts since a State is a much larger unit of measurement. A State or Tribal section 316(b) regulatory program should also consider reductions in impingement mortality and entrainment at the relevant watershed level.

Performance standards

EPA should clarify the definition of calculation baseline.

Regulatory Reference: Subpart J Requirements Applicable to Cooling Water Intake Structures for "Phase II Existing Facilities" Under Section 316(b) of the Act

125.93 What special definitions apply to this subpart? (p. 17220)

Calculation baseline means an estimate of impingement mortality and entrainment that would occur at your site assuming you had a shoreline cooling water intake structure with an intake capacity commensurate with a once-through cooling water system and with no impingement and/or entrainment reduction controls.

DOMINION COMMENTS: EPA should clarify the definition of calculation baseline by assuming that the baseline plant is equipped with standard 3/8-inch mesh screens and the hypothetical baseline intake has the similar cooling water requirements as the actual facility.

EPA Response

Please see response to comment 316bEFR.063.022.

The methods of measuring the calculation baseline should be redefined.

Regulatory Reference: Preamble VII. Implementation

B. What Information Must I Submit to the Director When I Apply for My Reissued NPDES Permit?

4. Comprehensive Demonstration Study

(d) Design and Construction Technology Plan (p. 17176)

Reductions in impingement mortality and entrainment from this calculation baseline as a result of any design and construction technologies already implemented at your facility would be added to the reductions expected to be achieved by any additional design and construction technologies that would be implemented in order to determine compliance with the performance standards. Facilities that recirculate a portion of their flow may take into account the reduction in impingement mortality and entrainment associated with the reduction in flow when determining the net reduction associated with existing technology and operational measures. This estimate must include a site-specific evaluation of the suitability of the technology(ies) based on the species that are found at the site, and/or operational measures and may be determined based on representative studies (i.e., studies that have been conducted at cooling water intake structures located in the same waterbody type with similar biological characteristics) and/or site-specific technology prototype studies. If your facility already has some existing impingement mortality and entrainment controls, you would need to estimate the calculation baseline. This calculation baseline could be estimated by evaluating existing data from a facility nearby without impingement and/or entrainment control technology (if relevant) or by evaluating the abundance of organisms in the source waterbody in the vicinity of the intake structure that may be susceptible to impingement and/or entrainment.

DOMINION COMMENTS: The preamble to the proposed rule says that the calculation baseline could be estimated by evaluating existing data from a nearby facility. This method should be written into the rule itself with some clarification. The representative facility need not necessarily be "nearby" or even on the same waterbody. A permittee should be able to use fish or larval abundance data from power plant locations similar to its own to estimate how much impingement mortality and entrainment would occur with no reduction controls. Also, a permittee should be allowed to do upstream studies in an area near the intake to predict baseline impingement mortality and entrainment.

EPA Response

For discussions on the basis for and implementation of the calculation baseline, please see response to comments 316bEFR.308.014 and 316bEFR.063.022, as well as the preamble to today's rule.

RFC: Use of previous demonstration studies

316(b) should be a one-time only requirement.

Regulatory Reference: Subpart J-Requirements Applicable to Cooling Water Intake Structures for "Phase II Existing Facilities" Under Section 316(b) of the Act

125.98 As the Director, what must I do to comply with the requirements of this subpart?

Permit Application. (p. 17224)

As the Director, you must review materials submitted by the applicant under 40 CFR 122.21(r) and 125.95 before each permit renewal or reissuance.

(1) After receiving the permit application from the owner or operator of a Phase II existing facility, the Director must determine which of the standards specified in 125.94 to apply to the facility. In addition, the Director must review materials to determinecompliance with the applicable standards.

(2) At each permit renewal, the Director must review the application materials and monitoring data to determine whether requirements, or additional requirements, for design and construction technologies or operational measures should be included in the permit.

DOMINION COMMENTS: Once best technology available is determined for a plant, installing and operating that technology ought to relieve the plant of further 316(b) obligations unless or until the plant is significantly modified. The location, design, construction, and capacity of the cooling water intake structures are matters of design and construction, not operation. Congress could not have intended that power plants be in the business of redesigning, demolishing, and reconstructing their physical plant every five or ten years. The most appropriate way to apply 316(b) would a one-time review designed to achieve minimal adverse environmental impact at a reasonable cost.

EPA's proposed rule suggests a comprehensive reevaluatio of the 316(b) demonstration every time a permit is renewed. Once a successful 316(b) demonstration is made, maintaining and operating the technology for the life of the plant should be sufficient. Dominion suggests that 125.98(a)(2) be changed as follows: "Unless there have been significant changes in plant operations or adverse changes to the aquatic population, after a successful demonstration of compliance with EPA's performance standards, at each subsequent permit renewal the permit writer should accept the initial demonstration."

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to 316bEFR 041.126 for a discussion.

Monitoring requirements

Compliance monitoring should verify BTA efficiency.

Regulatory Reference: Preamble VII. Implementation

D. What Would I Be Required To Monitor? (p. 17179)

Proposed 125.96 provides that Phase II existing facilities would have to perform monitoring to demonstrate compliance with the requirements of 125.94 as prescribed by the Director. In establishing such monitoring requirements, the Director should consider the need for biological monitoring data, including impingement and entrainment sampling data sufficient to assess the presence, abundance, life stages, and mortality (including eggs, larvae, juveniles, and adults) of aquatic organisms (fish and shellfish) impinged or entrained during operation of the cooling water intake structure. These data could be used by the Director in developing permit conditions to determine whether requirements, or additional requirements, for design and construction technologies or operational measures should be included in the permit. The Director should ensure, where appropriate, that any required sampling would allow for the detection of any annual, seasonal, and diel variations in the species and numbers of individuals that are impinged or entrained. The Director should also consider if a reduced frequency in biological monitoring may be justified over time if the supporting data show that the technologies are consistently performing as projected under all operating and environmental conditions and less frequent monitoring would still allow for the detection of any future performance fluctuations. The Director should further consider whether weekly visual or remote or similar inspections should be required to ensure that any technologies that have been implemented to reduce impingement mortality or entrainment are being maintained and operated in a manner that ensures that they function as designed. Monitoring requirements could be imposed on Phase II existing facilities that have been deemed to meet the performance standard in 125.94(b)(1) to the extent consistent with the provisions of the NPDES program.

DOMINION COMMENTS: Dominion recommends that after a verification monitoring period, the data should be analyzed to determine whether the newly installed technology is indeed achieving the projected 80-95% reduction in impingement mortality and 60-90% reduction in entrainment. As long as the data shows performance within these ranges, the technology should be deemed to comply with the rule. Assuming the data showed performance within the ranges given, then biological monitoring requirements should be significantly reduced. Thereafter, the permittee should be required only to monitor and document that it continues to operate and maintain the technology.

On the other hand, if the initial monitoring showed that the technology was not meeting the performance standards, then a period of additional study should be provided to determine why projected reduction targets are not being met and what should be done to fix it. Once the permittee had demonstrated that the technology performed within the performance standard ranges, it would have only to maintain and operate the same technology for the life of the plant and would not have to make repeated demonstrations. This is a reasonable proposal, given that 316(b) is a construction-oriented requirement and that fish populations are highly variable and subject to many stresses other than cooling water intakes.

EPA Response

Monitoring requirements

Two years of verification monitoring could be shortened.

Regulatory Reference: Subpart J Requirements Applicable to Cooling Water Intake Structures for "Phase II Existing Facilities" Under Section 316(b) of the Act

125.95 As an owner or operator of a Phase II existing facility, what must I collect and submit when I apply for my reissued NPDES permit?

(b) Comprehensive Demonstration Study

(7) Verification Monitoring Plan. (p. 17178)

You must include in the Study a plan to conduct, at a minimum, two years of monitoring to verify the full-scale performance of the proposed or implemented technologies, operational measures, or restoration measures. The verification study must begin once the technologies, operational measures, and restoration measures are implemented and continue for a period of time that is sufficient to demonstrate that the facility is reducing the level of impingement and entrainment to the levels documented pursuant to paragraphs (b)(4)(iii), (b)(5)(ii), and/or (b)(6)(iii)(B) of this section. The plan must describe the frequency of monitoring and the parameters to be monitored and the basis for determining the parameters and the frequency and duration for monitoring. The plan must also describe the information to be included in a yearly status report to the Director. The Director will use the verification monitoring to confirm that you are meeting the applicable requirements of 125.94.

DOMINION COMMENTS: A two-year period of verification monitoring is excessive and unnecessary. If a plant had already collected abundant data and no change to the plant was required by the new rule, then this period should be shortened to a maximum of one year or waived.

RFC: Definition of "adverse environmental impact"

Author Name Joyce Livingstone

Organization Dominion Environmental

Dominion suggests assigning a three-level standard of significance to the definition of adverse environmental impact - SMALL, MODERATE or LARGE - used by the Nuclear Regulatory Commission to evaluate environmental issues and developed using the Council on Environmental Quality guidelines.

SMALL - Environmental effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource, i.e. population structure.

MODERATE - Environmental effects are sufficient to alter noticeably, but not to destabilize, important attributes of the resource.

LARGE - Environmental effects are clearly noticeable and are sufficient to destabilize important attributes of the resource.

If a facility had determined that impingement or entrainment losses are SMALL or MODERATE, the facility should be eligible for a site-specific determination of best available technology independent of whether either of the cost tests for site-specific determination have been met.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule. In addition, EPA does not believe it is necessary to redefine the terms "small", "moderate", or "large" to relate to environmental impact.

Subject Matter Code SUP

General statement of support

EPA's proposed rule for applying § 316(b) of the Clean Water Act to "existing" facilities is based on two "performance standards," which EPA says reflect the reduction in impingement mortality and entrainment achievable by certain intake technologies (wedgewire screens, fine mesh screens, fish returns, and aquatic fabric filter barriers) that EPA considers the "best technology available" (BTA). Where they apply, these performance standards call for reducing impingement mortality by 80-95% and reducing entrainment by 60-90% in comparison to a "baseline."

This proposed rule has some merit. For one thing, it recognizes that the technologies EPA has identified can be effective in reducing impingement mortality and entrainment but that no single technology will be the "best available" in all cases. In this conclusion, EPA is correct; the technologies named above may meet EPA's performance standards at some sites, though not all.

EPA Response

EPA notes the comment. No response necessary.

Subject Matter Code OPP

General Statement of Opposition

There are, however, at least four problems with the proposed rule. First, it does not go far enough to accommodate site-specific features and local species that must be considered in § 316(b) decisions. Second, although the rule needs a provision allowing for relief from the performance standards where the cost of complying would be excessive, EPA's test of having the costs be "significantly greater" than benefits or than the costs EPA considered has no basis in the discipline of economics. Third, EPA has overestimated the "benefits" of all the regulatory alternatives it considered. Fourth, the numerical performance standards themselves, if made into enforceable requirements in NPDES permits, may create uncertainty and unfairness as operators try continually to prove percentage reductions in impingement mortality and entrainment in the face of natural fluctuations in fish populations.

Moreover, the rule still lacks a definition of the statutory term "adverse environmental impact." It is the lack of such a definition, which should focus on population-level impacts, that has led EPA to assume, by implication, that any impingement mortality and any entrainment is adverse.

Despite these shortcomings, the proposed rule will be workable if the alternative for a site-specific analysis in case of excessive costs is sensibly crafted and certain refinements are made. EPA proposes to allow a site-specific analysis of best technology available if the costs of meeting the performance standards are "significantly greater than" either the benefits of complying or the costs that EPA considered. There is no rational basis for this test in the economic literature, and the alternative "wholly disproportionate" test is even worse.

UWAG proposes in these comments that the correct test of what technology is BTA for a site is the technology that maximizes "net benefits" (that is, benefits minus costs). This is the only standard that is supported by economic theory. However, if EPA retains the numerical performance standards with a site-specific exception for excessive costs, the exception might be triggered (and a site-specific analysis allowed) when the cost of installing and operating the technology exceeds the benefit (all discounted to present value) by any amount. In this way, no additional technology would be required if it would make society worse off overall – if, that is, the incremental cost of the technology exceeded the benefits.

EPA Response

Comment ID 316bEFR.041.003

Author Name Hunton & Williams

Organization obo Utility Water Act Group

Subject Matter Code OPP

General Statement of Opposition

UWAG continues to believe that its own "Decision Principles" (Appendix 1) are the best way to implement § 316(b). The UWAG Decision Principles provide several conservative rules of thumb for determining quickly, where they apply, that a facility's intake does not adversely impact the aquatic environment. Where these simple rules are not enough, the UWAG Decision Principles propose a more detailed decision process based on EPA's Ecological Risk Assessment Guidelines.

However, in case EPA insists on retaining its performance standards, UWAG also suggests in these comments ways in which the proposed performance standards should be improved, mostly by adding alternatives to EPA's proposal. One of UWAG's recommendations would allow a permittee to install the most cost-effective of EPA's approved intake technologies (wedgewire screens, fine mesh screens, an aquatic fabric filter system, or a traveling screen with fish return system). After installing the technology, the permittee would have to monitor only the proper installation, operation, and maintenance of the technology rather than percentage reductions in fish impinged or entrained.

UWAG also recommends modifying EPA's proposal to encourage States to continue successful State programs and to take advantage of knowledge already collected about facilities. Where a facility already has made a successful § 316(b) demonstration based on sound scientific and technical information and nothing important has changed, or where experience at a facility shows that impingement mortality and entrainment are small and regulatory authorities or resource agencies have accumulated enough knowledge about the waterbody to be confident that entrainment and impingement are not causing an adverse impact, EPA should allow (even encourage) them to rely on this knowledge.

Finally, these comments show that EPA is correct not to designate wet cooling towers (let alone dry cooling) as "best technology available," since (1) the cost of such a requirement would be enormous – greater even than EPA estimates – and (2) EPA has no authority to require cooling towers, because they are not "cooling water intake structures" (CWISs).

In a nutshell, UWAG is recommending in these comments one of two alternatives. The preferred approach is a site-specific one along the lines of UWAG's Decision Principles (or the PSEG alternative). The second-best solution consists of several additions to EPA's proposal along the following lines:

Two Alternatives

Available I&E technologies

EPA'S PROPOSAL WOULD REQUIRE PERCENTAGE REDUCTIONS IN IMPINGEMENT MORTALITY AND, AT MANY SITES, ENTRAINMENT, COMPARED TO A "BASELINE"

In the preamble to the proposal, EPA says that it considered several options for site-specific implementation of § 316(b), including a proposal by UWAG, but rejected them for a more technology-based approach with specific performance standards based on two factors: plant flow and source waterbody type. 67 Fed. Reg. 17,159 col. 1. At the same time, EPA rejected – correctly, in UWAG's view – alternatives that would have required some or all existing facilities to install closed-cycle cooling systems (that is, cooling towers or impoundments). 67 Fed. Reg. 17,155 col. 1, 2.

Under EPA's proposal, the performance standards can be met by either (1) cooling towers (or ponds or similar methods of recirculation) (see 67 Fed. Reg. 17,130) or (2) 80-95% reduction in impingement mortality and, for many plants, 60-90% reduction in entrainment. The only plants that would not have the entrainment requirement would be facilities on lakes (other than the Great Lakes), facilities withdrawing 5% or less of the mean annual flow of a freshwater river or stream, and facilities with a capacity utilization rate less than 15%.

EPA bases its impingement mortality standard (80-95% reduction) on four technologies: (1) fine and wide mesh wedgewire screens; (2) aquatic filter barrier systems (sometimes called by the trade name "Gunderboom"); (3) barrier nets; and (4) modified screens and fish return systems, fish diversion systems, and fine mesh traveling screens and fish return systems. 67 Fed. Reg. 17,142 col. 1. EPA bases its entrainment standard (60-90% reduction) on three technologies: (1) aquatic filter barrier systems, (2) fine mesh wedgewire screens, and (3) fine mesh traveling screens. Id. Selecting an appropriate technology or technologies for a given site would be site-specific and involve comparing the proposed technology to a "calculation baseline" reflecting the amount of impingement and entrainment that would occur if the facility had a shoreline intake and no impingement or entrainment reduction controls.

EPA's proposal allows permittees to use restoration measures (for example, creating or restoring a wetland or operating a fish hatchery) instead of, or along with, intake technologies if they can show that restoration measures will maintain fish and shellfish in the waterbody, including community structure and function, at a level of protection comparable to what could be met by intake technologies. 67 Fed. Reg. 17,146-48, proposed § 125.94(d), 67 Fed. Reg. 17,221-22, § 125.95(b)(5), 67 Fed. Reg. 17,223 col. 3. EPA's proposal also allows the permittee to obtain an alternative site-specific performance standard if he can demonstrate that the cost of compliance with the performance standards would be "significantly greater" than either the costs EPA considered or the benefits. EPA also proposes to allow alternative requirements where the Nuclear Regulatory Commission (NRC) determines that compliance with the rule would conflict with NRC-established safety requirements. Proposed § 125.94(f), 67 Fed. Reg. 17,222 col. 1.

Finally, EPA's proposal appears to require substantial engineering and biological studies, first studies to determine "baseline" conditions and select the "best available" technology and then monitoring during the permit term. Proposed § 125.95, 67 Fed. Reg. 17,222 col. 1. The proposed rule also establishes deadlines for permit applications and for achieving compliance with the rule.

With some qualifications, explained below, UWAG supports EPA's endorsement of intake technologies, such as wedgewire screens, fine mesh screens, aquatic filter barriers, and fish diversion or return systems, because EPA appears to recognize the following:

1. There are workable, protective intake technologies that can approach or meet EPA's performance standards at many appropriate sites and are more reasonable than wet cooling towers, dry cooling, or operating restrictions;

2. Performance and effectiveness of these technologies are determined by site-specific factors;

3. At some sites, these technologies can reduce impingement mortality and entrainment within the ranges EPA has identified and (at some subset of those sites) at a cost that is not excessive; and

4. At sites where the costs of these technologies are excessive, or where meeting the performance standards with the technologies is not practicable, an alternative is needed to establish different intake requirements on a site-specific basis. An alternative is offered by EPA's proposed "significantly greater" cost tests, though, as we explain below, the "significantly greater" standard itself has no rational basis in economics.

EPA Response

EPA agrees with the commenter's assessment of the availability and practicability of the many technologies used to minimize adverse environmental impacts associated with cooling water withdrawals. EPA also agrees that the determination of the most appropriate and cost-effective strategy for meeting the requirements of today's rule is best achieved on a facility-specific basis and has maintained this flexibility in today's final rule. EPA notes that today's rule also includes a site-specific alternative for meeting the requirements of today's rule based on cost-cost or cost-benefit considerations.

Comprehensive demonstration study (7 parts)

Author Name Hunton & Williams
Organization obo Utility Water Act Group

THE RULE SHOULD CONTAIN A STREAMLINED ALTERNATIVE FOR FACILITIES THAT ALREADY HAVE PROVED THEY ARE NOT HARMING THE AQUATIC COMMUNITY

The rule will be significantly improved if it includes a streamlined process for approving a cooling water intake structure that already has been demonstrated to have the best technology available (BTA) or not to cause adverse environmental impact (AEI). In general, there are two situations where this is true:

1. Where a facility already has performed satisfactory § 316(b) studies in the past and has shown to the satisfaction of its regulatory agency that the facility complies with § 316(b). This would include the case where an existing facility is modernized or largely replaced but the existing intake structure continues to be used, where previous § 316(b) studies have demonstrated that the structure satisfies § 316(b), and where the permittee can show that the modernized facility will have no greater flow or, for other reasons, will have no greater environmental impact than the original facility.

2. Where experience at the facility shows that impingement and entrainment are low and where knowledge of the local fishery gives regulatory authorities confidence that fish populations are not being harmed by impingement and entrainment. This includes cases where the permit writer has enough information to conclude that the cost of additional biological monitoring would not be justified by the benefits that would be gained by further study.

In such cases, the permitting agency should be allowed to conclude, after a fresh review of existing information but without additional monitoring, that no change to the present intake technology is required.

EPA Response

EPA has added several streamlining components to today's final rule. Please see EPA's response to comment 316bEFR.034.005 for details. EPA disagrees, however, that existing best technology available (BTA) determinations should be used to meet the requirements of today's final rule. For EPA's position on the use of existing BTA, please refer to the final rule preamble and EPA's response to comment 316bEFR.040.001. With regard to the second example, where a facility does not cause impingement mortality or entrainment of organisms to a level above that of the performance standards, EPA agrees that this might be the case under certain circumstances. For example, if a facility has reduced its intake capacity commensurate with that of closed cycle cooling, that facility would be considered in compliance and would be exempt from the performance standards (see § 125.94(a)(1)(i)). In addition, a facility might already meet the performance standards through technologies, operational measures, and/or restoration measures (see § 125.94(a)(2)). Such a facility would also be considered in compliance and would not be required to install additional technologies or utilize additional operational or restoration measures. In that case, the Director will make determinations as to how much monitoring would be needed.

RFC: Use of previous demonstration studies

Where a Successful § 316(b) Demonstration Has Been Done Already, Its Conclusions Should Be Accepted if its Studies Were Scientifically Sound and Conditions Have Not Changed

If there already is a successful § 316(b) demonstration that meets acceptable minimum technical standards and that justifies an existing intake technology, then the regulatory agency should be empowered to reapprove the existing intake unless either (1) the plant or its operation has been altered so as to affect the previous determination or (2) there is evidence that the CWIS is contributing to a decline in the health of the aquatic community (or the population of some representative species). (In the chart above, we refer to this as "reapproving" an existing § 316(b) demonstration.) EPA might set criteria for deciding what past § 316(b) decisions are entitled to be reapproved; for example, a State decision that followed EPA's 1977 draft § 316(b) guidelines ordinarily should be accepted (absent changed circumstances).

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule; however, existing data that is reflective of current conditions may be used to support the required studies. Please see response to comment 316bEFR.040.001 for details.

Organization obo Utility Water Act Group

Subject Matter Code 21.05

Role of States and Tribes (alt./equiv. programs)

Successful State § 316(b) Programs Should Be Continued

As with individual § 316(b) demonstrations, so with entire State § 316(b) programs, if they are technically sound: EPA's § 316(b) rule should encourage the continuation of State programs that have been successful in assessing, preventing, or mitigating adverse environmental impact. In the proposed rule, EPA proposes to allow States to continue to use "alternative regulatory requirements" they have adopted, if they can show these requirements are "functionally equivalent" to the new federal rule – that is, if they would result in environmental performance in each relevant watershed that is comparable to the reductions in impingement mortality and entrainment that would be achieved under EPA's proposed § 125.94 (67 Fed. Reg. 17,180 col. 1-2).

The concept of allowing successful State programs to continue is a good one, though EPA's proposal can be improved. In particular, EPA's proposal appears to require that a State show that its program achieves the same percentage reductions in entrainment and impingement mortality as EPA's performance standards (60-90% and 80-95%, respectively). But a good State program may have focused on larger-scale effects, such as impacts on fish populations (as indeed UWAG maintains they should). For that reason, the State may know that its program has successfully protected local aquatic populations but not necessarily be able to demonstrate that entrainment, for example, has been reduced by 60-90 percent. EPA should allow States to continue successful State programs without having to force-fit them into EPA's new performance standards.

Many States have incorporated § 316(b) into their water permit programs by adopting the federal § 316(b) language and then writing regulations or adopting guidance (which often references EPA's 1977 draft § 316(b) guidance). Such a program should be eligible for consideration as an alternative regulatory program that is "functionally equivalent" to proposed § 125.94. Also, it is appropriate to consider habitat restoration or enhancement projects undertaken as a result of § 316(b) permitting when evaluating whether a State program is functionally equivalent to the federal § 316(b) rules. In many instances, States have found that greater environmental benefits accrue from restoration or enhancement projects than from other regulatory approaches.

EPA Response

EPA recognizes that some States have worked diligently over the years to develop comprehensive 316(b) programs. However, EPA's goal under today's final rule is to set national minimum requirements for cooling water intake structures that reflect the best technology available for minimizing adverse environmental impact. EPA believes that these national requirements will promote more effective and consistent implementation of section 316(b) requirements and ultimately result in reducing impingement mortality and entrainment at these structures. In today's final rule, EPA has allowed approval of State programs that meet rule requirements at 125.90(d). The State or Tribe may use any methodology, including restoration, that it deems appropriate to achieve these levels. See response to 316bEFR.023.001 for additional detail.

Comprehensive demonstration study (7 parts)

Where Entrainment and Impingement Impact Is Known to Be Minimal, Extensive Biological Studies Need Not Be Done

Likewise, if a facility has data showing (1) that there is so little entrainment and impingement that there is no appreciable harm to the aquatic community or (2) that the environmental impact of entrainment and impingement is of so little economic and environmental significance that the cost of a full § 316(b) study would be significantly greater than its likely benefits, then there should be no requirement for further intake evaluation or additional intake technology.

EPA Response

In today's final rule, a facility may request a site-specific determination of best technology available for minimizing adverse environmental impact based on a demonstration, to the Director that costs of compliance under alternatives (1) through (4) would be significantly greater than the benefits of complying with the applicable performance standards in § 125.94. This pertains only to the facility's costs of implementation, and not to the costs of the studies themselves. EPA disagrees that the cost-benefit analysis should pertain to the studies themselves, but has included this option in today's final rule to alleviate burden to facilities whose implementation costs would be significantly greater than the environmental benefits of complying with the rule (see § 125.94(a)(5)). EPA believes that the studies required by today's final rule are reasonable. Furthermore, EPA did consider the costs for data collection efforts by facilities. EPA's cost analyses are housed in the Information Collection Request (ICR) (see EPA's Phase II Final Rule, Docket OW-2002-0049, DCN 6-0001). For EPA's position on the commenter's first example, that the impingement mortality and entrainment impacts are less than those set forth by today's performance standards, please see EPA's response to comment 316bEFR.041.007.

Option: UWAG's recommended approach

EPA SHOULD ADOPT EITHER OF TWO SITE-SPECIFIC APPROACHES INSTEAD OF THE PROPOSED RULE

For years, EPA's draft § 316(b) guidance (and even its previous § 316(b) rules, which were suspended by the U.S. Court of Appeals for the Fourth Circuit on procedural grounds) required site-specific BTA determinations. Later, when EPA commenced the present § 316(b) rulemakings, UWAG urged the Agency to continue to take into account the site-specific factors that make entrainment and impingement impacts so variable from one site to another. See, e.g. UWAG 2000 Phase I Comments, pp. 12-15.

Consider, for example, nuclear power plants. Most nuclear units have unique features that make a generalized approach to § 316(b) difficult. The NRC in NUREG-1437, Generic Environmental Impact Statement for License Renewal of Nuclear Plants (GEIS), has listed 92 environmental issues. Of these 92 issues, 69 are characterized as generic to all nuclear sites (Category 1), while 21 are designated as site-specific issues (Category 2). (Two issues are classified "Not Applicable.") The GEIS assigns the site-specific rating to the issues of "Entrainment of Fish and Shellfish" and "Impingement of Fish and Shellfish." Thus, the NRC recognizes that entrainment and impingement are site-specific issues.

Nothing has changed to make site-specific factors less important than when EPA wrote its 1977 draft guidelines. The public will be best served, then, if EPA adopts a § 316(b) rule focused on assessing site-specific factors that determine the impact of impingement and entrainment. Either of the proposals from UWAG and PSEG Services Corporation (PSEG) would do.<FN 2>

UWAG understands that EPA's proposed rule is itself "site-specific" in some respects: the calculation of the reduction in impingement mortality and entrainment necessarily takes site conditions into account to some extent, and the rule allows for site-specific analysis where costs are "significantly greater than" benefits or EPA's rulemaking cost estimates. Also, EPA's proposed rule shows some flexibility in that it sets ranges .<FN 3> of percentage reductions rather than single numbers and it recognizes more than one acceptable intake technology (wedgewire screens, aquatic fabric filter barrier systems, and fine mesh screens, for example). But UWAG submits that a better "site-specific" approach would be the UWAG Decision Principles or the PSEG proposal.

Footnotes

2 With respect to PSEG's proposal, we note, however, that UWAG does not endorse the use of a "wholly disproportionate" cost-benefit test. See Section XII to these comments, below.

3 EPA says that it is proposing ranges because of the uncertainty inherent in predicting the efficacy of a technology on a site-specific basis. 67 Fed. Reg. 17,141 col. 3. EPA anticipates that facilities will select technologies or operational measures to achieve the greatest cost-effective reduction possible within the range. 67 Fed. Reg. 17,142 col. 1.

EPA Response

While EPA rejected a purely site-specific approach, EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b) determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact associated with cooling water intake structures.

Option: UWAG's recommended approach

Instead of its Own Proposal, EPA Should Adopt the UWAG or PSEG Proposals Which Offer a Consistent Process for Addressing Site-Specific Factors

EPA's proposed rule, summarized in Section I above, while meritorious in some respects, is not the best way to implement § 316(b). Instead, EPA should adopt either of the two site-specific approaches that have been proposed, one by UWAG and the other by PSEG. The general framework of both proposals offers a consistent process for assessing the features of a site, including the species of fish found there.

1. Impingement and Entrainment Are Determined by Factors that Vary from Site to Site

Assessing and then "minimizing" the environmental impact of entrainment and impingement depends on many site-specific features and varies from site to site. EPA has coped with this complexity in its proposal, first, by setting ranges (80-95% reduction of impingement mortality, 60-90% reduction of entrainment) instead of single-number standards and, second, by providing an alternative when the cost of meeting the standards would be "significantly greater" than either the benefits or the costs that EPA has estimated. The flexibility offered by these features is helpful.

But the performance standards, at least for impingement mortality, nevertheless apply (unless one of the cost tests is met) at every site, no matter what its physical characteristics or biology. This approach presumably serves the interests of regulatory agencies by making their job easier, but it does not reflect the best science. A better course would be to abandon the performance criteria in favor of a systematic process that would consider site-specific factors in the first place rather than ignoring them unless they were too costly. "Consistency" should lie in setting a consistent process for assessing a site, not in a one-size-fits-all percent reduction range.

The degree of entrainment and impingement by cooling water intake structures depends very much on site-specific factors: the shape of the shoreline, the location of the intake, the flow of the river or size and character of the estuary tidal prism, the time of year, the time of day, the species present at the site, and many more factors (Appendix 4). The evidence for this diversity is overwhelming, based on 30 years' experience with § 316(b) and a growing body of scientific literature. For example, impingement depends on the swimming speed of the fish at the site and the ability of fish to perceive the area in front of the intake as a danger zone and swim away. Entrainment impact depends on whether there are eggs and larvae present; on whether the eggs sink, float, adhere to surfaces, or are deposited in redds or nests; and on the fecundity of the species, the chance of encounter with the intake, and the life history of the species, which determines when the larvae are vulnerable to entrainment..<FN 4>

Beyond factors that address the degree of impingement and entrainment is the question of whether impingement and entrainment losses are biologically significant. An ongoing study being conducted by Oak Ridge National Laboratory (ORNL) on behalf of the Electric Power Research Institute (EPRI) surveyed multiple Texas and Tennessee reservoirs and attempted to find a relationship between reservoir withdrawals and species composition or abundance..<FN 5>   ORNL's analysis showed no relationship between intake rate and fish population responses at reservoir withdrawal rates of 1 to 5,200 MGD. Examples from other waterbody types also demonstrate that impingement and entrainment losses have not caused long-term population declines. EPRI. 2001. Electronic Proceedings of Workshop: Connecticut River Ecological Study Workshop - Re-Visiting the Impacts of a Power Plant. EPRI Workshop at University of Connecticut Marine Laboratory, Avery Point, CT, November 15-16, 2001. EPRI CD #1006900, Palo Alto, CA.

Facilities that use cooling water are sited on different types of waterbodies, each with its own physical characteristics (flow, substrate, and shoreline) and its own variety of plants and animals. Similar facilities on the same reach of a river can have different impacts, depending on how the intake is designed and where it is placed relative to where the fish breed and how they behave. See Wisniewski, J. 2000, Power Plants & Aquatic Resources: Issues and Assessments. D. A. Dixon, D. E. Bailey, C. Jordan, J. R. Wright, Jr., and K. D. Zammit (guest eds.), J. Envtl. Sci. & Pol'y Vol. 3, Supplement 1. EPRI 1000767 (1998-99 EPRI Workshops).

Likewise, the feasibility, effectiveness, environmental impacts, and cost of technologies to reduce CWIS impacts vary from site to site. Some technologies (barrier nets, for example) cannot be used where there are strong currents, ice, or floating debris. See EPRI, Fish Protection at Cooling Water Intakes: Status Report (TR□114013 December 1999) (EPRI Fish Protection Report), pp. 2-21 to 2-22. Wedgewire screens require a screen slot size small enough to block the smallest lifestage to be affected, low through-slot velocity, an ambient current cross-flow to carry organisms and debris around and away from the screen, and an environment where there is not too much biofouling and siltation. Id., at 2-5; see also UWAG 2000 Phase I Comments, pp. 21-25, 36-39.

To complicate the analysis further, intake technologies may have negative impacts on navigation or even on habitat. For example, some types of screens in some waterways may interfere with boating. These and other site-specific factors need to be considered in making § 316(b) decisions.

2. Congress and EPA Have Recognized the Importance of Site-Specific Factors

a. Congress Intended § 316(b) to Be Implemented Site-by-Site

Congress was aware of the site-specific nature of impact assessments for cooling water. The legislative history of the companion statute, § 316(a) governing thermal discharges, shows that the interest in national uniformity served by effluent limitations guidelines and new source performance standards for other pollutants was thought not to apply to heat. 118 Cong. Rec. 33,761 (1972), reprinted in Leg. Hist. at 263 (statement of Representative Don H. Clausen).

Moreover, it had been "persuasively shown during the hearings . . . that the appropriate type and level of control over thermal discharges varies [sic] substantially among different waters and regions of the country." 118 Cong. Rec. 33,761 (1972), reprinted in Leg. Hist. at 263. Thus, the Committee on Public Works concluded that regulations should be developed and the costs and benefits evaluated for thermal discharges on a case-by-case basis. See H.R. Rep. No. 911, 92nd Cong., 2nd Sess. 120, reprinted in Leg. Hist. at 807.

Ultimately, Congress treated heat like any other pollutant, subject to national uniform effluent limitations and standards of performance like other pollutants. But in § 316(a), a compromise was reached that reflected the House bill by allowing point sources to obtain case-by-case variances based on the "balanced, indigenous population" standard. This was intended to balance the effects of heat with the economic impacts of control technologies and to accommodate the need to regulate heat on a case-by-case basis. See Leg. Hist. at 267-68, 273-74.

The timing and placement of § 316(b) suggest that Congress regarded it as different from other purely technology-based requirements and intended it to be applied taking into account site-specific environmental impacts. See Anderson and Gotting (2001). Part of the rationale for case-by-case regulation of heat – that the nature of electric power generating stations permits easy identification and enforcement – applies to § 316(b) as well.

b. EPA Originally Called for Site-specific § 316(b) Decisions

EPA recognized the site-specificity of § 316(b) decisions very early. EPA's draft 1977 guidance for § 316(b) says "[t]he exact point at which adverse aquatic impact occurs at any given plant site or waterbody segment is highly speculative and can only be estimated on a case-by-case basis by considering the species involved, magnitude of the losses, years of intake operation remaining, ability to reduce losses, etc." (emphasis added). U.S. EPA, Office of Water Enforcement, Guidance for Evaluating the Adverse Impact of Cooling Water Intake Structures on the Aquatic Environment: Section 316(b) P.L. 92-500 at 11 (Draft May 1, 1977) (1977 316(b) Guidance).

Similarly, in the preamble to its 1976 regulations, EPA said that many factors determine when AEI is occurring, and all of them need to be considered:

Section 316(b) requires that the best technology available be used to minimize adverse environmental impacts. As noted in the Development Document, there are many factors that should be considered when determining whether an adverse environmental impact exists or is likely to exist. The factors noted by the commenters are among those to be considered. All pertinent factors, rather than reliance on a single factor, should receive adequate consideration.
41 Fed. Reg. 17,387, 17,389 col. 1 (Apr. 26, 1976) (emphasis added). These observations in 1976 and 1977 are as true today as when they were made.

3. EPA Should Stay with its Original Understanding that Site-Specific Factors Are Crucial

Yet, in the proposed rule of April 9 (presaged by the Phase I rule for new facilities, published December 18, 2001), EPA changes its approach, concluding that a uniform national technology-based criterion is needed. At the heart of this change appear to be two ideas. First, EPA evidently believes that every cooling water facility must "do something" to reduce environmental impact (compared to a "baseline") even if it does not need to.

Second, EPA is too much influenced by a desire to make the regulator's job simpler. As the April 9 proposal makes clear, EPA is worried that site-specific decisions on environmental impact will require time and effort by permitting agencies. EPA, therefore, tries to simplify the § 316(b) decision by setting a numerical criterion, not one addressed to the complexities of aquatic populations but merely a prescribed reduction in the number or mass of individual animals lost.

UWAG members are well aware of the resource constraints State and federal regulators face. But even on EPA's own terms, the appeal of the proposed rule to administrative convenience is illusory. The record does not establish that a well-conceived site-specific rule (as distinguished from past experience with no rule at all) would consume large amounts of agency time and manpower. Nor is it obvious that reviewing a site-specific analysis according to UWAG's Decision Principles would take more resources than reviewing a demonstration that a new intake technology will reduce impingement mortality by 80-95% and entrainment by 60-90% compared to a hypothetical baseline. EPA's proposal makes the goal (60-90% reduction, for example) more numerically precise, to be sure. But proving that the goal is met will require permit writers to consider the effects of the same site-specific factors that have always been considered. Indeed, some appreciable amount of site-specific analysis would be required for any reasonable, sustainable rule EPA might develop.

In any event, most of the burden of implementing a site-specific approach, conducted in accordance with a clear and consistent decisionmaking process (like that described in UWAG's Decision Principles) would fall on regulated facilities, not regulators. UWAG members are prepared to collect information and perform studies reasonably necessary to allow scientifically and environmentally sound § 316(b) decisions. Such a process would supply the technical, legal, and policy tools for decisionmaking that may have been lacking in the past. It is the absence of EPA-approved tools, not the site-specific nature of the decisionmaking process, that caused a few States to spend significant resources on a few § 316(b) decisions in the past.

Footnotes

4 In its Case Study Analysis (DCN:4-0003), EPA attempts to characterize the impacts of CWIS by waterbody type. See Case Study Analysis, chapter A8. This chapter essentially reproduces the same flawed analysis EPA offered to support its proposed Phase I rule. As UWAG showed in its comments on the Phase I rule, that analysis wholly fails to demonstrate EPA's claims about the "dire" effects of existing CWISs. In fact, if anything, it showed how very site-specific, and often, in a larger context, insignificant, such effects really are.

5 EPRI. 2002. Impacts of Intake Flow Rate on Fish Populations and Communities. DRAFT Report prepared for EPRI by Oak Ridge National Laboratory and appended (Appendix E) to EPRI's Comments on EPA's Phase II Rule, August 7, 2002. EPRI Report 1005178, Palo Alto, CA (EPRI 2002a).

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Option: UWAG's recommended approach

The UWAG Site-Specific Proposal Is Preferable to EPA's Proposed Rule

Either UWAG's or PSEG's proposal,.<FN 6> both of them driven by the fact of site diversity rather than by administrative convenience, would be a better approach. EPA also offers for comment its own sample site-specific rule. 67 Fed. Reg. 17,159-61. UWAG agrees with many aspects of that sample rule, such as allowing use of relevant existing data, allowing continued use of past determinations as long as circumstances have not changed, considering net environmental effects, including energy effects, allowing voluntary restoration measures as an alternative to technology deployments, and recognizing existing State programs. But UWAG does not agree with those aspects of the sample rule that (1) focus on minimizing impingement and entrainment (albeit on mortality in each case), without regard to the environmental and social importance of such effects, (2) authorize States to set more stringent requirements, (3) imply that permit writers could impose operating limits, and (4) appear to require the permit writer to revisit its § 316(b) decision at the end of each permit term.

UWAG's proposal for applying § 316(b) to existing facilities, stated as "Decision Principles," is Appendix 1 to these comments..<FN 7> The UWAG Decision Principles incorporate the following ideas.

Footnotes

6 While these comments do not directly address PSEG's proposal, UWAG finds the proposal commendable in its emphasis on site-specificity and its workable regulatory framework, although we do not subscribe to the "wholly disproportionate" cost-benefit test.

7 In describing UWAG's Decision Principles, EPA says that UWAG recommended a number of conservative "decision criteria" for judging whether adverse environmental impact will occur. 67 Fed. Reg. 17,163. To the contrary, the screening criteria proposed in UWAG's Decision Principles are highly conservative and, even if not met, would not necessarily indicate a risk of AEI.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

UWAG definition of "adverse environmental impact"

EPA Should Define "Adverse Environmental Impact" to Emphasize Population-Level Effects

EPA should adopt a definition of "adverse environmental impact" (AEI), or at least state what AEI is not. In particular, the loss of a single fish or a single egg, or even a large number of them, need not cause AEI. Instead, AEI occurs when the loss of fish or other organisms causes declines, at the population level, so great as to adversely affect the sustainability of the population or its social, economic, or ecological function. An appropriate definition <FN 8> of AEI would recognize that, as a matter of basic biology, losses (indeed very large losses) occur naturally even without a CWIS and have little or no effect on the health of aquatic populations. Moreover, an appropriate definition would recognize that some losses have little or no effect on the public's use and enjoyment of aquatic resources.

Instead of defining AEI to focus on population-level effects, EPA focuses (for entrainment) simply on reducing the absolute number or mass of organisms entrained. But, as UWAG's Phase I comments showed, raw numbers of fish eggs, larvae, juveniles, and adults entrained or impinged are not an adequate basis for establishing environmental "impact" (UWAG 2000 Phase I Comments, p. 162).

For some fish species a single female may spawn a million or more eggs per year, and billions or trillions of eggs may be spawned by the population as a whole (id. 160). Several hundred tons of impinged alewives or bay anchovy represent very small numbers compared to the population of these abundant forage species (id.).

For example, UWAG's Phase I comments showed that independent estimates of alewife in Lake Michigan suggested that there were 0.5-2.7 billion mature female alewife in the lake during the study period. Alewife in the Great Lakes typically produce around 11,000 to 22,000 eggs per year; to be very conservative, we can use the lower figure of 11,000. Thus, the egg production in Lake Michigan should be between 5,500 and 29,000 billion (55-290 trillion) eggs per year. So even if we were to assume that only one in a thousand eggs survived to be cropped by entrainment, 150 million larvae entrained each year would represent a mortality of only 0.5 to 2.70% a year. This low pre-compensatory mortality would have almost no effect on a species such as alewife that has a high compensatory reserve (id. 171).

Consider also threadfin shad, of which 1.37 million was the largest number reported impinged by the Cumberland steam plant on the Barkley Reservoir in Tennessee. This amounted to an impingement rate of only 1%, suggesting strongly that there was no meaningful "adverse" impact.

Estimating the compensatory reserve of threadfin shad to be 17.1, UWAG's consultant calculated that impingement of 1.37 million organisms resulted in an estimated reduction of 0.06% for impingement of this species. Even if one assumed that the rate of impingement was greatly underestimated and actually was 5% and that the compensatory reserve was much lower, the equilibrium spawner abundance would decline by only 1.2%, even assuming that all impingement occurred pre-compensation, when the population effect would be greatest. If all impingement occurred post-compensation, then the estimate of reduction in mean spawner biomass would be slightly less than 1%. In either case, it is highly unlikely that the level of impingement cited could have had any "adverse" impact on the population's ability to sustain itself and, indeed, to thrive (id. 166).

Footnotes

8 UWAG recommends this definition:

Adverse environmental impact is a reduction in one or more representative indicator species that (1) creates an unacceptable risk to the population's ability to sustain itself, to support reasonably anticipated commercial or recreational harvests, or to perform its normal ecological function and (2) is attributable to the operation of the cooling water intake structure.

EPA Response

Please see the response to comment 316bEFR.002.019 for the discussion on the definitions EPA rejected for adverse environmental impact in this rulemaking.

Fish Population Modeling

The Rule Should Recognize that Density Dependence Mitigates Losses of Fish

As noted by Myers (Appendix 5 to these comments) and Rose et al. 2001, the concept of density dependence is fundamental to understanding and managing biological resources. For any biological population to persist, reductions in population size caused by natural environmental fluctuations must result in increased survival, growth, or fecundity of the remaining individuals. Density dependence has been well-studied in both terrestrial and aquatic systems. The compensatory response to reductions in population size is the key factor that permits fish populations to sustain themselves despite enormous natural mortality for early life stages and even intensive harvesting of adults (see Appendix 5).

a. Long-term Surveys Have Demonstrated Density Dependence

Long-term surveys have demonstrated density dependence in a variety of marine, estuarine, and freshwater fish species (see Appendix 5). Field experiments in which fish population sizes are manipulated artificially also have been used to demonstrate density dependence. Id. Appendix 5 contains a table of about 50 recent studies demonstrating specific mechanisms responsible for density dependence in a variety of fish species. Most of these studies have been published in the last ten years.

b. The National Research Council Acknowledges Density Dependence

The National Research Council (National Research Council 1998, p. 44) has recognized the importance of density dependence for modern fisheries management:

Many species appear to have strongly compensatory [spawner-recruit] relationships; that is, per capita recruitment increases significantly as stock size decreases. Reference levels are now more commonly based on a % [SSBPR], but the percentage is often specified by analogy with other stocks or by using the results [of comparisons among other biological reference points]. A knowledge of the compensatory capacity of the stock is necessary to define the most appropriate [biological reference points] for a stock. Even without such knowledge, however, a conservative % [SSBPR] still can be selected.

(Citation omitted.) Spawner-recruit relationships of the type discussed by the National Research Council are used to manage two of the estuarine-dependent fish species, striped bass and weakfish, listed in Tables 11-10 (annual entrainment in estuaries) and 11-11 (annual impingement in estuaries) of EPA's Economic and Engineering Analyses (EEA) for the § 316(b) Phase I rulemaking. Methods discussed by the National Research Council can be used to incorporate the concept of density dependence in management strategies for species for which spawner-recruit data are not available.

Fisheries scientists have demonstrated the importance of density dependence for ensuring the continued persistence of fish populations, and fisheries managers routinely consider it when establishing harvesting regulations. Density dependence also should be considered when calculating the environmental impact of entrainment and impingement.

c. Experience at Power Plants Shows Density Dependence at Work

Density dependence helps to explain why there are several sites where long-term monitoring demonstrates negligible effects from large once-through facilities (e.g., Connecticut Yankee and the mid-Hudson power plants), where density dependence and other mechanisms clearly are operating to mitigate individual losses..<FN 9>

In short, entrainment and impingement may not be “adverse” to the aquatic ecosystem as a whole where density-dependent factors allow remaining fish to grow larger and reproduce more effectively. Moreover, entrainment and impingement may not be “adverse” where (i) a population has been shown to reproduce at high and stable levels over a long period of time despite entrainment and impingement (e.g., alewives or gizzard shad in the Great Lakes), (ii) the losses are of weakened or diseased organisms that are affected by other stressors and would not have survived anyway, (iii) the primary species affected are nuisance or exotic species, or (iv) the losses help achieve other fishery management goals (for example, where cropping one abundant species makes it possible for a less resilient but nevertheless valued species to thrive or otherwise increases diversity).

Footnotes

9 For example, intake volume at the Cayuga (CGS) and Wabash River Generating (WRS) Stations each exceed 10% of the Wabash River’s annual flow, well above the 5% cutoff suggested by EPA’s proposed rule. Without taking survival into account, annual egg/larvae losses in the late 1980s were estimated to be 27 million at CGS and 108 million at WRS. Section 316(b) assessments at both facilities concluded that the impacts to fish populations were negligible (EA 1988, EA 1989). This position is supported by long-term (30 years’) community-level monitoring, which demonstrates that fish populations in the Wabash River are as good as or better than when monitoring began in the late 1960s (Gammon 1998).

Another example is the Muskingum River, where community-level studies show that the areas near both the Muskingum River and Conesville Power Plants fully attain biocriteria goals designed to measure attainment or nonattainment of the designated aquatic life use (Seegert 2002). Similarly, the Ohio River Ecological Research Program has demonstrated that, in general, conditions upstream and downstream of each plant studied are similar, and conditions over the past 20 years have generally improved, which is the opposite of what one would expect if impingement and entrainment losses were adversely affecting fish populations. (EA 2001).

Fish Population Modeling

The § 316(b) Rule Should Be Based on Fisheries Management Science

EPA's § 316(b) rule should use the lessons of fisheries management science. The use of concepts like spawner-recruit relationships are mentioned above, and UWAG's 2000 Phase I Comments contain a more detailed discussion of the tools and concepts used by fisheries managers. If the impact of a facility is in the range of impacts known by fisheries managers to be within normal variation or not of concern to the viability of the fishery, it is not creating AEI.

EPA Response

Option: Site-specific determination of BTA

The § 316(b) Rule Should Allow Risk Assessment

Risk assessments, which are included specifically in UWAG's proposal, should play a role in some § 316(b) determinations. That is why UWAG's proposed decisionmaking process includes as one option a process based on EPA's 1998 Guidelines for Ecological Risk Assessment. This process would identify explicit measurement endpoints and criteria for assessing AEI before studies were conducted. If the studies showed that predetermined endpoints had not been exceeded, then the proposed intake structure would be considered not to cause AEI. If one or more endpoints had been exceeded, the facility would identify alternatives for BTA or restoration projects to eliminate AEI. EPRI's recent report Evaluating the Effects of Power Plant Operations on Aquatic Communities (EPRI Report 100758 July 2002) (EPRI 2002b) offers one "ecological risk assessment framework" for § 316(b) demonstrations.

This does not mean that a full-fledged risk analysis is necessary in every case. Where preexisting data show that a facility is not creating AEI or where the facility is willing to commit to a highly protective intake technology (such as the ones on which EPA bases its proposal),.<FN 10> then the BTA decision should be straightforward. But permittees should be allowed to use ecological risk assessment – as to which EPA itself has produced guidance in which it presumably has confidence – to prove what technology is "best" for a site under § 316(b).

Under the risk assessment approach, the burden of producing information on which a decision can be made would fall on the permittee. Permittees have an incentive, after all, to produce enough data and present it clearly so as to enable the permitting agency to make an expeditious decision. Thus, State permit writers should not fear that their own budgets would suffer as the result of such an approach.

Footnotes

10 Simply installing one of the approved technologies, such as wedgewire screens, is the essence of the simpler alternative approach that UWAG recommends in section VI below.

EPA Response

The rule does not require a determination of whether an adverse environmental impact is occurring is a preliminary step in implementing 316(b). Please refer to the response to comment 316BEFR.313.001 for more information on EPA's position on minimum impacts at existing facilities.

Option: Site-specific determination of BTA

EPA's Reasons for Rejecting a More Site-Specific AEI Approach Are Unfounded

EPA appears to have two reasons for choosing performance standards requiring percentage reductions in impingement mortality and entrainment rather than a more site-specific approach:

1. its fear that a site-specific approach will have "inconsistent results" from one site to another and

2. its fear that a site-specific approach will impose too great a burden on State and federal permit writers (see, e.g., 67 Fed. Reg. 17,153 col. 1).

Both of these concerns are unfounded.

By "consistency," EPA may mean "uniformity." Full "consistency" in this sense is neither desirable nor achievable for intake controls, because the choice of technology, the cost, and the environmental results will vary greatly, even under EPA's proposed approach. (Even cooling towers have different costs and different environmental impacts from site to site.) But consistency can be achieved by implementing a process for determining BTA on a site-specific basis.

EPA says it is concerned that a more site-specific approach to § 316(b) would cost too much time and manpower for agencies. But EPA cannot reasonably assume that a site-specific alternative based on a clear and consistent decisionmaking process would have as high a cost as a few States say they incur now. The difference is that those costs were incurred in the absence of a rule and with only minimal guidance and mere draft guidance at that. Lack of guidance produces fear of litigation, which in turn produces excessive paperwork and the inability to select and focus on the most important details.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

While EPA rejected a purely site-specific approach, EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

RFC: EPA rationale to not require closed-cycle

AS EPA CORRECTLY RECOGNIZES, COOLING TOWERS CANNOT BE JUSTIFIED AS A NATIONAL STANDARD

EPA considered alternatives that would require closed-cycle cooling (cooling towers) at all or many existing facilities. EPA reached the correct conclusion that cooling towers are too costly to be justified as "best technology available."

As EPA says, "[c]onverting to a different type of cooling water system . . . is significantly more expensive than the technologies on which the proposed performance standards are based (generally by a factor of 10 or greater) and significantly more expensive than designing new facilities to run on recirculating systems." 67 Fed. Reg. 17,154 col. 3. EPA did not select closed-cycle, recirculating cooling systems as the best technology available for existing facilities because of the "generally high cost of such conversions." 67 Fed. Reg. 17,155 col. 1-2. EPA estimates that capital costs for individual high-flow plants to convert to wet towers generally ranged from 130 to 200 million dollars, with annual operating cots in the range of 4 to 20 million dollars. 67 Fed. Reg. 17,155 col. 2.

EPA reached this conclusion even though, as these comments will show, it assumed that entrainment and impingement from steam electric plants would be higher than is likely, that reducing these effects would result in major biological, social, and economic benefits that in fact are unlikely to occur, and that the costs (economic and otherwise) of retrofitting cooling towers would be lower than they actually would be.

EPA Response

EPA has not based the final rule on cooling tower retrofit technologies. As such, the comment supports this decision for the final rule.

Cooling system costs (e.g., dry, wet, recirculating)

EPA Underestimates the Costs of Cooling Towers

EPA's estimate of the costs of retrofitting existing facilities with cooling towers is far too low. EPA's analysis of costs is in its Technical Development Document for the Proposed Section 316(b) Phase II Existing Facilities Rule (DCN:4-0004) (Phase II TDD), which in turn relies heavily on information developed for the § 316(b) rule for new facilities. See Technical Development Document for the Final Regulations Addressing Cooling Water Intake Structures for New Facilities (EPA-821-R01-036) (Phase I TDD)..<FN 11>

It appears that EPA took its Phase I estimates of the capital costs of installing cooling towers at new facilities (which were based on a number of factors,.<FN 12> including an assumed design approach temperature of 10°F that EPA derived for newer facilities constructed between 1998-2000);.<FN 13> scaled by circulating water flow; multiplied these "national average" capital costs by a "state-specific capital cost factor" (which for 40 of the 50 states drove the "national average" capital costs down anywhere from .03% to 25% (Phase II TDD 2-24-2-25)); and then multiplied the result by a factor of 1.2 (for which no foundation or explanation is provided), which is intended to account for the higher cost of retrofitting an existing facility. Finally, according to the Economic and Benefits Analysis for the Proposed Section 316(b) Phase II Existing Facilities Rule (Phase II EBA) at B1-4, EPA applied a 10% contingency factor to this result,.<FN 14> though no explanation of this 10% factor or how it was derived appears in the Phase II TDD.

Footnotes

11 UWAG commented extensively on the assumptions EPA made in the draft version of the Phase I TDD. EPA addressed some, but not all, of our comments. Where relevant, we will address flaws in the assumptions EPA made for both new and existing facility retrofit costs.

12 EPA also assumed that redwood would be used for cooling towers for fossil units and concrete for nuclear units. The difference in cost between redwood and concrete is about 25%. For redwood towers, the new facility ("Greenfield" facility) cost is about $50/gpm. When adjusted for retrofit costs, this becomes $60/gpm.

13 For purposes of assessing its national estimates, EPA compared those estimates to the actual retrofit costs incurred by three existing facilities, which it says compared favorably (within 25% or less) except that the design approach for the three facilities exceeds 10 degrees F. Phase II TDD at 2-22. This illustrates the importance of EPA's approach assumption.

14 The explanations of EPA's cost methodology in the Phase II TDD and the Phase II EBA provide somewhat contradictory descriptions of the order in which these factors were applied. Compare Phase II EBA at B1-4 with Phase II TDD at 2-27, 2-28, 2-32, 2-33. Obviously, if EPA scaled its retrofit factor up or down by applying the state-specific cost factor to it, it reflects the assumption that these "retrofit" costs also will vary regionally. Because EPA has not explained how it derived its retrofit factor, we cannot assess this assumption.

EPA Response

No response to this comment is necessary because it simply restates EPA's methodology at proposal.

Cooling system costs (e.g., dry, wet, recirculating)

The 20% Retrofit Factor Is Unjustified

EPA estimates retrofit costs by raising the capital cost of cooling towers at new facilities by 20 percent for “activity necessary to convert cooling systems.” Phase II TDD, p. 2-28. Where upgrading of cooling water intake structures and screens also was deemed necessary, EPA developed estimates of those capital costs and applied a 30% retrofit factor to them. Id. This “retrofit factor” is offered with no apparent supporting data.

More than that, the 20% factor seems questionable in concept. It assumes that the cost of retrofitting is a function of the size of the tower – the larger the tower, the greater the difference between retrofitting it and building it as part of a new facility. And yet, as the discussion below points out, the cost of retrofitting depends far more on features of the site and the existing facility (how long the piping run between the tower and the condenser, for instance) than on the size of the tower.

There is reason to believe the 20 percent retrofit factor underestimates retrofit-related costs in many cases. In an EPRI study called Cooling System Retrofit Cost Analysis, Dr. John Maulbetsch.<FN 15> points out that very high retrofit factors will be encountered at many facilities. Dr. Maulbetsch makes the following points:

-Site-specific retrofit cost studies show a high degree of variability from costs based on commonly accepted scaling methods. Cooling tower cost estimating methods are often based on the use of dollar-per-gpm rule of thumb. This approach is used by tower vendors, A&E firms, and experienced users and is based almost entirely on the field’s experience with tower construction at new sites. EPA used this approach as well. It, therefore, can be reasonably assumed that the variability in careful engineering estimates of site-specific retrofit costs (documented later in Dr. Maulbetsch’s report) is due to differences in the degree of difficulty associated with the retrofit aspects of each project. (Site-specific features that can increase costs are discussed in the next section of these comments.)

-It is also reasonable to assume that the lower bound of these costs is associated with the “easiest” retrofit cases, which would correspond most closely to a new facility project free of the interferences encountered at most existing facilities. The lower bound of the case data corresponds reasonably well with the “greenfield” cost estimating rules proposed by EPA, while the mid-range of the data is 40 to 60 percent higher, with many cases ranging to a factor of 2 to 4 times more expensive.

-Discussions were held with project managers at sites where actual construction projects similar to cooling system retrofits either were underway or had been estimated in detail for potential future site modifications. In all cases, the cost increments associated with constraints imposed on the project by the complexities of construction at an existing site were claimed to be significantly greater than 20 percent, with estimates ranging from 50 percent to 100 percent. This range is reasonably consistent with what might be inferred from the case data that Dr. Maulbetsch discusses in his report. The reasons given for the incremental costs included many that apparently were not included (or at least not specifically identified) in EPA’s discussion of its 20 percent retrofit cost factor.

Using a percentage increase to account for retrofit costs may be useful as a simplifying assumption, but it cannot account for site-specific factors that make retrofits different from constructing cooling towers at a greenfield site.

Footnotes

15 Among other things, Dr. Maulbetsch analyzed the Stone & Webster study in Appendix 6 to these comments and also an earlier analysis by Washington Group International, also appended to these comments.

Cooling system costs (e.g., dry, wet, recirculating)

EPA Underestimates the Engineering Problems of Retrofitting Tower

Many site-specific problems increase the cost of retrofitting cooling towers at existing facilities. For the most part, EPA has not counted these costs.

EPA justifies one of its central assumptions (that new facility capital costs are adequate surrogates for existing facility costs) based on several further assumptions, or "principles":

-recirculating systems can be connected to the existing condensers and operated successfully under a variety of conditions (though not all);

-condenser flows generally do not change due to the conversions;

-significant portions of the condenser conduit systems can be used for the recirculating tower systems;

-existing cooling water pumps generally would be replaced with new circulating water pumps, or else booster pumps would be installed to increase the pumping energy of the circulating system;

-the existing intake structures can be used for supplying make-up water to the recirculating towers (though demolition and replacement of the intake pumps may be necessary);

-pumping distances from tower systems to condensers can be significant, but existing piping runs, in some cases, can be used to reduce the amount of new circulating piping installed;

-tower structures can be constructed onsite before connection to the existing conduit system; and

-modification and branching of circulating piping are necessary for connecting the recirculating system to the existing conduits and for providing make-up water to the towers.

Several of these assumptions are unrealistic. For example, the assumption that recirculating systems can be connected to existing condensers and operated successfully under a variety of conditions does not account for several factors that will affect the practicability of such retrofits, including availability of suitable terrain and ability of the condenser to accommodate the higher pumping pressures typical of a closed-cycle system. So even if the new and old systems could be tied together and operated in theory, other factors would make that difficult or impossible in some cases. EPA's assumptions that significant portions of existing condenser conduit systems can be reused, that existing intake structures can be reused to supply make-up water, and that tower structures can be constructed onsite before connecting them to the existing conduit system (presumably while the plant remains in operation) also are unrealistic for many facilities.

Cooling system costs (e.g., dry, wet, recirculating)

Nuclear Units Present Special Problems

EPA's assumptions are especially inappropriate as applied to nuclear power plants. Nuclear plants (especially those where service water systems, which are safety-related, would be affected) may have no choice but to build an entirely new intake structure to be sure that intake flow is never compromised. They may incur significant additional costs to address safety and security concerns, as well as the cost of safety reviews.

The suggested use of "significant portions of conduit systems," presumably while the plant remains in operation, is completely inconsistent with nuclear power plant operations. It is also inconsistent with utilities' out-of-service and modification design process, which would govern the installation of upgraded intakes and traveling screens. Anything that would alter or affect the flow of safety-related service water or nonessential service water systems at a nuclear unit would require an equipment outage and might have to be completed during a unit outage.

Unit outages are mostly scheduled on an 18-month or 24-month frequency, and extending these scheduled outage timelines would have serious financial impacts on power producers,.<FN 16> which EPA has not recognized in its analysis. EPA does acknowledge that piping modifications could be significant, but it does not address the costs of additional unit downtime to perform the modifications.

All in all, there are at least three reasons to think that EPA has underestimated the outage time that would be required for cooling tower retrofits. First, all the information UWAG presents in these comments on the technical challenges and costs of retrofitting cooling towers suggests that the task is highly complex and time-consuming. Second, the limited data EPA has collected regarding the outage period associated with retrofitting cooling towers shows that outage periods are likely to be highly variable and, in some cases, quite long (i.e., ranging from 83 hours for the Jeffries Plant (a relatively small two-unit fossil-fueled plant) to 10 months for the Palisades Nuclear Generating Plant. These are values that EPA unfairly dismisses, but they are far more likely to be representative of a complex retrofit scenario than the one-month period EPA assumed. See Phase II TDD Chap. 4. Third, inquiries made by EEI to engineering experts with extensive experience in this field suggest that, for a fairly simple retrofit, two months would be a more reasonable estimate, while for more complicated situations three to four month outages would be the minimum expected.

As an example of the kinds of technical problems that retrofitting cooling towers could cause, consider the St. Lucie Nuclear Plant. Its Final Safety Analysis Report states that St. Lucie Units 1 and 2 use two independent water sources and a common discharge canal for the ultimate heat sink (UHS). The design of the UHS complies with Regulatory Guide 1.27, "Ultimate Heat Sink for Nuclear Power Plants." In the unlikely event of a loss of the intake, a second independent source of water is available from the Indian River Lagoon. By NRC Technical Specification requirements, the UHS must be operable at all times.

At St. Lucie, the number and size of large-diameter conduits that would be necessary to connect the discharge canal, cooling towers, and intake canal for a retrofit would be significant. Although it is hard to estimate the exact distances without a site-specific conceptual design, it is safe to say that retrofitting towers leaves less routing flexibility than construction at new facilities and pressures the designer to "settle for less" in trying to use some of the existing features for intake and discharge.

Any large construction project at an operating nuclear power plant is undesirable, and building cooling towers and modifying the associated piping are no exception. The post-September 11 security measures (which become more stringent almost daily) make this type of construction even more difficult than it used to be.

Footnotes

16 Over the past decade, power producers have labored to reduce the duration of scheduled outages, particularly nuclear refueling outages. According to the Nuclear Energy Institute, the median duration of nuclear refueling outages in 2000 was 35 days. See NEI, http:/www.nei.org/index.

EPA Response

The Agency agrees that nuclear units present special problems for retrofitting cooling towers. The Agency examined the only known case of a cooling tower retrofit at a nuclear plant at the Palisades station and found that this case an extended plant shutdown (of up to ten months) for completion of the retrofit. As such, the Agency estimated for the NODA that retrofits of cooling towers at nuclear plants would extend up to a net outage of 7 months.

Regarding the need for construction downtimes for retrofit of intake structures at nuclear plants, the Agency has considered and quantified unscheduled construction outages of complying facilities for some intake modifications in the final rule. As such, the commenter's concerns on the subject of intake modifications and downtimes have been met. In addition, the Agency accounts for the expected increased cost of technology modifications at nuclear facilities through capital and O&M cost multipliers. Each of these factors are discussed further in the Technical Development Document. The Agency has considered the nuclear safety considerations of retrofitting any type of technology to a nuclear plant in the final rule. The Agency considered extra safety costs in the capital and O&M costs of the final rule (in large part due to site safety). In addition, Today's final rule allows for a site-specific determination of best technology available if requirements conflict with Nuclear Regulatory Commission safety requirements (see § 125.94(f)).

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

Demolishing Old Piping and Connecting the New Towers to the Old System Raise the Costs

Besides not including in its capital cost estimates any costs for excavation, backfill, or other civil costs from intake piping modification (Phase II TDD 2.32), EPA may not have included the cost of demolishing old piping and other structures. Also, depending on how the retrofit handles technical matters like changes in the water pressure in the cooling system, there could be changes to condenser flow, significant changes to piping from the intake structure to the new closed-cycle system, and substantial pumping distances.

EPA also trivializes the tie-in of the new system to the old system. Cooling system engineers estimate this would take up to six months to complete, which amounts to a considerable loss of generation. They say that a retrofit would be complicated by the physical layout of the plant, the required modification to the low water pressure system at the existing plant, and the lack of space for towers near the plant.

A number of cost factors need to be considered. First, disposing of blowdown is not always a minor task. That aside, on a site-specific basis, one must consider the following:

1. Is there sufficient freshwater available or can the site deal with the impact of particulate air pollutants (PM10) from salt drift if seawater cooling towers are the only solution? At some sites, no freshwater is available, and the drift issue may be insurmountable.

2. If freshwater is available, how will the blowdown be managed? Costly treatment facilities (typically $8-10 million for a 600 MW combined cycle gas facility) and costly salt cake disposal (the cost depending largely on the presence of contaminants that can complicate disposal) can be a problem.

3. What modifications to pumps and piping will have to be made to adapt a once-through CWIS to wet cooling? The pumps likely will be far too large to work and may be in an unsuitable location, and the cooling line size likely will be incompatible. For example, adapting a new 1000 MW combined-cycle facility to an existing once-through CWIS at Moss Landing, California, required over $40 million in improvements for the same type of cooling system.

EPA says that it excluded the cost of new or refurbished make-up pumps from its capital cost estimates. Apparently it did so on the assumption that, in most cases, the existing make-up pumps could be reused (and, in any case, the estimated cost of such pumps is small, according to EPA). See Phase II TDD at 2-32. Yet on p. 2-16 of the Phase II TDD, EPA acknowledges that demolition and replacement of intake pumps may be necessary in some cases.

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

Saltwater Retrofits Are Especially Costly

Among the alternatives EPA has considered are requiring cooling towers at all existing facilities or at all facilities on saltwater. These alternatives would be unreasonably costly, much higher than the costs of cooling towers for new facilities would suggest. For example, the approximate costs for wet cooling towers at two greenfield sites in the West, one at Avenal, California, and one at New Olympia, Washington, are in the range of $4-5 million, but the installed cost of wet cooling at Morro Bay (currently using a once-through seawater cooling system) would be more like $7-9 million, and even this does not account for a very costly noise abatement package that would be required to meet the local noise ordinance, potentially adding $3 million or more to the $7-9 million. (All these costs are for gas-fired, duct-fired, combined-cycle facilities of approximately 600 MW.) Another cost, especially in the West, is the potentially significant cost to secure the water or water rights and then to treat the water to a quality that allows multiple cycles through the cooling towers. See UWAG Phase I Reopening of NODA Comments, pp. 3-4.

EPA Response

For a discussion of cooling tower costs, see response to comment 316b.EFR.208.002.

EPA notes that its cost development for the cooling water intake technologies (i.e., non-cooling tower technologies) included as the basis for the final rule includes separate and well researched costs that account for the construction of intake technology retrofits suitable to salt water environments.

Organization obo Utility Water Act Group

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

Operation and Maintenance Costs Would Be Higher than EPA Supposes

As for operation and maintenance (O&M) costs, EPA assumed that such costs would be no higher than for a new facility. This is so even though EPA considered auxiliary power (that is, power required to run the pumps and fans that are part of the cooling system) as O&M costs and, in the Phase II EBA, acknowledges that auxiliary power needs will increase after a retrofit. Nevertheless, EPA appears to have assumed that auxiliary power costs would be the same for new facilities with towers and existing facilities required to retrofit them. See Phase II EBA at B1-4, B1-6, B1-7; Phase II TDD, 2-22 through 2-24, Ch. 5.4. EPA then reduced its O&M costs by $0.03/kWh, which reflects the cost the Agency assumed the facility would have incurred even if it had retained a once-through system.

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

Energy Penalties from Cooling Towers Would Be Significant

EPA also attempted to assess the cost of energy penalties associated with turbine back pressure, which EPA says could significantly affect net plant capacity. Phase II TDD Ch.5.3. See also Phase II TDD 5-31 through 5-34. In the end, however, EPA assumed that turbine backpressure for a retrofitted plant would be the same as for a new facility with cooling towers. Clearly, this assumption is erroneous.

EPA estimates an annual energy penalty cost from retrofitting cooling towers of $364 million. Dr. Maulbetsch, using an estimated 1 percent energy penalty applied to the 350,000 MW from EPA's cost analysis and assuming a 50 percent capacity factor and an average full cost of $2.50 per million Btu, calculates an annual energy penalty cost of about $700 million. This is about twice EPA's estimate, which Dr. Maulbetsch, in light of the considerable uncertainties and approximations, considers reasonable agreement.

Shaw Stone & Webster, Inc. (Stone & Webster) estimates that cooling towers reduce the efficiency of power plants by about 1 percent (annual average) and 2-4 percent during peak summer conditions. This means that requiring cooling towers everywhere would require about 20 new 400-MW power plants to replace the generation losses due to cooling towers in summer (Appendix 6).

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

Environmental Restrictions Would Raise Costs at Many Sites

EPA also claims to have examined the non-water quality impacts associated with cooling tower retrofits, but it made no effort to include these impacts in its economic analyses (Phase II TDD, Ch. 6). In many cases, EPA's assessment apparently led it to conclude that the likely effects of cooling towers, including effects from increases in air emissions, water consumption, salt drift, noise, aviation hazards, land use, and solid waste disposal, would be minimal. UWAG believes that EPA's analysis is flawed in many respects.

In States that have NEPA-type laws, non-water impacts easily can make it impossible for a project to comply with the law, or at least require costly mitigation. This is likely to be the case at Morro Bay, California, where an attempt to require dry cooling likely will be defeated by land use, visual, and noise impacts associated with dry cooling that cannot be mitigated to an insignificant level. Salt drift alone, because it would violate PM10 emissions requirements for which PM10 offsets are not available, would prevent the project from using saltwater cooling towers.

Organization obo Utility Water Act Group

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

Environmentally Sensitive Areas Increase Costs

Some possible locations for cooling towers are in environmentally sensitive areas. For example, an area that otherwise is feasible for towers at the St. Lucie Nuclear Plant is a protected mangrove swamp. Since the NRC has concluded that the entrainment and impingement of fish and shellfish at St. Lucie have an insignificant impact on the fisheries near the site, <FN 17> there would be no net environmental benefit in destroying acres of mangroves to accommodate cooling towers. Facts such as these support the need for a site-specific analysis to determine BTA under § 316(b).

The existing intake structures at St. Lucie might, it is true, be useful for supplying makeup water for wet saltwater cooling towers. However, the only entrained (or "entrapped") organisms that inhabit the one mile-plus intake canal that have received attention at St. Lucie have been sea turtles. The turtles are most at risk when water flows are low in the intake pipes (between the velocity caps in the ocean and the headwall). Without a strong current, the turtles will enter the velocity cap and not be carried along. If they linger in the pipe too long (as may occur with reduced flow with a cooling tower) they may drown, because they cannot surface for air.

Careful analysis would be necessary before deciding how best to use the existing velocity caps at St. Lucie if cooling towers were required. Flow rates required for make-up water and discharge from a wet saltwater cooling tower would need to be studied. Harm to sea turtles could be an unintended consequence of requiring cooling towers.

Performance standards

EPA Has Overestimated the Benefits of Cooling Towers

In addition to underestimating the costs of wet cooling towers, EPA has overestimated their benefits. EPA appears to have calculated the reduced impact of towers by assuming that a tower will reduce the flow of a once-through cooling system by a certain percentage, starting with the open-cycle system's design flow rather than its actual flow. But, since actual open-cycle cooling systems often will operate below their design flow, the actual, real-world reduction in flow will be less than EPA assumes. See e.g., TDD p. 2.39 (Figure 2-1). That is, EPA assumes that an open-cycle cooling system would be withdrawing the maximum amount of water it was designed to use, rather than the lesser amount it would actually use, and counts as a "benefit" of cooling towers a percentage reduction from that larger number (which EPA does not specify, saying only that it assumes maximum effectiveness) (see Phase II EBA, p. C1-6). Because the make-up requirement for the cooling tower would not be reduced proportionately with the reduction from design to actual flow for the open-cycle system that is being compared, this approach is likely to overestimate the reduction in flow, and thus the assumed reduction in entrainment and impingement, attributable to cooling towers.

Moreover, EPA assumes that a reduction in flow results in a proportional reduction in entrainment and impingement impact. This assumption, although it has often been used in the past, seems highly questionable in light of the EPRI draft report finding a lack of correlation between flow and impact.<FN 18>

Cooling system costs (e.g., dry, wet, recirculating)

UWAG's Analysis of Retrofit Costs Shows that EPA's Estimates Are Too Low

To determine the reasonableness of EPA's estimates of the costs of retrofitting wet cooling towers to existing facilities, UWAG's consultants at Stone & Webster conducted an independent analysis. (This analysis is Appendix 6 to these comments.) It covers over 1,000 units.

Stone & Webster's cost estimates use several cooling tower retrofit case studies developed for existing generating units. The units addressed by the case studies have several advantages that make it relatively easy to retrofit cooling towers: sufficient land close to the condenser/circulating water system, no noise abatement requirements, and the ability to use the existing circulating piping in the closed-cycle system without reinforcement. The result is that the Stone & Webster cost estimates are conservative "low end" costs for cooling tower retrofit projects, assuming that such retrofits would even be feasible.

Stone & Webster find that the total cooling tower retrofit costs for the population of over 1,000 units are approximately $25 to $28 billion in 2002 dollars. Operation and maintenance costs (including energy penalties) are $5 to $12 million in 2002 dollars per year. These O&M estimates come from utility experience at several nuclear plants, and the actual costs for other plants may vary depending on size, water source, electricity prices, and design.

In Section 3 of Appendix 6, Stone & Webster summarizes the complications that can increase the cost of retrofitting cooling towers. For example, most of the piping and components of existing circulating water systems are concrete and supported on (or embedded in) reinforced concrete foundations. Removing existing plant equipment likely would be required to afford access for demolition of existing piping and major thrust blocks (concrete pipe supports) so as to facilitate installing new circulating water system piping to and from the cooling towers. Preliminary engineering evaluations for two conventional natural draft towers at one facility, for example, suggest that the retrofit at that site would require excavating more than 250,000 cubic yards of soil and installing more than four miles of seven-foot-diameter pipe as just one phase of the project.

Require closed cycle cooling

EPA Lacks Legal Authority to Require Cooling Towers

UWAG supports EPA's decision not to require cooling towers for existing facilities, and indeed UWAG believes EPA lacks the legal authority to do so. Even if the costs of cooling towers were lower and their benefits higher, EPA could not, as a legal matter, require closed-cycle cooling under § 316(b). Congress has never given EPA authority to approve or require one type of cooling system over another. By its terms, § 316(b) addresses "intake structures," not cooling systems and not cooling water flow. Unless there is evidence to the contrary, Congress should be taken to mean what it says. UWAG's reasoning on this point is found in its 2000 Phase I Comments, pp. 25-28.

As Bill Anderson says in his article on § 316(b), much of the disagreement about the scope of § 316(b) focuses on the word "capacity." Anderson and Gotting (2001). Anderson concludes that Congress never intended § 316(b) to affect, directly or indirectly, the type of cooling system used at a particular steam-electric plant. Whereas Congress defined "effluent limitation" in § 502(11) to mean a "restriction . . . on quantities, rates, and concentrations of pollutants," in § 316(b) it used instead the word "capacity," which focuses on the physical intake structure rather than the flow of water through the plant. Thus, "capacity" means the size of the intake structure itself and refers to the fact that, for a given flow of water through the plant, the velocity at the intake can be decreased to protect fish by increasing the size of the intake structure. Id. at 36. Another way to think about the issue is by analogy to a drinking glass; the capacity (or volume) of the glass is the full amount it will hold, not whatever amount of water happens to be in it. Similarly, the capacity of a CWIS is its physical size, not the flow through it.

That Congress did not intend EPA to regulate the use of cooling water (that is, flow or volume) is made particularly apparent by Clean Water Act § 101(b), which says that it is the policy of the Congress to preserve and protect the "primary responsibilities and rights of States . . . to plan the development and use (including restoration, preservation, and enhancement) of land and water resources." 33 U.S.C. § 1251(b). More to the point, § 101(g) says that "[i]t is the policy of Congress that the authority of each State to allocate quantities of water within its jurisdiction shall not be superseded, abrogated or otherwise impaired" by the Clean Water Act. 33 U.S.C. § 1251(g). And it is the policy of Congress that nothing in the Clean Water Act "shall be construed to supersede or abrogate rights to quantities of water which have been established by any State." Id. In PUD No. 1 of Jefferson County v. Washington Department of Ecology, 511 U.S. 700 (1994), Justice O'Connor allowed the State of Washington, using § 401 of the Clean Water Act, to impose a minimum instream flow requirement on a hydroelectric project licensed by the Federal Energy Regulatory Commission. Justice O'Connor found that § 101(g) (and § 510(2), providing that nothing in the Clean Water Act shall "be construed as impairing or in any manner affecting the right or jurisdiction of the States with respect to the waters . . . of such States," 33 U.S.C. § 1370), leaves the States their traditional authority to allocate water rights. Also, the SWANCC case tells us that the provisions of § 101 of the Clean Water Act are to be taken seriously. See Solid Waste Agency of Northern Cook Co. v. U.S. Army Corps of Engineers, 531 U.S. 159 (2001).

In short, even if EPA wanted to require cooling towers (despite their high cost), it would not have legal authority to do so.

EPA Response

In this final rule, performance standards are not based on cooling tower technology, however, one of five compliance alternatives is the reduction of flow commensurate with the use of cooling towers, since such a level of performance meets the rule performance standards. See preamble to the final rule, particularly sections III, VII, and VIII.

Dry Cooling

Dry Cooling Is Even Less Justifiable Than Wet Cooling Towers

UWAG also agrees with EPA that dry cooling cannot be justified as a national standard. If closed-cycle cooling (i.e., wet cooling towers) cannot be justified, as argued above, the case for dry cooling is even worse. Even for new facilities, EPA has concluded that dry cooling is too expensive to require on a nationwide basis. As UWAG's comments on the new facility rule pointed out, dry cooling is unreasonably costly and does not work well in some parts of the country.

As part of UWAG's 2000 Phase I Comments, UWAG's consultants performed an analysis of wet and dry cooling systems for combined-cycle power plants, attached to these comments as Appendix 7. This analysis shows how costly the widespread installation of dry cooling towers would be just at new combined-cycle plants.

Assuming that 100% of new combined-cycle capacity over the next 20 years will be constructed with either wet or dry cooling towers, the projected costs (all in July 1999 dollars with future values escalated with a 4% annual rate and present values determined with a 7% annual discount rate) are as follows:

Table 3. Summary of Projected Costs for Wet Cooling Systems

Geographic Group	Capital Costs ($ Millions)	Total O&M($ Millions)	Total Costs($ Millions)
1 - Northeastern U.S.	791.3	347.9	1,139.2
2 - Upper Central U.S.	605.6	237.9	842.5
3 - Southeastern U.S.	1,190.6	547.3	1,738.2
4 - Lower Central U.S.	1,020.1	506.9	1,527.0
5 - Western U.S.	774.3	344.5	1,118.8
Total U.S.	4,382.2	1,984.5	6,366.7

Table 4. Summary of Projected Costs for Dry Cooling Systems (2000-2020)

Geographic Group	Capital Costs ($ Millions)	Total O&M Costs($ Millions)	Total Costs ($ Millions)
1 - Northeastern U.S.	1,388.5	616.5	2,005.0
2 - Upper Central U.S.	1,064.2	422.9	1,487.1
3 - Southeastern U.S.	2,105.1	974.4	3,079.5
4 - Lower Central U.S.	1,813.3	902.9	2,716.2
5 - Western U.S.	1,348.7	608.8	1,957.5
Total U.S.	7,719.8	3,525.5	11,245.3

An estimate of the cost per megawatt can be derived by referring to the new capacity estimates in Tables C1 through C10 of Appendix 7 to these comments.

Regionally and nationally, the estimated capital and total O&M costs for dry cooling systems exceed those for wet cooling systems by about 75%. At $6.4 billion and $11.2 billion for wet and dry systems, respectively, the total costs are significant. If annualized at a 7% rate for the 20-year study period, the estimated national costs for wet and dry cooling systems at new combined-cycle power plants are $0.6 billion/year and over $1 billion/year, respectively.

The analysis in Appendix 7 reaches the following conclusions:

1. By almost any economic measure, a dry cooling system for a new facility costs about 75% more than an equivalent wet cooling system. The higher cost reflects two inherent characteristics of dry cooling: lower performance than wet cooling and greater sensitivity to climatic conditions. The efficiency of dry cooling depends on the ambient dry-bulb temperature at the site.

2. The importance of ambient dry-bulb temperature in determining the performance of a dry cooling system means climatic conditions are important. Therefore, depending on climatic conditions, certain locations in the country will have a higher probability of incurring larger dry cooling energy penalties.

3. Dry cooling systems have greater and more expensive energy penalties than wet cooling systems. The highest probability for incurring an energy penalty is during the warmest times of year, when the demand and the price for electric power are greatest.

4. Dry cooling systems use less water than wet cooling systems. But the unreliability of dry systems at times of peak power demand, as well as the excessive capital and O&M costs, makes closed-cycle cooling less desirable than wet cooling systems.

UWAG has not analyzed dry cooling costs for existing, as opposed to new, facilities. But it is certain the costs would be higher for existing facilities than the costs summarized in Appendix 7. It should be noted that for dry cooling systems it is difficult to estimate energy penalty costs due to hour-to-hour and day-to-day variations in ambient temperatures and the market price of electric power. A recent paper by Micheletti and Burns.<FN 19> points out that using daily averages for dry bulb temperatures and electricity price cannot account for extreme energy penalties that might occur briefly during the hottest times of the day.

Footnotes

19 Micheletti and Burns 2002.

EPA Response

The Agency does not consider dry cooling to be a viable technology for retrofitting an existing power plant cooling system, and as such agrees with the basic conclusion of the comment. See response to Comment ID 316bEFR022.002.

RFC: EPA rationale to not require closed-cycle

Under the Proposed Rule, Permit Writers Could Not Require a Permittee to Consider Cooling Towers Among the Candidates for BTA

UWAG argues above that EPA lacks authority to require closed-cycle cooling, notwithstanding that it has included closed-cycle cooling as one means of satisfying the rule. It follows that a permit writer cannot require a permittee to consider cooling towers as a candidate for complying with the BTA requirement. It follows also that EPA's own determination is that closed-cycle cooling is not BTA.

What should happen, then, if a permittee analyzed each of the technologies on which EPA bases its performance standards (wedgewire screens etc.) and found that none of them would reduce impingement mortality by 80% at the site in question? In that event, the permittee would need to show that the costs of using the technologies to meet the performance standards exceeded either EPA's estimated costs or the benefits of using them, and then resort to a site-specific analysis of BTA. But the permittee would not be required to consider cooling towers as an option for meeting the performance standards before going to the site-specific analysis, nor as an alternative that had to be considered in the site-specific analysis.

EPA Response

The permittee would not be required to consider cooling towers as an option for meeting the performance standards before going to the site-specific analysis, nor as an alternative that had to be considered in the site-specific analysis. The reason for this fact is that EPA did not consider cooling towers retrofit projects in the cost analysis of the requirements of the final rule.

Benefit Estimation Methodology

EPA HAS OVERESTIMATED THE BENEFITS OF REDUCING IMPINGEMENT MORTALITY AND ENTRAINMENT

In its economic analysis of cooling towers, discussed above, EPA underestimates the cost of retrofitting, operating, and maintaining cooling towers. UWAG also believes that EPA also does not adequately take into account the “cost” of the energy penalty that cooling towers will exact. Electric power, after all, is a social “good” just as surely as fish are, and the benefit of producing electric power (or the cost of restricting its production) is no less important to society than, for example, the commercial fishing industry.

At the same time that EPA underestimates the cost of cooling towers, it overestimates the benefits of reducing entrainment and impingement. That overestimation is the subject of this section of these comments.

Throughout its economic analyses, EPA has overestimated both the number of fish likely to be impinged or entrained by Phase II facilities and the value of reducing losses of those fish. To estimate the benefits of reducing entrainment and impingement, EPA (1) developed loss estimates at each case study facility; used them to develop estimates of age-1 equivalents, foregone fishery yields, and foregone biomass production; then divided these estimates by flow to develop a loss/flow ratio; (2) for some waterbodies, applied the loss/flow ratio to other plants on the same watershed to develop a watershed-wide loss estimate; (3) used a variety of methods (the choice among which is usually not well explained) to estimate the economic value of the losses, then divided those by flow to develop a dollar/unit flow ratio; and (4) applied this ratio to various regulatory scenarios, assuming the reduction in losses would be directly proportional to reduction in flow for cooling towers and that reductions would be as specified for other technologies.

Although EPA says that its approved technologies will vary widely in performance, based on site-specific factors, and the Agency therefore proposes to express performance standards as a range, EPA apparently took the opposite tack in estimating the reductions in impingement mortality and entrainment that different regulatory alternatives would achieve. In the Phase II EBA, p. C1-6, EPA says that for purposes of estimating impingement and entrainment benefits, the Agency assumed that each technology would work at maximum effectiveness. EPA does not say exactly what that means, as a percentage for each technology, but the fact remains that EPA’s estimates will be high.

Appendices 8, 9, and 10 to these comments, prepared by nationally recognized fisheries biologists and resource economists, <FN 20> provide a detailed critique of the data and methods EPA used to assess the losses associated with once-through cooling, as well as the likely benefits of requiring cooling towers and various intake structure technologies. As these appendices demonstrate, EPA has vastly overestimated the extent of the entrainment and impingement losses caused by cooling water intakes nationwide, the implications of such losses for consumers and society at large, and the economic benefits of reducing losses.

Footnotes

20 Appendix 3 lists the professional qualifications of the experts who prepared reports for these comments.

EPA Response

EPA has decided not to base the requirements of the final rule on cooling tower technology. If the commenter's claim that EPA underestimated the costs associated with retrofitting, operating, and maintaining cooling towers prove to be true, then the outcome would serve reinforce and support the Agency's decision to not base the requirements of the final rule on this technology.

For a discussion of EPA's consideration of power losses, please refer to the responses to comments 316bEFR.072.209 and 316bEFR.072.301 in subject matter code 9.03.

In the appendices referenced by the commenter three main topics were covered: density dependence, entrainment survival, and the calculation of production foregone. For a discussion of EPA's assumptions about density dependence, please see response to Comment 316bEFR.025.015. For a discussion of EPA's conclusions about entrainment survival, please see response to Comment 316bEFR.306.506 and Chapter A7 of Part A of EPA's Regional Study Document for the Phase II rule. Regarding the calculation of production foregone, please see response to Comment 316bEFR.305.003.

Overview of I & E effects on organisms

Besides these appendices, recent EPRI studies support the conclusion that EPA's benefits estimates are too high. The ongoing study by the Oak Ridge National Laboratory funded by EPRI (EPRI 2002a) concludes that there does not seem to be a dose-response pattern between volume of water withdrawn and effects on fish populations. Where long-time series of data on the factors affecting fish productivity along with data on fish population dynamics are available, volumetric flow relationships have not ranked high as determining factors.

EPA Response

The commenter asserts that certain studies have indicated that there is no linkage between the volume of intake water and fish population dynamics. EPA acknowledges that many factors besides I&E can affect fish population dynamics. EPA's approach to the I&E assessment did not include attempts to model fish population dynamics; nor did it include attempts to determine the relative effects of I&E among all other factors contributing to their dynamics. EPA's approach focused on simple, direct estimates of the foregone yield associated with I&E losses to single cohorts only. See EPA's response to Comment 316bEFR.005.009 and Comment 316bEFR 025.015.

EPA does not understand the reasoning behind the commenter's assertion that EPA's benefits estimates are too high. The assertion appears to be unrelated to the observations about the results of study cited.

Regarding the underlying issue of EPA's method of estimating I&E based on intake flow, EPA notes that there are a number of alternative ways to estimate I&E rates, depending on the purpose of the analysis. Given that the goal of EPA's benefits analysis was to develop regional (not facility-specific) estimates of I&E, EPA believes that it was reasonable to assume that I&E rates are proportional to intake flow. This approach allowed EPA to estimate the relative magnitude of I&E for the nation as a whole despite significant data limitations, including a lack of data for many facilities in scope of the rule.

EPA maintains that, for the purpose of estimating a regional average or total I&E, it is reasonable to extrapolate I&E results from a sample of facilities in proportion to average flow. It is not necessary to have precise, facility-specific estimates for all facilities in a region for this purpose.

EPA notes that the assumption that I&E is proportional to flow is not unusual or inconsistent with other predictive studies, including those by industry. For example, a key assumption of the Spawning and Nursery Area of Consequence (SNAC) model (DCN # 6-2070) is that entrainment is proportional to cooling water withdrawal rates. The SNAC model has been used as a screening tool for assessing potential I&E impacts at Chesapeake Bay plants. As a first approximation, percent entrainment has been predicted on the basis of the ratio of cooling water flow to source water flow (DCN # 1-3027-BE).

Empirical studies also support EPA’s assumption. A study of power plants on the Great Lakes (DCN # 1-3034-BE) demonstrated an increasing relationship (on a log-log scale) between plant "size" (electric production in MWe) and impingement and entrainment. There is scatter in these relationships, not just because there is variation in the cooling water intake for different plants having similar electric production, but also because of the imprecision (sampling variability) inherent in the usual methods of estimating impingement and entrainment. These relationships are nonetheless strong. More recently, a study of plants from both the U.S. and Great Britain concluded that “pumping rate is considerably more important than locality and intake configuration in determining the number of fish impinged or entrained” (316bEFR.077, Comment 1.77 in W-00-32, 316(b) Phase II). EPA’s 1976 “Development Document for the Best Technology Available for the Location, Design, Construction and Capacity of Cooling Water Intake Structures for Minimizing Adverse Environmental Impact” (DCN 1-1056-TC) concluded that “reduction of cooling water intake volume (capacity) should, in most cases, reduce the number of organisms that are subject to entrainment in direct proportion to the fractional flow reduction.”

Fish Population Modeling

Another paper, prepared by Dr. Lawrence W. Barnthouse for EPRI, examines EPA's use of calculated entrainment and impingement losses at case study facilities to extrapolate to losses of age-1 equivalent fish and to losses of pounds of commercial and recreational fish, both for fish that are directly exploited as part of a fishery and for fish populations reduced by reductions in forage fish. The Barnthouse paper shows that EPA's failure to account for density dependence causes a significant overestimate of the likely effects, made even worse by other errors EPA made. EPRI 2002c.

EPA methods: age 1 equiv, yield, prod foregone

EPA Has Used Questionable Methodology to Extrapolate from Losses to Age-1 Equivalents and from Age-Equivalents to Pounds Lost to Commercial and Recreational Fisheries

EPA's methodology for evaluating entrainment and impingement is documented in Chapter 5 of the Case Study Report. It has four major components:

1. Estimating entrainment and impingement losses by life stage;

2. Extrapolating stage-specific losses to losses of age-1 equivalent fish;

3. Extrapolating age-equivalents of exploited fish species to pounds of fish lost to commercial and recreational fisheries; and

4. Extrapolating age-1 equivalents of forage fish to losses in production of commercial and recreational fish.

Dr. Barnthouse has reviewed this methodology, focusing on steps 2 through 4 (extrapolation of age- and stage-specific losses to estimates of reductions in recreational and commercial harvests). One potentially significant assumption in EPA's methodology is that no compensatory processes (e.g., density-dependent growth or survival processes) are operating in the modeled populations. A critique of EPA's justification for this assumption, which it propounds in

Chapter A6 of the Case Study Report, is addressed in Dr. Barnthouse's review.

1. EPA's Extrapolation of Age-equivalents of Exploited Fish Species to Pounds of Fish Lost to Commercial and Recreational Fisheries Is Unclear and Oversimplified

EPA's approach, at least in concept, is similar to approaches used in site-specific assessments, such as the 1999 NJPDES permit application for the Salem Generating Station. However, as discussed below, this approach ignores biological compensation and therefore provides upper-bound estimates on the number of age-1 equivalents lost due to entrainment and impingement. Several other significant uncertainties are inherent in EPA's methodology.

It is important to understand that a single female fish, as noted above, may spawn a million or more eggs a year. Carp, for example, produce approximately 100,000 fertilized eggs per kilogram of body weight, and females begin to spawn at 4 kilograms and can reach sizes of 20 kilograms. Thus the entrainment of 20 million eggs and larvae might represent the production of only 10 or 20 females for one year. And this is an underestimate, because many eggs and larvae will die before they are entrained, but many others will survive entrainment (UWAG 2000 Phase I Comments, p. 164). Under natural conditions, only a small fraction of the eggs produced survive to adulthood. Hence EPA's assumption that a loss of some small percentage of eggs or larvae is a substantial problem ignores the basic biology of natural fish populations.

EPA used a formula (Equation 1) to calculate early life stage survival rates when empirical data are unavailable: Seq = 2/fa, where Seq is the probability of survival from the egg to the expected age of spawning females. Equation 1 assumes (1) that the population being modeled is stable over time and (2) that survival is constant over the period between the spawning and adulthood. The first of these (the stability assumption) is reasonable as a first approximation, because, measured over long time spans, the average sizes of most populations are relatively constant.

The assumption of constancy over all life stages, on the other hand, clearly is an unreasonable oversimplification, because mortality of all life stages and ages of fish is size-dependent. Survival rates of early life stages are very low; survival rates increase with increasing size and age. It is not clear from Chapter 5 of the Case Study Report how EPA apportioned Seq among different life stages when more than one life stage was entrained or impinged.

Moreover, it is not even clear how EPA used Equation 1 to calculate survival rates. For example, consider the estimation of early life stage survival rates using Equation 1. The variable fa in Equation 1, the expected lifetime total egg production of a female recruit, is not directly measurable. It represents the number of eggs expected to be produced over the lifetime of a female fish that has just reached reproductive age, accounting for both the number of eggs produced by the fish at each subsequent age and the probability that the fish will survive to reach that age:

[see hard copy for equation]
where (Equation 2)

Si = fraction of fish surviving from the age at first reproduction to age i
Mi = number of eggs spawned by a female fish at age i
S1 =1.

Estimates of age-specific fecundity and survival are unavailable for many species, and, even within a species, different populations can have substantially different life histories. Uncertainty concerning values of age-specific fecundity and survival rates for adult fish translate, therefore, into uncertainties in lifetime egg production and early life stage survival. Again, it is not clear from Chapter 5 how EPA obtained the necessary age-specific fecundity and survival rates.

Given estimates of stage-specific survival rates, EPA calculates survival from the stage of entrainment or impingement to age 1 using the following equation:

[see hard copy for equation] (Equation 3)

Sj,1= cumulative survival from stage j until age 1
Sj = survival fraction from stage j to stage j+1
= adjusted Sj
jmax = the stage immediately prior to age 1

The adjusted survival fraction in Equation 3, S*j, also is a potentially significant source of error. This adjustment is included to account for the fact that typical entrained or impinged organisms already will have spent a certain amount of time in the life stage where they were entrained or impinged and so already will have survived some natural mortality. The probability that such fish would have survived to age 1 had they not been entrained or impinged is higher than it would have been had they been entrained or impinged on the first day of that life stage. Because of the adjustment, Sj* is always larger than Sj.

The adjustment formula assumes that fish are equally vulnerable throughout the entire duration of the life stage – that is, that the daily probability of entrainment or impingement is constant. If fish become progressively less vulnerable during a given life stage, because of growth, then the adjustment will produce estimates that are biased high, especially if the life stage is long in duration. Juvenile fish, for example, often are vulnerable to entrainment immediately after transformation from the larval stage (~20 mm in length for many species). However, juvenile fish grow very rapidly and, in many species, reach a length of 100 mm or greater by age 1. Beyond a length of ~40 mm, they may be too large to be entrained. In this circumstance, the actual average age of entrained juveniles would be much younger than assumed in EPA's model, so that EPA's extrapolation of the losses to age-1 equivalents would be inflated.

The importance of the two sources of uncertainty, early life stage survival rates and the survival rate adjustment factor, are illustrated in Figure 1 in Dr. Barnthouse's review. As in most of the case studies modeled by EPA, the "juvenile" period (i.e., the period from transformation to the juvenile life stage and the end of the first year of life) is divided into two substages, called "juvenile 1" (J1) and "juvenile 2" (J2). Figure 1 plots the number of age-1 equivalents lost per 10,000 entrained J1 fish. Figure 1 assumes a survival rate of 40% for J2 fish, similar to values for striped bass and weakfish used in the Delaware Estuary case study. A range of values is used for J1 fish, from about 4% to 12%. These values span the range of values assumed for various fish species in EPA's case studies.

For a typical range of 5-10% J1 survival, EPA's methodology produces a range of 381-727 equivalent one-year-olds per 10,000 entrained J1 fish. If juveniles were susceptible to entrainment only at the beginning of the J1 stage, however, then the same 10,000 losses would equate to only 200-400 age-1 equivalents.

These uncertainties translate directly into uncertainties concerning the magnitude of reduced harvests caused by entrainment and impingement. Because EPA's model is linear, a factor of 2 uncertainty in number of age-1 equivalents per lost fish translates into the same factor of 2 uncertainty in pounds lost and economic value.

EPA Response

Regarding compensation, please see EPA's response to Comment 316bEFR.025.015. Regarding the method for adjusting survival rates of entrained juveniles, please see EPA's response to Comment 316bEFR.074.101

Fish Population Modeling

EPA Has Not Justified its Assumption that There Is No Density Dependence

Chapter A6 of EPA's Case Study Report discusses the use of "population models" in assessing long-term consequences of mortality due to entrainment and impingement. Here, "population models" means the use of classical spawner-recruit models such as the Ricker and Beverton-Holt models (both of which have been used for fishery population management) to quantify the influence of density-dependent population regulation (compensation) on the abundance of fish populations and to calculate estimates of long-term effects that include the influence of density dependence. Specific topics covered in the chapter include:

-The general concept of population regulation and the principal models used by fisheries scientists to quantify density dependence,

-The way in which these models can be used to calculate quantities of interest to fisheries managers (e.g., maximum sustainable yield),

-Modifications of the models made to apply them to CWIS impacts,

-Various uncertainties that limit the ability of stock-recruitment models to predict responses of fish populations both to harvesting and to entrainment/impingement losses, and

-EPA's rationale for not quantifying impacts on populations and, instead, using models that assume no density dependence.

EPA asserts that stock-recruitment models do not account for impacts on multiple species, do not include impacts of multiple intake structures, do not account for other sources of human-related mortality (e.g., toxic chemicals), do not incorporate interspecies interactions, and do not consider interactions between density-dependent and density-independent processes. Case Study Analysis, p. A6-6. Because of the high degree of uncertainty associated with stock-recruitment models and because many of the fish species that are vulnerable to entrainment and impingement already may be depleted by overfishing, a "precautionary" approach to impact assessment is appropriate, according to EPA. The precautionary approach, EPA says, entails (1) use of entrainment and impingement losses as direct measures of potential impacts, analogous to the use of toxicity testing to predict the potential impact of pollutant discharges; and (2) use of density-independent models to project estimates of entrainment and impingement losses to estimates of reduced harvest and production foregone. Case Study Analysis, pp. A6-6 –A6-7.

In the first place, EPA's statement that many fish species may already be depleted as justification for a precautionary approach is not, and probably cannot be, supported. Before relying on this idea, EPA needs to show the public, if it can, which of the hundreds of sites and several hundred species affected by cooling water intakes are depleted by overfishing.

UWAG's primary concern with this assumption of overfishing, however, is that it inappropriately confuses the phenomenon of biological compensation with the mathematical models that have been used by fisheries biologists to quantify compensation. In addition, this assumption oversimplifies the use of compensation in fisheries management.

The operation of density-dependent processes in fish populations has been demonstrated in literally dozens of empirical studies, including statistical analyses of long-term databases and direct manipulative studies in small ponds and lakes. (See Appendix 5 to these comments.) Moreover, density dependence is explicitly recognized in fisheries management regulations implemented by the National Marine Fisheries Service (NMFS), which state that exploitation that reduces the size of populations by greater than 50% below the unexploited stock size are consistent with the long-term sustainability of populations (NMFS 1998b).

In focusing on a few types of simple models, EPA greatly oversimplifies the biological basis for life stage density dependence and ignores the fact that compensation is acknowledged explicitly by fisheries management regulations. The Ricker, Beverton-Holt, and other stock-recruitment models are used in fisheries management only when large quantities of high-quality data are available. In other cases, the approach most commonly used for establishing fishing rates that protect the reproductive capacities of fish populations is the "spawning stock biomass per recruit" (SSBPR) approach (Goodyear 1993). The SSBPR approach implicitly considers life stage density dependence by quantifying influence of fishing mortality on the reduction in number of eggs produced per female recruit over her lifetime. To maintain a stable population, the survival rate of each spawned egg must increase in order to offset the reduction in lifetime egg production caused by harvesting. As noted by Goodyear (1993), the SSBPR model was first described in 1977 (Goodyear 1977) as a method for indirectly quantifying life stage density dependence in power plant impact assessments.

Technical committees of the Atlantic States Marine Fisheries Service have, in fact, developed stock-recruitment models for two fish species that often are entrained and impinged at East Coast power plants: striped bass and weakfish (NMFS 1998a, NMFS 2000). These models are used as an input to the management process for these species, although they are not used to calculate numerical harvest limits. Although spawner-recruit models are not yet widely used in fisheries management, life stage density dependence is at least implicitly included.

Many of the uncertainties inherent in EPA's biological assessment method (e.g., estimation of stage-specific natural mortality rates) could lead to inaccurate estimates of the potential harvest lost due to entrainment and impingement. Ignoring compensation, on the other hand, can lead only to an overestimate of harvest reduction and, therefore, to an overestimate of the benefits to be gained by implementing technologies to reduce entrainment and impingement. The magnitude of the bias introduced by assuming a linear relationship between losses and harvest reduction is difficult to quantify, but it would be expected to be relatively small for fish stocks that are severely depleted and have a very low compensatory reserve, but relatively large for fish stocks that currently are being exploited at sustainable levels. EPA has made no attempt to quantify the degree of bias or the influence of such bias on the benefits assigned to alternative intake technologies.

It clearly is true that the precision of typical spawner-recruit models usually is too low for use in managing specific fish stocks. However, this degree of precision may not be necessary for a national-scale benefits analysis such as the one performed by EPA. For example, the methods developed by

Myers et al. (1999) for estimating the compensatory reserve of fish populations based on meta-analysis of hundreds of published stock-recruitment data sets could be used to develop such models for use in the benefits assessment. Rose et al. (2001) showed that this method produces estimates of compensatory reserve that are consistent with expectations derived from fish life history theory. Although the benefits predictions derived from a model that included compensation would be uncertain, they at least would not contain a consistent bias toward underestimation or overestimation of benefits.

As for EPA's resort to the "precautionary principle," UWAG has several observations. First, the precautionary principle is not mentioned in the Clean Water Act, and Congress did not direct that EPA use it. Second, the precautionary principle is one way of dealing with uncertainty in scientific studies but not the only one. Third, EPA's resort to the precautionary principle for applying § 316(b) seems to be based on an unsupported and unjustified assumption that cooling water intakes are causing widespread damage, which in fact is not true. Fourth, resorting to the precautionary principle whenever it is convenient to get past a point of uncertainty in the analysis tends to compound conservatisms until the end result is hyperconservative (overprotective) and therefore needlessly costly from a public policy standpoint. Fifth, EPA's goal should be to make its scientific estimates as realistic as possible and only then, if at all, to use the precautionary principle to set a margin of error in the final regulatory limit. Invoking the precautionary principle willy-nilly during the course of purely factual analyses risks producing a result that is unrealistic and, worse, unrealistic in a systematically biased way.

EPA Response

For its final analysis for the 316b Phase 2 rule, EPA did not include the material in Chapter A6 of the Case Study Document (DCN #6-0003) discussed by the commenter. However, EPA has addressed the issues raised by the commenter elsewhere in its responses to comments. Please see responses to Comment 316bEFR.005.009 on fish population modeling, Comment 316bEFR.025.015 on compensation, and Comment 316bEFR.005.026 on the term "precautionary approach."

Extrapolation of Case Study Ben. to National Level

EPA's Methodology for Extrapolating Baseline Losses at Case Study Facilities to National Baseline Losses Is Flawed

In Chapters C2 and C3 of EPA's Phase II EBA and Chapters B3, C3, and D3 of EPA's Case Study Analysis, EPA describes its method for estimating national losses of fish from impingement and entrainment. The method starts with actual measured losses at a few specific plants (the ones in its "case studies") and then extrapolates those numbers to produce a nationwide estimate. The assumption that impingement and entrainment are strictly proportional to flow (see, e.g., CSA C3-22) is critical to EPA's extrapolation method.

UWAG submits that EPA has never tested this assumption and, in fact, the available evidence and analyses show that it is not supported. Indeed, as discussed in Appendix 8, a review of the only EPA data set that is sufficiently extensive to permit quantitative analysis shows plainly that this core assumption is not true.

UWAG's review of this extrapolation methodology is primarily contained in Appendices 8 and 10. UWAG has five major concerns with EPA's extrapolation method.

1. The Tampa Bay and Ohio River Facilities Are Not Representative

First, the assumptions on which EPA's extrapolations for the Tampa Bay and Ohio River waterbodies are based are likely not valid. As EPA itself says, "[e]ven similar facilities on the same waterbody can have very different impacts, depending on the aquatic ecosystem in the vicinity of the facility." Phase II EBA, p. C1-1. EPA then proceeds to ignore its own advice. The fish community near the Big Bend facility has not been shown to be representative of the fish community in Old Tampa Bay and Hillsborough Bay (an assumption required by EPA's method). And, further, Tampa Bay cannot be considered representative of the entire Gulf Coast since the bay is not affected by sediments from the Mississippi River's silt plume. Estuaries from Mobile Bay, Alabama, to Corpus Christi Bay, Texas, experience higher levels of turbidity in comparison to those in Florida. Estuaries in Louisiana and along the upper Texas coast experience the highest ambient TSS levels. In addition, these Gulf Coast estuaries have extremely high levels of particulate organic matter (POM) that form the basis of a complex and extremely productive detrital food web.

For the Ohio River, the data presented for case study facilities in the Markland pool of the Ohio River (the only pool containing at least three case study facilities) indicate that impingement and entrainment losses are not proportional to intake flows (another assumption required by EPA's method). Appendix 8, p. 8-9, and Figure 1.

2. EPA Did Not Select the Case Study Facilities at Random

Second, for all waterbody types, EPA did not ensure representativeness of reference facilities by selecting the facilities on which it bases its extrapolations randomly. Indeed, the limited information in the case studies suggests that the reference facilities are not representative of all facilities within their waterbody types. EPA says it selected the case studies to represent a range of characteristics, but it does not say how the studies selected represent those characteristics. Instead, after naming important factors, EPA simply claims that the case study sites used for extrapolation are "considered representative of the majority of steam electric generators in the United States." Phase II EBA, p. C1-1 to C1-2. This is a truly astounding and wholly unsupported claim.

In fact, EPA appears to have selected for analysis only facilities with substantial existing data. Through use of that selection criteria, EPA biased the selection process. Those facilities with the most complete data sets tend to be the "high profile" sites that developed the data to allay perceptions about potential environmental impacts. The many sites that do not have extensive data sets may be more representative of typical CWIS impacts than facilities that have been heavily scrutinized and therefore have amassed extensive data and information.

3. EPA's Flow Index Extrapolation Method is Not Valid

Starting from the assumption that impingement and entrainment are strictly proportional to flow (which, as we have shown, is not the case), EPA developed biological loss estimates for a relatively small number of non-randomly selected plants. That is, for purposes of national extrapolation, EPA relied on impingement and entrainment data for 13 out of the 539 in-scope plants, or roughly 2% of the in-scope plants.

It then used a variety of methods to estimate the economic value of that impingement mortality and entrainment (which, in the case of entrainment, it assumed was entrainment mortality, despite the existence of data showing appreciable entrainment survival for at least one of the plants). Using this information, EPA applied a Flow Index Extrapolation method to derive estimates of the economic value of losses nationwide. Like EPA's biological loss estimates, the legitimacy of this rests on the truth of the assumption that the economic value of impingement and entrainment, and thus the economic loss to society, is strictly proportional to flow. EPA made no attempt to test this critical assumption. Given that the Agency's underlying assumption about the proportionality of biological losses and flows is unsupported, as Appendix 8 shows, it seems equally likely that this second assumption is also false.

4. Using the Angling Index Is Not a Valid Method

UWAG's fourth major concern is EPA's use of its Angling Index as a basis for extrapolation. Although it may have some superficial heuristic appeal, the Angling Index simply is not a valid method for estimating the value of national baseline losses. If used at all, it should be applied only to the portion of value lost that is attributable to reductions in recreational catch. Even for that portion, the Angling Index likely would produce biased results because the losses at the reference stations appear to be substantially higher than the average losses at other case study facilities.

There are at least three factors that inflate the Angling Index values: (1) the method uses double, treble, and maybe even quadruple or more counting; (2) EPA may not have accurately evaluated fishermen's choices of where they would go fishing (many anglers in Ohio would travel 20 miles to fish in the Ohio River but not 120 miles to fish in Lake Erie); and (3) a loss of fish does not automatically translate into a benefit if it is suddenly protected (fish that have compensatory reserves may be at the carrying capacity of the waterbody, and a reduction in mortality from one source would only serve to increase mortality from other sources). EPA's method fails to account for any of these.

EPA has applied the Angling Index method so as to overestimate angling days by failing to account for facilities that are within the 120-mile radius of another plant for which EPA developed an estimate. Basically, EPA assumed that each plant would serve a separate set of anglers, which is not the case.

5. EPA Uses High Estimates for the Great Lakes and Ocean Waterbody Types

UWAG's fifth major concern is with EPA's basis for choosing "best" estimates. EPA's rationale for using the high estimates (rather than a midpoint of high and low estimates) for the Great Lakes and Ocean waterbody types seems to contradict its rationale for using benefits transfer techniques for its initial estimates of the value of baseline losses. Moreover, EPA's sole reliance on HRC (habitat replacement cost) estimates ignores the range of estimates of value that it compiled.

Also, EPA's method for selecting "best" estimates is inconsistent and poorly justified. A detailed quantitative assessment of the effects of eliminating the Angling Index extrapolation method and of standardizing the choice of "best" estimates is not possible, given the limited data and information presented in the EPA reports.

A simple analysis can provide a sense of the magnitude of the effects of these errors. EPA reported its "best" estimate of the value of national baseline losses (for the 539 in-scope facilities) due to entrainment and impingement to be $1,521,000,000 (from Phase II EBA Table C3-6). Using midpoints as "best" estimates for all waterbody types (rather than using the upper bound estimates as "best" estimates for the Great Lakes and Ocean waterbody types) reduces the national baseline estimate from $1,521,000,000 to $1,350,000,000. Eliminating the use of EPA's Angling Index method of extrapolation (and use of only the Flow Index extrapolation method) further reduces the national baseline estimate to $1,081,000,000.

In short, EPA's use of the invalid Angling Index method (rather than only the Flow Index method, which itself relies on very simplistic and conservative assumptions), coupled with its inconsistent method for choosing "best" estimates (rather than using midpoints of high and low estimates for all waterbody types), has the effect of increasing EPA's national baseline estimates by over 40%.

The overall effect of these errors in EPA's methodology is to overstate significantly the estimate of nationwide losses. Although there is reason to question the validity of EPA's Tampa Bay and Ohio River loss estimates, the data and information presented in the Case Study Analysis and the Phase II EBA do not support a quantitative assessment of the effects of possible errors in those estimates. The same is true regarding the effects of apparent violations in assumptions of the Flow Index extrapolation method.

EPA Response

Regarding the commenter's comment that EPA's estimates of losses are flawed and biased, please see responses to (1) Comment 316bEFR.305.003 on EPA's production foregone method, (2) Comment

316bEFR.306.506 on EPA's conclusions regarding entrainment survival, (3) Comment 316bEFR.025.015 regarding compensation, (4)Comment 316bEFR.005.035 on the habitat-based replacement cost method and benefits analysis, (5) Comment 316bEFR.005.029 on EPA's commercial fishing benefits analysis, and (6) Comment 316bEFR.075.504 on EPA's recreational fishing benefits transfer methods.

In response to the commenter's request for a clarification of baseline, EPA notes that it has defined the I&E baseline as EPA's estimates of current average annual I&E rates (i.e., rates without the rule). The terms "case study facility" and "model facility" are used interchangeably to refer to the facilities with I&E data that were evaluated by EPA and used in its regional extrapolations.

The extrapolation approach described in the comment pertains to the approach applied by EPA at proposal, and is no longer used. The Tampa Bay and Ohio case study extrapolations presented at proposal are no longer included. As described in the NODA, for its final analysis EPA examined I&E losses, and the economic benefits of reducing these losses, at the regional level. The estimated benefits were then aggregated across all regions to yield a national benefit estimate.

The angling index is no longer used in extrapolation. Please see response to Comment 316bEFR.041.804 for information on the flow index. Regarding EPA's assumption that I&E is proportional to intake flow, please see EPA's response to Comment 316bEFR.041.037.

The primary objective of the regional extrapolation approach was to refine the scale of resolution of the benefits case studies conducted for proposal, so that extrapolations were within regions rather than nation-wide. Extrapolation was necessary because not all in scope facilities within a given region have conducted I&E studies. (For more detail on the regional approach, please see Chapter C1 of the EBA -- DCN #6-0002.)

Extrapolation was performed between facilities in the same region with similar technical characteristics. I&E data from multiple facilities in each region were used to develop each regional estimate. In some cases, all of the facilities in a region were evaluated (e.g., California). Data from a total of 46 facilities were used to develop I&E estimates for 7 regions. All extrapolations were based on losses per unit of average annual operational flow. Operational flows were obtained from EPA's survey of the industry.

EPA believes that this extrapolation approach was appropriate for the purposes of its analysis. EPA was concerned with developing regional estimates of I&E, not facility-specific estimates. For this purpose, it is important that estimates average out, but they don't have to be exact on a facility-specific level.

Ecological Evaluation Methodology

EPA Has Disregarded Benefits of Open-Cycle Cooling

EPA also has overstated the benefits of cooling towers by disregarding some of the counterbalancing benefits of open-cycle cooling. At some sites, losses from open-cycle cooling are offset by benefits from open-cycle cooling, such as (in some cases but not others) increased dissolved oxygen from increased water circulation. There may be benefits, for example, where cropping of one species by impingement or entrainment benefits a more desirable species. And, at some sites, the warm discharge of an open-cycle cooling system may be beneficial for some animals, like manatees.

Moreover, entrained animals that are captured and returned unharmed to the environment cannot be considered an "adverse impact" or a "cost." For example, approximately 600 sea turtles entered the intake canal at the St. Lucie Plant in 2001, and over 99% were successfully captured and returned to the Atlantic Ocean. Before being released, the turtles are examined, weighed, and measured. The result is an enormous amount of scientific information (which NMFS considers to be very valuable) about sea turtles. Also, any turtles that are injured or ill (generally for reasons unrelated to the power plant) are taken to a nearby facility for rehabilitation and then released. The operator, Florida Power & Light Company (FPL), is constantly modifying and improving this program.

FPL also is permitted to capture at the St. Lucie Plant fish that are trapped in the intake canal. Many of these fish are captured and released, while others are removed and relocated to aquariums all over the world. This reduces the number of specimens the aquariums would otherwise have to acquire from some other source.

Also, the fact that wet cooling towers increase consumption of water imposes an important cost that EPA should take into account. Parts of the country suffer from droughts, and not just in the West, and water shortages are expected to be an increasingly important issue in the future.

EPA Response

Today's final rule does not require the use of wet cooling towers.

Benefit Estimation Methodology

EPA's Calculation of "Benefits" Is Too High

In Appendix 9 to these comments, Triangle Economic Research (TER) finds serious flaws and inconsistencies in EPA's economic benefits analysis. TER has extensive experience in valuing natural resources and in conducting high-quality benefit-cost analyses and cost-effectiveness studies. In many cases, TER finds, EPA used methods that are not consistent with EPA's Guidelines For Preparing Economic Analyses ("Guidelines"). Nor is EPA's application consistent with the OMB guidelines for conducting regulatory impact analyses.<FN 21>

EPA has estimated that national benefits for the proposed rule would amount to $734,728,000. TER estimates that, once various flawed methodologies are corrected, this number should be closer to $41,776,000. In short, EPA appears to have overstated the "benefits" of the proposed rule by over 17 times. To put it another way, EPA's estimate of benefits should be reduced by 94.3% if it is to reflect sound methodology.

The EPA benefits transfer application routinely violates both the "similarity" and "soundness" criteria used to evaluate the appropriateness of a transfer. The Agency's choice of the studies to represent the case study areas reflects many bad economic judgments. Moreover, EPA's failure to account for the appropriate timing of future benefits leads to significant overstatement. The commercial fishing benefits estimation methods use assumptions that are without economic foundation, leading to a substantial overstatement of benefits. The nonuse benefit estimates are calculated using a rule of thumb method that is based on studies conducted more than 20 years ago and are inappropriately transferred to the CWIS application. The Agency's rule of thumb fails to account for any of the recent studies that have raised serious concerns about the reliability of nonuse value estimates. EPA's method of extrapolating benefits to the national level systematically biases estimates upwards. Finally, the valuation methods referred to as Habitat Replacement Cost and Societal Revealed Preference confuse the fundamental concepts of benefits and costs, invalidating them for use in a benefit-cost analysis.

Below is a summary of the major problems with EPA's benefit estimate methods that TER identified.

Footnotes

21 Economic Analysis of Federal Regulations under Executive Order 12866 (OMB 1996).

EPA Response

This comment refers to EPA's proposed rule analysis. For the final rule analysis, EPA has made significant changes in its methods and applications. For recreational fishing valuation, EPA has estimated original regional RUM models for most regions. The exceptions are the North Atlantic region, where benefit function transfer is used, and the Inland region, where benefit transfer is used. For EPA's response to comments on the benefits transfer method used at proposal, please see comment # 316bEFR.075.504.

As stated in the NODA, EPA has discounted benefits to account for timing of benefit flows in the Section 316(b) Phase II rule analysis.

As stated in the NODA, the rule-of-thumb approach to estimating non-use is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. Given the unavoidable uncertainties in estimating non-use benefits for this rule, the Agency presented a qualitative assessment of the benefits of the environmental protections at issue in the final 316(b) benefit cost analysis.

The HRC method is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the HRC method, please see the response to comment # 316bEFR.005.035.

The SRP method is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the SRP method, please see the response to comment # 316bEFR.005.006.

For EPA's response to comments on the extrapolation method used at proposal, please see the response to comment #316bEFR.041.041

Use of Replacement Costs (HRC and hatchery-based)

EPA's Habitat Replacement Cost Benefit and Societal Revealed Preference Estimates Are Without Economic Foundation

EPA's Habitat Replacement Cost (HRC) method and the Societal Revealed Preference method are inherently flawed. Both methods use costs of one type or another as a substitute for benefit estimates. This assumption that benefits equal costs is fundamentally flawed. Consumer surplus, not cost, is the basic measuring concept for estimating benefits. There is no justification for using costs as a proxy for benefits in the economics literature, nor is this approach consistent with EPA's Guidelines for Preparing Economic Analyses (Guidelines). EPA provides various rationales for using these non-economic methods to measure benefits. In its report, TER refutes each of the purported rationales for these approaches. In several instances, the rationales are inconsistent with EPA's own benefits analysis for the proposed Phase II rule.

EPA Response

EPA does not use the Habitat-based Replacement Cost (HRC) method in the cost benefit analysis for the final Section 316(b) Phase II rule. Please see the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003) for additional discussion of the HRC method. Please also see EPA's response to comment #316bEFR.005.035.

EPA does not use the Societal Revealed Preference (SRP) method in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the SRP, please see the response to comment #316bEFR.005.006

Comment ID 316bEFR.041.045

Subject Matter Code 10.02.02

Commercial Fishing Benefits

Commercial Fishing Benefits Are Significantly Overstated Because of Suspect Empirical Analysis

The methods EPA uses to calculate the benefits of increased commercial dockside landings are suspect. Areas of particular concern include incorrect specification of benefit timing and inappropriate benefit transfer. EPA's benefit timing assumptions ignore the time from implementing the CWIS investments to the time that fish mature sufficiently to be caught for commercial purposes. Any potential benefits accruing to commercial anglers will begin some time in the future and should be discounted appropriately. EPA's Guidelines clearly state that, "present consumption is valued differently from future consumption" (p. 34). In addition, only some surviving age 1 equivalents are caught in their first year of adulthood. Others in this cohort are partially harvested each year of their remaining expected lifetime.

The magnitude of incorrectly specifying this time profile on benefit estimates depends on the appropriate discount rate, which is 7 percent for commercial fishing. The effect of time-lag to adulthood and partial benefit realization on net present value also is species dependent. However, EPA's analysis recognizes that more valuable fish such as striped bass and black drum take the longest to reach adulthood and live the longest. Thus, the appropriate discounting has a greater effect on the benefits from the most valuable species. Completely accounting for the effects of benefit timing and discounting is beyond the scope of TER's review. However, assuming a five-year lag to benefit accrual and harvesting of an entire cohort in its first year of adulthood produces an 11.9 percent reduction in EPA's benefit calculations. <FN 22> Table 1.1 in TER's report, reproduced below, details the effects of appropriate adjustments to commercial fishing benefits on overall benefits estimates:

[see hard copy for table]
Table 1.1 Adjustments to EPA National Benefits

Moreover, the assumptions and studies used by EPA to obtain societal benefits from commercial benefits are inappropriate. In particular, EPA's approach of scaling benefits estimates arising from short-run analyses to a long-run situation is improper. In a short-run analysis, commercial anglers can change only the amount of labor, fuel, or other variable inputs. In the long run, anglers can purchase new boats or make other capital improvements.

More important, the longer the time period, the more likely that new entrants will be attracted by economic profits or larger producer surpluses. Thus, economic theory dictates that long run producer surplus, and thus benefits to commercial angling, should be zero. EPA provides no alternative theoretical explanation for why the basic theory should not hold, nor does the Agency provide any empirical evidence required by its Guidelines to support this adjusted transfer. Thus, EPA's assumption that commercial fishermen will receive long-run profits ranging from 40–70 percent of increased dockside value is unwarranted. Removing the effect of these incorrect assumptions results in the 4.8 percent reduction in EPA's total benefits estimates depicted in Table 1.1.

EPA's multimarket producer surplus estimates hypothesize that long-run increases in producer surplus also accrue to related fish markets. Here again, EPA inappropriately transfers a 4.5 benefit multiplier from a short-run study. The existence of long-run producer surplus in any open market is an anomaly. According to a study cited by EPA, striped bass wholesalers receive markups of between "10 and 20 percent of the price paid to fishermen" (Norton et al. 1983). Prices are determined not by wholesalers, but by supply and demand situations at the Fulton Fish Market. Clearly, this is a description of a competitive industry with market participants receiving only normal market returns. Removing these inappropriate benefits from EPA's calculations results in a 36.6 percent reduction in EPA's total benefits estimates. Thus, the inappropriate inclusion of commercial fishing benefits leads to a combined overstatement of benefits of 41.4 percent.

Footnotes

22 This conservative assumption employs a 7 percent discount rate and does not spread benefit accrual over the life cycle of a fish cohort.

EPA Response

In the results presented in the Regional Study Document (DCN #6-0003), EPA discounts commercial and recreational fishing losses and benefits using discount rates of 0%, 3%, and 7%.

For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits, please see the response to comment 316bEFR.005.029. This comment response also addresses the need for discounting.

Recreational Fishing Benefits

Recreational Fishing Benefit Estimates Are Overstated and Based on Inadequate Methodologies

EPA estimates recreational fishing benefits using benefits transfer and random utility model (RUM) analysis. Major areas of concern with EPA's recreational fishing benefit analysis include inaccurate characterization of the timing of benefits, <FN 23> incorrect specification of random utility models, and improper selection of studies for benefits transfer.

In the context of § 316(b) regulations, random utility models provide the best opportunity for correctly valuing increased catch hypothesized to result from entrainment and impingement reductions. These models are the most widely used method for valuing recreational fishing. They assume that a fishing site is a bundle of features such as accessibility, aesthetics, relative fishing success, and distances from anglers' homes. The RUM models also assume that anglers choose fishing sites that will maximize their satisfaction or utility. By observing the choices anglers make and the distances they are willing to travel, it is possible to measure the value of increasing a single feature of a recreation site, such as improved fish catch, which would be associated with the § 316(b) regulations.

However, EPA's analysis, as presented, is unsuitable for this purpose. In particular, with the random utility approach, the specification of opportunity cost of time and the estimation technique employed are key features of the model. EPA's random utility analysis contains several errors in these areas that invalidate their results. In particular, departures from standard random utility methods in terms of sampling methodology, calculation of implicit trip costs, and participation modeling lead to inflated benefit estimates many times those found in typical RUM studies.

Because EPA's RUM-based per-fish valuation numbers arise from nonstandard techniques and appear greatly inflated, TER concludes that they are inappropriate for the current application. Relying solely on benefits transfer numbers reduces overall benefits estimates by 8.4 percent as shown in Table 1.1. Furthermore, as Table 1.1 shows, the combined effect of adjusting for the timing of benefits and relying only on benefits transfer numbers reduces EPA's benefits estimates by 9.5 percent.

For benefits transfer, EPA focuses on comparing the physical characteristics of the study areas to each case study site. Studies chosen for the transfer are based on waterbody type, geographic location, and relevant species of fish. However, there are other aspects in which the studies used are not similar. These include the comparability of affected populations and the nature of the effects being valued in the study.

Furthermore, EPA selects recreational fishing studies to use that are not scientifically sound in terms of the response rate and estimation techniques, thereby violating the soundness criterion for benefits transfer. Moreover, because some of the studies are dated, they result in estimation methodologies that are no longer consistent with the best practices in the economics profession.

In violating the similarity and soundness principles of the benefits transfer method, EPA produces recreational fishing estimates that are upwardly biased. Correctly implementing original random utility studies or performing a detailed meta-analysis <FN 24> of existing recreation valuation studies would provide the best opportunity for measuring the recreational benefits hypothesized to arise from § 316(b) regulations.

Footnotes

23 Corrections to benefit timing and discounting in recreational benefits analysis are similar to commercial corrections but less influential (2.3%) due to a lower (3% versus 7%) discount rate.

24 Meta-analysis is the statistical synthesis of a large number of similar studies.

EPA Response

The commenter states that EPA's analysis of recreational fishing benefits presented at proposal is flawed because the Agency did not follow steps for developing a benefit transfer approach outlined in EPA's Guidelines for Preparing Economic Analyses. For EPA's response to comments on the benefits transfer approach used at proposal, see response to comment #316bEFR.075.504.

The commenter further states that "random utility models (RUM) provide the best opportunity for correctly valuing increased catch." The commenter, however, identifies several methodological flaws in EPA's RUM analysis.

EPA agrees that "random utility models (RUM) provide the best opportunity for correctly valuing increased catch" and has therefore expanded its use of the RUM method to include all study regions except the Inland region in the final 316(b) analysis. The Agency disagrees that its RUM approach is "unsuitable" for estimating recreational fishing benefits of the 316(b) regulation. For EPA's response to comments on the RUM method, please see responses to comment 316bEFR.041.452, 316bEFR306.320, and 316bEFR337.010.

Valuing Forage Species (incl non-use and non-landed)

The Conceptual and Empirical Bases of the Nonuse Benefit Estimates Are Flawed

There is considerable agreement that some people hold nonuse values, also referred to as existence or passive-use values, for some resources. Whether nonuse benefits should be included in a benefit-cost analysis is more controversial (Madariaga and McConnell 1987; Hausman 1993). Citing difficulties with contingent valuation (CV), EPA employs a benefits transfer approach for nonuse valuation. EPA cites Fisher and Raucher (1984) as well as Freeman and Sharma (1977) in stating that nonuse values should conform to a simple 50 percent (of use values) "rule of thumb." According to this approach, the theoretical existence of positive nonuse values justifies an approximation. The 50-percent rule of thumb approximation is based on an average of resources for which both use and nonuse values have been calculated.

However, EPA makes no effort to investigate the similarity of these situations to CWIS improvements. For example, because nonuse values do not depend on direct contact, concepts such as uniqueness, awareness, and the motives people may have for nonuse values are important factors in their determination. A cursory investigation indicates that the marginal improvements to fisheries being studied here are not likely to be unique or create substantial awareness. In addition, EPA's argument that nonuse values result from existence and bequest motivations is unconvincing. EPA provides few data or results to support effects that are not captured in use values. For this regulation, TER concludes that nonuse values are not zero but are likely to be negligible. Table 1.1 above includes nonuse values that are 10 percent of the combined use values, which reduces the EPA benefits estimates by 8.6 percent.

EPA Response

EPA agrees that many people hold non-use values for some resources, including fish lost to I&E.

The commenter suggests that the improvements expected from the rule are not likely to create substantial awareness. However, EPA notes that significant numbers of fish are expected to be spared from I&E and that only a small portion are valued in the commercial and recreational fishing analysis. (Please see EPA's response to comment #316bEFR.336.009 for a discussion of issues related to valuing the unlanded fraction of fish spared from I&E.)

The commenter also suggests that non-use values should be just 10% of combined use values and uses these values in calculating total benefits. But the commenter does not provide justification for this assumption.

EPA notes that the 50% rule-of-thumb is not used to estimated benefits for the final rule. For EPA's response to comments on the use of the 50% rule-of-thumb, please refer to EPA's response to comment #316bEFR.005.034.

Please also refer to EPA's response to comments on the HRC methods (316bEFR.005.035) and the SRP methods (316bEFR.005.006); the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003); and to EPA’s Guidelines for Preparing Economic Analyses (EPA 240-R-00-003).

Extrapolation of Case Study Ben. to National Level

EPA's Aggregation of Benefits to the National Level Uses Improper Statistical Methods Resulting in Biased Estimates

EPA developed an extrapolation method to estimate national benefits from the proposed Phase II rule and five regulatory alternatives. National baseline losses from I&E are estimated by extrapolating data from the facilities in the five case study areas to 539 in-scope facilities. Only a subset of these facilities is included in the actual aggregation, further limiting the size of the sample for estimating aggregate national benefits.

Moreover, several fundamental flaws in the EPA extrapolation methodology render the results unreliable. One of the biggest problems is the manner in which EPA chooses the case study facilities. EPA does not select a random sample of facilities for the case studies, which introduces a systematic bias to their results. EPA's grouping of the case study facilities into five waterbody types does not allow for variability of habitat, fish populations, and resulting I&E risk within a waterbody category. The habitat and respective I&E risk of the selected facility is applied to all in-scope facilities in that waterbody type, resulting in biased benefit estimates.

Additionally, EPA introduces a systematic bias into its results by computing estimated fish lost per million gallons per day (MGD) based on flow indices. Estimates are developed for each waterbody type based on an arbitrary selection of a facility within that type. The fish populations near that particular facility determine the magnitude of the estimates. These fish loss estimates are then applied to all facilities within that waterbody type regardless of the nearby fish populations.

Calculating a weighted average by waterbody type reveals the extent of the bias in these calculations. Although not all data are available, TER's preliminary calculations suggest that flaws in EPA's aggregation methods overstate benefits by more than 12 percent. See Appendix 8 for a more detailed explanation of EPA's procedure.

Finally, EPA's method of computing angling indices for each facility results in an overestimate of angling days due to EPA's lack of consideration of substitute fishing sites. Overestimating angling days leads to an overestimate of benefits. Again, EPA bases extrapolations on estimations of recreational catch from only one facility per waterbody type. A cursory examination indicates that the degree of bias is similar to that found in EPA's flow index extrapolation method. Heimbuch (2002) contains a more thorough critique.

EPA Response

For the cost-benefit analysis for the final 316(b) Phase II rule, EPA addressed many of the issues raised in this comment. More case study facilities were used. All facilities analyzed are included in the extrapolation. Extrapolations were made within regions rather than waterbody types, and were based on a variety of factors including flow. The angling indices was not used.

For details on EPA's response to comments on extrapolation methods, please see the response to comment #316bEFR.041.041.

Case Study Specific Comments

EPA's Case Study Facilities are Unrepresentative from a Biological Standpoint

In Appendix 10 to these comments, Dr. Kyle J. Hartman of the Wildlife & Fisheries Department, Division of Forestry, College of Agriculture, Forestry, and Consumer Science of West Virginia University, assesses the biological validity of EPA's methods for baseline loss estimates at the case study facilities and the extrapolation to national estimates. Dr. Hartman did not include a critique of the validity of EPA's impingement mortality and entrainment loss estimates for individual facilities. Many of the companies whose facilities are the subject of those case studies will be submitting comments challenging those estimates.

Dr. Hartman identifies a number of problems with EPA's analysis. In each case study examined, Dr. Hartman finds potential violations of assumptions regarding suitability of extrapolation because of species, distribution, and abundance.

EPA Response

EPA wishes to point out that the purpose of its analysis was to develop a general estimate of the relative magnitude of I&E losses nationwide, and the costs of reducing those losses, not to develop precise estimates for individual facilities or particular fish species. Nonetheless, EPA took considerable care to identify the best life history information available for the species evaluated based on consultation with local biologists and review of both published and unpublished information. If there is a legitimate basis for other biologists to challenge the information obtained by EPA, it only points to the considerable uncertainty that exists concerning the "true" value of many fish life history parameters, including rates of growth and mortality of the early life stages most vulnerable to I&E. EPA used a regional rather than case study approach for the final rule.

Delaware

EPA Relies on Salem, which is Further Down-Estuary than the Other Facilities on the Delaware

First, EPA's extrapolation of data from the Salem facility to represent all in-scope facilities for the Delaware Estuary case study results in overestimates of entrainment and impingement impacts because of differences in organism distribution over the estuary, perhaps related to salinity. These differences in distribution for key species, such as bay anchovy, Atlantic croaker, and weakfish, show that abundances up-estuary from Salem are lower than at Salem. Since all other in-scope facilities are situated up-estuary from Salem, differences in distributional density between Salem (where the I&E estimates were generated) and the other in-scope facilities will result in lower availability of these species for possible entrainment and impingement. Thus, applying the higher I&E rates to the other in-scope facilities based on flow will overestimate the true impact of cooling water intake structures on the Delaware Estuary.

EPA Response

EPA's final analysis considers I&E for the entire mid-Atlantic region based on I&E data extrapolated from six facilities located throughout the region (Calvert Cliffs, Chalk Point, Morgantown, Salem Indian River and Indian Point). This study design was intended to capture the range of ecological conditions in this region. Please see response to Comment 316bEFR.041.041 for a discussion of EPA's regional extrapolation approach.

J.R. Whiting

J.R. Whiting Is Not Representative

Second, for the Great Lakes waterbody type, EPA used I&E data from the J.R. Whiting facility to represent all facilities on the Great Lakes. Available data indicate that J.R. Whiting is not representative of all, or perhaps even most, of the facilities in the Great Lakes waterbody type. J.R. Whiting is situated in the most productive section of the most productive of the Great Lakes, Lake Erie. Other things being equal, then, extrapolations from Whiting to other facilities will be biased toward higher impacts than a similar facility situated in areas with lower productivity. The size of this bias will vary from facility to facility, but there is no doubt that this is a serious error that overstates the I&E impacts for this waterbody type.

EPA Response

Please see response to comment 316bEFR.207.023, which addresses this issue.

Tampa Bay

Organisms Are More Abundant Near Big Bend than Near Bartow

For the Tampa Bay case study, the key feature in EPA's extrapolation is the use of Big Bend I&E estimates to extrapolate to the Bartow facility. Available data suggest that water quality is lower (low dissolved oxygen and generally higher salinity) for the species affected by Big Bend. These differences in habitat quality (low dissolved oxygen) necessarily will result in lower abundances of organisms near the Bartow facility, which in turn will amount to lower potential I&E. Thus, extrapolation to Bartow will result in elevated estimates of I&E for the Tampa Case study and the waterbody type.

EPA Response

For its final analysis, EPA used a regional extrapolation approach, rather than a case study approach. I&E estimates for the Gulf Coast Region were based on other facilities in addition to Big Bend. Details of the Gulf Coast analysis are provided in Part F of the Regional Analysis Document (DCN # 6-0003). For additional information on EPA's regional extrapolation approach, please see Chapter A5 of the Regional Analysis Document and response to comment 316bEFR.041.041.

Ohio Watershed

The Ohio River Data EPA Used Are Out of Date

Similarly, the Ohio River Watershed extrapolations are plagued by a combination of antiquated data, spatial gaps in data, and an ill-conceived extrapolation methodology. The data used by EPA were collected in 1977-79, and many changes in fisheries abundance, composition, and associated vulnerabilities to cooling water intakes have occurred during the 25 years since then. Moreover, I&E data were available only downriver to river mile 560, yet EPA extrapolated the estimates from Clifty Creek downriver for 280 miles to the extent of the in-scope facilities. Thus, estimates from only one plant were expanded to approximately 25% of the length of the river. Any errors in the Clifty Creek estimates or violations of the assumption that Clifty Creek is unbiased are compounded by this reliance on Clifty Creek data and extrapolation over a large area. In fact, species abundance changes along the Ohio River. Hence, extrapolations of data from Clifty Creek to facilities downriver are invalid. Very high estimates of I&E at Clifty Creek for sucker spp. result in elevated estimates of loss of this species for the facilities in the 280 miles below Clifty Creek.

Estimates of smallmouth bass I&E in the case study also are biased high, due to a 193 river mile data gap between Kyger Creek and W. C. Beckjord. In this case, instead of using an average of I&E that was weighted by distance from the closest upstream and downstream plants, EPA used a weighted average from three plants situated downstream. Two of these three plants have the highest estimated impacts to smallmouth bass, much higher than for the other seven facilities. The use of these data to estimate impacts in the data gap zone results in biased high estimates of smallmouth bass impact for the case study. These high estimates then spill over into in-scope estimates for the Ohio River.

EPA Response

The extrapolation approach described by the commenter was not used for EPA's final analysis for the Phase 2 rule. For a discussion of EPA's extrapolation method for the final rule, please see Chapter A5 of the Regional Analysis Document (DCN # 6-0003) and please see response to Comment 316bEFR.041.041.

Additionally, EPA notes that its analysis was constrained by the available facility-provided I&E data. EPA was not provided with I&E data for the downriver area referred to by the commenter. However, EPA notes that for the analysis of the Inland region for the final rule, which replaces the Ohio River case study presented at proposal, EPA based the regional extrapolation on a number of additional facilities (a total of 11 facilities, including Albany, WC Beckjord, Dickerson, Cardinal, Clifty Creek Kammer, Kyger, Miami Fort, WH Sammis, Philip Sporn, and Tanners).
The Inland analysis is described in Part H of the Regional Analysis Document (DCN # 6-0003).

As noted in EPA's Introduction and Chapter A5 of the Regional Analysis Document, the goal of EPA's analysis for the final rule was to develop I&E estimates for 7 regions throughout the country. Extrapolation was necessary because not all in scope facilities within a given region have conducted

I&E studies. (For more detail on the regional approach, please see Chapter C1 of the EBA -- DCN #6-0002) and EPA's response to Comment 316bEFR.041.041.

Subject Matter Code 10.03.05

Brayton Point

EPA Used Data Not Representative of Current Impingement and Entrainment at Brayton Point Station

In addition to the case studies evaluated by Dr. Hartman, it is clear EPA's loss estimates for Brayton Point are not representative. EPA used impingement and entrainment data collected prior to 1985 to calculate current losses attributable to Brayton Point. This approach is plainly incorrect and, because fish abundance has decreased significantly since 1984, results in a large overstatement of current losses.

As justification for refusing to base its analysis on current impacts, EPA offers two explanations: (1) it assumes that the Station should be responsible for possible future losses, and (2) it assumes that populations will recover to levels that existed several decades ago. <FN 25> These statements are without basis and are contradicted by statements in the preamble to EPA's proposed rule. For example, EPA states "[o]wners and operators may use existing data for the Study as long as it adequately reflects current conditions at the facility and in the waterbody from which the facility withdraws cooling water." 67 Fed. Reg. 17,143 col.1. Because fish abundance has declined since 1985 – for many reasons unrelated to Station operations – the numbers EPA used are not representative of current levels of impacts. EPA's failure to adjust the numbers to reflect the general decline in fish abundance in the area creates an upward bias in EPA's measurement of impingement and entrainment. Incredibly, on p. F3-1 of the case study, EPA claims that these inflated numbers may underestimate the true levels because the fishery was already in decline by 1984. This misleads the reader as to the impacts under consideration. There is simply no basis under § 316(b) for considering any impacts other than those that would be caused by the facility under present conditions.

Footnotes

25 EPA states in the Brayton Point Case Study (Page F1-2) that, in order to "evaluate the potential benefits of the proposed rule, EPA estimated expected I&E at Brayton Point under current (emphasis added) operations based on an analysis of I&E rates before the accelerated fish population declines that followed the 1984 conversion of Unit 4, as discussed in Chapter F3." Specifically, EPA compared current operations to a time series of I&E data for Brayton Point Station collected between 1974-1983. EPA points to its conclusions (page F3-1 of the case study) that fish populations in Mount Hope Bay currently are depressed well below historical levels as justification for the comparison (i.e., current operations to fish populations from several decades ago).

EPA Response

EPA disputes the commenter's claims about its evaluation of Brayton Point Station (BPS) I&E data. EPA only evaluated 1974-1983 data for this facility for several important reasons: (1) year-round entrainment sampling of all species began in 1972 and ended in 1984; BPS began entrainment monitoring again in 1993, but only for winter flounder, (2) 1984 and 1985 were not considered because of the use of "piggyback" cooling during some of this time, (3) Unit 4 did not go into service until 1974, so data from 1972 and 1973 were not included, and (4) this time period is prior to a dramatic decline in fish populations beginning in 1985. EPA believes all of these reasons justify its selection of data to evaluate for the purposes of estimating the total average annual I&E at BPS.

EPA believes that it is appropriate to assess I&E losses before the collapse of finfish stocks in Mt.

Hope Bay for several reasons. First, after extensive analysis, EPA Region 1 has concluded that operations at BPS have been a significant contributor to the collapse of Mt. Hope Bay fish populations. If the Agency had considered post-collapse data, which is also unavailable for most species, average annual I&E would have been underestimated. This, in turn, would result in biased estimates of the economic benefits of installing technologies to reduce I&E. Basing the evaluation solely on post-collapse data could lead to continuation of a serious downward spiral, where, as resources decline, the depleted resource is used as an economic justification for refusing to restore or protect those resources.

Case Study Specific Comments

EPA Has Consistently Chosen Higher-Impact Facilities

It appears, in fact, that in every case EPA chose to use the highest possible impact scenario for extrapolation. This appears to be true both in selecting for in-depth studies facilities that appear to be at the peak of biological activity and productivity for each waterbody type and in ignoring biological and distributional patterns that affect the validity of extrapolations. Although it appears that EPA attempted to place some bounds on impacts, this was not attempted until numbers of organisms affected already were computed. Thus, the “bounds” for the estimates are really based only on how much an additional unit of an organism may be valued. A better approach would be to use both liberal and conservative bounds for estimates made in generating numbers of organisms affected by cooling water intake structures.

EPA Response

EPA’s analysis does not include only high-impact facilities. See EPA's response to Comment 316bEFR.043.016.

Case Study Specific Comments

EPA Has Applied Multiple Conservatisms in its Case Study Analysis

EPA's Case Study Analysis demonstrate the potential for serious overestimations to result from multiple conservative assumptions. As discussed in an appendix to EPRI's comments prepared by Dr. Elgin Perry, a biostatistician, the application of multiple conservatisms in a multi-step analytical process can lead to an end result that is overly conservative, sometimes to the point of being clearly unrealistic. Dr. Perry examines the multi-step process EPA used to evaluate impingement and entrainment losses (and, thereby, the estimated benefits of the rule), and identifies the independent variables in each step. Dr. Perry also identifies a number of conservatisms applied by EPA that, in his opinion, "push [the] estimated benefits off the scale of realism." Those conservatisms include:

1. setting entrainment and impingement survival to zero;

2. not using models that employ compensatory mechanisms when estimating equivalent adults;

3. estimating production by life-stage categories using constant mortality and growth within life stages;

4. summing direct (e.g., loss of commercial/recreational fish) and indirect (e.g., loss of forage fish) losses;

5. estimating use-based benefits on the basis of replacement costs rather than on the basis of increasing the value of the resource; and

6. estimating non-use benefits as a multiplier of use-based benefits when quantification of these benefits is very uncertain.

UWAG supports Dr. Perry's conclusion that these multiple conservatisms result in an overly conservative estimate of impingement and entrainment losses for the case study facilities.

EPA Response

See response to Comment 316bEFR.074.201 on the question of "multiple conservatisms."

Extrapolation of Case Study Ben. to National Level

EPA Has Not Adequately Explained How it Used the Case Studies to Estimate the Benefits of Regulatory Alternatives

The preceding comments, and the comments EPA will receive from several companies whose facilities are the subject of the case studies (many of which are UWAG members), detail numerous flaws in EPA's assessment of biological losses from existing power plants and the economic value of those losses. In addition to these serious problems, it is far from clear how EPA used the case study information to develop estimates of the benefits of various regulatory alternatives for reducing impingement mortality and entrainment at existing facilities.

In Chapter C4 of the Phase II EBA, EPA presents its estimates of the potential benefits from each of seven regulatory options (including the proposed rule):

-Option 1: Track I of the waterbody/capacity-based option

-Option 2: Tracks I and II of the waterbody/capacity-based option

-Option 3: The proposed rule

-Option 3a: Impingement and entrainment controls everywhere, without exception

-Option 4: Use of closed-cycle cooling everywhere

-Option 5: Use of dry cooling for larger facilities in estuaries, tidal rivers, and oceans

-Option 6: Similar to Option 1, but requires closed-cycle cooling for all facilities, regardless of their capacity, on estuaries, tidal rivers, and oceans.

See also Phase II EBA A1-6. Based on its descriptions in Phase II EBA Chapters C4 and A1, EPA apparently used a multi-step approach for assessing the expected benefits from each regulatory option. As to each step, UWAG has questions about the validity of EPA's analysis and the legitimacy and consistency of the assumptions it made.

First, EPA assumed compliance responses for the 539 in-scope facilities. Specifically, EPA made assumptions regarding which facilities within each waterbody type would elect (or be required) to implement one of four types of technology:

1. Impingement mortality controls only (which EPA assumed (i) would involve retrofitting adding fish returns and (ii) would meet its performance standards in all cases);

2. Impingement controls and entrainment reductions controls (which EPA assumed (i) would involve retrofitting fine mesh traveling screens and fish returns and (ii) would meet EPA's performance

standards in all cases);

3. Reduction of intake flows commensurate with closed-cycle, recirculating cooling systems; or

4. Reduction of intake flows commensurate with dry cooling systems.

A summary of EPA's assumptions regarding compliance responses (i.e., the number of in-scope facilities, from among the total of 539, that would elect (or be required) to implement each technology type under each regulatory option) is presented in Phase II EBA Table A1-1, p. A1-9. At the end of that table, EPA cites as the basis for those totals the data provided in Appendix A of the Phase II TDD, which lists, among other things, each of the 539 "model" plants, its waterbody type and flow, whether or not retrofitting would be required, and, if so, what technology EPA assumed would be required if the proposed rule were adopted.

But the values in Appendix A of the Phase II TDD do not appear to support the numbers presented in Phase II EBA Table A1-1. For example, Table A1-1 says that, for Option 4 (the proposed rule), 241 facilities would need to install impingement controls only and 229 facilities would need to install impingement and entrainment controls. A manual count of the data in Appendix A indicates that, based on the technology EPA has assumed would be retrofitted, the number of facilities required to retrofit (and therefore the expected net reductions in impingement mortality and entrainment) would be far lower than EPA has assumed. According to Appendix A:

(1) 155 (not the 241 facilities EPA estimated) would be required to retrofit only impingement controls (i.e., fish handling and return systems); and

(2) Of the 189 facilities that Appendix A indicates would be required by the proposed rule to have both impingement and entrainment controls,

(a) 58 already have impingement controls and thus would be required to retrofit only entrainment controls, and

(b) Only 131 facilities would be required to retrofit both types of controls (both fine mesh screens and fish handling/return systems).

Second, for each facility and applicable technology type (i.e., the technologies EPA assumed a facility might implement, as discussed in step (1), EPA estimated the percent to which it expected those technologies to reduce the "baseline" impingement mortality and entrainment it had estimated, as described above, by extrapolation from limited case studies:

The percent reduction in baseline losses for each facility reflects EPA's assessment of (1) regulatory baseline conditions at the facility (i.e., current practices and technologies in place), and (2) the percent reductions in impingement and entrainment that EPA estimated would be achieved at each facility [by the technology] that the Agency believes would be adopted under each regulatory option.

(Phase II EBA Chapter C4, page C4-1 [likely correction to apparent typographical error].)

Although EPA does not provide any specific percentages, it says that for purposes of estimating benefits it assumed that all technologies “would be operated at the maximum efficiency assumed by EPA in its estimates of technology effectiveness.” Phase II EBA, p. C1-6. To the extent these percentage reductions are not achieved, EPA goes on to say, the benefits will be lower.

As EPA has made clear in its own proposal and supporting documents, all the technologies – even closed-cycle cooling <FN 26> – have a range of performance that varies from site to site and even within species and life stages at a given site. Indeed, for that very reason, EPA has proposed to express the performance standard as a range. It therefore seems at best disingenuous to claim that the benefits of this rule can be characterized based on the highest possible percentage reduction (which may have been 90%-95% – EPA never says) across all sites, all species and all life stages.

Third, EPA then took those facility values and, for each waterbody type, estimated the overall (i.e., overall in-scope facilities within the waterbody type) percent reduction in entrainment and impingement that it expected would result from implementing the regulatory option. EPA estimated the overall percent reductions as “flow weighted average reductions across all facilities in each water body category for each regulatory option” (Phase II EBA Chapter 4, page C4-1). EPA presented its estimates of overall percent reduction for impingement and entrainment in Phase II EBA Tables C4-1 and C4-3, respectively. (Note that Table C4-3 contains obvious typographical errors in the column under “Option 6,” which contains entries in dollars rather than percents, and refers to “impingement reductions.”)

Fourth, for each waterbody type, EPA appears to have estimated the potential national benefits of the regulatory option by multiplying EPA’s national baseline economic loss estimate times EPA’s estimate of the expected overall reduction in impingement and entrainment for the regulatory option:

Using the national baseline loss estimates reported in Chapter C3: National Extrapolation of Baseline Losses, EPA estimated the potential benefits of each regulatory option by applying a set of estimated percent reductions to baseline losses.

(Phase II EBA Chapter C4, page C4-1). EPA presented its estimates of potential benefits from impingement and entrainment for each regulatory option in Phase II EBA Tables C4-2 and C4-4.

With respect to steps 3 and 4 above, EPA simply has not provided enough information from which we can deduce how it arrived at its numbers. We request that EPA present in the NODA a breakdown of the data it used and the assumptions it made by facility and waterbody type.

Footnotes

26 Although EPA does not in this rulemaking discuss the reduction in flow that it expects cooling towers to achieve, in the proposed Phase I rule, it opined that cooling towers used at new facilities would reduce design flow by 96% to 98% in freshwaters and 70% to 96% in saline waters. 67 Fed. Reg. 49,060, 49,087 (Aug. 10, 2000). As UWAG points out elsewhere in these comments, the extent of reduction in actual flows (versus design flows, which EPA’s own data suggest many existing facilities are well below (see Phase II TDD, p. 2.39, Figure 2-1)) likely would fall considerably below these optimal percentages. Even more important, as we discuss elsewhere in these comments, a reduction in flow will not necessarily translate into a corresponding, linear reduction in the percentage of entrained organisms and are even less directly correlated with reductions in impingement. See also UWAG 2000 Phase I Comments, pp. 108-18.

EPA Response

For impingement and entrainment separately, EPA estimates the overall percentage reductions in a

region by calculating the following for each facility:
expected % reduction at facility * % of total regional flow at facility.

This value is summed across all facilities in a region to calculate the overall % reduction expected in the region.

To estimate the total benefits in each region, the estimated current losses are multiplied by the expected overall % reduction. This calculation is performed separately for impingement and entrainment.

To generate a national estimate of impingement and entrainment reductions associated with the various frameworks considered for today's final rule, EPA evaluated data collected from the Detailed Industry Survey and the Short Technical Survey and made general assumptions about the control technologies, if any, a facility had in place. EPA used benchmark values of 80 percent for a reduction in impingement mortality and 60 percent for a reduction in entrainment and assumed this base level of performance for all facilities operating an acceptable technology. EPA cautions that the estimates made for each individual facility in the national aggregate may not reflect the true nature of impingement and/or entrainment reductions, if any, occurring at a particular facility. EPA did not have the level of detail required to develop a more accurate profile for each individual facility. EPA believes, however, that the national benefit estimates are an accurate assessment of the overall scope of benefits that will be achieved by the selected option.

Option 2--Implement performance requirements

EPA SHOULD SUBSTITUTE A SIMPLER REGULATORY APPROACH THAT ACCOUNTS FOR THE ACTUAL PERFORMANCE OF EPA'S RECOMMENDED TECHNOLOGIES

A. A Simpler, Alternative Approach Would Work Without Resort to Numerical Performance Standards

UWAG, as explained above, prefers a § 316(b) rule that is based on a reasonable, population-level definition of AEI and allows a permittee to undertake a detailed assessment of the site-specific factors that determine entrainment and impingement losses, like the UWAG or the PSEG proposals discussed in Section III above.

Instead, EPA's proposed approach reflects generic performance standards (80-95% reduction in impingement mortality, 60-90% reduction in entrainment) based on four impingement control technologies and three entrainment control technologies:

Impingement Mortality

1. Fine and wide mesh wedgewire screens

2. Aquatic filter barrier systems

3. Barrier nets

4. Modified screens and fish return systems, fish diversion systems, and fine mesh traveling screens and fish return systems

Entrainment

1. Aquatic filter barrier systems

2. Fine mesh wedgewire screens

3. Fine mesh traveling screens

As noted above, UWAG agrees with EPA that these can be highly effective technologies and are capable of achieving appreciable reductions in impingement mortality and entrainment in those cases where they are practicable to deploy. But proving that one of them will achieve a certain numerical reduction that cuts across all aquatic species and life stages, as the performance standards appear to require, may prompt development of more biological data and more analysis than is warranted. Moreover, meeting the numerical reduction standards may not be possible at some sites either because hydrological conditions are not present for technological effectiveness or due to species sensitivity.

Assuming that EPA nevertheless chooses to follow a technology-based approach, the Agency should substitute for the current proposal a simpler approach that would require evaluation of the same technologies that underlie the numerical performance standards but would not impose those standards as the per se measure of performance or necessarily require proof of a numerical reduction in impingement mortality and entrainment. This alternative would require only that the permittee analyze (using site-specific data as necessary) the EPA recommended <FN 27> technologies on which the performance standards are based. From this analysis, the permittee would identify, from among those feasible for the site, the one that most cost-effectively reduces impingement mortality and, where applicable, entrainment <FN 28> at the site. The overall level of impingement mortality or (where required) entrainment reduction achievable by this most cost-effective technology would then become the basis for evaluating any alternative technologies or voluntary restoration proposed by the permittee, or for application of the cost-cost or benefit-cost tests.

As discussed below, the approach would need to include appropriate provisions for site-specific determinations based on cost and benefit considerations. It also would need to give permittees appropriate credit for the CWIS technologies (including siting) which they already have installed and encourage innovation by authorizing the use of alternative, equivalent technologies or voluntary restoration.

There is no legal reason why a technology-based regulation under § 316(b) has to have numerical standards. Section 316(b) itself requires that adverse environmental impact be minimized but does not require numerical standards for "impacts" or numerical reductions in impingement mortality or entrainment. Even if EPA does include a numerical standard in the regulation, nothing in the Clean Water Act prohibits the number from being used as a goal or benchmark rather than a binding limit. Moreover, even if a numerical goal is written into an NPDES permit, there is no legal reason why the number cannot be used only as a trigger for additional monitoring or analysis rather than for creating an enforceable noncompliance. Finally, there is nothing to prevent EPA from writing a regulation that, without setting numerical limits, requires a permittee to operate and maintain intake technology in an appropriate way.

Footnotes

27 UWAG uses the terms "EPA-recommended" or "EPA-approved" only as shorthand to refer to the technologies, named in the preamble to the proposed rule, on which EPA bases its performance standards. UWAG does not mean to imply that EPA has "approved" these technologies in any formal sense or to tie EPA to any particular technology.

28 For purposes of this discussion, UWAG will refer to "entrainment reduction," because that is what EPA's proposal currently requires. As we argue elsewhere in these comments, however, UWAG believes firmly that any final rule should focus on entrainment mortality, just as it does on impingement mortality.

EPA Response

EPA agrees that the CWA does not require § 316(b) requirements to be expressed as numeric standards. EPA further agrees that § 316(b) standards, when numeric, can function as goals. The TIOPs authorized in today's rule are non-numeric requirements that use the performance standards as prompts for adaptive management and optimization. EPA is not adopting the exact approach suggested by the commenter, but has provided ample flexibility in the final rule. Please refer to the response to comment 316bEFR.019.014.

Option 2--Implement performance requirements

This Alternative Approach Would Select the Most Cost-Effective Technology

Before deciding which of the EPA-approved technologies to install, the permittee would have to analyze site conditions and satisfy the permit writer that the selected technology was likely to be effective at the site. EPA could help by issuing guidelines on what site conditions make one technology preferable over another. Wedgewire screens, for example, are not as effective where there is inadequate flow.

Also, the permittee would have to look at both engineering data and biological data to determine which of the technologies would achieve the most cost-effective reduction in impingement and, if necessary, entrainment. This analysis should focus on the technology that is the most cost-effective at protecting the species and lifestages that are of most concern at the particular site (the Representative Indicator Species (RIS), in other words). Like the numerical performance standards, the most cost-effective recommended technology approach would require the permittee to assess how much protection to indicator species each technology would achieve. But this would require in most cases less biological data than currently required for the baseline calculation.

This alternative approach would permit the permittee simply to install the most cost-effective of the intake technologies (wedgewire screens, etc.) that EPA bases its performance standards on. The NPDES permit would not contain a numerical limit on the number or mass of fish entrained or impinged or on the percent reduction, but the commitment to install, operate, and maintain an approved technology would be enforceable. Once the permittee had installed the approved technology, his continuing obligation would be to verify periodically that he was properly maintaining and operating the technology. For example, the permittee might be required to inspect intake screens regularly to make sure they were not clogged or damaged. <FN 29>

With time, newer intake technologies could be approved and added to the “toolbox.” Meanwhile, research studies should be conducted to investigate new technologies under different site conditions. If such an approved technology was installed and properly operated, the presumption would be that the § 316(b) rule, and § 316(b) itself, were satisfied. It would be far better policy to spend resources on testing intake technologies under various conditions than on after-the-fact monitoring to show numerical reductions in the mass or the individual counts of fish or eggs impinged or entrained.

Of course, in some cases, none of the five recommended technologies will be feasible for the site or capable of achieving reductions at an appropriate cost. <FN 30> UWAG believes it remains essential to include in the rule provisions for selecting BTA on a site-specific basis, using appropriate cost-cost and benefit-cost tests that would work as described elsewhere in these comments. Due to the site-specific factors, for some facilities to achieve a significant reduction, the cost to construct and operate the most cost-effective recommended technology may be greater than the costs EPA considered (e.g., extensive dredging and dredge spoil disposal may be required) or the benefit in terms of impingement or entrainment may be far less than the construction, operation, and maintenance costs of the technology.

Footnotes

29 Of course, if a facility that installed an EPA-recommended technology undertook a significant design or operational change that affected the CWIS, it would be appropriate to revisit the BTA determination at that point.

30 According to EPA, the appropriate cost is one not significantly greater than the technology costs EPA considered or than the benefits of the technologies' application at a particular site. With respect to comparison of costs and benefits, UWAG elsewhere in these comments urges a more sensible, defensible test, rooted in economics – that is, costs that maximize net benefits.

EPA Response

EPA is not adopting the exact approach suggested by the commenter, but has provided ample flexibility in the final rule. Please refer to the response to comment 316bEFR.019.014.

Option 2--Implement performance requirements

The Simpler, Alternative Approach Would Be Crafted to Account for Existing Controls and Foster Innovation

Provision also would need to be made for existing facilities which already have impingement mortality or entrainment control, as EPA's proposal recognizes. This need not be cumbersome. Only where a permittee wished to account for reductions in impingement or entrainment achieved by existing CWIS technologies would it need to evaluate which of the technologies was most effective for its facility if one assumes it had a basic CWIS configuration (that is, a shoreline intake structure without any without impingement or entrainment controls). At such a site, the adequacy of technologies or other alternatives offered by the permittee would be evaluated against the estimated overall performance of the most cost-effective EPA-recommended technology, as applied to a basic configuration. This would be the overall target reduction level. Such an approach is very similar to the type of analysis EPA's proposal would require.

In this way, the cost-effective approach should allow a permittee to show that some new or different technology – or the location of its intake in a place where entrainable and impingeable organisms are not much found (such as an oxygen-deficient part of the waterbody) – provided protection comparable to the level achieved by the most cost-effective of the EPA-approved technologies. This would encourage innovation and recognize that a suitable "location" can satisfy § 316(b) without elaborate technology.

Thus, if the permittee was able to show that the existing location and technology of the intake was likely to be as effective as the most cost-effective of wedgewire screens, fine mesh screens, and aquatic fiber filters at a site, then no additional protection would be required. Again, there would be no numerical limit in the permit for a percentage reduction, and, again, the permittee would have to verify periodically that it was operating the alternative technology properly. Also, because the permittee would not be using one of the EPA-recommended technologies, the permit writer could choose to require some appropriate amount of biological monitoring to evaluate the technology's actual effectiveness. However, if the permittee demonstrated that intake location alone was achieving equivalent protection, no further verification would be necessary; at most, the permittee should be required to verify every 10 years that nothing about the waterbody had changed that would render the chosen location significantly less protective than it had been in the past.

EPA Response

EPA is not adopting the exact approach suggested by the commenter, but has provided ample flexibility in the final rule. Please refer to the response to comment 316bEFR.019.014.

Option 2--Implement performance requirements

UWAG's Simpler, Alternative Approach Has Numerous Benefits

The simpler approach UWAG advocates would have a number of benefits. First, it would encourage development and application of EPA's recommended technologies, as the Agency desires, while at the same time more accurately reflecting the site-specific factors that determine performance. Second, it would be flexible enough to foster innovation. Third, it would provide the technology template which EPA believes is needed to simplify and expedite the BTA selection process for State and federal permit writers, thereby conserving resources. Fourth, by not arbitrarily constraining the range of performance that can be considered, ignoring the inevitable trade-offs among different species and life stages, or gauging performance by reference to an inflexible numeric standard, it would avoid contentious debates over the "right" performance standard. Fifth, it would better ensure environmental protection and allow for informed public participation, because it would focus on real technology capability, not a generic number. Sixth, it would avoid unnecessary compliance monitoring and conserve future permitting resources by focusing on tools for gauging proper operation and maintenance, rather than inflexible numeric standards that could only be fairly interpreted and applied after collection and careful interpretation of significant data that accounts for natural variability.

EPA Response

EPA is not adopting the exact approach suggested by the commenter, but has provided ample flexibility in the final rule. Please refer to the response to comment 316bEFR.019.014.

RFC: 5% threshold and supporting documents

EPA's 5% Mean Annual Flow Is Not Supported by the Record

To support its proposal to require Phase II facilities on freshwater rivers and streams to meet standards for entrainment control, EPA claims that (1) such a CWIS otherwise would entrain more than 5% of the organisms in its vicinity and (2) EPA believes that is unacceptable. 67 Fed. Reg. 17, 151 col. 2. EPA's reasoning is baseless for several reasons.

First, EPA's claims necessarily assume that all organisms in the vicinity of the CWIS are evenly distributed (otherwise, the relative flow withdrawal would not be a good predictor of the relative magnitude of entrainment). As UWAG showed in its comments on the proposed Phase I rule, uniform organism distribution within the water column does not always occur and tends to be a conservative assumption. UWAG 2000 Phase I Comments, pp. 111-12.

Second, EPA seems to assume that all organisms in the vicinity of the CWIS will be subject to entrainment. This too is false. Only organisms of an entrainable size – usually very early life stages – will be at risk of entrainment. These are precisely the organisms that tend to have very high natural mortality and, thus, would not survive anyway even if the intake were not present.

This relates to EPA's third assumption, namely that entraining 5% of the entrainable-sized organisms would be "unacceptable." EPA offers no analysis either of the value of the entrained organisms per se or the effect, if any, such losses have on the larger population. Absent any attempt to assess these key questions, UWAG believes EPA has no basis for selecting a 5% threshold or any other across-the-board threshold that would trigger additional requirements. EPA has made an arbitrary and unsupported choice which is likely to impose enormous costs for very little real gain. EPA cannot explain in any meaningful qualitative or quantitative terms why 5% is more unacceptable than, say, 4.8%, and why a larger percentage – say 10% – would not be just as acceptable. In fact, as UWAG's Phase I comments showed, many rivers support excellent fisheries despite much higher percentage flow withdrawals.

To support this threshold, EPA also points to its discussion in the Phase I Notice of Data Availability (NODA), concerning the proposed 5% relative flow design criterion that the Agency has now adopted as a "technology" criterion for new facilities. 67 Fed. Reg. 17,151 col. 2. Of course, unlike the Phase II proposal, in the new facility rule the 5% criterion was used as a separate design requirement, not a trigger for application of entrainment controls. In its comments on the NODA, UWAG showed that the 5% criterion was extremely conservative and could be justified only as a screening criterion. UWAG Phase I NODA Comments.

EPA nevertheless chose to adopt it principally (it appears from EPA's Response to Comments) because it would further reduce effects and because the Agency thought most new facilities could meet it. It concluded this, according to the Phase I proposal, because it did a study of existing facility and found that 89% of existing non-nuclear facilities would fall at or below the threshold if they installed wet recirculating cooling towers. 65 Fed. Reg. 49,086 col. 1. If anything, this demonstrates the widespread effect EPA's proposed 5% threshold will have on Phase II facilities.

EPA Response

Subject Matter Code 14.01

RFC: 5% threshold and supporting documents

Permittees Should Be Able to Choose Between Applying EPA's 5% Mean Annual Flow Threshold and a 5% Flow Test When Organisms Are Vulnerable to Entrainment or Impingement

A facility must meet the 60-90% entrainment reduction standard if, among other things, its design intake flow is greater than 5% of the mean annual flow of a freshwater river or stream. Proposed § 125.94(b)(3), 67 Fed. Reg. 17,221 col. 2. The mean annual flow standard is highly conservative as a regulatory standard, and in some cases a permittee may be able to justify a different measure that is still conservative but more biologically appropriate. For instance, the permittee may have collected data to show the period of time when the most vulnerable RIS is present. If the permittee can show that the facility's design intake flow is less than 5 percent of the river or stream flow during the biologically appropriate time, the facility should not have to meet the entrainment performance standard. The permittee, based on available data and information, should choose between the 5% mean annual flow test and a similar test applied when entrainable organisms are present. Both tests achieve the objective of exempting facilities from entrainment reduction only when their likely impact is minimal.

EPA Response

EPA has retained in the final rule the 5% threshold based on design intake flow, rather than actual flow, for several reasons. Design intake flow is a fixed value set based on the design of the facility's operating system and the capacity of the circulating and other water intake pumps employed at the facility. This allows a clear and timely classification of facilities. The design intake flow does not change, except in those limited circumstances when a facility undergoes major modifications or expansion, whereas actual flows can vary significantly over sometimes short periods of time. EPA believes that an uncertain regulatory status is undesirable because it impedes both compliance by the permittee and regulatory oversight, as well as achievement of the overall environmental objectives. Further, using actual flow may result in the NPDES permit being more intrusive to facility operation than necessary since facility flow would be a permit condition and adjustments to flow would have to permissible under such conditions and applicable NPDES procedures. It also would require additional monitoring to confirm a facility's status, which imposes additional costs and information collection burdens, and it would require additional compliance monitoring and inspection methods and evaluation criteria, focusing on operational aspects of a facility.

The 15% Capacity Utilization Rate Threshold Needs to be Clarified

A facility must meet the entrainment reduction standard if, among other things, it has a "capacity utilization rate" of 15% or greater and withdraws its cooling water from a tidal river or estuary, an ocean, or one of the Great Lakes. See proposed § 125.94(b)(3), 67 Fed. Reg. 17,221 col. 2, 17,153-54. Typically, the capacity utilization rate is judged on a unit-by-unit basis, not for a facility as a whole. This is because different units at a facility may have different capacity utilization rates. For example, it is not uncommon for a facility to include one or more baseload units, along with one or more peaking units. EPA does not explain how it intends each permittee to arrive at a capacity utilization rate for the whole facility. Neither does it explain how it decided what the net capacity utilization rate was for the in-scope facilities, for purposes of determining which would need entrainment controls. Presumably, EPA used some sort of average or mean, but exactly what it did it does not reveal. Obviously, EPA needs to explain what it did and propose what it intends Phase II facilities will do to make this calculation.

Equally important, EPA should consider whether to treat all units at a site as part of the facility for purposes of this calculation, even if one or more units operating at or below 15% capacity utilization are served by separate intakes. UWAG submits that EPA has not likely considered the costs of requiring such separate retrofits and, therefore, should clarify that in such circumstances the peaking unit is not subject to entrainment controls.

1. Low-Capacity Facilities Should Be Allowed to Show that They Operate Only When Representative Organisms Are Not Vulnerable

Plants that do not fall below the 15% threshold nevertheless should be allowed to show, on a site-specific basis, that their periods of operation each year do not overlap with the times that entrainable species of concern are vulnerable to entrainment.

2. A Facility Should Get Credit for Legal or Practical Limits on Capacity Utilization

If a facility's capacity utilization rate is limited as a practical matter, then the facility should be deemed to have a capacity utilization rate no greater than the practical limit dictates. Also, if the permittee agrees to limit its capacity utilization to below the threshold (15% in EPA's proposal), either by agreement with the permitting authority or by permit condition, then the facility should be deemed to be below the threshold.

3. EPA Should Use DOE's Definition of Capacity Utilization Rate

For calculating the "capacity utilization rate," EPA should make sure it is consistent with DOE's calculation method. Because electricity is not easily stored, power plants follow the load across demand cycles. Maloney 2000. Capacity utilization can be captured empirically in two ways. One is generation relative to capacity when a unit is connected to the system. The other is the percent of time the unit is disconnected. EPA needs to consult with DOE to ensure consistency between the two agencies.

EPA Response

The Agency has allowed for facilities to calculate capacity utilization rates on intake-specific bases when the generating unit and intakes can be isolated. Hence, the commenter's recommendation on this matter has been met.

The Agency has not allowed for intakes/facilities that do not fall below the 15 % threshold to "qualify" for the reduced requirements of the threshold. The Agency has, however, allowed for facilities in the demonstration of compliance to account for strategic flow reduction (i.e., strategic operation to minimize the potential to entrain species of concern in high densities and vulnerable life stages) in the calculation of their entrainment reduction.

The Agency has allowed for facilities to make agreements as part of their permit to not operate an intake/facility above the capacity utilization threshold for the projected period of the permit. Hence, this recommendation from the commenter has been met.

If a facility's capacity utilization rate is limited as a practical matter, then the facility will be able to show that it has a historically low capacity factor or agree to not operate above a future projecting agreement in their permit. Hence, the commenter's concerns have been met.

The Agency has ensured that the final rule's definition of capacity utilization is consistent with the Department of Energy, Energy Information Administration's definition of capacity utilization to the extent possible. Both definitions agree that the basis for the definition is generation relative to capacity when a unit is connected to the system. As such, the commenter's recommendation has been met.

Withdrawal threshold of 50 MGD

Rarely Used Emergency Service Water Should Not Count Toward the 50 MGD Flow Threshold

The "existing facilities" to which the proposed rule would apply are facilities with a design intake flow of 50 million gallons per day (MGD) or more. Proposed § 125.91(c)(4), 67 Fed. Reg. 17,220 col. 2. In applying this 50 MGD threshold, EPA should distinguish between ordinary cooling water intakes and emergency service water intakes. An emergency service water intake may operate only a few hours each month, enough to ensure that it stays in working order. It may have a capacity greater than 50 MGD, but the design flow of an intake that is used only rarely should not be counted in determining whether a facility is subject to the § 316(b) rule.

Performance standards

EPA NEEDS TO CLARIFY HOW THE PERFORMANCE STANDARDS (PERCENT REDUCTIONS) WOULD BE MEASURED

Although EPA's proposed rule is less suitable than the UWAG and PSEG proposals discussed above in Section III, or the simpler alternative described in Section VI, it may serve as a suitable framework for § 316(b) decisions if certain changes are made. This Section VIII recommends specific ways in which EPA's proposed performance standards should be changed and clarified, if they are kept in the rule.

A. EPA Should Provide Guidance on Determining the "Calculation Baseline"

EPA's proposed rule defines an intake structure, which at many sites will be a hypothetical one, to serve as the "baseline" from which impingement/entrainment reductions are measured. This "calculation baseline" is defined as a "shoreline cooling water intake structure with an intake capacity commensurate with a once-through cooling water system and with no impingement and/or entrainment reduction controls." Proposed § 125.93, 67 Fed. Reg. 17,220 col. 3. Some existing facilities do not have shoreline intakes – for example, river plants with main channel submerged intakes, estuarine or oceanic plants with submerged intakes, plants with intakes angled out from the shoreline, and plants with intake canals. These facilities, and others that do have shoreline intakes but have already installed impingement/entrainment reduction technology, will have to evaluate what the plant's impact would be if it had been designed or situated differently.

The concept of the calculation baseline starts from a good premise: existing plants that already have reduced their potential impact, either by location of the intake or by design features, should get credit for the reductions. It would be unfair to penalize facilities that reduced impacts early by requiring them to meet the rule's performance standards using the already-improved intake as the baseline from which more reductions must be made.

However, EPA needs to provide better guidance on how to measure the baseline level of impingement mortality and entrainment. For entrainment, egg and larval densities in the nearfield of the hypothetical intake should provide a basis for estimating baseline impacts, since entrainable organisms tend to behave like passive particles, particularly at early life stages. (This approach has been used by the mid-Hudson plants and is known to work.) Of course, life history information would need to be used to ensure that monitoring programs capture predictable spatial variations in density (such as behavioral factors that might cause densities of some species to vary over time or within the water column). But determining the baseline will be harder for impingement.

Also, fluctuations of fish populations over time will complicate the baseline calculation. Populations vary from year to year based on natural conditions. A baseline population value should be based on more than one year of data, or else adjusted to account for natural population fluctuations.

Performance standards

For Entrainment, EPA Should Develop an "As Built" Alternative to the Calculation Baseline

In order to avoid the problem of fluctuation over time and the uncertainty of estimating the effect of a hypothetical intake, for entrainment alone UWAG recommends that the calculation baseline be supplemented with an optional alternative approach. A facility that chooses this option should be allowed to install a technology (wedgewire screens, for example) and then measure the amount of entrainment with the new technology by recording the number or mass of eggs and larvae found at the discharge point after passing through the plant. To determine whether this entrainment was 60-90% less than before, it could be compared to one of two measures: (1) the number or mass of entrained organisms at the outfall before the technology was installed (for facilities that have records of such "before" entrainment) or (2) simultaneous entrainment sampling in the nearfield of the intake. In other words, the "baseline" would be either actual historical measurements of entrained organisms before the new intake technology was installed, or else measurements of entrainable organisms at the intake at the same time that entrained organisms are sampled at the outfall.

-This can be called the "as built" approach. Its potential benefits include the following:

-The facility assumes the risk of proving that the technology will perform as anticipated;

-Facilities install new technologies sooner than they would under the "calculation baseline" approach because pre-deployment studies are not necessary; and

-The "baseline" numbers are actual samples of entrained or entrainable organisms.

For entrainment, facilities should be free to choose either EPA's calculation baseline approach (with its accompanying sampling and analysis regime) or the "as built" approach outlined above.

The "as built" approach, however, is not appropriate for impingement. Impingement is highly species-specific and life stage-specific, and in most cases there will be no reliable way to measure "impingeable" organisms by sampling near the intake. To apply the performance standards to impingement, it is necessary to have data from before the new intake technology was deployed. The "baseline" (pre-deployment) impingement numbers then can be compared to the post-deployment numbers to calculate the percent reduction in impingement mortality.

EPA Response

Please see response to comment 316bEFR.063.022.

Comment ID 316bEFR.041.068

Author Name Hunton & Williams

Organization obo Utility Water Act Group

Subject Matter Code 7.02

Performance standards

The Calculation "Baseline" Needs to Be Better Defined

In addition to supplementing the calculation baseline approach with the "as built" approach outlined above, EPA needs to refine the definition of, and methods for measuring, the calculation baseline. First, EPA should amend the definition of "calculation baseline" by clarifying that the baseline plant should be assumed to be equipped with standard 3/8-inch mesh screens. <FN 31>

Second, the preamble to the proposed rule says that the calculation baseline could be estimated by evaluating existing data from a nearby facility. This should be written into the rule itself, and the facility need not be "nearby" or necessarily on the same waterbody. What matters is how closely comparable the environmental conditions that drive entrainment or impingement are likely to be. A permittee should be able to use data on fish or larvae abundance from power plants in similar locations and impacting species similar to its own to determine how much impingement mortality and entrainment there would be with no reduction controls. On a free-flowing river, a permittee should be allowed to do upstream studies near the intake to predict baseline impingement mortality and entrainment. UWAG acknowledges, however, that where impingement is concerned, site-specific differences are important. Impingement data from one site should be used for another site only with caution, and only where there is good reason to judge that the one site is representative of conditions at the other.

Third, EPA should be flexible in allowing use of data that are some years old. For a facility that has made improvements to its intake over the years, data most representative of a "baseline" condition with no impingement or entrainment reduction controls may be data collected years ago. EPA should not disallow such data just because they are not recent. So long as data are scientifically sound and reasonably representative of the condition one is trying to characterize (a "baseline," in the present example), they should be usable.

Fourth, in cases where the actual facility has an intake at the end of a cooling water intake canal instead of at the shoreline, the permittee should be allowed to use as the baseline either a hypothetical shoreline intake or the actual intake. It is possible that, in some cases, an intake canal might attract fish or provide a protective habitat and thus be more suitable baseline against which to determine reduction than a hypothetical shoreline intake. EPA should provide that permittees may, if they choose, calculate the reduction in impact from new technology measured against the as-built intake rather than a hypothetical shoreline intake.

As for the location of the hypothetical "baseline" intake at the shoreline, in cases in which it does not actually exist, the permittee should be allowed to choose the location of the hypothetical shoreline intake, so long as the location is one where an intake might have been placed in the exercise of sound engineering judgment, without regard for fish protection.

Fifth, in setting the baseline for impingement, the permittee should either (1) select the RIS, as suggested in UWAG's Decision Principles, or (2) use the entire number (or mass) of animals lost by impingement under baseline conditions. A choice of methods is necessary because demonstrating a 80-95% reduction in impingement mortality for compliance purposes will present different problems for different species and sites.

Sixth, EPA should leave flexibility in what kind of data can be used to calculate "baseline" at sites where a shoreline intake with no impingement or entrainment reduction controls does not presently exist and may never have existed. Since the permittee in such cases must deduce the level of entrainment and impingement mortality at a hypothetical intake, some considerable uncertainty is inevitable. Since it may not be possible to collect empirical data that show the level of impingement mortality and entrainment that would have occurred at the baseline, the permit writer and permittee will need flexibility in determining what data are reasonably available or can reasonably be collected and how such data are to be interpreted. Intensive biological studies to support the calculation baseline should not be required.

Likewise, in predicting the reductions in impingement mortality and entrainment to be achieved by technologies that have not yet been installed, the estimates of performance, being predictive, will have considerable uncertainty, especially in light of the wide fluctuations in fish populations even under natural conditions. Again, reasonable predictions, based on reasonably available scientifically sound information, should be accepted, based in part on experience with the variability in performance of technologies like wedgewire screens and aquatic filter barriers.

Footnotes

31 The hypothetical baseline intake would, of course, have the same cooling water requirements as the actual facility. Also, the awkward "and/or" in the definition could better be rendered simply "or" or, more clearly, "no impingement reduction controls and no entrainment reduction controls."

EPA Response

Flow Reductions Should be Counted Toward Meeting the Performance Standard for Entrainment

If a new facility is constructed to replace an old facility but continues to use the same intake with reduced flow, the flow reduction should be credited toward meeting the performance standard for entrainment. Specific standards could be written for determining the appropriate credit. For example, the permittee could choose one of the following:

1. Credit based on actual flow under operation where, for example, a Habitat Evaluation Procedure (HEP) is funded over time;

2. Credit based on a baseline of the existing facility's (versus the new one's) permitted maximum design flow; or

3. Credit based on the existing facility's flow (calculated so as to exclude years when there were major maintenance outages).

EPA Response

The definition of an existing facility is "any facility that commenced construction as described in 40 CFR 122.29(b)(4) on or before January 17, 2002; and any modification of, or any addition of a unit at such a facility that does not meet the definition of a new facility at § 125.83." For a more detailed discussion on what constitutes an existing facility and how it applies to today's rule, please see section II.2 of the preamble.

In general, EPA agrees with the commenter. If a facility does not significantly modify a cooling water intake structure but reconfigures its power generation system (e.g. installation of a combined cycle turbine) such that the requirements for cooling water are less, credit should be considered towards compliance with today's requirements.

EPA does not believe this situation would warrant specific standards as discussed by the commenter.

RFC: Entrainment vs. entrainment mortality

The Entrainment Standard Should Consider Entrainment Mortality

EPA's proposed performance standards apply to impingement mortality, but they apply not to entrainment mortality but to total entrainment, whether or not entrained organisms survive. A facility gets no credit for an egg or larva that passes through the cooling system unharmed, as many do.

This is unrealistic. If an entrained egg or larva survives and thrives, it should not be counted as part of an "adverse impact." Moreover, many studies show that entrained organisms do survive. Survival varies widely depending on species, intake structure attributes, and waterbody characteristics. And there are tradeoffs: increasing cooling water flow may entrain more organisms, but it also reduces the temperature increase they experience and the time they are exposed to it.

UWAG acknowledges EPA's concern that some past survival studies may not have been robust enough to qualify survival for some species or life stages. However, permittees willing to conduct technically sound studies to demonstrate the rate of survival should be allowed to use these when calculating compliance with the performance standards. Survival rates, like so many other things, are species- and site-specific. But the fact that entrainment survival does not occur everywhere at the same rate is no reason to refuse to consider it at all, especially at a site where the permittee has data establishing survival rates.
