Similarly, studies conducted for the Connecticut Yankee power plant, situated on the Connecticut River, suggest little or no long-term impact from the plant's thirty years of operation. The Connecticut Yankee example provides a unique opportunity to assess the potential effects of long-term impingement and entrainment because its preoperational studies were thorough and well-documented. EPRI will finalize papers on the Connecticut Yankee case study in 2004.

Additionally, data on Lake Wheeler indicates no harm to the lake's biological communities from the long-term operation of Browns Ferry Nuclear (BFN) Station. BFN operates two units supported by six intake pumps with a rated total capacity of 2,312 MGD.<FN32> Although standing stock estimates for the reservoir exhibit extreme fluctuations, regression analysis revealed no significant increasing or decreasing trend for either total numbers (fish/hectare) or biomass (kg/ha) during the 30 years of monitoring. <FN 33>

In short, there is little or no evidence that impingement/entrainment losses occurring at power plants have had or are having any meaningful effect at the population level or any other level meaningful from a resource management perspective. While this does not mean that no effects would ever occur under any circumstances, or that controls on impingement or entrainment are wholly unnecessary, UWAG submits that it does suggest two things: (1) EPA's evaluation of non-use benefits is wildly inflated and wholly unrealistic and (2) no matter how much effort EPA applies, no credible, realistic estimate is likely to show that non-use benefits are significant enough to make a difference in the benefit-cost analysis. Thus, EPA would be fully justified in making no further effort to quantify them or include them in its analysis.

Such an approach is entirely consistent with the approach EPA has taken to estimating the more indirect economic and social costs of this rule, which EPA has only partially quantified and has largely excluded from its benefit-cost analysis. Costs such as aesthetic effects, increased land use, effects on navigation and instream habitat, water consumption, and a host of others are much more certain to occur than are the non-use values EPA has struggled so long to quantify. Yet EPA has concluded that, while they indisputably will occur, they are unlikely to be so widespread or significant that they will significantly influence the outcome. We suggest that non-use values (EPA's incredible and inflated estimates not to the contrary) fall into the same category. In fact, given the results of EPA's "break-even" analysis, which shows that non-use values would have to be 30 times use values in order to equal the costs of the rule (at least for the two regions EPA considered), we think EPA can safely assume that that margin would more than capture any plausible non-use value (and almost certainly significantly exceeds non-use values).

EPA Response

Please see response to comment 316bEFR.025.018 for the discussion on environmental impacts associated with cooling water intake structures. This comment highlights a fact that EPA contends, that is, many environmental and anthropogenic factors work concurrently on the environment. It is extremely difficult to separate out any one factor to determine the extent of its effect on fish populations. The intention of section 316(b) of the Clean Water Act is to minimize the adverse environmental impact of cooling water intake structures specifically and does not seek to eliminate stress on fisheries due to habitat alteration, overfishing, or pollution. There are other sections of the Clean Water Act which seek to reduce other environmental stressors to improve fishing and swimming in the waters of the United States.

With regard to EPA's example of the environmental effects at the San Onofre Nuclear Generating Station. EPA thanks the commenter for the submission of their theory why the kelp beds have been destroyed in the vicinity of the facility. EPA has also received information that the destruction of the kelp beds has attributed to discharge turbidity and scouring. Mention of the kelp beds at San Onofre was removed from the text in the preamble to the final rule.

With regard to the issue of whether non-use values may exist at levels that merit any further consideration or empirical investigation, the Agency must respectfully disagree with the commenter's assertion that such values could not possibly be significant enough to potentially sway the outcome of a benefit-cost comparison or that, as a consequence, such values are not worth further consideration or investigative effort. First, there is a very large number of living organisms that are prematurely killed due to I&E, and the percentage that are directly embodied in the limited analysis the Agency has conducted of direct use benefits is very small (e.g., 2%). Thus, there is potential for a high ratio of non-use values to direct use values, based solely on the respective magnitudes of physical injury between total impacts and the portion embodied in direct use values (see, for example, the response to comment 316bEFR.336.009).

Second, the potential relevance and magnitude of non-use values remains an empirical matter. Experts and lay persons alike can and have hypothesized at great length on whether non-use values might or might not be applicable and significant for the 316b-related I&E injuries. In fact, the comments received by EPA reveal both sides of the argument very clearly -- some argue the values are likely to be appreciable, others (such as this commenter) argue that they think the values would not be high enough to matter in the policy-making context. Ultimately, these comments reflect speculation only, and the core issue remains an untested matter for empirical research. For further discussion of the approaches and constraints associated with conducting the type of empirical research that could shed light on this matter, please see response to comment 316bEFR.306.105.

Performance standards

As UWAG has said in its previous comments, the assessment of adverse environmental impact for § 316(b) purposes should be done by a structured ecological risk assessment process. See UWAG August 2002 Comments, at 26-27. This approach is also recommended in UWAG's "Decision Principles," which were first submitted to EPA as Appendix 1 to the August 2002 comments, and were submitted again in a revised, peer-reviewed version by letter of March 20, 2003.

EPA nevertheless focuses in the NODA on its performance standards, which are ranges of percentage reductions in impingement mortality and entrainment. The comments below focus on how those numerical ranges should be applied.

In the proposal and the NODA, EPA asks whether the performance data show that the performance standards can be met by existing facilities.<FN 34> UWAG has said that those standards probably can be met in many, but not all, cases if the performance standards are properly interpreted and applied. See UWAG August 2002 Comments, at 83. In fact, implementation issues are so important that, until they are addressed, most existing facilities cannot determine whether or how they would meet the standard.

As UWAG has stressed in its previous comments, selecting and operating entrainment and impingement controls and gauging their performance is not the same as meeting discharge limits for pollutants, and EPA has never attempted to treat them as the same. UWAG August 2002 Comments, Section III. Fish are not under the control of the NPDES permittee, and a permittee cannot choose which fish are around its plant and in what numbers. The variability of fish in waterbodies is likely to far exceed the variability of even the most complex effluent in most cases. To ensure the rule is fair and reasonable despite these complexities, EPA needs to address several distinct, but closely related questions:

- What purpose should the numeric performance standard serve?

- Must each performance standard range be reduced to a single performance value, or may the range itself be used?

- What is the performance standard meant to protect?

- What metrics should be used to evaluate technology performance? <FN 35>

- What are the design elements of the calculation baseline design, and how should the calculation baseline be used?

UWAG's August 2002 comments on the proposed rule addressed these issues in some detail in Section XIX. We continue to believe that the ideas we offered in those comments are sound.

Footnotes

34 Actually, EPA asks whether the data "support the determination that the proposed performance standards are best technology available and that the existing facilities can meet these standards by implementing design and construction technologies either singly or in conjunction with other design ad construction technologies (including operational and restoration measures)." 68 Fed. Reg. 13,539 col. 2. UWAG assumes, however that EPA means to ask whether the performance standards it has proposed accurately reflect the level of entrainment and impingement achievable by technologies it has identified as BTA candidates. Both 316(b) and the other CWA technology-based provisions clearly require that performance standards reflect the technology identified as the "best available," not vice versa. In addition UWAG asks EPA to clarify that it does not mean by this tatement to suggest that facilities can be required to undertake restoration measures or operational controls, neither of which EPA has authority to require under 316(b), because they are not CWIS intake technologies.

35 For reasons discussed above, we do not believe the purpose of post-installation monitoring should be assess "compliance" per se. Instead, we think compliance should be based on evaluation of whether the permittee adheres to a process, set forth in the permit, that requires completion of specific actions. As discussed later in these comments in the section on compliance, that same concept could be used to establish objective, enforceable, pre-installation process requirements for submitting a study plan, completing that study within a reasonable period after approval, submitting a BTA technology proposal for approval, and installing the technology after it has been approved.

EPA Response

Please see response to comments 316bEFR.307.064, 316bEFR.311.002, 316bEFR.063.005 and 316bEFR.029.040.

For discussions on the basis for and implementation of the calculation baseline, please see response to comments 316bEFR.308.014 and 316bEFR.063.022, as well as the preamble to today's rule.

Subject Matter Code 7.02

Performance standards

What purpose should the numeric performance standards serve? Should they be binding, enforceable "limits"? Or should the performance ranges instead serve as a consistent basis for setting permit conditions that require their use for purposes of (1) identifying a technology or technologies (or other measures) that will achieve the performance range (or an alternate range justified by the cost-cost or cost-benefit test) with appropriate operating and maintenance specifications adapted to the technology and the site; (2) installing, operating, and maintaining the chosen technology in accordance with the operating and maintenance specifications approved by the permit writer; (3) performing appropriate monitoring to gauge performance; and (4) refining or adjusting operation, maintenance, or other factors in light of initial monitoring.

UWAG's previous comments have said that the latter approach – using the standard to set enforceable permit conditions requiring the permittee to take stated actions, without making the numeric standards themselves enforceable – is the reasonable and efficient course. See UWAG August 2002 Comments, Section XVIII. The more rigid course, making the numeric standards enforceable per se, would be unwarranted for a number of reasons.

First, it would be inconsistent with EPA's own technology performance data, which show that the performance of any intake technology will vary at different sites and that it will vary over time even at a single site in response to widely varying biological, physical, and even chemical conditions in the waterbody. Unlike discharges of pollutants produced and controlled by a discharger, varying instream conditions, particularly the high natural variability of biological populations and communities, are not under the permittee's control, and the permittee cannot reasonably be expected to anticipate and adjust for such fluctuations. Technology performance varies over time in response to factors beyond the facility's control.

Second, the more rigid approach would have a number of undesirable consequences, which the less rigid, but no less enforceable, approach would avoid. The rigid approach would tend to stifle innovation, making facilities wary of pursuing promising new technologies for fear they will face enforcement action should the technology fail to work exactly as expected. A "performance-standard-as-enforceable-limit" approach also would require far more extensive and expensive data collection and analyses than EPA has projected, as facilities are likely to need to collect more data to hedge against variability that might suggest noncompliance in spite of overall good technology performance. And the rigid approach would lead to far greater administrative burdens and delays, as permittees and permit writers debate exactly what is the "right" number to pick and belabor exactly how to measure it. These resources would be much better spent evaluating, refining, and optimizing technologies for fish protection.

The more rigid approach also would be inconsistent with EPA's approach for facilities having recirculating cooling systems. EPA's proposal properly does not require facilities having or proposing to install cooling towers to show that they meet any given level of entrainment or impingement reduction vis-à-vis a baseline. EPA should not require appreciably more of other facilities than it requires of those with recirculating cooling systems.

In the NODA section addressing compliance schedules, deadlines, and determinations (68 Fed. Reg. 13,586 col. 2), EPA notes that commenters have described the difficulty of ensuring uniform “performance” and have suggested the need for a “shakedown” period before the performance standard becomes enforceable. Certainly if the performance standard itself will serve as an enforceable limit or condition, such a period is essential, for the reasons UWAG has described. And if EPA decides that it has no choice but to go this route, then we believe that EPA should provide for a period at least as long as the initial permit term and should make that period renewable for cause. While some might argue for a shorter period, when one considers the time it will take to complete the initial demonstration process, install the technology, and get data over a representative time period, five years seems, if anything, too short a time.

In any case, for all the reasons described above, UWAG believes that a far more straightforward and reasonable course would be for EPA to specify that the performance standard is not enforceable. Rather it should be used in the process of technology selection, and once the technology is installed, it should serve as the basis for evaluation and, if necessary, further action. This approach is supported both by regulatory precedent and current technological and biological realities.

EPA Response

EPA has provided examples of facilities in different areas of the country sited on different waterbody types that are currently meeting or exceeding the performance standards promulgated today. The ability of these facilities to do so suggests that while site-specific factors can influence the performance of a given technology, it is the exceptional situation where no design or construction technology is capable of meeting the performance standards. EPA opted for performance ranges instead of specific compliance thresholds to allow both the permittee and the permitting authority a certain degree of flexibility in meeting the obligations under the final Phase II rule. Further, EPA recognizes that precise results may not be able to replicated in different waterbody types in different areas of the country. Methods of determining compliance with today's rule are left to the permitting authority who may, for example, authorize the use of a Technology Installation and Operation Plan. Performance standards

Must Each Performance Standard Range Be Reduced to a Single Performance Value, or May the Range Itself Be Used?

Even if EPA applies the performance standard within the process-based approach that UWAG endorses, it will need to explain whether the "BTA" technology must be designed to meet a selected value within the performance range or whether it is sufficient for the permit to present a reasonable amount of information showing that the current or proposed technology will reduce impingement or entrainment to within the performance range (or an alternative range established pursuant to the site-specific provisions of the rule). Again, UWAG believes that the available data, as well as administrative efficiency, support the latter course. As noted above, selecting just one perfect number is extremely difficult and is likely to engender endless debate for little or no environmental gain.

Performance standards

What is the performance standard meant to protect?

What is the performance standard meant to protect? The proposed rule speaks of "all life stages of fish and shellfish," but the NODA properly suggests that EPA did not intend to require the standards to apply equally to all life stages, all species, or each life stage of each species. In other words, the performance standard is not meant to require a permittee to show that its chosen technology reduces entrainment or impingement to a percentage within the performance range for each species, for each life stage, or for each species/life stage combination. That EPA does not intend to require this is apparent from the NODA discussion of two possible metrics for evaluating technology performance. Both approaches contemplate that organisms would be measured, either individually or as biomass, without taxonomic measurement or differentiation.<FN 36> See 68 Fed. Reg. 13,582. This makes good sense, especially given that the technology database shows that there are no technologies that could meet the performance targets for all species, much less for all life stages of all species. Even cooling towers, as we have said, would not achieve that result, nor would they be either environmentally necessary or desirable.

Footnotes

36 Requiring the facility to demonstrate a percent reduction in impingement mortality and enrainment for every species would require the permittee to adjust the entrainment and impingement samples to account for interyear variability. Doing this for every species would be impractical. Ineryear variability sampling generally will not cover all species, because some gear types are designed for benthic species, others for pelagic species, and others for nearshore species, and in addition different gear varies in effectiveness for different size classes. Facilities would have to use every gear type for each species or size class, and the rule would be unworkable.

EPA Response

EPA believes that the performance standards in today's final rule will achieve an acceptable level of protection for the source waterbody. In recognition of the difficulty in establishing a uniform means of measuring compliance with these standards, today's final rule defers to the Director to determine the most appropriate means by which compliance with the rule is to be measured. The Director is therefore best suited to make such a determination. See also response to comment 316bEFR.063.005.

Impingement and Entrainment Assessments

UWAG also urges EPA to clarify that permittees are not required to achieve any reduction in entrainment or impingement of species that have been formally or informally classified by the state or federal agency as "nuisance" species or otherwise have been targeted for control or eradication. EPA and states have identified the proliferation of such species as a major threat to aquatic ecosystems, and in some places millions of dollars are being spent to control the spread of such species. See EPA, Nonindigenous Species – An Emerging Issue for the EPA, Vol. 2: A Landscape in Transition: Effects of Invasive Species on Ecosystems, Human Health, and EPA Goals (2001). Requiring facilities to protect such species from impingement and entrainment would be the opposite of minimizing adverse environmental impact. While care would need to be taken to avoid penalizing facilities that have such organisms in their baseline by simply eliminating them from the baseline, UWAG believes that appropriate analyses could be conducted to ensure that facilities are not required to protect nuisance species.

EPA Response

Please see EPA's response to comment 316bEFR.074.023.

for purposes of measuring technology performance, what metrics should we use? Should the permittee collect and evaluate "all species," or should it collect and evaluate only representative important species, which if properly selected can serve as an appropriate proxy for any other species that might be entrained or impinged? Under what circumstances might it be appropriate to identify the species and life stages of organisms collected for evaluation, even if all the impinged or entrained organisms are later aggregated, as EPA suggests it intends (see 68 Fed. Reg. 13,582 col. 1)? And is performance best evaluated by looking at individuals or at biomass?

UWAG believes there is no single metric or measurement system that can or should be used for all cases. Both the endpoint (i.e., numbers or biomass, or
representative species or all species) and the period over which those data should be reviewed depend on a number of factors. These include the following:

- whether one is assessing impingement, entrainment, or both;

- what types of data already exist;

- what species and life stages are most likely to be affected; and

- what techniques will be used to achieve the standard (i.e., restoration measures vs. hardware).

Because of the complexity of applying the performance standards at different sites, UWAG urges EPA to make the rule flexible enough to allow several different approaches to these questions.

EPA Response

Organization Hunton & Williams obo Utility Water Act Group

Subject Matter Code 12.0

Impingement and Entrainment Assessments

In the NODA, EPA asks whether it should allow permittees to evaluate technology performance by measuring entrainment or impingement of "representative species." UWAG has said consistently that we believe a representative species evaluation will be the most practical approach in many cases. Many § 316(b) studies using representative species have been done. This approach has worked well by providing a focus for evaluating technologies that could be designed with particular species in mind.

Even with representative species, though, it is important to use a composite measure of compliance instead of requiring a numeric reduction in entrainment or impingement mortality for each and every representative species. Especially when a representative species is relatively uncommon, it may be hard to achieve the same percentage reduction that can be achieved for species that are more abundant or hardier. EPA should use a holistic measure of compliance that does not unduly focus on a single taxon.

EPA Response

Please see EPA's response to comment 316bEFR.074.023.

Comment ID 316bEFR.307.070

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

Subject Matter Code 12.0

Impingement and Entrainment Assessments

EPA also has asked how "representative species" should be identified, and what term should be used. 68 Fed. Reg. 13,582-83. UWAG has outlined principles for identifying "Representative Indicator Species" or "RIS" in a paper entitled "UWAG's Proposed Decision Principles for Applying § 316(b) to Existing Facilities," which EPRI peer-reviewers have endorsed (Bailey 2003). UWAG has submitted that document and the peer review to EPA. We believe that the principles for identifying representative species that we have outlined there remain valid, and we encourage EPA to use them as the basis for any rule or guidance on representative species.

As to the appropriate term to be applied, if EPA is concerned that the term "representative indicator species" will be confused with the term "representative important species" (a term used in the § 316(a) context), then we suggest EPA simply use the term "representative species" with appropriate definition. This term has not been used previously and therefore will avoid confusion about the relationship between term and terms (like "critical aquatic organisms") used in the past. <FN 37>

EPA has suggested a large number of representative species (15). This number should be much smaller in most cases. At some plants, four or five species make up over 95% of impingement or entrainment numbers. A demonstration should focus on the four or five species and add to the list only if there is another species of special concern.

Footnotes

37 EPA used six criteria for critical aquatic organisms in its 1977 draft 316(b) guidance, but UWAG believes that all six are captured in the following four categories:

- Commercial and recreational importance

- Federal or state threatened or endangered or specially designated species;

- Importance in local ecological community structure and function; and

- Species and life stage vulnerability

EPA Response

Organization Hunton & Williams obo Utility Water Act Group

Subject Matter Code 12.0

Impingement and Entrainment Assessments

There are circumstances in which an "all species" approach can make compliance demonstrations simpler and somewhat less expensive so long as the taxonomic identity of collected organisms is not required. Thus, this approach would not be suitable for use in cases where taxonomic identification is needed (e.g., where eggs and larval stages are converted to Age-1 equivalents).

The all species approach might well be used for those technologies that EPA approves in advance under prescribed conditions, such as wedge wire screens, as EPA proposes in the NODA. If the technology can be demonstrated to be highly effective under conditions at the facility (e.g., the facility is situated on a river where the flow velocity is high enough to carry organisms past a wedge wire screen), a case can be made that intensive performance monitoring on a species-specific basis is not warranted. Similarly, if a facility uses a prototype aquatic filter barrier or wedge wire screen and demonstrates that it is highly effective at the site, then species-specific performance monitoring may not be necessary after the full-scale technology is installed.

Measuring either biomass or total undifferentiated numbers of organisms for all species, instead of identifying individual species, would also be appropriate if certain restoration options were used. If wetland restoration is used, for example, then monitoring entrainment of total biomass would allow comparison with the biomass contributed by the wetland.

Measuring Organisms by Counting Their Numbers

If the number of organisms is counted, the very early lifestages (eggs and prolarvae) will dominate the numbers and therefore dominate the compliance determination, even though most of them would have suffered enormous natural mortality losses even without entrainment. The appropriate way to address this is by identifying entrainable organisms to genus, family, or species and using appropriate life history data, where available, to convert those life stages to a common unit, such as equivalent juveniles, so that each lifestage is appropriately weighted. In such cases the results of those calculations will need to be aggregated and the total number used for any comparison.

EPA Response

Please see EPA's response to comment 316bEFR.074.023.

Organization Hunton & Williams obo Utility Water Act Group

Subject Matter Code 12.0

Impingement and Entrainment Assessments

Measuring Organisms by Biomass

For biomass, the numbers will be dominated by later larval stages even though the number of these organisms per unit weight will be small compared to eggs and larvae. Again, one way to deal with this would be to convert to a common unit, such as equivalent juveniles. This would make sense for forage fish, where biomass is an appropriate measure of the organisms as a food source for commercial and recreationally important species. If biomass was used to measure forage species, numbers still could be counted for commercial and recreational representative species.

For many species, identification is possible for eggs or very early lifestages only at the genus or family level. Comparisons might best be based on genus or family for these early lifestages. As a practical matter, it is probably better to count these lifestages and convert the numbers to biomass based on values from the literature, rather than to collect eggs and weigh them.

As noted above, if the restoration option is used, it makes sense to use total biomass as the measure. There will almost never be a one-for-one species-for-species compensation when habitat restoration is used. If a permittee chooses to restore a wetland or other habitat, the appropriate measure is to determine total biomass produced by the enhanced habitat.

Determination of compliance

Averaging Period for Performance Evaluation

In its comments on the proposal, UWAG stressed that any performance evaluation should allow for appropriate averaging periods over which to review data and assess performance. EPA has requested additional comment on this topic, offering several possibilities: (1) a one-year average, (2) a three-year average, (3) a five-year running average, (4) use of basic arithmetic means, and (5) leaving the decision to the permit writer. 68 Fed. Reg. 13,584 col. 1.

Of these options, UWAG believes that only the last – allowing averaging periods to be set case-by-case – is really feasible. As with the other issues discussed above, the appropriate averaging period depends on site-specific characteristics, including the characteristics of the species in question and the nature and extent of existing data that can be used to adjust data collected in the future. UWAG believes that the rule should direct the permit writer to set an appropriate averaging period as necessary to account for variability, but EPA should not specify an averaging period for all cases.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027.

Submittal of required information

EPA also requests comment on whether to use data collected at other locations. 68 Fed. Reg. 13,581 col. 3. In its previous comments, UWAG said that EPA should let permittees use data from other sites, albeit with appropriate analysis of the data and the conditions at the collection site to ensure that conditions are comparable and that the information is relevant to the permittee's site.

UWAG recognizes that site-specific circumstances can complicate analysis of data from other sites, as other commenters apparently have pointed out. This does not mean, however, that data from other sites with similar characteristics necessarily are irrelevant. Such data can be used to make initial judgments about the likely presence or absence of species and life stages at different times of year, to make judgments about population variability and year class strength for various species, and to assess likely reactions of motile organisms to different intake configurations. Thus, UWAG believes EPA should allow use of such data.

EPA Response

EPA agrees with the commenter and notes that the definition of calculation baseline in 125.93 allows a facility to estimate the calculation baseline using historical impingement and entrainment data from its facility or another facility with comparable design, operational, and environmental conditions; current biological data collected in the waterbody in the vicinity of the cooling water intake structure; or current impingement mortality and entrainment data collected at it's facility.

Subject Matter Code 21.04
Determination of compliance

Author Name David E. Bailey
Organization Hunton & Williams obo Utility Water Act Group

What Are the Appropriate Elements of the Calculation Baseline Design, and How Should the Calculation Baseline Be Used?

The proposed performance standards are percentage reductions from a “baseline.” Determining an appropriate “baseline” is therefore important and deserves just as much attention as do the performance numbers themselves. One cannot evaluate the achievability or cost of meeting the performance standards without understanding how they will be interpreted and measured against the baseline.

Approaches for Defining the Calculation Baseline Design

The NODA requests comments on two approaches to defining the calculation baseline design: (1) a standardized baseline design and (2) the “As Built” approach. Following are UWAG’s comments on each.

EPA’s Baseline Design

In the NODA, EPA offers additional details to define the baseline configuration, which it says provides facilities “a consistent basis for determining compliance and allows them to take credit for fish protection technologies already in place.” 68 Fed. Reg. 13,580 col. 2. In effect, the baseline design serves as a typical design for facilities that have not used locational strategies, technologies, or operational measures to reduce impingement mortality or entrainment. See 68 Fed. Reg. 13,580-81.

As in the proposal, EPA defines the “baseline” intake structure as located at the shoreline with a screen face parallel to the shoreline. This is appropriate in most cases, though there may be facilities for which it is not representative. In the NODA, EPA appropriately notes that, in cases where this configuration does not represent the worst case, it is appropriate to allow a different baseline configuration to avoid making the control requirements, in effect, more stringent. UWAG agrees that this flexibility is necessary.

The NODA clarifies that EPA conceives the baseline structure to have a traveling screen with a standard 3/8-inch mesh. This is an appropriate description of the typical intake structure.

EPA defines “baseline practices and procedures” as those that the facility would maintain in the absence of operational controls that are, in whole or in part, for the purpose of reducing impingement mortality and entrainment. It would be better to define the baseline as full-flow operation. EPA’s definition, which requires determining the “purpose” of operating practices, will cause disputes. For example, some plants in the northern United States operate at reduced flows during the winter months. The reduced flows are operationally efficient because they eliminate subcooling of the condensate and reduce auxiliary power requirements or prevent ice damage. But they also may reduce impingement. If impingement reduction was part of the “purpose” of reducing the flow, then the baseline condition would be full flow. If impingement reduction was only incidental, then the reduced flow would be the baseline. Much confusion will be avoided if EPA defines the baseline as full-flow operation, and UWAG recommends this.

UWAG also recommends that EPA clarify that "operational" changes may include flow reductions that occur as a result of a permittee's decision to repower or replace units or any other change that can be shown to have reduced impingement or entrainment mortality, regardless of the reasons for that decision. A clarification would encourage such changes.

Another source of confusion with the proposed "baseline" comes from the scheduling of maintenance outages. When a plant is shut down for maintenance, entrainment and impingement may be reduced while the cooling water pumps are out of service. If a plant typically scheduled its outages at a time of high entrainment by chance, and not with the purpose of reducing entrainment, then its "baseline" would include an outage at that time. This would lock the plant into the same maintenance schedule in the future, reducing flexibility for future operations. In contrast, if the station had scheduled its outages purposefully to coincide with high entrainment periods, the reduction would not be part of the baseline. Again, this confusion can be eliminated by defining the baseline as full flow and full operation, the operational practices that would be used if § 316(b) were not considered at all. This also avoids a continually changing baseline as maintenance and operational schedules change over time.

In short, a baseline that reflects unrestricted operation at full design capacity will provide a relatively easy-to-calculate, fair baseline that will allow the performance standards to be applied uniformly at all plants. The baseline should be defined as year-round operation at maximum design capacity.

In the same vein, EPA should clarify that the baseline configuration (which is intended to reflect the "worst case") has no entrainment or impingement survival and assumes that all fish were alive, not already dead or moribund, before they were impinged. EPA's assessment of the impacts from once-through systems and its estimates of the benefits of different technologies are based on the assumptions (1) that there is no entrainment or impingement survival and (2) that all fish are alive and healthy at the time they are impinged. To be consistent, EPA's baseline should make the same assumptions. This will both simplify the baseline and performance evaluations and allow permittees to take credit for the efforts they already have made to improve survival of healthy organisms that are entrained and impinged. These same assumptions would apply both to any baseline calculation used to select a technology in the first place and then to any "as built" assessment of performance as the facility operates.

For purposes of performance evaluation, however, UWAG agrees with EPA's proposal to allow facilities to show that impinged organisms may have been dead or moribund before they reached the intake structure and to omit them from impingement calculations. Fish kills caused by natural waterbody conditions are a common occurrence. In March 2003, the Michigan Department of Natural Resources issued a press release reminding residents to expect fish kills in many lakes throughout the state, and noting that spring fish kills are most often naturally caused by the weather shift from a long, cold winter to above normal spring-like temperatures. Michigan DNR Web Page, "Fish kills expected statewide," March 20, 2003 (Michigan DNR at http:www.michigan.gov/dnr/0,1607,7-153-10371_10402-63902--M_2003_3,00.html). Another DNR web page explains how natural fish kills can occur in winter, spring, and summer. Michigan DNR Web Page, "Fish Kills," (Michigan DNR at http://www.michigan.gov/dnr/ 0,1607,7-153-10364_10951_18964-45765--,00.html). Similarly, in February 2001 the Illinois Department of Natural Resources reported that "minor to extensive fish kills" had occurred on lakes and ponds throughout northern and central Illinois, and that fisheries biologists blamed "[t]hick ice and heavy snow cover on many ponds and lakes . . . result[ing] in dissolved oxygen levels in the water being too low for many fish to survive." Illinois DNR Web Page (http://dnr.state.il.us/pubaffairs/2001/Feb/2001Feb22wpd.htm).

UWAG concurs with EPA's definition of "moribund" (68 Fed. Reg. 13,583) and believes that this definition, combined with established methods for assessing the condition of organisms, <FN 38> will improve the rule.

Footnotes

38 UWAG suggests that dead or moribund organisms can be distinguished from organisms harmed by the intake structure by using fisheries management data evaluating well established seasonal die-off rates, looking for symptoms of advanced disease likely to lead to death, and other methods discussed in the literature.

EPA Response

As discussed in the NODA, EPA considered many suggestions for the approach to determining the calculation baseline, and has clarified its definition of calculation baseline in today's final rule (see §125.93). For explanation of EPA's definition of calculation baseline, please refer to EPA's response to comment 316bEFR.034.013 and EPA's definition of calculation baseline at § 125.93, along with the accompanying preamble text. For EPA's position on the factoring of naturally dead or moribund organisms, please see EPA's response to comment 316bEFR.306.116.

EPA agrees that operational changes may include flow reductions that occur as a result of a permittee's decision to repower or replace units or any other change that can be shown to have reduced impingement or entrainment mortality, regardless of the reasons for that decision.

Subject Matter Code 21.04

Determination of compliance

EPA requests comment on the “As Built” approach. For entrainment, the As Built approach would determine the baseline either by using historical measurements of entrained organisms before a new intake technology was installed or by sampling immediately in front of the new technology and counting the organisms small enough to pass through a standard 3/8-inch screen. To determine entrainment reduction, the facility would sample and count (or weigh) entrained organisms behind the new technology or at the outfall.

UWAG believes the “As Built” approach is reasonable at those facilities where the efficacy of a technology can be assessed by directly measuring entrainment or impingement or both. Such an approach would help to simplify assessment and increase accuracy in instances where no credit is being sought, where the facility does not have the baseline condition, or where the facility can reduce the potential for error associated with inter-annual variability or other factors (such as gear changes or changes in sampling location) by evaluating technology performance within a given year.

EPA Response

EPA agrees that the “As-Built” approach is an acceptable method for establishing the calculation baseline. Therefore, a facility may choose to use the current level of impingement mortality and entrainment as the calculation baseline (see EPA’s definition of calculation baseline at § 125.93).

Determination of compliance

EPA itself defines the baseline calculation as an estimate of impingement mortality and entrainment. As UWAG has said in past comments, the biological variability over hours, days, months, seasons, years, and generations makes the baseline only an estimate, and indeed one bounded by large confidence intervals. It would be irrational to make this rough estimate into a precise numerical legal requirement that permittees must meet in all circumstances.

Although providing further details on the baseline configuration will help to make the rule clearer and more workable, a number of important implementation issues remain. Under the current proposal, the calculation baseline plays an essential role both in selecting the intake technology initially and in determining whether it is performing. As EPA explained in its proposal, the calculation baseline is the means by which facilities that already have installed technologies or made other adjustments to reduce impingement and entrainment will be given credit for those controls. In fact, for some BTA control options, the calculation baseline may offer the most accurate means of capturing the benefits of the existing or future controls.

While having a standardized "baseline" intake configuration is important, the natural tendency of fish populations and communities to vary over time, and indeed to vary widely, makes it difficult to assess technology performance by comparing contemporary entrainment and impingement data with a calculation baseline established using data from the past. This will be true no matter what "metric" (individual or biomass, RIS or all species) is used to gauge performance. And it is by no means clear that the difficulty could be resolved even if there were a large initial baseline database (which there will not be in many cases) and even if entrainment and impingement data were collected over a long-enough period going forward.<FN 39> Even if Phase II facilities that use cooling towers were to measure entrainment and impingement over time, those results would vary widely year to year, even though the make-up flows remained stable. The same would be true for other technologies. Therefore, while UWAG believes that there will be circumstances in which the permittee should use historical baseline data to set the baseline, EPA should make it clear that this is not required. Instead, the baseline design assumptions (as opposed to historical baseline data) should be allowed as the basis for comparison.

To illustrate this point, suppose that a facility on a freshwater river determines that it can install a fish handling system that increases the survival of impinged organisms by 80% on average, based on the performance of such systems at other sites. To show compliance, it should be sufficient simply to monitor impingement survival going forward and compare it to a baseline configuration in which no fish handling is used and impingement mortality is 100%. This approach would be both straightforward and consistent with EPA's assumptions.

By contrast, there will be situations in which it makes sense to use available baseline data both to determine BTA initially and to evaluate its performance after it is installed. For example, where the BTA technology (particularly for impingement control) involves fish diversion (a barrier net or aquatic filter barrier) or a behavioral deterrent (as opposed to a handling and collection device to improve survival), it may be better to compare impingement rates with the technology in place to impingement rates before the technology was installed. As UWAG explained in its comments on the proposed rule, the difficulty of accurately sampling the subset of impingeable-sized organisms that would have been impinged but for the diversion or deterrent would make this type of comparison more efficient and accurate in some cases. This is especially true where (1) the facility has collected impingement (and, ideally, population) data long enough to allow it to conduct statistical analyses to account for natural variability and (2) evaluation of performance data going forward allows for analysis of data over an appropriate averaging period, using appropriate statistical techniques.

It is apparent that one of the key issues facilities will face is the issue of evaluating performance in the context of large inter-annual population fluctuations. For some situations (for instance, where a barrier net has been deployed to reduce impingement), this will require comparisons before and after net deployment and use of some measure to adjust for the relative abundance of the population year-to-year. In other situations, by contrast, it may be possible to avoid the need for such adjustments by evaluating technology performance within a given year. For instance, where an aquatic filter barrier is used to reduce entrainment, the facility could measure the density of eggs and larvae inside and outside the barrier.

In fact, in every case the right structure for the performance evaluation will depend on a number of factors, including the following:

- what is the nature and extent of existing impingement or entrainment or both;

- whether the assessment is for impingeable or entrainable organisms;

- whether the technology consists of collection systems, diversions, behavioral barriers, location changes, or flow changes;

- whether the facility has data to establish the baseline configuration; and

- whether the facility proposes to use restoration or request alternative limits based on the benefit-cost test.

UWAG does not believe there is any single, simple approach suitable for all performance evaluations. Instead, for the reasons illustrated above and discussed in our comments on the proposed rule, UWAG believes it is essential that EPA expressly give permittees and permit writers flexibility to develop appropriate site-specific performance evaluation requirements that consider these and other relevant factors. As one element of this approach, we believe it is important that EPA distinguish between the use of the calculation baseline for predictive purposes (i.e., for evaluating technologies and demonstrating that selected technologies will achieve reductions within the performance standard range and thus are BTA) versus the use of historical baseline data to evaluate technology performance going forward.

Footnotes

39 In any case, given the cost of entrainment and impingement sampling and analysis, we do not believe that extended monitoring requirements would be economically practicable or environmentally warranted. Such monitoring would be of little assistance in improving technology performance and ensuring better fish protection, which should be its main purpose. As UWAG said in Section XIX.E. of its August 2002 Comments, the most appropriate way to ensure compliance would be

to require the permittee to install one of the selected technologies and then monitor simply to be sure that it is being maintained and operated correctly.

EPA Response

EPA agrees that historical data may not be appropriate in all cases for determining a facility's calculation baseline. As discussed in the NODA, EPA considered many suggestions for the approach to determining the calculation baseline, and has clarified its definition of calculation baseline in today's final rule (see §125.93). For additional detail please see EPA's response to comment 316bEFR.034.013. EPA also acknowledges that populations will experience natural variations in abundance over the course of a year. Please see EPA's response to comment 316bEFR.034.017 for EPA's position on episodic impingement mortality and entrainment episodes due to natural conditions and other factors and EPA's decision to authorize the use of TIOPs. Finally, EPA agrees that a single approach for evaluating performance is not appropriate. In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Permit applications/implementation schedule

Compliance Timelines, Schedules, and Determination

The NODA raises several questions about the time for complying with the new rule, once it becomes final (Section C, "Compliance Timelines, Schedules, and Determination," 68 Fed. Reg. 13,584-86).

First, EPA says it is considering options that would require full compliance with the rule after the effective date, to the extent the best technologies will not be available immediately after promulgation of the final rule. Id. at 13,584 col. 2. EPA observes, correctly, that the nature of this regulation is such that facilities may need to test and verify the efficacy of the technology option that they choose. EPA requests comment on this approach.

We are advised that NPDES permits issued by some states say something like "the permittee will comply with the schedules and requirements of EPA's 316(b) regulations." States using such language seem to anticipate that EPA will resolve the issue of when the requirements become enforceable by including "schedules" in the regulation. Otherwise, permit language of this sort will leave everyone in doubt. Thus, the timing of compliance needs to be clarified in the rule itself, or else permit writers need to be directed to include in individual permits reasonable schedules that make the § 316(b) permit requirements enforceable in the future after sufficient time for coming into compliance.

In order to fulfill their duty to provide electric power, power companies must be able to (1) forecast necessary expenses for budgeting purposes, (2) forecast needs for personnel resource allocation planning and scheduling, and (3) coordinate intake modification construction with scheduled outages. These issues are critical not only for business practices but for successful compliance with the § 316(b) regulation. Consequently, EPA must structure the § 316(b) compliance requirements so that the industry has the time to complete these activities.

A worst-case timeline for complying with the regulation may take up to five years, once regulatory agency approval time is factored into the process. The compliance timeline must take this into consideration.

EPA has requested comment on the CAFO (concentrated animal feeding operation) approach. The CAFO approach (apart from the NPDES administrative requirements) requires that all CAFOs develop and implement a nutrient management plan by December 31, 2006, and that large CAFOs comply with the effluent guideline requirement (land application area) by the same date (68 Fed. Reg. 7,184). Since the rule was published February 12, 2003, this provides a compliance time of almost four years. A four-year period is inadequate for successful compliance with the § 316(b) rule, because as much as 4-5 years might be needed for studies and construction and because there will be a shortage of consulting and field resources if the entire industry crowds in compliance activities at the same time. Consequently, the CAFO time is too short for § 316(b) efforts unless the final compliance date is set as late as 2012.

For more recent effluent guidelines, <FN 40> EPA has simply stated that existing dischargers must comply with limitations as soon as such requirements are imposed in their NPDES permits, without addressing the schedule in detail. Apparently, this has allowed permittees and the permitting agencies to work out a permitting schedule that makes allowance for the time needed to achieve compliance. EPA should consider these precedents in addressing compliance with the § 316(b) rule.

Permit applications/implementation schedule

Time for Facilities to Comply with the Rule Once the State Program Is Updated

Whether it is done by specifying a schedule as part of the rule itself or by directing permit writers to write reasonable future compliance dates into permits, it is essential that the requirements of the rule be phased in over time. Making new requirements immediately enforceable would violate due process of law and probably cause endless disputes.

The key is not to write a rule that puts permittees in “violation” as soon as the rule becomes final or shortly thereafter. It will not be sufficient to make the rule immediately effective and then offer a “compliance schedule” as a matter of agency discretion. The rule would invite legal challenge if it was structured so that companies were technically in violation of the law for a period of time before they were able to install new intake technologies. Much of this problem could be avoided by careful drafting. EPA must take care not to allow anyone, including citizen plaintiffs, to claim that there is a period of “noncompliance” or “violation” simply because there is an unavoidable need for time to do biological sampling and to choose the best technology, design it, implement it, and test it.

UWAG addressed this issue in Section XIX of its August 2002 Comments. We will not repeat those comments here, but they are as pertinent now as they were in 2002. UWAG’s proposal was summarized in a timeline as follows:

(See Graph on pg 78)

Organization Hunton & Williams obo Utility Water Act Group

Time for the State to Adopt the New Federal Rule or Demonstrate Existing Program is Comparable

The above schedule does not account for time for the state to promulgate a state regulation consistent with the new EPA rule, or to demonstrate, as provided in proposed § 125.90(d), that the existing state program will produce environmental benefits that are comparable to the rule's performance standards. Every state will have to create a regulation to implement the new federal rule or demonstrate the comparability of its program. In some cases a state may even need to have its legislature enact a statute.

The state then will have to submit its § 316(b) regulation or program demonstration to EPA for approval. For new regulations, EPA approval would presumably be handled under 40 C.F.R. 123.62. If EPA determines that the proposed program revision is "substantial," it will have to give at least 30 days' notice to the public, followed by EPA approval.

EPA must decide whether the schedule for phasing in compliance with the new rule should begin immediately when the federal rule is promulgated or whether it should wait until the state has revised its own permit program or secured EPA approval of its existing § 316(b) program. If the latter, then the schedule must begin with at least a six-month period to allow the state to enact the necessary regulation and to get EPA approval. Indeed, almost certainly more than six months will be needed.

If, on the other hand, EPA wishes to begin phasing in the new § 316(b) requirements immediately, then the federal rule must be written so as to address permit renewal applications that are submitted before the state has enacted its § 316(b) regulation.

In light of the 30 years that have already passed while § 316(b) was applied case-by-case without significant damage to the environment, it would seem that EPA can afford to proceed in an orderly fashion and begin the phase-in process several months after the federal rule becomes final. Unless this initial period for the states to change their law is more than a year, however, there will be some states (especially if there are any that must enact statutes) that will require more time. Some provision must be made for these states as well.

There is no great danger in allowing a long period before the regulation goes into effect, because all that would happen during that period would be the same process, the case-by-case application of § 316(b), that has, in our view, worked well enough for the past 30 years.

EPA Response

Irrespective of today's rule, NPDES permits must contain requirements consistent with § 316(b). See 40 C.F.R. § 401.14. Today's amendment to Part 125 establishes specific § 316(b) requirements for certain existing facilities within its scope. Permits issued by States for cooling water intake structures must comply with the requirements of today's rule in conformity with the timeframes specified in the rule. Today's rule authorizes the Director to establish a schedule for the submission of certain studies required by today's rule. EPA created this authority to account for the fact that some NPDES permits would expire – and applications would need to be filed under Part 122 – prior to the time when the studies required under today's rule would be complete. EPA intends that this provision addresses the concerns raised by the commenter.

EPA is aware that States may need to make statutory or regulatory revisions to reflect the requirements of today's regulations in their own State law. However, the requirements of the Clean Water Act and EPA's regulations implementing it must be incorporated into NPDES permits under federal law, so such revisions are not a necessary pre-condition to State implementation of today's regulations.

Subject Matter Code 21.09

Permit applications/implementation schedule

Time for All Parties to Properly Implement the Rule

Regulators and permittees alike will benefit from an explicit, phased-in compliance period. States will benefit because they will have time to promulgate regulations or demonstrate the efficacy of existing programs. States also will benefit because the burden of implementing § 316(b) will be distributed across several years. EPA will benefit because it will have time to better assess technologies (e.g., through its ongoing wedge wire screen studies) and to develop much-needed § 316(b) implementation guidance.

Facilities will benefit because they will have adequate access to experts and vendors familiar with § 316(b) issues and technologies. At present, only a handful of consultants have the range of disciplines required (biology, statistics, engineering, and economics) and the experience to manage a comprehensive § 316(b) demonstration. Without phased-in compliance, the demand for such consulting services will quickly outstrip the supply. Furthermore, vendors and consultants are not likely to invest in equipment and employee development and training if all the available work will be completed in a single five-year span. A phased-in approach to compliance, however, would provide an incentive for better long-term staffing plans and development of new and improved technologies.

Finally, phased-in compliance will allow companies with multiple facilities to plan and budget for capital expenditures needed to comply with the rule. UWAG surveyed its members to determine how each facility will deal with the burdens of complying with the rule. Out of 178 responding facilities, 45 (about 25%) reported that they expect to perform both biological and engineering studies to support a § 316(b) determination. Another 42 reported that they had not yet developed a plan for compliance with the rule. And 20 expect that, in addition to any biological or engineering studies, they will need to resort to either the cost-cost test or cost-benefit test and therefore will have to develop economic information. It is clear, even from this informal survey, that the analytical work required for § 316(b) decisions will take considerable time and effort on the part of the permittee. Thus, it makes sense to phase in compliance over a number of years.

Subsequent Permit Renewals

As UWAG said in Section XX of its August 2002 Comments, the analysis of BTA for a facility should not have to be redone every time the permit is renewed. Once a successful § 316(b) demonstration is made, maintaining and operating the technology for the life of the plant should be enough. At a minimum, there should be no reconsideration for at least ten years, unless there is evidence that conditions have so changed that the aquatic community is threatened.

Another way to put it is that, after a successful demonstration of compliance with EPA's performance standards, at each later permit renewal the permit writer should accept the initial demonstration, unless there have been significant changes in plant operations or material adverse changes to the aquatic populations. This has been EPA's position, as reflected in guidance issued by EPA's Office of General Counsel to the regions over 20 years ago (Cooper 1982). Conservation of scarce administrative resources (which EPA claims is essential) and practicality weigh in favor of retaining that policy.

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. See response to comment 316bEFR 041.126 for a discussion.

Subject Matter Code 16.0

Capacity Utilization

Determining Capacity Utilization Rates (68 Fed. Reg. 13,586)

In the proposed rule, a facility with a "capacity utilization rate" of less than 15% does not have to meet the performance standard for reducing entrainment. The proposed rule defined capacity utilization based on the generating capacity of the entire facility, including both steam electric and non-steam generators. EPA now is considering defining capacity utilization based on only the steam electric part of a facility, because only the steam electric generators use cooling water.

The Definition Should be Limited to the Steam Electric Part of the Facility

UWAG supports this change. Because the definition of capacity utilization rate is intended to identify facilities with large inflows of cooling water, the definition should focus on the part of the facility that uses cooling water. UWAG therefore agrees with the "steam electric part" of EPA's new proposed definition of capacity utilization rate, which reads in full as follows:

Capacity utilization rate means the ratio between the average annual net generation of the steam electric part of a facility (in MWh) and the total net capability of the steam electric part of a facility (in MW) multiplied by the number of available hours during a year. The average annual generation must be measured over a five year period (if available) of representative operating conditions.

The Definition Should Not Penalize Facilities for Downtime

However, EPA's proposed definition of "capacity utilization rate" unfairly penalizes facilities that might suffer an extended outage. Under EPA's definition, the "capacity utilization rate" is calculated by multiplying by the number of "available" hours during a year. Much depends on what "available" means. UWAG is concerned that EPA might regard a power plant as "available" if it is physically available, even though it might not be available as a practical matter because of a planned outage for maintenance, an unexpected outage, or a permit limit restricting operation. Suppose, for example, that a plant has operational limitations allowing it to run only a fraction of the time during certain parts of the year. Although the facility could physically operate during these times, it cannot operate in fact because of either a permit restriction or its internal procedures. Such a period of time when the plant cannot operate should not be counted as "available" time.

Indeed, there is no good reason for EPA to make up its own definition of "capacity utilization factor" at all. EPA should adopt the definition of the Energy Information Administration, which reads as follows:

Capacity Factor - The ratio of the electrical energy produced by a generating unit for the period of time considered to the electrical energy that could have been produced at continuous full-power operation during the same period.

See www.eia.doe.gov/cneaf/solar.renewables/rea_issues/glossary.html.

The Five-Year Period Penalizes Small Older Facilities

Finally, EPA should change the five-year period over which the capacity utilization rate is calculated. For the past five years, parts of the United States have been suffering the worst drought in decades. This has required some plants, particularly small older facilities, to operate more than is customary. Using the highly unusual last five years for the capacity utilization rate would artificially inflate the capacity utilization rate of many facilities. Accordingly, EPA should change the five years to ten years. Alternatively, EPA should allow uncharacteristic (unrepresentative) years to be excluded.

EPA Response

The comment supports EPA's position on defining capacity utilization rate based on steam generating capacity.

The Agency agrees that the term "available" is not necessary in the definition of capacity utilization and has removed it for the final rule.

Regarding the Energy Information Administration (EIA) definition of capacity utilization factor, the Agency has reconciled this definition with the Agency's. Although the Agency could not accept the EIA definition verbatim, the principles are carried into EPA's definition.

The Agency does not agree that calculating the capacity utilization factor based on five-years is necessarily penalizing of small plants. The Agency allows for facilities in the final rule to calculate their capacity utilization based on their previous permit-cycle (or five years) or to incorporate a "forward looking" capacity utilization rate into their permit that forms an agreement to operate their plant at a certain average capacity factor in future years. For the case of small older plants, this will allow for flexibility to consider drought periods and account for the continued aging of the plant (i.e., decreased operation in the future) in their capacity utilization calculation.

Source data used by EPA

The NODA Gives Inadequate Notice of the Analyses EPA Has Done

UWAG said in Section XXII of its August 2002 Comments that at that time it was virtually impossible to assess EPA's analysis of costs and benefits, because EPA had not clearly explained its reasoning. Although EPA had summarized the benefit-cost analysis in the preamble to the proposed rule and included underlying technical documents and a large number of worksheets in the record, the method EPA used to determine costs and benefits was so poorly articulated that a reader could not follow it. UWAG argued that generating many pages of calculations and tables of numbers was not enough to satisfy the Administrative Procedure Act or due process of law. UWAG argued that EPA is required to provide enough explanation of its reasoning to enable reviewers to identify the strengths and weaknesses of the analysis.

UWAG renews those arguments now with respect to the NODA. The analyses summarized in the NODA are impossible to follow in detail. Several consultants have reported that they cannot follow EPA's analyses step-by-step because details are missing and the reasoning is not clearly explained. This is especially true of the analysis of nationwide costs and benefits.

Some parts of the analysis are missing altogether. For example, EPA's analysis of benefits considers only two of eight regions. UWAG sees mistakes in the analysis of those two regions and must presume that there would be mistakes for other parts of the country as well, if such analyses were presented. When will EPA present its methodology and use benefits for the other regions? Will interested parties be given an opportunity to comment on these benefit analyses? EPA states that "for the final rule analysis, the Agency intends to expand the Tampa Bay case study used in the proposed rule analysis to include the whole Gulf of Mexico region and to develop an original travel [cost] model for the Great Lakes Region" (68 Fed. Reg. 13,546). When will these evaluations be completed? Will they be made available for review?

UWAG believes that EPA's explanation of the reasoning underlying the proposed rule does not now meet the standards of the Administrative Procedure Act or of Due Process of Law.

EPA Response

EPA has made substantial efforts to help explain the complex issues involved with 316(b), and done a great amount of public outreach, including responding to comments, creating a publicly available record and hosting conference calls.

In regard to the comments on EPA's analysis of benefits, EPA has continued its regional approach to the estimation of benefits for the 316b rule. The methodologies followed in each region are detailed in the Regional Analysis Document (DCN 6-0003). The Tampa Bay case study was not used in the summation of monetized benefits for the final rule. EPA did estimate a RUM for recreation benefits in the Great Lakes region, it is presented in detail in Chapter G4 of the Regional Analysis Document.

EPA believes that today's rule is reasonable and supported by the; therefore, the standards of the Administrative Procedure Act are met.

Role of States and Tribes (alt./equiv. programs)

Approval of Functionally Equivalent State Programs is Essential to Implementation Success

EPA's proposal would allow states to demonstrate that they have adopted "alternative regulatory requirements that will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment that would otherwise be achieved" through the rule's performance standards. Proposed § 125.90(d).

As UWAG previously commented, <FN 41> EPA should allow states to continue successful § 316(b) regulatory programs without having to force-fit them into EPA's new performance standards. For a state to demonstrate that its program would always provide environmental benefits comparable to what could be achieved by applying the rule's performance standards would be a daunting undertaking. Therefore, proposed § 125.90(d), if promulgated as proposed, will be a "dead letter" provision, because states will find it safer to adopt the performance standard approach than to risk disapproval of their existing program.

Yet many existing state programs, such as Maryland's, are effective and well-established means of implementing § 316(b). Those programs deserve a better opportunity to prove their effectiveness. UWAG recommends that EPA amend § 125.90(d) to specify the following factors to be considered in approving alternative state programs:

- whether the state program has effective procedures for review of § 316(b) demonstrations;

- whether the state program adequately assesses costs of technologies in light of their associated environmental benefits;

- whether state-issued permits have addressed § 316(b) for subject facilities in a consistent manner, considering site-specific factors; and

- whether the state program, to the extent it permits mitigation/restoration measures, has been implemented so as to ensure proper completion and evaluation of such measures.

RFC: Three-option framework for determining BTA

EPA has made progress on its thinking about the Phase II § 316(b) rule as shown by some of the changes in its benefit-cost analysis and the questions it asks in the NODA. These questions tend to reflect the fact that the impacts of entrainment and impingement are site-specific. UWAG's answers to the questions in these comments show that flexibility is needed in the rule in order to cope with the many different situations that will arise at different sites. It is in that spirit that the above recommendations by the Utility Water Act Group are offered.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes, however, that it rejected an entirely site-specific alternative for the final rule. Please refer to the preamble for more information.

Overview of I & E effects on organisms

we note that EPA has no data on the extent to which flow reduction technologies will reduce impingement and entrainment losses, but instead appears to assume that such reductions will be roughly equivalent to the percent reduction in flow. Although UWAG agrees that flow reduction will produce appreciable reductions in entrainment, and may also reduce impingement (although the extent of any reduction is difficult to predict, since velocity rather than flow is the significant variable), we do not agree that EPA may assume that such options will produce a concomitant reduction in entrainment and impingement.<FN 5> A report prepared by Drs. Charles Bevelhimer and Charles Coutant for EPRI shows that the extent to which volume of water withdrawn or intake rate is related to impingement or entrainment is highly site-specific and not necessarily linear. See EPRI Technical Report, Impacts of Volumetric Flow Rate of Water Intakes on Fish Populations and Communities (March 2003). And, as the report indicates, the relationship between intake flow volume and effects at the population level and higher are even less well correlated.

Footnotes

5 Comments submitted by the Riverkeeper on the Phase II proposel include a paper prepared for Riverkeeper by Pisces, Ltd. (Pisces conservation Ltd., August 2002 Comment 1.77, which presents regression equations purporting to show that entrainment and impingement increase not linearly but exponentially with flow. However, a review of the Pisces analysis and some of the underlying data on which Pisces relied shows that it is without foundation. As Dr. Laryy Barnthouse concluded in a review prepared for EPRI (see Barnthouse Appendix to EPRI June 2003 Comments), the actual degree of non-linearity is trivial.

Equally important, a review of the 1979 paper on which Pisces' analysis is based (Kelso, and Milburn 1979(DCN4-1665)) shows that (1) although this article indicates a general relationship between flow and impingement of clupeids based on flow increases varying over many orders of magnitude, the data do nothing to support any relationship between flow and impingement over the less-than-single order of magnitude associated with retrofitting a Phase II facility with wet closed-cycle cooling; (2) even so, the actual correlation between impingement and entrainment and Mwe (which Kelso and Milburn used as the proxy for flow) looks relatively weak for all specias other than clupeids (I.d. gizzard shad and alewife), which dominated the impingement totals; (3) even for clupeids, a review of individual data points suggests that plants with higher flows in some cases had impingement or entrainment levels below plants with lower flow; and (4) the authors did not provide any deterministic statistics that would have allowed exploration of cause-and-effect relationships, nor did they examin any other factors, such as velocity, that might have had a greater correlation with some of the data.

EPA Response

Please see response to Comment 316bEFR.041.037 regarding the assumption used by EPA for its benefits analysis that I&E are proportional to flow.

Subject Matter Code 10.02.01

Recreational Fishing Benefits

EPA's revised recreational benefits estimate uses a promising method, regional random utility modeling, but neglects to ensure that data sources and survey methods used in the underlying studies are adjusted for bias and make appropriate assumptions about factors such as lost wages.

EPA Response

The comment states that EPA neglected to ensure that data sources for the RUM models are adjusted for bias, and that EPA made inappropriate assumptions about lost wages in the RUM models. EPA disagrees. EPA believes that both the National Marine Fisheries Service (NMFS) and Michigan Department of Natural Resources (MDNR) have adequately corrected for sampling bias through long-established and tested survey and statistical methods (see DCN #6-3189 for NMFS and DCN #6-3176 for MDNR). In addition, EPA does not believe that the Agency's analysis incorrectly calculates opportunity cost of time in the RUM models. If anything, EPA's measure of opportunity cost of time would result in downward bias in estimates for regions where income was reported for extremely small numbers of respondents. For regions where income was estimated using median household income from the U.S. census, it is impossible to determine the direction of bias, if any, because, without collecting primary data, there is no way to compare the median income of anglers to the median income of all households in the region. EPA has followed standard, generally-accepted methods of RUM modeling. See response to comment #316bEFR.041.452 for additional details.

Valuing Forage Species (incl non-use and non-landed)

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

EPA's new estimate of non-use benefits, based on a benefits transfer approach, suffers from a number of flaws that make both the method and the conclusions unusable. As a result, EPA vastly overestimates the non-use values of impingement and entrainment reductions in the North Atlantic Region.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

EPA methods: age 1 equiv, yield, prod foregone

In the NODA (68 Fed. Reg. 13,546 (§ X.B.3.b(4)), EPA says that several commenters pointed out that all fish impinged will not be Age I, as EPA had originally assumed. Therefore, EPA says, "the current studies relax the assumption that all impinged fish are Age I, and assume instead that the ages of impinged fish are Age 1 and older, and follow an age distribution that is implied by the associated survival rates." As a result, "the effect of this adjustment is that a higher proportion of impinged fish are assumed to survive until harvest. As a result of this adjustment, the estimate of foregone yield associated with impingement increases by a factor ranging from about three to ten, depending on a species' age-specific survival rates." Unfortunately, EPA's attempt to correct the original error will lead to a much more significant error, because EPA's revised approach ignores the largest Age Class, Age 0 (young-of-the-year, or "YOY"). As documented below, impingement in many waterbody types is usually dominated not by Age I and older fish, but by YOYs. Because the survival rate of YOYs is much lower than the survival rate for all older age classes, EPA should be lowering, rather than raising, its production foregone estimates.

Compounding this fundamental error, EPA says that it assumed that the fish age 1 and older "follow an age distribution that is implied by the associated survival rates." Id. Even if EPA's assumption that all impinged fish are Age I and older was correct, which it is not, EPA has provided no basis for determining the distribution of older fish. EPA says it has used a distribution "implied by survival rates," but I was unable to find in the record the data underlying that assessment. In any case, as documented below, impingement does not reflect a random or representative sample of the size distribution for the species occupying the waterbody (much less the survival rate of those organisms post impingement). Therefore, even if the size distribution of each at-risk species within the waterbody is known, that is not the distribution that will be seen in impingement samples.

Documentation that Impingement is Dominated by YOY (Age 0) Fish

Numerous impingement studies from a wide variety of waterbody types and geographic areas were reviewed. As documented below, it is clear that in freshwater rivers, as well as in lakes and reservoirs, impingement typically is dominated by YOY fish. We examined fewer estuarine studies, but dominance of YOYs at such sites also appears to be typical. At Great Lakes plants, the age distribution of impinged fish appears to vary considerably depending on the plant in question. However, even at sites where YOYs do not predominate, EPA's assumption that all fish impinged will be Age I and older still is erroneous. At such sites, EPA production foregone estimates may be "less wrong" than at sites where YOYs predominate, but they are still wrong.

1. Freshwater Rivers

According to DOE figures (Puder and Veil 1999), roughly half the nation's steam-electric generating capacity is located on freshwater rivers. Thus, this is a particularly important category. And, as documented below for numerous freshwater rivers, impingement at such facilities almost always is dominated by YOYs.

Muskingum River (EA Engineering, Science, and Technology Inc. 1978a)

The Muskingum River is a large river in SE Ohio. Based on a one-year impingement study at the Muskingum River Plant (MRP), the authors estimated that 1,733,544 fish were impinged, of which 99.3% were gizzard shad. They further noted that 99.2% of the 1.72 million impinged shad were YOYs. They also reported that 70% of the 3,153 channel catfish impinged (the second most frequently impinged species) were YOYs.

Muskingum River (Dames and Moore 1979)

This study was conducted at the Conesville Generating Station, which is located upstream of the MRP. Gizzard shad (73.4%) and channel catfish (5.6%) again were the two most commonly impinged fish. Based on length frequency data provided in the report (Table 5.1), 98.9% of the gizzard shad and 91.4% of the channel catfish were YOYs.

Ohio River (Geo-Marine 1978)

Gizzard shad dominated (78.9%) the impingement catch at the Sammis Power Plant, which is located on the upper Ohio River. According to data provided in the report, 86.6% of the shad impinged were £100 mm and thus were definitively YOYs. The actual percentage is certainly higher because some, and perhaps most, of the shad between 100 and 120 mm likely also were YOYs.

Ohio River (EIA 1978a)

Gizzard shad also dominated (56.7%) the impingement catch at the Tanners Creek Plant located on the middle Ohio River. According to data provided in the report, 44.7% of these shad were <100mm long and thus definitively YOYs. Another 35.4% were between 100 and 140 mm and were probably YOYs. Skipjack herring was the second most commonly impinged fish (22.1%) at the Tanners Plant. More than 99% of the skipjack herring impinged were YOYs. For freshwater drum, the third most commonly impinged fish (11.0%), 72% were YOYs.

Ohio River (EIA 1978b and EA 1987)

Impingement studies were conducted at the Clifty Creek Power Plant in both the 1970's (EIA 1978b) and 1980's (EA 1987). The authors of the earlier study reported that gizzard shad dominated (86.3%) the catch and reported that YOYs dominated the shad catch during the summer and fall. Inspection of the length frequency data provided by the authors (Table C-1) indicates that 80-90% of the catch was comprised of YOYs.

During the latter study (EA 1987), gizzard shad again dominated (84.9%) the impingement catch. The authors noted that at least 80% and probably more than 90% of the shad impinged were YOYs. The authors also noted that catches of freshwater drum and bluegill, the next two most commonly impinged species, were also dominated by YOYs, 90% and 89%, respectively.

Wabash River (EA 1988)

A 6-month impingement study was conducted at the Cayuga Power Plant on the middle Wabash River in Indiana. The authors reported that the most commonly impinged species were gizzard shad (59%) and channel catfish (32%). They reported that 78% of the impinged shad were YOYs and 87% of the channel catfish catch were YOYs.

Wabash River (EA 1989)

A similar 6-month impingement study was conducted at the Wabash River Station located near Terre Haute, Indiana. At this plant, channel catfish was the most commonly impinged species (36%). Over 99% of the channel catfish impinged were YOYs. The authors also reported that YOYs dominated catches of all larger species (e.g., bass and redhorse).

Kankakee River (EA 1990)

This year-long study was conducted at the Braidwood Nuclear Station, which is a closed-cycle plant located on the lower Kankakee River in Illinois. Gizzard shad dominated (69.1%) the impingement catch, and the authors reported that 86% of the shad were YOYs. They also reported that centrarchids (smallmouth bass, rock bass, and longear sunfish), which were also common, were dominated by YOYs. For example, 90% of the smallmouth bass impinged were YOYs.

Illinois River (ESE 1987)

This impingement study was conducted at the Dresden Nuclear Station during 15 June-30 September 1986. The two most abundant species impinged were gizzard shad and freshwater drum, which together accounted for 70% of the fish impinged. The authors did not provide specific percentages according to age class, but inspection of the tabular summaries they provided indicates that 80-90% of the shad impinged were YOYs and >95% of the drum were YOYs. The authors noted that “the great majority of the fish collected during the impingement studies were small YOY fish (p. 152)” and that “YOY fish have historically been impinged in higher numbers than adults at most power plants throughout the midwest” (p. 152).

Mississippi River (LMS 1999)

Impingement sampling has been conducted at the Quad Cities Nuclear Plant annually for 25 years. The authors reported gizzard shad and freshwater drum always dominate the impingement catch and that for both species YOYs dominate the catch.

Various Sites in SE US (Loar et al. 1977)

These authors reviewed impingement data for 24 southeastern power plants. Their data set included a combination of river and reservoir sites. They reported that 98% of the fish impinged at the 24 sites were clupeids (threadfin shad and gizzard shad). Although exact percentages were not reported, the authors noted that “most” of the fish impinged were small (<90mm), probably YOYs and Age 1's. Based on length data provided by the authors (their Table 2), it appears that YOY dominated the catch.

Columbia River (Page et al. 1977)

This study was based on impingement sampling at the Hanford Reservation in Washington. The authors reported that during the period of study (May-June 1977) yellow perch and Chinook salmon accounted for 99.2% of the fish impinged and that all the perch and salmon that were impinged were fry (=YOY). They further reported that previous studies had shown that >90% of the fish impinged at this site were Age 0 (YOY).

Monongahela River (EA 1978b)

Based on studies conducted at the Elrama Power Plant, the authors found that three species -- gizzard shad, pumpkinseed, and bluegill -- accounted for 93% of the impingement catch. They further noted that the mean lengths of each of the species fell into the range for YOY fish reported in the literature.

In summary, it is clear that, regardless of the portion of the country considered, impingement catches are strongly (often >90%) dominated by YOY fish, not Age I and older fish as now assumed by EPA.

2. Lakes and Reservoirs

Lake Sangchris (Porak and Tranquilli 1981)

This study was done at the Kincaid Power Plant in central Illinois. The study authors reported that the majority of the gizzard shad and yellow bass (the two dominant species) and 12 other species impinged were YOYs.

Newton Lake (EA 1984a)

Newton Lake is a cooling lake located in east central Illinois. Based on a one-year impingement study, the authors reported that gizzard shad accounted for 92% of the fish impinged with bluegill accounting for 6%. The authors reported that 84% of the shad, the species that strongly dominated the impingement catch, were YOYs.

Various Sites in SE US (Loar et al 1977)

As described previously, these authors evaluated impingement data at 24 lakes, reservoirs, and rivers in the SE. They found that clupeids were by far the most frequently impinged fish and that most of these clupeids were YOYs.

Given that clupeids dominate impingement catches at lakes and reservoir sites and that YOYs invariably dominate the age distribution of those shad that are impinged, it is clear that EPA's decision to represent impingement by assuming that all impinged fish will be Age I and older cannot be supported for either freshwater rivers or lakes and reservoirs.

3. Estuarine Sites

Although the composition of fishes impinged at estuarine is obviously much different than at freshwater sites, it is clear, as documented below, that impingement at estuarine sites often is dominated by YOYs.

Indian River Estuary (EA 1978)

Atlantic menhaden, spot, Atlantic croaker, and weakfish are four of the dominant species impinged at the Indian River Power Plant. With regard to size, the report provides the following quotes regarding these species:

-“The Atlantic menhaden appear on the screens and are affected primarily as young-of-the-year during warmer water seasons.”

-“The summer catches [of spot] that climbed rapidly in 1976 are a reflection of the incoming, developing juveniles [i.e., young of year] using areas of the estuary as nursery ground…”

-“The catches [of Atlantic croaker] consisted primarily of young-of-the-year individuals.”

-“… the weakfish is a migratory visitor to the estuary and…the catches, consisting primarily of young-of-the-year, are a reflection of the use of the estuary as a nursery ground by this species.”

Thus, it is clear that YOYs dominated the catch at this plant.

Sacramento/San Joaquin Delta, California (EA 1981)

This study was conducted in the late 1970’s at the Pittsburg Power Plant. The authors estimated that 133,809 striped bass, one of the main species of concern, were impinged. They reported that the mean fork length for each month ranged from 57 to 122 mm over the course of the study. Based on this size distribution, the authors concluded “that primarily young-of-the-year were impinged.”

Upper Chesapeake Bay (EA 1979)

These results are based on the studies at the C.P. Crane Power Station. The authors reported that, for Atlantic menhaden and spot, YOYs accounted for 96% and 97%, respectively, of the numbers impinged of these two species. For white perch, another commonly impinged species, 25% were found to be YOYs.

Hudson River (Barnthouse and Van Winkle 1980)

Based on data collected at six Hudson River power plants, these authors estimated that YOY white perch accounted for 80-92% of all the white perch impinged.

4. Great Lakes

Species composition varies considerably among the Great Lakes. Also, composition has changed considerably since many of the studies were done in the 1970’s due to declines in some species (e.g., rainbow smelt and alewife in Lake Michigan) and increases in other species (e.g., white perch, gobies, and bloaters). Nonetheless, the data that are available indicate that YOYs can make up a significant part of impingement.

Lake Erie (EA 1984)

This study at the Monroe Station was done in the fall and early winter, a period when gizzard shad impingement has been high historically. The study found that in October, November, and December, the catch was predominantly YOYs, whereas in January somewhat larger fish (probably Age I) dominated impingement. In conjunction with the draft Phase II rule, Detroit Edison filed comments to the effect that impingement at the Monroe Station is usually dominated by YOYs.

Lake Michigan (Wisconsin Electric 1976a)

This study was conducted at the Oak Creek Power Plant near Milwaukee, Wisconsin, from March 1975 through February 1976. The authors reported that 79% of the fish impinged were alewives. The authors did not provide specific length data but, based on summary tables and graphs they provided, it is apparent that YOY, Age I, and adult alewives were represented. Age I fish appeared to be the most common age class. Similar results were obtained at the nearby Port Washington Power Plant (Wisconsin Electric 1976b).

Lake Michigan (LMS 1993)

During 1991 and 1992, impingement studies were conducted at the Zion Nuclear Plant. Alewives dominated the impingement collections with rainbow smelt also being common. The authors reported that fish ranging from Age 0 (i.e., YOYs) to Age VI were present in the impingement collection, with adult fish, Ages 3 through 6, accounting for about 50% of those collected. The authors reported that YOYs co-dominated the smelt catch in 1991 but that in 1992 the impingement catch was dominated by Age II and III smelt.

The data summarized above show that, in contrast to the other waterbody types, impingement at Great Lakes power plants does not appear to be dominated by YOY fish. On the other hand, these same data show that YOYs were impinged at all the sites considered and that, depending on the species and site, YOYs can provide a sizeable contribution to the impingement catch. Clearly, YOYs cannot be ignored for the Great Lakes as EPA proposes.

Recommendations

In the NODA, EPA says it will assume that impinged fish all are Age I and older. Clearly, this approach is not supported by the data. Based on the studies reviewed herein, it would be appropriate for EPA to assume that 80-90% of the fish impinged at sites located on rivers, lakes, and reservoirs are YOYs, 10-20% would be Age I, and a very small percentage (no more than 1-2%) would be Ages II and older.

For estuarine sites, we have not reviewed enough studies to provide definitive guidance, but based on those studies we have reviewed, it appears that an assumption of about 50% YOYs would be reasonable.

For the Great Lakes, especially Lakes Michigan and Erie, the changes in species composition that have occurred over the past 20-30 years are substantial enough to make any assumptions rather tenuous. Nonetheless, it is clear that impingement on the Great Lakes includes significant percentages of YOYs, and this contribution cannot be ignored

EPA Response

The commenter expresses concern EPA's assumptions about the age distributions of impinged fish. EPA has revised its assumptions about age distributions of impinged fish in a manner that acknowledges that YOY may be predominant among impinged fishes, as described in the EPA response to EFR.029.105.

Benefit Estimation Methodology

Comments on Benefit Estimation in EPA's Proposed Phase II 316(b) Rule as Summarized in the Notice of Data Availability

Final Report

Prepared for: The Utility Water Act Group

Prepared by: Matthew F. Bingham, William H. Desvousges, Ateesha F. Mohamed
Triangle Economic Research, 2775 Meridian Parkway, Durham, NC 27713

June 2, 2003

EXECUTIVE SUMMARY

1.1 Introduction

On April 9, 2002, the U.S. Environmental Protection Agency (EPA) published a benefit cost analysis (BCA) supporting proposed standards for Cooling Water Intake Structures (CWIS) at "Phase II" facilities (existing power plants with flows over 50 million gallons per day). EPA received numerous comments and data submissions during the subsequent 120-day public comment period. On March 19, 2003, EPA released a related Notice of Data Availability (NODA). The NODA presents a summary of new data, discusses how those data might be employed in a revised analysis supporting proposed standards, details possible refinements to the proposed regulations, and provides additional information about data quality. Triangle Economic Research (TER) has prepared this report for Utility Water Act Group (UWAG) members involved in commenting on EPA's proposed §316(b) Rule for Phase II Existing Facilities.

This report addresses EPA's revisions to its original benefits analysis, as described in the NODA. However, the NODA provides only a very general description of the methods and data EPA intends to use for estimating regional benefits. <FN 1> In particular, this review is limited by the following:

-EPA presents benefit estimates for only two of eight regions: the North Atlantic and the Northern California regions.
-EPA only calculates nonuse benefit estimates for the North Atlantic region.
-The NODA docket only includes partial information on the methods EPA may use.
-EPA does not include a description of all the databases on which it may rely (68 Fed. Reg. 13543–45).

For these reasons, we cannot fully comment on EPA's methods or the implementation of these methods. Furthermore, as the text in 68 Fed. Reg. 13546, col. 2 suggests, EPA intends to rely somewhat on methods and data similar to those in its earlier proposal. To the extent that this is the case, EPA's current estimates are subject to problems discussed in our previous comments. Finally, the issues identified in this report are primarily relevant for the North Atlantic and Northern California regions.<FN 2> EPA's benefit estimates for the remaining six regions may raise additional issues.

1.2 Overview

EPA's proposed rules for CWIS at Phase II facilities contained a benefit cost analysis supporting the proposed regulations. In this analysis, EPA estimated that the total benefits of eliminating all impingement and entrainment (I&E) are $735 million per year for the entire U.S. TER's review indicated that due to a number of theoretical and empirical errors, this figure was overstated by as much as 16 times.

In response to public comments, the NODA has made or proposes to make several significant changes to the existing cost-benefit analysis. Major changes to the benefit analysis include the following:

-Eliminating multi-market producer surplus
-Replacing the case study-based benefit extrapolation with a regional approach
-Accounting for the impact of benefit timing through discounting
-Correcting the assumption that all fish spared due to CWIS modifications are harvested by recreational or commercial anglers
-Exploring new options for calculating commercial benefits
-Using regional random utility models (RUMs) to estimate recreational fishing benefits
-Developing a revised analysis of nonuse benefits.

The NODA makes no mention of a key issue raised in our previous comments, namely, EPA's erroneous reliance on the Habitat Replacement Cost (HRC) and Societal Revealed Preference (SRP) methodologies. Therefore we cannot determine whether EPA intends to employ cost-based measures any further in this rule-making. For all the reasons discussed in our comments <FN 3> on the proposed rule, and reiterated in this Executive Summary, we urge EPA to reject any further use of these methods for benefits estimation related to this rule.

The elimination of multi-market producer surplus is a clear methodological improvement that we consider briefly in this Executive Summary. Incorporating a regional approach for benefits, accounting for benefit timing through discounting, and relaxing the assumption that all spared fish are harvested address deficiencies in the previous analysis related primarily to the amount and timing of catch. This review does not analyze the many biological assumptions underlying the benefits analysis. <FN 4> We note, however, that other experts' comments indicate that EPA has made inappropriate assumptions on each of these points, resulting in vast overestimates on each score. <FN 5> Recent comments (Barnthouse 2003) demonstrate that EPA overestimates production forgone due to impingement, for the Salem plant, (one of four plants for which EPA had I&E data in the North Atlantic region) by factors ranging from 70 for weakfish to 2.3 for white perch. <FN 6>

The difficulty of accurately quantifying biological impacts highlights two additional caveats that apply to this critique. First, EPA omits any analysis of the uncertainty inherent in its biological estimates. This limits our ability to definitively assess the dollar values EPA presents as benefit estimates. As a result, this evaluation takes the biological values EPA used to calculate economic benefits as a given. This should not be interpreted as an endorsement of their validity. Rather, any economic assessment of §316(b) benefits relies directly upon biological estimates. In fact, the economic assessment is only as accurate as the underlying biological estimates. Second, the difficulty EPA has had quantifying biological impacts, underscores the substantial uncertainty surrounding the ultimate impact of §316(b) regulations on fish stocks and catch. In the §316(b) context, this uncertainty should have been assessed as part of EPA's benefit analysis. An appropriate benefit cost analysis should consider all biological sources of uncertainty and the influence of this uncertainty on economic values.

We these limitations, we comment briefly in this Executive Summary on EPA's three modifications related to the amount and timing of catch. We also refer the reader to our previous comments for appropriate methods of applying economic techniques such as discounting. The final set of proposed changes to benefit estimation—new calculations for commercial benefits, regional RUMs to estimate recreational benefits, and a revised method for analyzing nonuse benefits—are potentially major modifications. We discuss these modifications in both the Executive Summary and Detailed Discussion sections.

Improvements

As indicated in TER's prior comments for UWAG, both the HRC and SRP methods employ costs of one type or another as a substitute for benefit estimates. There is no justification for using costs as a proxy for benefits in the economics literature, nor is this approach consistent with EPA's Guidelines for Preparing Economic Analysis (hereafter Guidelines). Eliminating these techniques from the benefits analysis is essential. In the NODA, EPA does not say what its plans are for further application of these methods. However, for the reasons given in our previous report and in other comments on the proposed rule and the NODA, including Stavins (2003a, 2003b), EPA should make no further attempts to rely on such methods for national benefits estimation and must state clearly that they are not justified for site-specific benefits estimation.

In its original BCA, EPA contended that total benefits accrue not only to the commercial fishing sector, but also to processors and retailers. This factor justified the inclusion of multi-market producer surplus in commercial fishing benefit estimates. Our previous investigation of relevant market conditions indicated that fish processing and retailing in the U.S. are both relatively atomistic industries with tens of thousands of market participants (See Desvousges et al. 2002, pp. 16–23 for TER's earlier comments to UWAG on the nature of fish markets). The competitive nature of these markets invalidates the existence of long-run producer surplus in fish processing and retailing. In the NODA, EPA has apparently removed multi-market producer surplus from its estimate of benefits expected to accrue in commercial fish markets. Elimination of multi-market producer surplus is a clear improvement to EPA's benefits analysis.

Potential Improvements

Based on our review of the NODA, potential improvements include: incorporating a regional approach for national benefits; accounting for discounting and benefit timing; and relaxing the assumption that anglers catch all spared fish. The importance of correctly incorporating these factors was considered at length in our earlier comments. Areas of particular concern included extrapolation and aggregation methodologies, harvest rates, and fish maturation requirements.

Regional Aggregation Approach

EPA originally estimated national baseline losses by extrapolating data from the facilities in the five case-study areas to 539 in-scope facilities. As discussed in previous comments (see Heimbuch 2002 and Desvousges et al. 2002, pp. 44–48), several fundamental flaws in the previous EPA extrapolation methodology rendered those results unreliable. EPA now intends to evaluate impingement and entrainment losses as well as potential benefits from CWIS modifications on a regional level. EPA intends to aggregate regional benefits into national benefit estimates. <FN 7> EPA believes that these regional definitions "are both ecologically and economically meaningful, and offer a better scale of resolution upon which to base estimates of national impacts and benefits." <FN 8>

The impact of EPA's regional aggregation approach on the quality of benefit estimates depends upon appropriate biological extrapolation and the degree of regional homogeneity in economic factors. In particular, the ability to appropriately characterize regional biological benefits requires both accurate and representative I&E data, as well as an appropriate extrapolation method. Extrapolating data to multiple plants within a region requires a statistically valid normalization procedure that identifies and accounts for varying biological factors across facilities. <FN 9> Given an appropriate biological extrapolation, the value of regional aggregation for economic estimates depends upon similarity of preferences within a region. For example, aggregation of the North Atlantic region requires that people throughout the Northeast hold similar nonuse values. Thus, while we feel that regional aggregation is a conceptual improvement upon EPA's prior approach, the ultimate value of this change lies in its empirical implementation. Areas of concern include the accuracy and representativeness of underlying data, appropriateness of biological extrapolation, and demonstration of similarity for relevant economic factors within a region.

Proportionality between Stock and Harvest

In the original BCA, EPA apparently assumed that all fish spared by CWIS modifications and surviving to adulthood would be caught. Currently, EPA intends to correct this by assuming "linearity between stock and harvest" (See 68 Fed. Reg. 13547). In implementation, this adjustment implies that for example, "if 20% of the current commercially targeted stock is harvested, then 20% of any increase in stock due to this rule would be harvested." <FN 10> The exact implementation of this linearity between stock and harvest is not clear. However, comparing the number of landed and unlanded fish is instructive. <FN 11> We interpret this to mean that EPA expects approximately 20% of spared winter flounder to be harvested. Based on the limited data available in the record, we were unable to perform a detailed review of the merits of this assumption.

Account for Benefit Timing with Discounting

The final potential improvement is in EPA's accounting for benefit timing. In the original BCA, EPA assumed all fish species are commercially and/or recreationally harvestable at age 1. However, some more highly valued fish such as striped bass and black drum take more time to reach a harvestable age. <FN 12> Thus, any potential benefits to anglers will accrue in the future. According to the NODA, EPA benefit estimates will now reflect this consideration with appropriate discounting. Specifically, benefit calculations will now be affected by "the range of ages at which different types of fish are typically landed by commercial or recreational anglers and the discount rate applied in the analysis" (see 68 Fed. Reg. 13548). Completely evaluating EPA's methodology for calculating the timing of benefits is beyond the scope of this review. For a thorough treatment of appropriate discounting in this context, we refer the reader to previous TER comments (Desvousges et al. 2002).

1.3 Major Modifications

EPA's latest analysis of the benefits presumed to arise from 316(b) regulations is predicated upon growth in fish stocks due to decreased I&E. A small portion of these benefits accrues to recreational and commercial anglers through increased catch rates. The remainder of benefits is attributed to nonuse values for species that are commercially and recreationally valuable but not caught, and forage fish. Major changes to EPA's commercial, recreational, and nonuse benefit estimation methodologies are discussed in both this Executive Summary, and the following Detailed Discussion.

Commercial Fishing

EPA's latest analysis of commercial fishing benefits still bases benefit estimates on the gross revenue of lost commercial catch. However, while EPA's prior analysis assumed that producer surplus ranged from 40% to 70% of dockside value (gross revenue), EPA is currently considering a range of 0% to 40% of dockside value. <FN 13> EPA bases this adjustment on a review of current literature and recommendations made in comments on the EPA analysis at proposal. This adjustment is significant. However, EPA's methodology inappropriately characterizes the source and nature of societal benefits in this context.

The problem with EPA's approach lies in the misconception that the effect of I&E reductions can be approximated as some portion of increased dockside value. This notion is rooted in short-run production theory, which has no place in the analysis of benefits arising from I&E reductions. Short-run analysis is inappropriate in this context because any changes in harvest occurring as a result of reductions in entrainment and impingement will not occur immediately. <FN 14> This means, an appropriate analysis depends critically on the responsiveness of long-run prices to quantity changes. In our Detailed Discussion, we demonstrate an appropriate general framework for such an analysis. Our investigation indicates that societal benefits from §316(b) regulations under open markets should exceed gains observed with market restrictions. <FN 15> Using the assumptions of unit price elasticity and open markets we provide an illustrative example estimating that societal gains from the elimination of I&E in the North Atlantic region are $0.72 million as opposed to the EPA estimate of $0.28 million. The validity of this result depends upon correct estimates of commercial harvest increases, as well as the assumptions of unit price elasticity and open markets. Correctly valuing commercial benefits requires an in-depth study of fishery regimes and markets, as well as an appropriate framework for analysis.

Recreational Fishing

EPA plans to use region-specific random utility models (RUMs) with participation components to estimate losses to recreational fishing due to I&E. For the six coastal regions, EPA intends to use the National Marine Fisheries Service (NMFS) Marine Recreational Fishing Statistics Survey with the corresponding Add-On MRFSS Economic Survey (NMFS 1994, 1997, and 2000). For the Great Lakes, the Agency will use the 1995 Michigan Recreational Anglers survey. For the interior U.S. region, EPA will use the 2000 National Survey of Recreation and Environment and the 2000 National

Survey of Fishing, Hunting, and Wildlife-Associated Recreation (U.S. Fish and Wildlife Service 1996 and 2001).

RUMs are the most widely accepted method for valuing recreational fishing. In the context of §316(b) regulations, RUMs provide the best opportunity for correctly valuing increased catch hypothesized to result from I&E reductions. However, unadjusted data from the surveys cited by EPA may lead to an upward bias in benefit estimates. This is caused by (1) sampling procedures that over-sample avid anglers and (2) anglers' tendency to overstate their level of fishing activity. <FN 16> Another concern is that EPA incorrectly measures the opportunity cost of time, resulting in an overestimate of benefits.

Regional random utility modeling is the most theoretically appropriate method for valuing increases in recreational catch. Correctly implemented, such an approach provides the best opportunity for doing so. Therefore we endorse this method. However, this endorsement is tempered by a number of concerns with the type of data and estimation methods that EPA intends to use. General concerns are detailed in the body of this report. However, given the complexity of random utility modeling, a thorough critique requires access to data and programs. These are not available in the NODA, or NODA docket, limiting the scope of this critique.

Nonuse

According to EPA, the majority of organisms that will be spared from I&E through CWIS improvements are forage fish and valuable species that are not landed by commercial or recreational anglers. It's reasonable to believe that in the aggregate, these fish are likely to have some societal value external to their consumption. However, because these fish are not used directly, they cannot be valued through traditional means.

When individuals are affected by changes in resources that they do not use, the resource is said to have nonuse value. <FN 17> Whether nonuse benefits should be included in a benefit cost analysis is somewhat controversial (Madariaga and McConnell 1987; Hausman 1993). A particular limitation to the inclusion of nonuse values in benefit-cost analysis is that these values are not revealed through behavior. <FN 18> In attempting to overcome this difficulty, economists have developed hypothetical valuation methods (Freeman 1993). Currently, contingent valuation (CV) is the most widely used technique for attempting to measure nonuse values. <FN 19>

Citing difficulties with regulatory scheduling and resource requirements, EPA eschews primary research in favor of a benefits transfer approach for nonuse valuation. EPA's approach first assesses respondents' values for habitats (eelgrass and wetlands) that play a significant role in the production of fish and shellfish. It then estimates the quantity of this habitat that would be required to replace fish and shellfish lost to I&E. EPA then combines this information with population data to produce what it hopes will be an indirect estimate of aggregate values for fish and shellfish lost to I&E. Using this approach, EPA concludes that $76 million per year or 95.78% of the benefits from I&E reduction in New England fisheries is attributable to nonuse values.

However, EPA's approach to assessing nonuse values is entirely inadequate. In particular, the presumption that values for eelgrass and wetlands can be transformed into nonuse values for fish is unfounded. Economic research indicates that nonuse values are largely tied to the intrinsic value of resources rather than service flows from those resources. For example, the bald eagle provides ecological service flows, as do other birds of prey. But the nonuse value of the bald eagle is derived from intrinsic characteristics that are completely unrelated to its ecological services. By comparison, a vulture provides valuable ecological services as a scavenger, but likely has little nonuse value. Given how closely nonuse values are tied to the unique characteristics of particular resources, similarity between resources being valued in the policy case and those examined in the study case is all the more critical in a benefit transfer of nonuse values.

As demonstrated in our specific comments, EPA attempts to overcome the vast difference between the transfer study's hypothetical valuation scenario and the 316(b) policy context with a series of adjustments. However, the dissimilarity between what is valued in the transfer study (substantial losses of wetlands and eelgrass) and what EPA is attempting to value (marginal increases in forage fish and unharvested commercial and recreational species) is so dramatic that any values produced through benefits transfer are meaningless. EPA's attempt to overcome this disparity results in the remarkable conclusion that over 90% of benefits due to §316(b) regulations can be attributed to growth in the stock of forage fish. The fallacy of this result can be demonstrated through consideration of use to nonuse ratios and an analysis of the resultant implications of natural stock variations. Table 1 details EPA benefit estimates for the North Atlantic region by category.

Table 1. EPA Benefit Estimates for the North Atlantic Region
[see hard copy for table]

EPA estimates the nonuse value of unlanded fish that are commercially and recreationally valuable concurrent with its valuation of forage fish. EPA apparently estimates nonuse values at approximately 30% of use values on a per-fish basis. <FN 20> The true magnitude of nonuse values for these species is unclear. However, the approach that EPA used to reach this conclusion is invalid. In developing nonuse values for commercially and recreationally valuable species, it is important to consider that nonuse values exist primarily for the resource, a viable fishery, and that nonuse values for individual fish are a reflection of their contribution to the stock. Thus, in a viable fishery, the use/nonuse should be heavily weighted toward use. However, as a fishery declines, each remaining fish becomes relatively more valuable in nonuse than in use, changing the use/nonuse ratio. EPA's analysis of nonuse values for important commercial and recreational species should include this consideration.

In the original BCA, EPA relied heavily upon the Fisher-Raucher approach to estimate nonuse values for commercially and recreationally valuable species. <FN 21> TER argued against this approach on the basis that the Fisher-Raucher approach is not relevant for a resource in which use implies consumption. In the NODA, however, EPA assigns significant nonuse values to forage fish. Unlike commercially and recreationally valuable fish, the use of forage fish does not imply their consumption. <FN 22> In this situation, a comparison with the use/nonuse value ratio of other resources may be appropriate. However, EPA presents no use value for forage fish. Thus, applying the Fisher-Raucher approach to EPA benefit estimates points out a fundamental inconsistency. Specifically, EPA reports massive nonuse values, but no use values for forage fish. The Fisher-Raucher approach implies that any resource with zero use value would also have zero nonuse value.

Another implication of EPA's nonuse valuation relates to the implied effect of natural population fluctuations on nonuse value. For the North Atlantic, EPA's predicted increases in commercial catch indicate that EPA anticipates approximately a 3% increase in commercial catch across species. EPA's assumption that there is a linear relationship between stock and harvest implies that there is an identical 3% increase in commercial fish stocks. Assuming the stock of forage species increases by the same magnitude as the commercial stock, the $76 million in nonuse benefits reported by EPA are due to a 3% increase in the stock of forage species. The natural variation occurring in many fish populations is typically orders of magnitude larger than 3% (Sissenwine 1984). Thus, by extension, EPA's result indicates that natural variation in stocks of forage fish are potentially worth billions of dollars per year in the North Atlantic alone. <FN 23> The suggestion that nonuse values are tied so dramatically to fluctuations in the stock of forage fish is nonsensical, as is EPA's conclusion that nonuse values respond dramatically to marginal increases in stock.

We conclude that EPA has failed to provide a credible approach to measuring nonuse values for 316(b) regulations. This lack of credibility can be directly traced to EPA's inability to articulate a coherent conceptual framework for nonuse values arising from §316(b) regulations. An appropriate conceptual argument should address these marginal changes in fish stocks on a regional basis. It should also recognize that these marginal changes may be swamped by the natural variability that occurs in fish stocks. Attempting to communicate such arguments in any type of stated preference study would be a significant challenge and unlikely to produce reliable benefit estimates.

These concerns also affect EPA's apparent intentions to estimate nonuse values for I&E reductions using a meta-analysis of studies containing both use and nonuse values. The studies listed at 68 Fed. Reg. 13575 are not on the docket. However, this table demonstrates the difficulty of calculating nonuse benefits for I&E reductions using any benefit transfer approach. <FN 24> Specifically, all of the studies listed (but one) are based on water quality improvements. To the extent that these water quality improvements are relevant for fish, they do not lead to marginal population changes. Rather, they improve the viability of the stock. A single study in EPA's list, (Olsen et al. 1991) does directly address fish increases. However, the values calculated are for doubling the population of salmon in the Pacific Northwest. This is quite a different situation than the marginal changes in less well-known species that comprise the majority of benefits expected to arise from I&E reductions.

In developing nonuse values for this regulation, EPA should be mindful of the elements that lead to significant nonuse values. Applying a concept that was originally intended to capture unmeasured values for a unique resource (the Grand Canyon) to this situation is questionable. To the extent that nonuse values do exist for this application, they are most likely for the stock of fish, not the individual. Thus, the nonuse value for a single fish should be based on its contribution to the stock. For most species, I&E reductions will have very little impact on stock. In fact, at optimal harvest, one fish more or less does not impact the viability of a stock at all.

These logical considerations highlight an additional inconsistency with EPA's approach toward calculating net benefits. Specifically, considering nonuse values is in keeping with EPA's belief that total value should be compared to total social cost. <FN 25> However, for reasons stated above, nonuse values for this regulation are likely negligible. In measuring costs, EPA determined that there were social costs to this regulation in addition to direct financial outlay. However, EPA deemed these costs inconsequential when compared with the effort required to estimate them. <FN 26> We submit that the nonuse values associated with this regulation fit into a similar category.

1.4 Summary

Our review indicates that EPA has potentially made some improvements in estimating the amount and timing of benefits arising from CWIS reductions. However, the EPA has not answered some critical questions about its plans for future reliance on the HRC and SRP methods. In addition, while EPA has potentially corrected some problems, it has introduced others. Consequently, EPA's benefit estimates, especially the nonuse benefits, are vastly overstated. A comparison of benefit sources across the two analyses demonstrates the magnitude of this problem. In the original BCA, benefit estimates for the Salem facility along the Delaware Estuary (comparable to the North Atlantic region) of approximately $23.2 million were distributed approximately 64% to commercial, 24% to recreation and 12% to nonuse. In the NODA, EPA estimates that the total benefits from reduction in I&E for the North Atlantic region is $79 million per year. Of this, $0.3 million (0.4%) is due to commercial benefits, $3.1 million (3.9%) is due to recreational benefits, and the remaining $75.6 million (95.7%) is from nonuse value. <FN 27>

This dramatic shift in the apportionment of benefits across categories is striking. In particular, the movement of benefits from use categories to the nonuse category is troubling. The remainder of this document addresses important aspects in EPA's estimation of commercial, recreational, and nonuse benefits, and provides some alternative benefit calculations to the extent that this was possible. In many cases, EPA's analytical intentions are partially developed but not completely implemented. Thus, our ability to evaluate some of the significant issues in the benefits analysis is limited.

[comment continued in 316bEFR.307.302]

Footnotes

1 Revised national benefit estimates will equal the sum of benefits from eight regions.

2 The issues identified are only partially relevant for the Northern California region because EPA did not estimate nonuse values for that region.

3 See Desvousges et al. (2002). Other economists with substantial expertise in natural resource benefits estimation have also commented forcefully against EPA's use of these methods. See Stavins July 2002 Comments 1.05 and August 2002 Comments 1.12; EPRI August 2002 Comments 1.74, Strand Appendix C; Detroit Edison Comments 1.65, Talhelm Appendix 2; Talhelm on behalf of Consumers Energy Co. August 2002 Comments 2.05.

4 These include evaluating impingement and entrainment (I&E), and I&E mortality at study plants; extrapolation from study plants to other plants in the region; translation of total I&E values to equivalent adults; calculation of forgone production and yield; and determining the acres of eelgrass or wetlands necessary to produce that number of equivalent adults.

5 See UWAG August 2002 comments and EPRI August 2002 comments.

6 This dramatic overstatement arises from a single inappropriate assumption about the life stages of impinged organisms. EPA did not provide enough information to assess this effect at other plants. However, current reviews strongly suggest that the same overestimate is likely to be true for much of EPA's data (Barnthouse 2003). Furthermore, this overstatement is due to a single factor. EPA's biological estimates are based on a series of assumptions that compound this problem.

7 This regional approach is discussed in the document entitled "Regional Methodology Used in the section §316(b) Phase II Notice of Data Availability."

8 These methods are presented in Chapter A5 of Part A of the section §316(b) Phase II Case Study Document. Changes in methods and analysis are provided in "Case Study Corrections and Clarifications" and "Impingement and Entrainment Methods."

9 For example, an important question is the degree of similarity between species at each plant. Species composition is

important in its own right. In addition, this factor influences biomass, age at impingement and trophic transfer rate (Barnthouse 2003).

10 These methods are presented in Chapter A5 of Part A of the section §316(b) Phase II Case Study Document. Changes in methods and analysis are provided in "Case Study Corrections and Clarifications" and "Impingement and Entrainment Methods."

11 For winter flounder in the North Atlantic region, the number of fish valued for recreational and commercial purposes (landed) is 1,742,461. The number valued for nonuse (unlanded) is 7,239,297.

12 Striped bass contribute the majority of benefits for the Northern California region. This means benefits from this species are heavily dependent upon correct consideration of benefit timing.

13 Producer surplus is the difference between the market price and the minimum price suppliers would be willing to accept for the product (Varian 1996).

14 Here we define the short-run as the period of time during which inputs to commercial fishing cannot be changed. The responsiveness of effort to availability within a commercial fishing season demonstrates that benefits from I&E reductions are best analyzed in a long-run context.

15 The outcome that societal benefits from increases in natural resource availability are greatest in competitive markets is a well-known implication of microeconomic theory.

16 Avidity bias is the over-sampling of frequent anglers. Recall bias is the tendency for anglers to overstate trip frequency.

17 Nonuse values are also referred to as existence or passive-use values.

18 Economists prefer value estimates generated through the revealed behavior of market actors as opposed to those based upon stated preferences.

19 In the NODA, EPA refers to CV as stated preference (SP). The term SP is often used in a different context. Here we use the term CV to refer to a survey-based approach for eliciting willingness-to-pay.

20 EPA says that 0.77% of I&E losses are commercially or recreationally valuable species that are not caught. Landed fish represent 0.15%, of the I&E losses, meaning that I&E in the region affects five times as many unlanded as landed fish. EPA recreational value for I&E elimination in New England is $3.07 million, nonuse values are $4.54 million. This means that on average, EPA values an uncaught fish (commercial or recreationally valuable) at approximately 30% (0.77 / 0.15 x 3.07 / 4.54) of a caught fish.

21 This approach assumes that nonuse values can be approximated as some portion of use values.

22 In their prior benefits assessment, EPA valued forage fish through their role as food for commercially and recreationally valuable species (trophic transfer). In the NODA, it is unclear whether or not EPA still values forage fish in this manner. If they do, this should be corrected, valuing both the existence of forage fish and their role as food for larger fish is double-counting.

23 In other WTP studies, EPA estimates the value of a human life to be $4.8 million and the value of avoiding an emergency room visit for asthma to be $194 per case (these are in 1990 dollars, see below) (taken from The Benefits of the Clean Air Act 1990 to 2010, [1999]). On this basis, marginal increases to the stock of forage fish 391,752 visits to the emergency room or saving 15.8 statistical lives each year.

24 Meta-analysis is a benefit transfer approach that statistically controls for differences across studies.

25 See page 1 of DCN 5-1001.

26 See § 316(b) Phase II TDD.

27 Commercial and recreational values are undiscounted, as stated at 68 Fed. Reg. 13578. Nonuse value is the low end of a

range stated at 68 Fed. Reg. 13579 of the NODA.

EPA Response

The comment states that EPA’s final rule analysis is improved in terms of “incorporating a regional approach for national benefits; accounting for discounting and benefit timing; and relaxing the assumption that anglers catch all spared fish.”

The comment addresses several issues that are no longer relevant to EPA’s final rule analysis.

The HRC method is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the HRC method, please see the response to comment # 316bEFR.005.035.

The SRP method is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the SRP method, please see the response to comment # 316bEFR.005.006.

The comment raises the issue of uncertainty in EPA’s analysis. Please see Chapter A6 of Part A of the Phase II Regional Study Document for a discussion of uncertainty in the context of EPA's analysis (DCN #6-0003). EPA notes that uncertainty analysis was impeded, in part, by a general lack of information in facility documents on the variance in facility I&E estimates.

For EPA’s response to comments on the methods used to estimate commercial fishing losses and benefits please see the response to comment 316EFR.005.029.

EPA realizes that the facilities evaluated do not constitute a random sample of in scope facilities. It was not possible to develop a random sample in a post-hoc analysis of limited information that was not collected as part of a study designed for the purpose of estimating I&E on a national scale. EPA used monitoring information prepared by individual facilities in the analysis. This material was provided in numerous formats and many degrees of completeness. Data for most facilities were very incomplete or non-existent, preventing an individual case study on those facilities. A novel, statistically rigorous, study designed to account for varying biological factors was not practical because of the difficulties in performing the study and characterizing all biological characteristics relevant to each CWIS at the over 500 facilities in scope of the Phase II rule, and to then obtain appropriate, corresponding estimates of I&E loss rates. EPA attempted to reduce any potential misrepresentation by conducting extrapolation only within major regions. I&E data from multiple facilities in each region were used to develop each regional estimate. In some cases, all of the facilities with I&E data in a region were evaluated (e.g., California). Given that the goal of EPA’s analysis was to develop estimates of impacts and benefits at the national scale, EPA believes that its regional approach provided a reasonable basis for extrapolation.

The commenter is wrong to assert that EPA assumed that all fish spared by CWIS are harvested. In fact, only about 2% of the fish lost to I&E are recreational or commercial fishery species. In addition, EPA's analysis does not assume that all individuals of these fishery species are harvested. Rather, in EPA's analysis harvest depends on species-specific fishing mortality rates (usually less than 20%). EPA used a simple, static model of foregone harvest that assumes that I&E losses of harvested species result in a reduction in the number of harvestable adults in years after the time that individual fish are killed by I&E and that future reductions in I&E will lead to future increases in fish harvest. The approach does not require knowledge of population size or the total yield of the fishery; it only estimates the incremental yield that is foregone because of the number of deaths due to I&E. EPA recognizes that the assumption that the key parameters in its yield model are static is an important one that is not met in reality. However, by focusing on a simple interpretation of each individual I&E death in terms of foregone yield, EPA concentrated on the simplest, most direct assessment of the potential economic value of eliminating that death.

The comment endorses EPA's use of regional RUM modeling, with some caveats. See responses to comments 316bEFR.041.452, 316bEFR306.320, and 316bEFR337.010 for EPA's responses to comments concerning the RUM analysis.

For the final 316b rule analysis, EPA has not included quantitative measures of national benefits associated with nonuse values. However, the Agency has explored several approaches that indicate the potential significance of non-use values, including a peer-reviewed meta-analysis of non-use values. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

The comment states that EPA's estimates of non-use value are around 30% of use values on a per-fish basis. It is not clear what numbers of fish the commenter is using. The comment states that the appropriate non-use value of individual fish is the value that reflects their contribution to the total stock of fish, so that, in a viable fishery, use values should be much larger than non-use values. If non-use values are 30% of use values then use values represent 70% of the value of these fish, a significant amount. EPA agrees that "as a fishery declines, each remaining fish becomes relatively more valuable in nonuse than use." The comment suggests that EPA should consider this fact in its analysis, but does not suggest a method for doing so.

The comment states that, because EPA presents no use value for forage fish, then non-use value for these fish must be zero. This comment has two flaws. First, EPA did include use values for forage fish that enter the food chain through trophic transfer to commercial and recreational species. Second, there is absolutely no basis for saying that a good must have measurable use values in order to have non-use values. Simply because the Fisher-Raucher approach implies that resources with zero use values have zero non-use values does not mean it is true. Numerous economic models have implications that are inconsistent with reality, simply because they are models which, by nature, are only approximations of reality. For example, many statistical functions pass through the origin. While these models may predict extremely well in the range of normal data, they may make no sense at all as they approach zero. Yet, these models are used every day in all kinds of economic analysis, very successfully, when applied with common sense.

The comment states that it is questionable to apply a concept originally intended to capture values for the Grand Canyon. However, non-use values are a conceptual category that apply equally on unique or common resources. The monetary valuation of unique and common resources is expected to be different. Nevertheless, non-use values have been measured and reported in the peer-reviewed literature for numerous resources that are not as unique and well-known as the Grand Canyon (e.g., small fish such as silvery minnow and striped shiner).. For example, see Berrens, R.P., P. Ganderston, and C.L. Silva. 1996. Valuing the Protection of Minimum Instream Flows in New Mexico. Journal of Agricultural and Resource Economics 21(2):294-309 (DCN #6-3110).

The comment states that, "at optimal harvest, one fish more or less, does not impact the viability of the stock at all." This may be true, but we are not talking about losses of one fish, but of millions of fish.

The comment concludes with the implication that, because the magnitude of total non-use values has increased from EPA's original analysis and the NODA analysis, that it cannot be correct. However, EPA's original analysis only considered a very small fraction of non-use values – those non-use values that accrue to commercial and recreational fishing users of the resource for the subset of species that have use values. In the revised NODA analysis, EPA included additional species that did not have use values, or that had only indirect use values, and these included a more reasonable population who are likely to hold these values.

Benefit Estimation Methodology

[comment continued from 316bEFR.307.301]

DETAILED DISCUSSION: MAJOR CONCERNS WITH EPA'S BENEFITS ANALYSIS

The remainder of this report presents a detailed discussion of the new benefit estimates EPA presents for the North Atlantic region (for which the Agency estimated commercial, recreational, and nonuse values) and the Northern California Region (for which EPA estimated only commercial and recreational values). <FN 28>

Footnotes

28 EPA includes a "break even" analysis for Northern California. This analysis computes the magnitude of nonuse benefits required for benefits to equal costs under the assumption that costs, commercial benefits and recreational benefits are calculated correctly.

29 As reported by NMFS for the ten-year period of 1991 to 2001.

30 EPA's previously asserted that producer surplus was between 40% and 70% of dockside value.

31 EPA provides no evidence that 0% to 40% of increased dockside value is appropriate for a long-run situation. Nor does it provide an explanation why the high end of this range was selected for the benefit estimation.

32 Price adjustments in fish markets take place daily eliminating the potential for significant producer surplus.

33 Economic theory implies that the long-run supply curve in many markets is horizontal. This may not be the case in natural resource industries, so this assumption should be considered an approximation.

34 Producer surplus represents the benefits to suppliers of a product or service. Producer surplus is the difference between the market price and the minimum price suppliers would be willing to accept for the product (Varian 1996).

35 In response to EPA question 1, this downward shift in the supply curve is the appropriate manner to characterize the effect of increased fish stock on commercial fishing.

36 Price elasticity of demand is also called simply elasticity or own price elasticity. It refers to the percent change in quantity associated with a percent change in price.

37 These are undiscounted total annual benefits. As shown in the tables, the welfare gains from catching additional winter flounder account for more than 85% of the total net benefits.

38 In studies where demand systems are estimated using retail price and quantity data, (Wessells and Anderson 1992; Wessells and Wilen 1994; DeVoretz and Salvanes 1997), demand elasticities average around –1.

39 This is an apt description of a market with output restrictions but without barriers to entry.

40 In response to EPA question 3, this analysis presumes no producer surplus currently exists. However, measures of existing producer surplus are not required for this benefit calculation, only measures of changes in producer surplus.

41 EPA used the 1994 MRFSS surveys for the North Atlantic region and the 2000 MRFSS surveys for the Northern California region. EPA also proposes to use the 1997 MRFSS survey. The MRFSS surveys will be used for the six coastal

regions.

42 Source: http://www.st.nmfs.gov/st1/recreational/index.html

43 Because of difficulties and uncertainties in calculating nonuse values, EPA includes a “break even” analysis for Northern California. This analysis computes the magnitude of nonuse benefits required for benefits to equal costs under the assumption that costs, commercial benefits and recreational benefits are calculated correctly.

44 Contingent valuation (CV) is the most widely used hypothetical valuation technique. Stated preference (SP), conjoint, and contingent choice all refer to choice-based survey methods that can be used to measure nonuse values. While more complex than CV, these methods still require respondents to value unfamiliar hypothetical commodities. As a result, they are subject to similar problems with hypothetical bias as CV.

45 Hypothetical bias is the potential error that results from not confronting an individual with a real situation. CV responses and SP responses likely reflect hypothetical bias. The validity of hypothetical data is the degree to which it measures the point of interest (Mitchell and Carson 1989, p. 190).

46 The 1992 NOAA panel discussed 24 issues that should be considered to maximize the reliability of CV studies.

47 EPA presumes that eelgrass is only valued for its role in the production of fish and shellfish.

48 National Oceanic and Atmospheric Administration’s (NOAA’s) proposed natural resource damage assessment (NRDA) regulations list three basic issues that researchers should consider when selecting transfer values:
-comparability of the users and the natural resource and/or service being valued
-comparability of the change in quality or quantity of the resources and/or services
-the quality of the studies being transferred (59 Fed. Reg. 1148[1994]).

49 OMB Draft 2003 Report to Congress on the Costs and Benefits of Federal Regulations (68 Fed. Reg. 5492 Feb. 3, 2003).

50 Reference utility is the utility level associated with the current situation.

51 See EPA, “Estimating Total and Non-use Values for Fish, Based on Habitat Values for Coastal Wetlands and Eelgrass (SAV) (March 12, 2003) (DCN 5-1010), p. 3. This illustrates the substantial expertise needed for this type of decision-making.

52 Specific data sources for per-acre abundance estimates and details of data analyses are presented in chapters F5 and G5 of the §316(b) Phase II Case Study Document. We have not reviewed those biological data, and we offer no assessment of their validity.

53 The Peconic Estuary survey states that eelgrass is “fish and shellfish habitat.” Because EPA knows of no other use for eelgrass they presume that 100% of its value is habitat value.

54 Using The Rhode Island Salt Marsh Restoration: 2001 Survey of Rhode Island Residents EPA determines that the mean proportion of value for fish habitat ranges from 20 to 32%. The proportion of value associated with shellfish habitat ranges from 22 to 35%.

55 Freeman (1993) provides a discussion of the difficulties associated with disentangling the use and nonuse components of total value.

56 The Peconic Estuary System is located on the east end of Long Island, New York.

57 Here EPA references the findings of Johnston et al. (2002). This study found that residents throughout Rhode Island (32.4 miles from the coast) have values for wetland restoration actions. There is no reason to believe that these values are constant with respect to distance, or that this result is relevant for the current situation.

EPA Response

The comment states that EPA’s benefit transfer is flawed because it does not recognize limitations in the original study, and because of significant differences between the hypothetical choice scenario and the policy context, including the reference utility level, valuation scenario, and affected population. EPA does not monetize national nonuse benefits in the analysis of the final rule due in part to uncertainty associated with application of nonuse values from existing studies. However, EPA explores approaches for nonuse benefits transfer and has found potential for significant nonuse benefits to exist (see response to comment 316bEFR.303.301.

The comment states that the reference utility in the Peconic study will result in decreased in wetlands and eelgrass, while the reference utility with no new expenditures for the 316(b) scenario will lead to unchanged environmental conditions. However, if no new expenditures occur in the 316(b) scenario, conditions will not be unchanged, but will continue to deteriorate as fish are impinged and entrained over time.

The comment also states that changes anticipated by I&E reductions are marginal while changes estimated in the Peconic survey are significant. The Peconic survey statistically estimates values for marginal changes in acres of habitat, based on realistic described changes in habitat. The changes in habitat required in EPA's case study areas to compensate for lost fish are similar in magnitude to those given in the Peconic survey. EPA, in measuring the value of habitat required to offset losses of fish, is using the concept of resource-based compensation, as described in more detail in EPA's reply to comment #316bEFR.307.061.

The comment says that expected changes in fish stocks are within the range of typical population fluctuations and thus seems to imply that these losses of fish have no value. Again, EPA has used the value of habitat to provide a means of indicating the magnitude of losses to fish, based on the use of resource-based compensation.

For EPA's responses to the issues of relating fish habitat to fish production, use vs. non-use values in the original study, the concept of intrinsic non-use values, the appropriate extent of the affected population and similarities between the study population and policy population, and the magnitude of non-use values, please see EPA's responses to comments #316bEFR.307.061, #316bEFR.303.020, #316bEFR.304.002, #316bEFR.304.004, #316bEFR.328.010, and #316bEFR.338.042.

EPA notes that the habitat-based approach is not used in the cost-benefit analysis for the final section 316(b) rule. Instead, the Agency used this approach to provide useful information for policymaking officials to consider in otherwise reviewing a final conclusion over the final 316(b) Phase II rule.

Commercial Fishing Benefits

2.1 Commercial Fishing Benefit Estimates

EPA's benefit analysis assumes that a reduction in I&E improves commercial fishing through an increase in catch. EPA calculates the direct value of yearly commercial harvest lost to I&E by multiplying hypothesized landing increases by dockside prices. <FN 29> EPA converts the change in dockside value to a change in societal benefits by assuming that producer surplus is the only benefit to commercial fishing, and that producer surplus is between 0% and 40% of dockside value. <FN 30> In the actual benefits estimation, EPA employs 40% of dockside value. <FN 31>

In developing its methodology, EPA seeks specific input regarding:

1. The likelihood that supply curves will shift, thereby creating the context for generating greater net surplus
2. How best to incorporate fishery management regimes into the analysis
3. Estimates of normal profit and how to interpret them to estimate a more suitable measure of producer surplus
4. The likelihood and magnitude of price changes that may result from increased harvest.

In response to EPA's request, we consider two relevant situations. The first case is an open access fishery. In an open access fishery, new entrants are expected as long as the price of anticipated catch exceeds the cost of entry. The entry of new suppliers (or increased effort of existing suppliers) tends to reduce the stock of fish, raising the cost of catching fish for all participants. Suppliers will continue to enter as long as expected profits are above the normal rate of return for this class of investment. Entry ceases when the price and average cost of harvesting fish are equated at the industry level. At this point, producer surplus is eliminated. Thus, once all adjustments are made, markets reach equilibrium and there is no producer surplus. <FN 32>

This situation is shown in Figure 1. Here, the original long-run supply curve is horizontal and producer surplus (represented by the area between the price line and supply curve) is zero. <FN 33, 34> As the stock of fish increases because I&E is reduced, the cost of catching fish drops. Because a supply curve represents costs, permanent lower per fish harvest costs can be depicted by a downward shift in the long-run supply curve (LRS1 to LRS2). <FN 35> When all anglers face lower harvest costs, they compete to sell additional fish by lowering prices. This leads to a decrease in long-run equilibrium price (P1 to P2). Once competition has caused prices to adjust, there is no producer surplus. Thus, in a competitive situation, benefits do not accrue to commercial anglers. The advantage this sector gains due to lower costs is completely offset by lower prices.

There is a societal benefit to lower harvest costs. However, this benefit accrues to fish consumers. Consumers benefit through lower prices. This benefit can be estimated by calculating the increase in consumer surplus that is associated with lower harvest costs. Consumer surplus is the difference between what consumers are willing to pay (as represented by the demand curve) and market price.

The change in consumer surplus associated with lower costs in a competitive market is the shaded area depicted in Figure 1.

The increase in consumer surplus can be calculated mathematically by:

[see hard copy for equation]

Inputs to this calculation are existing price and quantity, expected change in quantity, and expected change in price. EPA employs existing price and quantity data in their current calculations. The change in quantity is already developed through expected reductions in I&E and resultant catch improvements. In order to estimate the change in the long-run equilibrium price, EPA should use the price elasticity of demand for fish. <FN 36>   For example, if the price elasticity of demand is –1.5 and the percentage change in quantity is 1%, then the estimated percentage change in price would be:

[see hard copy for equation]

Figure 1. Commercial Fish Market
[see hard copy for figure]

This information can be used to calculate the new price level and estimate the change in consumer surplus. In Tables 2 and 3 below, we present the expected increase in consumer surplus associated with an increase in North Atlantic catch for oceans and estuaries when the price elasticity of demand is unit elastic (–1). <FN 37>   Unitary elasticity indicates that price and quantity change by equal proportions but in opposite directions. In response to EPA's question 4, a brief review indicates that assuming unitary elasticity (–1) is appropriate for many commercial fish species. <FN 38>   We have employed this number in calculations here for illustrative purposes. A complete analysis should include a more thorough investigation into species and region specific own-price and cross-price elasticities.

The tendency for producer surplus to reach zero in the long-run is a well-known foundation of microeconomic theory (Mansfield 1988). However, producer surplus elimination through competition depends upon price changes. It may be possible to have some long-run producer surplus if there are market restrictions such as quotas or regulations. To address this situation and respond to EPA's question 2, we present a model of fish stock improvement under a fishery regime that restricts output.

Table 2. Estimating Gains in Consumer Surplus in Commercial Fish Markets (Estuaries) for the North Atlantic Region
[see hard copy for table]

Table 3. Estimating Gains in Consumer Surplus in Commercial Fish Markets (Ocean) for the North Atlantic Region
[see hard copy for table]

In this model, the government sets a quota on the quantity of commercial stock sold and the quota is the equilibrium quantity (Q1). <FN 39>   As shown in Figure 2, there is no initial long-run producer surplus. <FN 40>   As the reduction in I&E leads to an increase in the commercial stock, the long-run supply curve shifts down from LRS1 to LRS2. However, the quantity supplied remains at Q1 (the quota level) and the corresponding equilibrium price remains at P1. In this situation, there would be an increase in producer surplus, because the equilibrium price exceeds average costs. The producer surplus is the difference between production costs and price (the shaded area of Figure 2) or (P1 – P2) * Q1. In this manner, existing price and quantity information can be combined with price elasticity of demand estimates to anticipate changes in producer surplus when there are market restrictions.

Figure 2. Commercial Fish Market (with a Quota)
[see hard copy for figure]

Summary

EPA has improved its preferred approach for calculating commercial benefits. However, any approach basing benefits on dockside landings, is inappropriate. Economic theory states that prices will change in competitive markets when costs change. As demonstrated in Figure 2, if there are market restrictions, estimating producer surplus is appropriate. However, as indicated in TER's prior comments for UWAG, it appears that there are no barriers to entry for most relevant species and commercial markets (see Desvousges et al. 2002, pp. 16–23 for TER's earlier comments to UWAG on the nature of fish markets). For these reasons, TER believes that estimating the commercial benefits using consumer surplus instead of producer surplus may be an appropriate method. In addition, as Figures 1 and 2 illustrate, the change in consumer surplus in free markets exceeds the change in producer surplus when there are market restrictions. This is a standard result arising from the welfare loss associated with departure from competitive equilibrium caused by market restrictions (Perloff 2000).

Assuming unit price elasticity, and taking as a given all other input parameters used by EPA, the estimated annual net benefits or total increase in consumer surplus before discounting is $718,976 for the North Atlantic region as compared to EPA's estimate of $281,889. We offer this calculation, not as an alternative estimate of commercial benefits (which it is not), but as a demonstration of how EPA's approach incorrectly estimates commercial benefits. The magnitude of this error depends upon the elasticity of demand for fish. This estimate suggests commercial benefits with open markets and unit price elasticity would be somewhat higher than benefits based on producer surplus alone. However, total commercial fishing benefits remain a small fraction of the $79 million in yearly benefits that EPA attributes to elimination of I&E elimination in the North Atlantic.

EPA Response

EPA did not find evidence that projected changes in catch would be capable of creating significant changes in market prices, and EPA determined that there is potential for regulation of fisheries affected by this rule. As a consequence, EPA relied upon changes in producer surplus to value commercial fishing benefits, while recognizing remaining uncertainty about long-term market impacts. For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits please see the response to comment 316bEFR.005.029.

Random Utility Model (RUM)

2.2 Recreational Fishing Benefit Estimates

For the final rule analysis, EPA proposes employing random utility analysis to calculate recreational benefits arising from the reduction of I&E. As discussed earlier, EPA employs a geographic approach in its final rule analysis. According to the NODA, the estimated annual recreational benefits for the elimination of all I&E for the North Atlantic region is $3.07 million (undiscounted). The Northern California region estimate is $1.4 million (undiscounted). Table 4 summarizes EPA's recreational analysis on the basis of the geographic region, analytical technique, data source, survey type, recall period, methodology, and annual undiscounted benefits for complying with the preferred option.

Table 4. Summary of EPA's Recreational Analysis
[see hard copy for table]

Analytical Technique

EPA intends to employ region-specific random utility models (RUMs) to estimate benefits to recreational anglers. RUMs were initially developed to analyze transportation-mode choices (McFadden 1974). More recently, they have been applied to recreation-site choices (Schuhmann 1998; Ruby, Johnson, and Mathews 1998). The RUM estimates the probability that an individual will choose to visit a given recreation site. This probability depends on the characteristics of that site, the characteristics of available substitutes, and the travel costs to all the sites in a recreator's choice set. This focus on site characteristics means that RUMs can be used to estimate the value of marginal changes in attributes (such as catch rate). Thus RUMs are well suited for many regulatory analyses. In addition, federal agencies have approved their use for valuing natural resources. (See U.S. Environmental Protection Administration, 2000, and National Oceanic and Atmospheric Administration, 1996 [61 Fed. Reg. 439–510]). Correctly applied, random utility analysis presents the best opportunity for valuing increased catch hypothesized to result from I&E reductions. The following sections discuss EPA's data sources, as well as concerns with these data sources, and the analytical approach described by EPA.

Data Sources and Survey Issues

For their random utility analyses, EPA chose to employ the 2000 National Survey of Recreation and Environment and the National Survey of Fishing, Hunting, and Wildlife-Associated Recreation for the interior region, the 1995 Michigan Recreational Angler Survey for the Great Lakes region, and MRFSS data combined with the corresponding Add-on MRFSS Economic Survey (AMES) <FN 41> for the six coastal regions. The first two data sources employ telephone surveys, and the MRFSS data uses a combination of telephone surveys and intercept surveys.

The National Survey of Fishing, Hunting, and Wildlife-Associated Recreation is primarily a telephone survey of more than 80,000 households nationwide and is conducted by the U.S. Bureau of

Census for the Fish and Wildlife Service. The purpose of the survey is to obtain information on the number of anglers, hunters, and wildlife-watching recreators in the United States. Respondents are limited to those at least 16 years old. The Michigan Recreational Angler Survey is a random digit dial (RDD) statewide telephone survey of more than 3,000 households. The RDD sample is stratified by county in proportion to the number of licensed anglers by county.

The National Marine Fisheries Service (NMFS) conducts the MRFSS on an annual basis. The MRFSS consists of two separate complementary surveys—a telephone survey and an intercept survey. The telephone survey is a random sample of more than 250,000 households. The telephone survey is used to identify households with saltwater anglers and to estimate marine fishing effort. The intercept survey or field survey provides catch information as trained personnel interview anglers at thousands of fishing sites across the United States. <FN 42>

The data EPA intends to employ come from RDD (telephone) surveys and intercept surveys. Intercept surveys select respondents at specific recreation sites. In this type of survey, over-representation of avid anglers occurs because the probability of surveying an angler is related to the number of trips the angler takes. This means that individuals who presumably value an activity most highly (frequent anglers) are disproportionately represented. The problem with this type of data for benefits estimation is that unweighted intercept data are not descriptive of the general population of anglers. Thus, while overall angling activity may be fairly represented, valuation estimates are incorrect. Appropriate population weights ensure that the sampled anglers are given importance proportional to the number of anglers they represent in the population. In the case of MRFSS data, the RDD telephone survey can potentially be used to adjust for avidity bias. Valid benefit estimates from MRFSS data depends upon an appropriate adjustment for avidity bias (see McFadden 1981).

Another problem with many telephone and intercept surveys for random utility analysis is that the responses of anglers typically exhibit recall bias. Recall bias is the demonstrated tendency of recreators to overstate the number of trips they take. Uncorrected, this leads to upward bias in benefit estimates. The MRFSS survey attempts to minimize this problem by limiting sampling to two-month trip-recall windows. However, daily trip logs are preferable. EPA's analysis should include an adjustment for recall bias (Westat Inc. 1989).

Analytical Concerns

Another concern with EPA's RUM estimation is in calculating the opportunity cost of time. The approach generally taken in the literature is to specify opportunity cost as one-third of the wage rate (McConnell and Strand 1981). However, in its analysis for the North Atlantic region, EPA's approach assigns the full wage rate to all respondents reporting lost wages. In this approach, these individuals travel costs are lost wages plus $0.30 per mile (1994 dollars) in traveling expenses. Travel costs for those who did not report losing income are $0.30 per mile. Thus, trip costs, and benefit estimates, depend heavily upon the validity of survey responses to questions about lost wages. For respondents reporting lost wages, forgone income must be correctly measured. It is unclear what question of the 1994 Add-on MRFSS Economic Survey provides justification for EPA assigning respondents to the "lost wages" category. Possibilities taken from the survey include:

26. Can you choose to work more or fewer hours per week?
28. Did you forgo any wages by taking this trip?

29. About how much money could you have earned if you hadn't taken this trip?

EPA's trip cost estimation technique focuses on wages lost due to travel time. For this reason, Question 28 from the 1994 Add-on MRFSS Economic Survey (which focuses on wages) is apparently the variable used to identify trip costs. This approach assumes that anyone losing wages lost the full pretax value of his or her average wage rate. This is an extremely generous allowance for the opportunity cost of time, which will tend to inflate value estimates (See Desvousges et al. 2002, pp. 33–35 for TER's earlier comments to UWAG on trip cost estimation and opportunity cost of time). For the Northern California region, EPA estimates opportunity cost as one-third of the wage rate for all respondents. EPA provides no explanation for employing different opportunity cost of time specifications in each region.

Summary

EPA is now using regional RUMs to estimate recreational benefits from the reduction in I&E. For this type of analysis, RUMs are the preferred method. However, it is likely that EPA's recreational benefit estimates are overstated due to incorrect population weights arising from avidity bias, uncorrected recall bias, and nonstandard specification of the opportunity cost of time. The complexity of random utility modeling means that a detailed critique requires access to programs and data underlying benefit estimates. These were not available for the two regional analyses EPA presented. For this reason, it is not possible to completely evaluate these factors at this time.

EPA Response

EPA agrees that "correctly applied, random utility analysis presents the best opportunity for correctly valuing increased catch hypothesized to result from I&E reductions." However, EPA does not agree with the commenter that its RUM approach is improperly applied. It appears that the commenter did not fully understand the data used and EPA's analysis. EPA did not use the 2000 National Survey of Recreation and Environment, as mentioned in the comment.

EPA follows standard and generally accepted practices for sampling methodology, calculation of trip costs, and participation modeling. See also response to comments number 316bEFR.041.452 for details regarding sampling, trip costs, and participation modeling.

Peconic-based approach

Author Name David E. Bailey

Organization Hunton & Williams obo Utility Water Act Group

2.3 Nonuse Benefit Estimates

In the NODA, EPA calculates nonuse values for only the North Atlantic Region. <FN 43> According to EPA calculations, 99.85% of total age 1 equivalent I&E losses in the North Atlantic region will never be caught by commercial or recreational anglers. Of this figure, 0.77% are recreationally and commercially valuable species. The remaining 99.08% are forage fish. Because these fish are never landed, their value is not included in EPA's commercial and recreational benefit categories. The appropriate benefit category for unlanded fish is termed nonuse. In contrast to the former BCA, the great majority of value from reductions in I&E are now attributed to nonuse benefits.

Nonuse values cannot be measured through observation because actions are not required to experience them (Freeman 1993). For this reason, economists have developed hypothetical valuation methods. These methods presume that nonuse values can be elicited with an appropriately designed survey. <FN 44> In practice, these surveys' reliance on hypothetical scenarios greatly undermines the reliability of resulting nonuse value estimates. <FN 45> As a result, the true magnitude of nonuse values is controversial. The major source of this controversy is the inability to externally validate nonuse value estimates with methods that do not themselves rely exclusively on hypothetical responses.

Although the validity of estimates based on hypothetical surveys is questionable, these are the only methods currently available for calculating nonuse benefits. For this reason, hypothetical survey practitioners generally attempt to establish validity through meticulous study design (Freeman 1993). This may consist of multiple rounds of focus groups and pretesting to appropriately characterize the valuation scenario and affected population. <FN 46> Even under the best of circumstances, developing a valid hypothetical survey requires great care and precision.

EPA does not attempt to estimate nonuse values with an original survey. Instead, EPA transforms values from a study that measures local preferences for aquatic habitat in the Peconic Estuary. This approach is flawed because it does not recognize the limitations of the primary study for generating dollar value estimates of the commodity considered in the valuation exercise. Within their text, Opaluch et al. (1995) specifically state that their study is more appropriate for calculating relative values than dollar estimates.

"However, we believe that the relative values of resources [derived from the contingent choice survey] are more reliable than are the dollar estimates of the values and recommend that relative values, rather than dollar values, be used in the process of selecting management actions" (Opaluch et al. 1995).

Proceeding under the assumption that the underlying study generates reliable dollar value estimates for habitat, EPA takes the following six steps in developing nonuse values for I&E reductions in the North Atlantic.

Step 1: Assess public values for fish and shellfish habitats.

EPA employed results from a site-specific study of environmental preferences for aquatic habitat in the Peconic Estuary (Johnston et al. 2002). This study elicited willingness-to-pay for coastal wetlands and eelgrass using the contingent choice method. Model results estimate that nonusers are willing to pay $0.054 per year per household for each additional acre of wetlands and $0.052 per year per household for each additional acre of eelgrass.

Step 2: Adjust habit values to reflect portion attributable to fish habitat.

Wetlands provide a variety of services. Thus, EPA allows that respondent values for wetlands are not solely due to their role in fish production. <FN 47> EPA adjusts for this factor with information from Rhode Island Salt Marsh Restoration: 2001 Survey of Rhode Island Residents. EPA interprets the results of this survey to mean that fish production accounts for approximately one-third of wetland value.

Step 3: Estimate per-acre production as per-acre density.

Because the exact role of wetlands and eelgrass in fish production is unknown, EPA relies on a survey of experts to identify species produced in wetlands and eelgrass. In place of production data, EPA estimates that production is equivalent to density. In this manner, EPA calculates that an acre of tidal wetlands produces between 205 and 351 winter flounder per year and that an acre of eelgrass produces 101 northern pipefish per year.

Step 4: Estimate quantity of habitat required to replace I&E losses.

The presumption that abundance of eelgrass directly represents production of fish allows EPA to calculate the amount of habitat needed to offset I&E losses. For example, production estimates of between 205 and 351 winter flounder per acre are combined with I&E loss estimates to calculate that between 25,589 and 48,813 acres of wetlands are required to offset uncaught winter flounder losses in the North Atlantic. For eelgrass, estimates were 1,205 acres for scup and between 105 and 180 acres for threespine stickleback.

Step 5: Combine data to estimate per-household values for fish and shellfish losses.

At this point, EPA has household habitat values and estimates of the number of acres of each habitat required to offset I&E losses. With this information, EPA calculates per-household per-year willingness to pay for I&E losses.

Step 6: Extrapolate per-household results to wider area to get total results.

Per-household willingness to pay estimates represent average losses. However, nonuse values depend critically upon the number of affected individuals. Based on the estimated value per acre to residents of counties abutting affected water bodies, EPA estimates that the nonuse value of restoring 25,589 acres of coastal wetlands is $73.9 million. Nonuse value solely for restoring 1,205 acres of eelgrass is $16.1 million.

In developing this exercise, EPA conducts a benefits transfer. Recent research has questioned the reliability of benefits transfer (Loomis et al. 1995; Downing and Ozuna 1996; Kirchoff, Colby, and La France 1997). However, practical considerations dictate that applied welfare analyses for environmental resources must often rely on benefits transfer. Both NOAA and EPA have suggested criteria to maximize transfer reliability. <FN 48> However, these suggestions do not specifically address the transfer of nonuse values. For these values, outcomes are particularly sensitive to the underlying hypothetical scenario. This concern underlies the Office of Management and Budget (OMB) admonishment that the hypothetical choice situation “corresponds closely with the policy context to which estimates will be applied.” <FN 49>

EPA’s benefits transfer is inappropriate because of significant differences between the hypothetical choice scenario and policy context. Areas of particular concern include the reference utility level, valuation scenario, and affected population. To demonstrate the magnitude of these problems, we have included a question taken from the Peconic Estuary survey. This is the primary survey instrument underlying EPA’s estimates of nonuse values for I&E reductions.

[see hard copy for table]

One major difference between the survey scenario and the valuation scenario associated with §316(b) regulations is in the reference utility. <FN 50> In the Peconic Estuary study, each survey question asked respondents to choose either the current situation or one of two hypothetical programs to restore or protect resources. In the sample question above, the reference utility or “No New Action” option is associated with no new expenditures. However, inaction leads to a dramatic decline in wetlands (25%) and eelgrass (10%). This outcome is the expected situation in the Peconic Estuary as determined by a Technical Advisory Committee. It is based on historical declines in habitat and expert judgment.

The reference utility associated with I&E reductions is quite different from that related to habitat in the Peconic Estuary. In particular, §316(b) regulations address modifications of CWIS at existing facilities. Thus, an appropriate characterization of the benefits associated with §316(b) regulations is that “No New Action” be associated with no new expenditures and unchanged environmental conditions. In the Peconic Estuary study, the respondent who selects the “No New Action” column pays nothing, but must accept a decline in habitat. The effect of transferring values with this disparity is that the transferred values will be overstated, when compared to a situation in which no decline in current conditions occurs in the absence of an expenditure.

An additional problem with EPA’s transfer is in the type of change considered in the valuation scenario. EPA’s transfer approach associates a number and type of fish with habitat improvement. For example, EPA relates fish to habitat using rates of 205 winter flounder per acre of wetlands and 101 pipefish per acre of eelgrass. EPA’s interpretation of values for habitat in terms of values for fish requires that respondents value both existing habitat and habitat changes for production and no other purpose. This requires that survey respondents understand the productive capacity of these habitats. It also requires that respondents are not valuing benefits of eelgrass or wetlands that EPA has not explicitly considered.

In developing its benefits transfer, EPA first convened two panels of experts, one to assess species associated with the Brayton Point Station, and one to assess species associated with the Pilgrim Station. These experts identified impinged and entrained species at each station that might be restored by provision of certain types of habitat. EPA notes that those panels came to different conclusions about the effectiveness of restoration techniques, based on site-specific differences affecting each species. <FN 51> EPA then based its per-acre habitat productivity calculation for these fish on per-acre counts of fish by site and type of habitat. <FN 52>

It is unlikely that survey respondents understand the productivity of wetlands and eelgrass in the manner required for this transfer. Certainly, EPA has provided no support for the proposition that they would have. Even if respondents were capable of such calculations, the survey did not indicate that they should do so. In fact, the survey only notes that eelgrass is habitat for fish and shellfish. The role of wetlands in fish production is not stated. Furthermore, even if respondents could assess the role of these habitats in fish production, the survey makes no distinction between the use and nonuse benefits of eelgrass and wetlands as fish habitat. Finally, the measure of production employed by EPA, abundance, is at best a very poor approximation for productivity. For these reasons, any values elicited by this survey cannot accurately represent values for fish.

It is doubtful that Peconic Estuary survey respondents have an accurate understanding of the role of habitat in fish production. Even if respondents do correctly understand the productive capacity of habitat, EPA's transfer requires that the value of this productive role be separated from any other value. EPA assumes that the entire value of eelgrass arises from its production of fish and shellfish. Having no direct knowledge that this is the case, EPA relies upon assertion and a parenthetical statement in the Peconic Estuary survey. <FN 53> EPA relies on an additional study to conclude that 30% of wetlands is attributable to fish production. <FN 54> In so doing, EPA has assumed that wetlands and eelgrass have no intrinsic nonuse value. This conclusion is strongly at odds with the ideas underpinning EPA's nonuse analysis. If people have strong nonuse values for forage fish, we should expect that they value aquatic vegetation and wetlands similarly. As a result, the values EPA attributes to habitat include both the habitat's value in producing wildlife and an intrinsic nonuse value. <FN 55>

Nonuse valuations with minimal bias appropriately characterize the relationship between willingness-to-pay and the type and size of environmental change being valued (Freeman 1993). Dissimilarity between the type of change being valued in the survey setting and valuation context undermine the reliability of EPA's benefits transfer. A further problem with transferring results from the Peconic Estuary study to a §316(b) regulation context is that the existing quantity and change in quantity being valued are very different. In particular, the changes anticipated by I&E reductions are marginal, while those considered in the survey are significant. For example, the Peconic Estuary survey set the existing stock of wetlands at 16,000 acres and the existing stock of eelgrass at 8,800 acres. The survey asked about the value of potential changes to the stock of eelgrass and wetlands that ranged from 10% to 25%. In the North Atlantic, fish stocks tend to be large and variable (Sissenwine 1984). Changes to fish stocks expected to arise from §316(b) regulations are comparatively minor. For example, EPA presumes that I&E reductions will lead to a 4% change in commercial catch of winter flounder. EPA's stated assumption of linearity in harvest implies that uncaught winter flounder likewise increase by 4%. According to EPA Guidelines for benefits transfer, both the base and extent of the change should be similar. EPA's transfer does not meet this criterion. In addition, the extent of change anticipated in fish stocks is within the range of typical population fluctuations.

Lack of similarity in reference utility and valuation scenarios invalidates EPA's calculated per-household nonuse values for I&E reductions. EPA compounds this problem by inappropriately identifying the population affected by 316(b) regulations. A significant aspect of developing nonuse estimates is in definition of the relevant population. EPA's benefits transfer relies upon responses to a questionnaire that elicits local preferences for habitat restoration in the Peconic Estuary. <FN 56> EPA takes per-household per-year values from this small, affluent area and applies them to a benefit population of either 210,357 or 737,711 households. EPA arrives at 210,357 households because that is the number of households in counties abutting affected water bodies. EPA's alternative benefit population of 737,711 households is the number of households within 32.43 miles of a facility that would be affected by §316(b) regulations. <FN 57>

Both the EPA's Guidelines and NOAA's NRDA regulations stipulate that reliable benefits transfer requires that affected populations are comparable. This is particularly important when one considers the source of nonuse values. Small per-household values can become quite large when aggregated over a significant population. Thus, the number of individuals holding nonuse values is as integral to the calculation of total nonuse benefits as is value per household. Appropriately identifying the geographic extent of the population with nonuse values and the effect of location on these values is essential to correctly identifying aggregate nonuse values (Johnson et al. 2001). EPA's assumption that the preferences of a small group of affluent individuals living in coastal communities represent those of millions of people is without merit and likely leads to overstated nonuse benefit estimates.

Summary

EPA expects that the great majority of benefits from 316(b) regulations are nonuse. However, research on the nonuse values associated with marginal changes in fish populations is not available. Because one result of aquatic habitat restoration/preservation is increased production of fish and shellfish, EPA feels that values people hold for these habitats may be indicative of the values they hold for fish and shellfish. Based on this presumption, EPA attempts to transfer values from a survey wherein respondents indicated preferences for preservation/restoration of eelgrass and wetlands. In so doing, EPA violates its own principals for benefits transfer and ignores research into the sensitivity of elicited nonuse values.

In particular, the EPA Guidelines (p. 87) permit transferring study results only when the basic commodities are essentially equivalent and where the baseline and the extent of change are similar. This clearly is not the case. Various types of scenario misspecification create a divergence between what the respondent understands about the choice situation and what the investigator hopes the respondent understands. Furthermore, a poor understanding of the affected population leads to bias in the aggregation of nonuse values. EPA's attempt at calibrating values to enhance the reliability of this transfer has dubious value in any circumstance. This approach is particularly questionable when transferring nonuse values. Surveys designed to elicit nonuse values typically go through extensive testing to minimize hypothetical bias. Unfortunately, hypothetical bias cannot be eliminated using the type of post-administration, ad hoc methods employed by EPA.

We conclude that EPA's approach to nonuse values is inconsistent with both sound theory and good empirical practice. Economic theory implies that nonuse values are most important for unique resources with high awareness levels. Yet, EPA finds that the great majority of nonuse benefits from its proposed Phase II §316(b) regulation are attributable to the nonuse values of forage fish. Our review of the available information provided by EPA and the current economic literature on nonuse values indicates that if nonuse values were relevant for the §316(b) regulations, they would be quite modest. It is unclear how nonuse values from I&E reductions should be evaluated. However, EPA's attempts at benefits transfer indicate that the available research cannot support the required evaluation. EPA should bear in mind that in this circumstance, misinformation does not inform policy (Smith 1992).

EPA Response

This commenter first summarizes EPA's procedure for estimating non-use values using benefit transfer from the Peconic Estuary study. The commenter then argues that EPA's benefits transfer is inappropriate because of significant differences between the hypothetical choice scenario and policy context. Specific concerns include the reference utility level, valuation scenario, and affected population.

EPA disagrees that the reference utility is significantly different between the Peconic Estuary survey scenario and the valuation scenario associated with §316(b) regulations. Under both scenarios, the reference utility or "No New Action" option is associated with no new expenditures. Inaction leads to a decline in wetlands (25%) and eelgrass (10%) under the Peconic Estuary survey scenario. Inaction under the valuation scenario associated with §316(b) regulations is also likely to lead to further decline in the affecter resources. For example, the fishery data suggest that the Mount Hope Bay fishery, one of the affected resources, has been declining in the last two decades. The Agency did not try to estimate the level of abundance that a healthy fishery would achieve once the adverse effects of CWS are controlled, along with continued management of fishing and continued water pollution control improvements, and then base its benefits analysis on that level. Rather, the EPA's analyses were simply based on existing plant data concerning losses to the plant intakes. The Agency, however, points out that "inaction" leads to continued losses of fishery resources that are likely to contribute to further decline in fisheries.

For EPA's response to comments regarding using habitat values to estimate values for fish and similarity between the study and policy resources, please see the response to comment #316bEFR.307.061.

For EPA's response to comments regarding the connection between values for habitat and values for fish and shellfish and respondents perception of the role of habitat in fish production, please see the response to comment #316bEFR303.020.

For EPA's responses to comments regarding comparisons of population demographics between the study region and policy region, please see the response to comment 316bEFR.304.004.

For EPA's response to comments regarding the allocation of values for various wetland services using the Johnston, et al. study, please see the response to comment #316bEFR.303.021.

EPA notes that the habitat-based approach is not used in the cost-benefit analysis for the final section 316(b) rule. Instead, the Agency used this approach to provide useful information for policymakers to consider in determining the final 316(b) Phase II rule.

General statement of support

Author Name Lynne H. Church

Organization Electric Power Supply Associaton (EPSA)

In general, EPSA believes EPA’s preferred approach recognizes the need for site specificity as opposed to a one-size-fits-all approach. EPA’s focus on alternative fish protection technologies, that permits facilities to develop site specific standards based on cost-cost or cost-benefit tests, and use voluntary restoration measures as an alternative to technologies is the basis of this recognition. EPSA sees each of these components as critical to an effective workable rule.

EPA Response

Today's final rule maintains the desired flexibility for both the permittee and the Director to determine the most appropriate and cost-effective means for meeting the requirements of today's rule. EPA also notes that compliance alternative 5 allows a site-specific determination to be made based on cost-cost and cost-benefit considerations.

RFC: Three-option framework for determining BTA

EPA has introduced significant new information into the record on the cost and efficacy of alternative technologies to meet applicable impingement and entrainment performance standards. The information is formatted into eleven cost modules and increases the cost estimates for alternative technologies. EPSA agrees with EPA's point that it is not possible to provide estimates for all technologies for the various site-specific circumstances that Phase II facilities will encounter. However, EPSA remains concerned about those facilities that cannot meet the performance standards with alternative technologies due to site-specific circumstances. We, therefore, believe it is critical to include the option to develop a site-specific performance standard in EPA's proposal.

As EPSA commented on the EPA Phase II proposal in August, 2002, we support EPA's preferred approach which regards those Phase II facilities that employ closed-cycle cooling to be in compliance with 316(b) Best Technology Available (BTA) requirements. Further, EPSA supports EPA's decision not to consider cooling water flow reduction through use of wet or dry closed-cycle cooling as a compliance requirement. EPSA believes that the costs and associated environmental disadvantages of retrofitting Phase II facilities, particularly in the context of the minimal environmental benefits, do not support use of this intake structure technology on a national or waterbody basis for compliance. EPSA further notes that EPA's proposed costs for wet closed-cycle retrofits in the waterbody/capacity based option underestimated their cost. Information supporting this underestimation was placed into the Docket by EPRI and DOE, and more recently was presented at the EPA's BTA symposium (ref. Maulbetsch and Micheletti Presentations).

EPA Response

The commenter has summarized parts of the NODA; therefore, no response to this portion of the comment is necessary. Please refer to the preamble for a discussion of the framework of the final rule. EPA notes that the final rule contains a site-specific compliance alternative.

EPA also notes that facilities with closed-cycle, recirculating cooling systems may demonstrate compliance under the first compliance alternative at § 125.94(a)(1). However, EPA is not requiring closed-cycle cooling at all facilities, as described in section VII.E of the preamble to the final rule. Please refer to the response to comment 316bEFR.029.004 for a discussion of EPA's estimates for recirculating cooling systems.

RFC: Appropriateness of "significantly greater"

In the NODA, EPA requested that stakeholders comment on the need for and definition of "significantly greater than". EPSA also believes that States should be given the flexibility to interpret the "significantly greater than" cost tests in a manner consistent with their individual environmental resources agencies. States with over-harvested commercial fisheries may wish to value these resources differently than inland fisheries where the fishery may be based on catch and release stocking programs, or where there is no commercial or recreational fishery present. EPSA believes that "significantly greater than" costs should be defined as any costs that are demonstrated to be greater than EPA's estimated cost of compliance, or benefits of compliance, after uncertainty in the estimates is taken into account.

EPA Response

See responses to 316bEFR.006.003, 018.009 and 045.012.

RFC: "Significantly greater" for eval. alt. req.

EPSA believes that EPA should provide clarification on the relationship of the new technology modules to the cost-cost test. The Docket and NODA seem to indicate the Technology Database is being used, but the specifics of this use are currently not clear.

EPA Response

The final rule in 125.94(a)(5)(i)(A) - (F) specifies the basic steps a facility would undertake to calculate the costs considered by the Agency in establishing the applicable performance standards. The relevant requirements and process are discussed in sections VII and IX of the final preamble.

Streamlined Technology Option

Author Name Lynne H. Church

Organization Electric Power Supply Associaton (EPSA)

EPSA supports use of the streamlined technology option as an additional compliance option. EPSA believes there is merit to both of the streamlined alternatives EPA discussed in the NODA. Results of EPA's research on the conditions under which fine-mesh wedgewire screens achieve a high level of protection support a streamlined approach based on that alternative. The final Phase II regulations will result in development of new alternative technologies or new data generated on existing alternative technologies that will provide the basis for a streamlined approach for other technologies.

EPA Response

EPA appreciates Electric Power Supply Association's support of EPA's Approved Design and Construction Technology option.

Benefit Estimation Methodology

Author Name Lynne H. Church

Organization Electric Power Supply Associaton (EPSA)

EPA has made revisions to the national benefits estimate for the 316(b) proposed preferred alternative. EPSA finds EPA's methods for assessing the benefits to users-- commercial and recreational fishing--to be generally reasonable in concept. However, we also support the comments on their application made by TER, Dr. Ivar Strand and Dr. Robert Stavins as submitted by UWAG and EPRI.

EPA Response

For EPA's responses to specific comments on commercial fishing methods please see response to comments # 316bEFR.005.029 and # 316bEFR.323.016.

For EPA's responses to specific comments on recreational fishing methods presented in the NODA please see responses to comments #316bEFR.041.452, #316bEFR.337.010, and #316bEFR.306.320.

Benefit Estimation Methodology

Author Name Lynne H. Church
Organization Electric Power Supply Associaton (EPSA)

EPSA also believes that EPA’s efforts to develop benefits estimates on a regional basis are an improvement over the previous national benefits estimate.

EPA Response

EPA agrees with the commenter. EPA has greatly expanded its analysis since the case studies were presented at proposal. EPA's final analysis evaluates many more facilities (a total of 46) and extrapolates I&E estimates within regions rather than across a waterbody type nationwide. Seven regions are evaluated-5 coastal regions (North Atlantic, Mid-Atlantic, South Atlantic, Gulf of Mexico, and California); the Great Lakes region; and the Inland region. I&E data from multiple facilities in each region were used to develop each regional estimate. In some cases, all of the facilities with I&E data in a region were evaluated (e.g., California). Given that the goal of EPA's analysis was to develop estimates of impacts and benefits at the national scale, EPA believes that this regional approach is more appropriate for the national benefit estimates. See the regional study document for detail, DCN # 6-0003.

Valuing Forage Species (incl non-use and non-landed)

With respect to non-use benefits, EPSA strongly supports EPA's decision not to base the benefits assessment on the habitat replacement cost method. However, EPSA strongly disagrees with EPA's new efforts to quantify non-use benefits of the rule. EPA's benefit transfer approach is based on a "willingness- to-pay" survey conducted by the National Oceanic Atmospheric Administration (NOAA) that creates wetlands to produce equivalent fish to offset impingement and entrainment losses. The willingness-to-pay survey was based on respondents' inclination to pay for wetlands lost as a result of damages. EPSA certainly supports the use of mitigation or restoration measures, such as wetlands creation, as a means of achieving the performance standard. However, wetlands are an inappropriate basis for the benefits quantification.

In the 316(b) context, the rule is not intended to generate wetlands on anything close to the scale assumed by EPA in the benefits assessment, rather the rule is intended to reduce impingement and entrainment. Use of this new benefits assessment is troubling because this value comprises 90% of the overall benefits assessment, dwarfing the estimated commercial and recreational values. Again, EPSA supports the detailed comments made by TER, Dr. Ivar Stand and Dr. Robert Stavins on the non-use benefits assessment.

EPA Response

EPA understands that the rule is not intended to generate wetlands. The benefit transfer method used by EPA is not based on a survey conducted by NOAA, but on a survey conducted by Economic Analysis, Inc. for the Peconic Estuary Program, funded under the National Estuary Program. This benefit transfer method used by EPA was intended to value the habitat required to compensate for, or offset, losses of fish and shellfish. For further details, please see EPA's response to comment #316bEFR.307.061.

Assumptions about I&E survival

Author Name Lynne H. Church

Organization Electric Power Supply Associaton (EPSA)

EPSA is also concerned with EPA's overall use of multiple conservative assumptions that make national benefits of the proposed rule highly unrealistic. These assumptions include:

- Assumption of No Entrainment Survival – While EPSA agrees that currently available entrainment data do not provide a sound basis to adjust entrainment baseline calculation data on a site-specific basis, these data are suitable for developing a reasonable range of outcomes for a national benefits estimate.

EPA Response

Please see the response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule. Please see the chapter, Entrainment Survival, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule.

Methods to Evaluate I&E

Author Name Lynne H. Church

Organization Electric Power Supply Associaton (EPSA)

EPSA is also concerned with EPA's overall use of multiple conservative assumptions that make national benefits of the proposed rule highly unrealistic. These assumptions include:

- Failure to Assume Impingement Survival – EPA has acknowledged in the rule that there can be substantial survival of impinged organisms. In fact, EPA's impingement performance standard is stated in terms of a reduction in impingement mortality. However, in EPA's assessment on the national benefits of the rule it does not appear to have assumed any impingement survival. Impingement survival can be quite high for some species as discussed by ASA in a recent presentation made at EPA's BTA Technology Symposium.

EPA Response

EPA took into account impingement survival in all cases where such information was provided in the facility documents that were used. Please see response to Comment 316bEFR.074.201 for a discussion of "multiple conservatisms."

Fish Population Modeling

Author Name Lynne H. Church

Organization Electric Power Supply Associaton (EPSA)

EPSA is also concerned with EPA's overall use of multiple conservative assumptions that make national benefits of the proposed rule highly unrealistic. These assumptions include:

- Failure to Assume Any Compensatory Response for Any Species – EPA has assumed no compensatory reserve for any species in any waterbody type. For purposes of the national benefits estimate, clearly such an assumption would be inappropriate for over harvested commercially important species. However, for many species such as gizzard shad and threadfin shad that often dominate impingement and entrainment in much of the Eastern United States, there is no commercial and/or recreational harvest and these species have a fairly large compensatory reserve. As a result, a reduction in impingement and entrainment for these species may cause little or no change in populations (i.e. benefits) for these species. At a minimum, some conservative assumptions could be made for unharvested species that would improve the benefit estimate. There is certainly far less uncertainty associated with such an estimate than the uncertainty associated with EPA's estimate of non-use benefits.

EPA Response

Please see responses to Comment 316bEFR.074.201 on the issue of "multiple conservatisms," Comment 316bEFR.005.009 on fish population modeling, and Comment 316bEFR.025.015.

EPA methods: age 1 equiv, yield, prod foregone

EPSA is also concerned with EPA’s overall use of multiple conservative assumptions that make national benefits of the proposed rule highly unrealistic. These assumptions include:

- Assumption of Age 1 Plus for Impinged Fish – The NODA states that since some impinged fish are older than Age 1, EPA has increased the estimate of impinged fish reaching maturity by assuming age 1 plus rather than age 1. In fact, the vast majority of impinged fish are young of the year (YOY) and are less than age 1. Thus, rather than achieving its goal of refining its estimate, EPA has instead significantly worsened its estimate since the technically appropriate measure would be to assume impinged fish are age 1 minus.

EPA Response

The commenter expresses concern EPA's assumptions about the age distributions of impinged fish. EPA has revised its assumptions about the age distributions of impinged fish in a manner that acknowledges that YOY may be abundant among impinged fishes, as described in the EPA response to Comment 316bEFR.029.105. For a discussion of multiple conservative assumptions, please see EPA's response to Comment 316bEFR.074.201.

Comment ID 316bEFR.308.013

Author Name Lynne H. Church

Organization Electric Power Supply Associaton (EPSA)

Subject Matter Code 10.01.02.01

EPA methods: age 1 equiv, yield, prod foregone

EPSA is also concerned with EPA's overall use of multiple conservative assumptions that make national benefits of the proposed rule highly unrealistic. These assumptions include:

- Trophic Transfer Assumptions – EPA indicates in the NODA that it is now assuming a net trophic transfer rate of 20%. The assumption is based on a NOAA document used for the purpose of assessing Natural Resource Damages for the Great Lakes. The NOAA document indicates that it used a range of values for estimation purposes and selected 20% as the best estimate. But an examination of the more recent papers listed by NOAA, based on a fairly robust examination of aquatic trophic models determined a mean transfer rate of 10%, with only a few of the 140 estimates used in 48 trophic models being 20% or higher. Thus, use of the 20% is unnecessarily conservative and inappropriate as a basis for the benefits assessment.

EPSA believes that the national benefit estimate of the preferred option should be revised. The compounding effect of the multiple conservative assumptions used in the benefits assessment creates an estimate that is highly unrealistic. EPA should consider developing a benefits assessment model that is based on more realistic assumptions, identifying the sensitivity of the model to those and perhaps provide a range of benefits depending on the nature of the aquatic resources impacted.

EPA Response

For EPA's response to the issue of multiple conservatisms, please see response to Comment 316bEFR.074.201.

In its final analysis, EPA assumed a trophic transfer efficiency of 10% based on a review article in Nature by Pauly and Christensen (1995) (see DCN #6-1004).

Subject Matter Code 7.02

Performance standards

EPSA supports EPA's proposed clarification of the calculation baseline and the principles discussed in the proposed definition. In particular, the definition of the baseline as 3/8 in. mesh to differentiate impingeable from entrainable organisms is quite helpful. EPSA continues to support use of the hypothetical design criteria as a method of allowing facilities that have installed fish protection measures to be provided with the opportunity to take credit for those measures. However, EPSA also supports the "as built" approach as an alternative and that would eliminate assumptions required by the hypothetical baseline calculation.

In addition, EPSA supports EPA's proposal to allow different but comparable facilities to share in the cost and effort to calculate baselines. This concept has been used with much success and cost savings at facilities on the west coast.

EPA Response

EPA is adopting an "As Built" approach to determining the calculation baseline as part of today's rule. As stated in § 125.93, a facility may choose to use the current level of impingement mortality and entrainment as the calculation baseline.

The calculation baseline against which compliance with the performance standards should be assessed is defined in § 125.93 as an estimate of impingement mortality and entrainment that would occur at a site assuming (1) the cooling water system had been designed as a once-through system; (2) the opening of the cooling water intake structure is located at, and the face of the standard 3/8-inch mesh traveling screen is oriented parallel to, the shoreline near the surface of the source waterbody; and (3) the baseline practices and procedures are those that the facility would maintain in the absence of any operational controls, including flow or velocity reductions, implemented in whole or in part for the purposes of reducing impingement mortality and entrainment. EPA has used this definition because it represents the most common default conditions the Agency could identify, while providing a clear and relatively simple definition. Based on comments received on the Phase II NODA , EPA has added additional criteria to the calculation baseline to provide clarity to the analysis. (EPA's proposed changes to the calculation baseline were discussed in the Phase II NODA, see, 68 FR 13580). In many cases, existing technologies at the site show some reduction in impingement and entrainment when compared to this baseline. In such cases, impingement mortality and entrainment reductions (relative to the calculated baseline) achieved by these existing technologies should be counted toward compliance with the performance standards. In addition, operational measures such as operation of traveling screens, employment of more efficient return systems, and even locational issues should be credited towards reduction in impingement mortality and entrainment. The calculation baseline may be estimated using: historical impingement mortality and entrainment data from your or another facility with comparable design, operational, and environmental conditions; current biological data collected in the waterbody in the vicinity of your cooling water intake structure; or current impingement mortality and entrainment data collected at your facility. See section IX of the preamble to today's rule for a discussion of how the calculation baseline is used to compare performance with the rule's performance standards.

Monitoring requirements

The NODA requests comment on compliance monitoring issues such as use of total numbers vs. total biomass and use of Representative Important Species (RIS). Compliance monitoring to demonstrate compliance with the performance standards needs to be done in a manner appropriate for the method selected to achieve compliance. In other words, compliance monitoring to demonstrate compliance of a facility that chose to use restoration measures will be different than monitoring done to evaluate compliance using technologies. Similarly, the nature of compliance monitoring to evaluate whether an alternative technology is meeting the compliance standard is highly dependent on the nature of the alternative technology selected.

Compliance monitoring for restoration measures will also vary depending on the nature of the restoration measure selected. In the case of an aquaculture project, the species, sizes and numbers of individual fish released can be stated very quantitatively. However, for habitat creation measures, such as a wetland restoration project used to offset entrainment losses, compliance might logically be based on total biomass production.

The design of compliance monitoring studies for technologies needs to be flexible since the nature of the monitoring will vary depending on the technology used and whether it is designed for meeting the impingement performance standard or both the impingement and entrainment performance standard. For example, some technologies such as fine-mesh traveling screens with fish handling systems are designed to collect and return fish to the source waterbody in good condition. Such technologies are not designed to reduce the number of organisms or the biomass of impinged or entrained organisms. Therefore, compliance monitoring must be designed to quantify the ability of the technology to meet the standard by reducing mortality.

In contrast, fine-mesh wedge-wire screens generally replace conventional traveling screen systems. Since the slot width of these screens is well below the 3/8 in. mesh standard traveling screen size and is combined with surface area design features to ensure proper flow, the need for compliance monitoring is virtually eliminated with this technology. For technologies such as the barrier net, it will be necessary to perform compliance monitoring in a manner that compares impingement levels before and after barrier net deployment (with appropriate methods used to measure relative abundance between years). However, for use of an aquatic filter barrier (AFB) to meet the entrainment performance standard, compliance monitoring could be performed after AFB deployment by comparing the densities or numbers of organisms inside and outside the AFB to demonstrate compliance, eliminating the need to address inter-year variability.

Comment ID 316bEFR.308.016

Author Name Lynne H. Church

Organization Electric Power Supply Associaton (EPSA)

Subject Matter Code 21.04

Determination of compliance

EPA requested comments on whether compliance monitoring for entrainment should be based on numbers or biomass. EPA correctly noted that for biomass, eggs and early life stages would have a very small biomass relative to later life stages. EPSA believes that the decision on which metric to use should be based on what is appropriate for the technology and the site-specific circumstances.

If a facility chooses to focus on numbers it is important to keep in mind that very early life stages (eggs and prolarvae) will dominate the numbers, and, therefore, the determination of compliance. This would be inappropriate since the majority of these early life stages have huge natural mortality losses regardless of cooling water intake structure entrainment. This problem is easily addressed by converting the various life stages of entrainable organisms to equivalent juveniles. This allows each life stage to be properly weighted for compliance purposes.

An equivalent juvenile conversion is a logical endpoint for entrainable organisms as they transition from entrainable to impingeable organisms. Using biomass has the opposite effect as later larval stages will dominate the biomass even though the number of organisms per unit weight will be very small relative to the number of eggs and larvae. Again, this issue can be addressed by converting the number of organisms into equivalent juveniles before calculating the biomass. From a practical standpoint, it will be desirable to count these life stages and then do a biomass conversion based on literature value weights rather than actually attempting to collect eggs and weigh them. It may make sense in the case of forage species to focus on biomass since their value is primarily as a food source for commercially and/or recreationally important species, while numbers or volume may be a more relevant focus for commercially and recreationally important species.

EPA requested comment on whether compliance should be based on an individual species-by-species basis, RIS, or total numbers or biomass. EPSA believes compliance based on demonstrating compliance for each species and life stage would be unworkable. First, for many entrainable organisms it is simply not possible taxonomically to differentiate species for eggs and early life stages. Short of requiring a DNA analysis, taxonomy will be limited to family or genus for these life stages depending on species. Second, for technologies such as barrier nets that require collecting data before and after deployment to assess compliance with the performance standard there will always be instances where species will be impinged after net deployment that were not present prior to deployment. A single such occurrence would result in failure of the performance standard. EPSA, therefore, believes that the RIS and total species numbers or biomass are the only viable alternatives. Use of RIS has been widely used in the past and has proven effective and manageable. It also results in protection of the most biologically important or valued species, as determined by the States' own natural resources agencies, which should be the overall intent of the regulation.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see , e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Comment ID 316bEFR.308.017

Subject Matter Code 21.04
Determination of compliance

Author Name Lynne H. Church

Organization Electric Power Supply Associaton (EPSA)

EPSA believes that impingement and entrainment performance standards should not be applied in the same manner as a water quality standard or technology based standard such that exceeding the performance standard is viewed as an enforceable noncompliance. While methods are clearly available to quantify the level of performance for alternative technologies they simply do not have the level of precision associated with the Part 136 methods for monitoring pollutants. Because the nature of this issue deals with many species of organisms, many technologies, and many site-specific circumstances, the final regulations must accommodate this variability if the final rule is to be workable.

EPSA strongly believes that a facility's responsibility for failing to achieve the performance standard should be limited to installation of additional technologies, establishment of operational measures, or use of voluntary restoration measures to achieve full compliance with the performance standard. EPSA believes this is completely reasonable as long as the facility submitted the compliance plan (i.e. specifying the technology or restoration plan) with documentation for Agency review and approval, constructed and operated the compliance measures in conformance with the approved plan and collected adequate biological performance monitoring data to demonstrate compliance. The facility simply will not know if compliance has been achieved until after monitoring has been completed, and it is unreasonable to subject the facility to fines and penalties if it has acted in good faith.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. RFC: Performance/effectiveness of restoration

Restoration Measures

EPA requested comment on several requirements for use of restoration measures that included quantification of uncertainty, use of adaptive management plans and peer reviews. In concept, EPSA does not have strong opposition to any of these requirements and notes they have been employed in many instances when restoration measures were implemented under State 316(b) regulatory programs. For peer reviews, EPSA recommends that deference should be given to State natural resource management agencies to determine the necessity for such reviews, as they may have Agency resources capable of evaluating the proposed restoration measures. Also, the level of formality of adaptive management plans and uncertainty quantification should be adjusted according to the size and complexity of the proposed restoration measure.

EPA Response

Under the final rule, permitting authorities determine the necessity of an independent peer review for any particular restoration measure. EPA believes the requirements for restoration measures in the final rule give permitting authorities and permit applicants the flexibility to conduct analyses commensurate with the complexity of a given restoration measure.

Permit applications/implementation schedule

Author Name Lynne H. Church

Organization Electric Power Supply Associaton (EPSA)

EPSA is very concerned with the form and schedule of the Phase II rule implementation. EPSA continues to believe that implementation of Phase II regulations would be best achieved through establishing a schedule for compliance through the NPDES permit as opposed to starting the process through the Form 2C application. The availability and review of much of the information that EPA contemplates for a demonstration study could be evaluated during permit renewal negotiations. However, the collection of new biological data, evaluation of alternative technologies and use of site-specific performance standards or restoration measures would be best implemented through a schedule placed as a special condition in the NPDES permit. It is important that several key issues be considered in implementation of the final rule:

- EPA must carry through on its promise of guidance to facilitate rule implementation.

- Delegated NPDES States must amend their State NPDES regulations to incorporate the rule, and EPA should consider the time required for States to complete this action when addressing the timing of compliance.

- Some level of baseline impingement and entrainment data will be necessary in most instances as a starting point for making compliance decisions. Baseline data is necessary for evaluating the form and scale of any restoration measures. Baseline data is also necessary to evaluate alternative technologies and determine if a site-specific performance standard is necessary. Finally, baseline data is necessary to determine the extent of additional biological monitoring for calculation baseline compliance studies (depending on the nature of the technology selected). While many facilities have conducted baseline studies under state 316(b) programs, in many cases this information may not reflect current conditions or the facility may need to do some level of sampling to determine whether or not it is reflective of current conditions. Due to the natural variability of biological populations, time needs to be allotted for facilities to conduct 2-3 years of baseline quantitative study depending on the waterbody type and technology being considered.

- EPSA believes that the timeframe from selection of a compliance technology to deployment for even the most simplistic technology (e.g. barrier net) is a minimum of one year and significantly longer for other technologies. This timeframe is based on the time required for (1) production of detailed engineering drawings, (2) obtaining necessary permits which could include waterway construction and tidal or non-tidal wetland permits, etc., (3) review and approval of NPDES permitting authority, and (4) vendor selection and construction. Weather could also delay construction depending on when regulatory approvals are completed.

- It is important to recognize that consultants are not currently staffed to support compliance, nor are vendors geared to provide technologies if all facilities are expected to comply at the same time. Again, phasing in the rule through the NPDES permit would distribute the workload to consultants and production of technology alternatives by vendors in a more reasonable manner.

316(b) Requirements After Compliance with the Performance Standard is Achieved

EPA requested comment from stakeholders on what requirements and/or additional monitoring should be required once initial compliance with the regulations is achieved. EPSA members are very concerned that compliance with the 316(b) regulations not be and endless do-loop of technologies and/or monitoring. EPSA believes that once compliance with the performance standards has been demonstrated, as long as there is no significant change to the design and operation of the BTA, no further action should be required on the part of the permittee. The only exception would be the deployed technology or restoration measure does not achieve full compliance with the performance standards and additional actions are necessary to achieve full compliance.

EPA Response

EPA disagrees that monitoring should be conducted only to gather information or should be discontinued if a facility achieves the performance standards. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027.

General Statement of Opposition

Author Name Mark V. Carney

Organization PG & E Energy Group

PG&E NEG's previously submitted comments on the initial Phase II rule identified critical flaws in the legal, technical, biological and economic analyses presented by EPA in support of its proposed approach to implementing Section 316(b) at existing facilities. These flaws included numerous instances in which EPA relied on unsupported and arbitrary assumptions and applied scientific and technical analyses that were unreasonable or wholly invalid. The cumulative effect of the errors in the EPA's documentation was to produce estimates of the costs of EPA's proposals that were unrealistically low and estimates of their biological and economic benefits that were unfounded and vastly inflated.

Given the severity of these flaws, PG&E NEG welcomed EPA's decision to release a NODA presenting revisions to the proposed rule and to the supporting documentation. Unfortunately, PG&E NEG's review of the NODA and the materials in the NODA docket indicates that, although EPA has made improvements to some aspects of its analyses, these improvements are overshadowed by significant uncorrected errors and by new errors introduced by the methods EPA uses in place of flawed analyses presented in the original Phase II rule. These errors result in estimates of the costs and benefits of the proposed rule that remain highly distorted and biased. Furthermore, EPA has continued to use these analyses to justify regulatory approaches that have not been demonstrated to be necessary or achievable and that exceed its authority under the Clean Water Act.

EPA Response

No response is required, as this comment summarizes the author's comments. Each issue is addressed individually in subsequent responses.

Performance standards

Appropriateness of Technology and Costs of Implementation

In the NODA, EPA significantly revised its approach to estimating the costs of implementing the technologies proposed for use under its preferred option. This revised analysis resulted in a significant upward adjustment of the costs of implementing those technologies.<FN 2> However, EPA's analysis remains inadequate to demonstrate the feasibility of attaining the performance standards at all or most facilities by implementing those technologies. Indeed, it is far from clear that Salem Harbor Station, Manchester Street Station or Brayton Point Station can achieve the proposed performance standards using any of the suggested technologies, due to their use of saltwater for cooling and other site-specific factors <FN 3> The circumstances of these facilities are far from unique and demonstrate the shortcomings of EPA's reliance on a uniform set of performance standards, as well as the critical importance of making site-specific evaluations readily available <FN 4>

Footnotes

2 See 68 FR at 13524 col. 3.

3 Fine mesh screens, one of the technologies proposed by EPA in its original rule to reduce both impingement and entrainment, cannot be used in salt water because of clogging. As PG&E NEG noted in its original comments, fabric filter barriers are also unusable at Brayton Point Station and Salem Harbor Station, because they would interfere with shipping traffic, and at Manchester Street Station, due the presence of a nearby hurricane barrier.

4 Below, PG&E NEG discusses how EPA's proposed cost-cost and cost-benefit tests should be interpreted to allow appropriate access to a site-specific determination.

EPA Response

EPA disagrees. While there may be some facilities that have difficulty meeting the performance standards under compliance options 2, 3 or 4, EPA expects this will be the exception rather than the norm. EPA agrees with the commenter that the circumstances of all facilities may be unique and in part for this reason, adopted performance standards instead of specifying a single Best Technology Available. In the event the performance standards are unattainable, compliance option 5 allows a facility to request a site-specific determination of best technology available for minimizing adverse environmental impact. Facilities are also authorized to seek approval from the director for compliance to be evaluated in accordance with a Technology Installation and Operation Plan.

Comment ID 316bEFR.311.003

Author Name Mark V. Carney

Organization PG & E Energy Group

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

EPA's failure to adequately demonstrate the feasibility of attaining the performance standards using these technologies also casts considerable doubt on whether EPA's estimates of costs accurately reflect the expenditures needed to comply with the performance standards.

The flaws in EPA's revised cost analysis are even more serious with respect to the "waterbody/capacity" option, which would require installation of cooling towers at certain facilities withdrawing cooling water from estuaries or oceans.

EPA Response

For discussion of the feasibility of attaining the performance standards, see section VII.B of the preamble to the final rule. For further discussion of the correlation between costs of the final rule technology basis and the performance standards, see response to comment 316b.EFR.317.012.

Comment ID 316bEFR.311.004

Author Name Mark V. Carney

Organization PG & E Energy Group

Subject Matter Code 2.04.01

Require closed cycle cooling

PG&E NEG strongly disputes EPA's position that it has authority under Section 316(b) to require cooling towers at any facility.<FN 5>

Footnotes

5 See Comments of PG&E National Energy Group on EPA's Proposed 3 16(b) Rule for Phase II Existing Facilities, 5 § III. A.1 (August 7,2002).

EPA Response

In this final rule, performance standards are not based on cooling tower technology, however, one of five compliance alternatives is the reduction of flow commensurate with the use of cooling towers, since such a level of performance meets the rule performance standards. See preamble to the final rule, particularly sections III, VII, and VIII.

Comment ID 316bEFR.311.005

Author Name Mark V. Carney

Organization PG & E Energy Group

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

However, even setting aside the question of EPA's authority, it is apparent that EPA has significantly underestimated the costs of retrofitting existing facilities with cooling towers by using unreasonably low cost assumptions and by failing to consider the substantial impact of site-specific factors. Because of these flaws, PG&E NEG believes this option should be withdrawn from further consideration.

In his comments on the NODA, Professor Robert Stavins reviewed the analyses developed by the Department of Energy ("DOE") for the capital cost of retrofitting cooling towers at four representative facilities.<FN 6> Professor Stavins found that DOE'S capital cost estimates in its initial report, which were based on limited, publicly-available site-specific information, were between 65% and 104% higher than those that would be produced by EPA's costing methodology.<FN 7> An addendum to the initial DOE report indicated that the inclusion of additional site-specific information submitted by the facilities after the initial analysis was completed results in further upward revisions of these estimates. Professor Stavins found that, once all relevant information was considered, the DOE estimates of the costs associated with cooling tower conversions at these facilities could be between 230% and 310% greater than would have been estimated by EPA.<FN 8>

The existence of systematic downward bias in EPA's approach to estimating costs is further supported by a comparison of the capital cost estimates prepared by Stone & Webster, Inc. for a cooling tower retrofit of Brayton Point Station <FN9> with estimates based on EPA's cost method. In preparing its estimate, Stone & Webster, a company with decades of experience in power plant construction, undertook a detailed review of what would be required to perform a retrofit at Brayton Point. Its analysis identified a number of site-specific considerations that would add to the difficulty of performing the retrofit, and therefore to the costs of doing so. The estimate that Stone & Webster developed on the basis of this site-specific information is 150% greater than the estimate that would result using EPA's approach.<FN 10>

Footnotes

6 See An Investigation of Site-Specific Factors for Retrofitting Recirculating Cooling Towers at Existing Power Plants ("DOE Retrofit Analysis") (DOE, October 8,2002); Addendum to Report An Investigation of Site-Specific Factors for Retrofitting Recirculating Cooling Towers at Existing Power Plants ("DOE Retrofit Addendum") (DOE, January 22,2003).

7 See Stavins Comments, p. 6

8 See Stavins Comments, p. 7

9 Stone & Webster's cost estimate for Brayton Point Station, submitted as part of Brayton Point Station's Final Demonstration for renewal of its permit under Section 3 16(a) and 3 16(b) of the CWA, was independently reviewed by Bechtel Power Corporation, another firm with extensive experience in building and modifying power plants. Bechtel reported that it was "in overall agreement" with Stone & Webster's estimate, although it identified some areas in which costs could actually be higher than Stone & Webster had calculated. Both the Stone & Webster and Bechtel cost estimates can be found in the docket for the Brayton Point Station NPDES Permit, MA0003654, EPA Region I.

10 Stavins Comments, p. 7

EPA Response

The Agency has not based the final rule on closed-cycle wet cooling technology retrofits. As such, the commenter’s concerns have been met.

Comment ID 316bEFR.311.006

Author Name Mark V. Carney

Organization PG & E Energy Group

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

DOE'S studies also indicate that EPA's assumption in the original proposed 316(b) rule that cooling tower retrofits can be accomplished with only four weeks of downtime on average for non-nuclear facilities would not necessarily be accurate once site-specific factors are taken into account. To the contrary, DOE found that, for at least two of the four facilities studied, extended outages could be required to retrofit cooling towers.<FN 11> In addition, DOE emphasized that reliable estimates of outage durations could not be made without a detailed engineering analysis.<FN 12> The case of Brayton Point Station is again instructive. Because of a number of unique site-specific factors affecting the retrofit of cooling towers at Brayton Point, Stone & Webster found that it would require seven additional months of downtime, above any scheduled outages, to complete the work. <FN 13>

Footnotes

11 Information presented in the DOE study indicated that the outage time required to retrofit the Hudson Generating Station would last between two and three months. DOE Addendum, p. 9. For the Big Bend Station, DOE found that the necessary outage would "significantly exceed a scheduled outage," but concluded that the precise duration of the outage would require a detailed engineering analysis. DOE Addendum, p. 6.

l2 DOE Addendum, p.6.

13 Stavins Comments, I.B

EPA Response

The Agency has not based the final rule on closed-cycle wet cooling technology retrofits. As such, the commenter's concerns have been met.

EPA notes for the record that its estimates of construction downtime for cooling tower retrofit projects exceed those of the Department of Energy's analysis for two of four cases. Therefore, in relation to the issue of construction downtimes alone, the commenter's assertion that the DOE study shows that the Agency has dramatically under-represented this factor is in error. Nonetheless, the Agency has not based the final rule on wet cooling towers, in part, based on the uncertainty related to predicted construction downtimes and the potential for extended downtimes approaching 7 to 10 months, as evidenced by the real-world, empirical retrofit projects documented in the Agency's record.

Organization PG & E Energy Group

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

In light of the foregoing, it is clear that EPA's present costing approach systematically understates the very high costs associated with the imposition of cooling tower retrofits under the waterbody/capacity option. Unfortunately, EPA has made no attempt in the NODA analysis to adjust its capital cost estimates for any facilities, or to modify its estimates of downtimes for non-nuclear facilities. EPA's continued reliance on data demonstrated to be in error is particularly troubling given that EPA has never provided, either in the original proposal or the NODA, any sound biological basis for imposing cooling tower retrofits on all facilities that meet the waterbody and capacity criteria EPA has proposed to adopt. Having failed to identify any valid basis for imposing the waterbody/capacity option, or to assess accurately the true costs of doing so, EPA should eliminate this alternative from further consideration.

EPA Response

The Agency has not based the final rule on wet closed-cycle cooling technology retrofits. As such, the commenter's concerns have been met.

Benefit Estimation Methodology

Benefits Estimates

In its previous comments, PG&E NEG identified numerous flaws in the biological and economic estimates used to develop EPA's benefits estimates for the proposed 316(b) rule. These flaws included errors in the biological assumptions used to calculate lost production that led EPA to vastly overstate the benefits of reducing losses from impingement and entrainment ("I&E"). These exaggerated biological benefits were compounded by flawed economic analyses that produced dramatically inflated estimates of the economic benefits reduced I&E would provide to commercial and recreational fishermen. In addition, EPA applied wholly invalid methods for estimating non-use benefits, including the Habitat Replacement Cost ("HRC") method, which used the cost of replacing fish lost to I&E by improving fish habitat as a measure of non-use benefits.

EPA's revised benefits analysis corrects several significant flaws in this analysis. However, the positive impact of these corrections is dwarfed by EPA's failure to correct even more significant errors and by its inclusion of a new, but no less invalid method for calculating non-use benefits.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values in the analysis of national benefits due to uncertainty in monetizing non-use values at the national level. The Agency, however, has explored several approaches that indicate the potential for significant non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, Non-Use Meta-Analysis Methodology, and Chapters C6, D6, and G6 of the final Phase II Regional Studies Document (DCN #6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN #6-0002).

EPA disagrees with the assertion that EPA's I&E analysis is flawed. Please see EPA's responses to comment 316bEFR.029.105 regarding the age of impingement, Comment 306.092 regarding the detection of ecological impacts, comment 316bEFR.074.101 regarding EPA's calculation of production foregone, comment 316bEFR.074.042 regarding multiple conservatisms, comment 316bEFR.005.009 regarding fish population modeling, and comment 316bEFR.025.015 regarding compensation.

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Biological Benefits

EPA's analysis in the NODA of the biological benefits associated with I&E reductions is, unfortunately, even worse than the analysis used in the original proposed 316(b) rule. In the NODA, EPA adjusts its calculation of the biological benefits associated with the I&E reductions under the proposed rule by increasing the trophic transfer rate, which measures the effect of reduced losses of forage fish on harvested species, from 2.5% to 2O%.<FN 14> EPA also revises its earlier assumption that entrained fish are age 1 and instead assumes that entrained fish may be age 1 or older.<FN 15> As UWAG discusses in its comments,<FN 16> both of EPA's assumptions are inaccurate and both impart an upward bias to the calculated impact of reducing I&E.

The revised trophic transfer rate of 20% is unjustifiably high, based on the relevant literature. <FN 17> As a result, EPA has clearly overestimated the positive effect of reduced losses of forage fish on the yield of harvested species. This overestimate is compounded because EPA now assumes that all lost production of forage fish would have been consumed by harvestable species, when in fact many forage fish are consumed by intermediate predators. <FN 18>

More significantly, EPA's revised assumptions regarding the age of impinged fish ignore the fact that, in many if not most cases, young-of-the-year ("YOY")--less than one year-old fish--account for the majority of fish impinged.<FN 19>This difference is important, because YOYs have a far lower natural survival rate. As a result, losses of this life stage would have a much smaller impact on fish of harvestable age than would losses of older fish. EPA's use of older life stages leads the agency to overestimate the effect of I&E reductions on commercially or recreationally valuable fish.<FN 20>

EPA methods: age 1 equiv, yield, prod foregone

Although these new errors introduced in the NODA are substantial, even greater overstatement of the biological benefits of I&E results from uncorrected errors identified in EPA's original analysis. In its previously submitted comments, PG&E NEG called attention to the fact that EPA's calculation of production foregone contained two serious errors. First, instead of using life-stage initial and final weights to compute initial biomass values and life-stage growth rates, EPA used mean weights of individuals at the midpoint of the life stage. Because mean weights are greater than initial weights, this results in a systematic upward bias in the calculation of production foregone. Second, EPA used life-stage weights that were far too heavy, sometimes thousands of times too heavy. The cumulative effect of EPA's errors was to produce vastly exaggerated estimates of the biomass lost due to I&E, and thus of the benefits of reducing I&E impacts.<FN 21>

A review of the data reprinted in the NODA makes clear that EPA has perpetuated these errors in its new national benefits analysis.<FN 22> In addition, the data relied upon in EPA's estimates of production foregone are riddled with errors and inconsistencies. For example, Table 1-5 1 in Appendix 1 to the NODA shows larval weights for winter flounder at Brayton Point Station and Millstone that are 10,000 times heavier than larval weights listed for the Pilgrim Power Plant in Table 1-52, despite the fact that the egg weights listed for all three plants are the same. In addition, the larval weights in Table 1-5 1 are 1,000 times larger than the egg values, despite the fact that EPA's own consultant indicated that larval weights should be only slightly greater than egg weights.<FN 23>

EPA Response

The commenter notes some problems concerning the assumed size of certain species of fish and the corresponding effects on calculation of production foregone. In response to similar comments, EPA has revised many such parameters, as noted in the EPA's response to EFR.305.003 on its production foregone calculations.

The regional differences noted by the commenter result from EPA's intentional use of geographically-relevant parameters whenever they were available.

Assumptions about I&E survival

A further upward bias is introduced into the biological benefit estimate by EPA's continued refusal to assume that any organisms survive entrainment,<FN 24> despite many studies showing that, at least for some species, survival rates can be quite high. As UWAG has noted, while EPA may have concerns about the representativeness or soundness of specific studies of entrainment survival, this does not justify assuming, contrary to all the available evidence, that there is no survival. Instead it suggests the need for appropriately addressing the uncertainty, perhaps through use of sensitivity analysis in EPA's calculations. <FN 25> The erroneous assumption of zero survival is particularly significant given that several of the technologies proposed, such as fine mesh screens, reduce entrainment while increasing the number of organisms that are impinged. Unless EPA uses reasonable estimates of both impingement and entrainment survival, EPA's performance requirements could have the perverse result of increasing overall mortality.<FN 26>

In light of the foregoing, it is clear that EPA's estimates are highly unreliable and overstate by a significant amount the biological benefits that could be expected to result from the cooling water intake technologies EPA has proposed. These calculations must be significantly revised to accurately identify the biological losses due to I&E and the benefits of reducing those losses.

Footnotes

24 68 FR at 13545, col. 3.

25 See UWAG Comments, 5 X.B.

26 See Englert Comments, p. 2. This perverse result could also occur if flow reduction measures are used as a means of reducing the numbers entrained. Reduced flows, including reduced flows due to closed-cycle cooling, may lower the numbers of individuals entrained but increase entrainment mortality, because of the higher temperature increases that occur in the system. This could offset or even eliminate the benefits EPA associates with reduced flows. Englert Comments, p. 2.

EPA Response

Please see the response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule. Please see the chapter, Entrainment Survival, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule.

Benefit Estimation Methodology

Use Benefits

EPA's use benefits analysis in the NODA addresses a number of criticisms of its earlier approach to calculating use benefits.<FN 27> In particular, EPA now discounts the future benefits to users, reflecting the delay in time between when I&E reductions occur and when the fish "saved" by these reductions are available for commercial and recreational fishing. EPA has also utilized a more reasonable method for calculating recreational fishing benefits and has eliminated its erroneous assumption that the benefits from increased fish catch could far exceed the benefits to commercial fishermen and their direct consumers. EPA is to be commended for addressing a number of the flaws in this component of its analysis, but, because the biological inputs to this analysis remain grossly overstated -- as discussed above -- the values EPA has calculated for these benefits remain similarly overstated. Furthermore, the effect of these improvements, which result in a downward adjustment to EPA's estimate of use benefits, is overwhelmed by the inflated values of non-use benefits discussed below.

Footnotes

27 See generally Stavins Comments, II.B.

EPA Response

The comment states that EPA made a number of improvements in its analysis for the final rule analysis. The comment states that biological inputs "remain grossly overstated," and therefore benefits estimates are overstated.

EPA disagrees with the assertion that EPA's I&E estimates are overstated. Please see EPA's responses to Comment 316bEFR.029.105 regarding the age of impingement, Comment 306.092 regarding the detection of ecological impacts, Comment 316bEFR.074.101 regarding EPA's calculation of production foregone, Comment 316bEFR.074.042 regarding multiple conservatisms, Comment 316bEFR.005.009 regarding fish population modeling, and Comment 316bEFR.025.015 regarding compensation.

The comment also states that EPA's non-use benefit estimates are inflated. For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values for national benefits due to uncertainty in monetizing non-use values for this rule. The Agency, however, has explored several approaches that indicate the potential magnitude for significant non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002). EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020

regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Valuing Forage Species (incl non-use and non-landed)

Non-Use Benefits

In its comments on the original proposed Phase II rule, PG&E NEG commented extensively on EPA's use of the invalid HRC method to estimate non-use benefits. PG&E NEG noted that, by using restoration costs as a proxy for benefits, the HRC approach is fundamentally incompatible with sound economic analysis. In addition, PG&E NEG advised EPA that the biological basis for the HRC method contained numerous errors. In developing its estimates of the amount of habitat needed to replace fish lost to I&E, EPA chose habitat types for some species that would do little or nothing to increase the numbers of fish, and relied on a method for calculating the population increase that would result from additional habitat that was biologically irrational. This resulted in estimates of the amount of habitat required that were both wholly unreliable and grossly overstated, leading to correspondingly exaggerated estimates of non-use "benefits." In the NODA, EPA makes no mention of the HRC method, which makes clear that EPA has recognized that this method has no place in a valid benefits analysis.<FN 28>

Unfortunately, EPA has adopted in its place an alternative approach<FN 29> to estimating non-use benefits that is equally incompatible with accepted economic practice and EPA's own Guidelines for Preparing Economic Analyses. In this approach, EPA first estimates the amount of habitat that would be required to replace species lost to I&E , using the same deeply flawed biological assumptions that formed the basis of the HRC analysis. EPA then attempts to develop per-household "willingness to pay" ("WTP") values for the fish production associated with that habitat. Finally, EPA extrapolates those WTP values to hundreds of thousands of households it claims would be expected to hold those values.

The problems with this approach are numerous and fundamental. First, EPA has done nothing to address the serious problems with the biological underpinnings of the HRC approach that were strongly criticized by PG&E NEG, and others, as completely inadequate to evaluate the use of habitat restoration to increase fish production. Among other critical errors, EPA has failed to identify appropriate types of habitat to increase the production of many species.<FN 30> For example, EPA assumes winter flounder populations would be enhanced by tidal wetlands habitat. Yet EPA itself has previously acknowledged that winter flounder do not rely on tidal wetlands for completing their life cycle.<FN 31> EPA also continues to use the abundance of species in a particular type of habitat as a proxy for the fish production that will result from increasing that type of habitat.<FN 32> However, it is well established that the number of fish that are found in a type of habitat at a particular point in time says little or nothing about whether that habitat fulfills a critical life function, or whether an increase in the habitat will increase production.<FN 33> These and other critical errors preclude reliance on EPA's estimates of the benefits that will result from the assumed habitat restorations.

Footnotes

28 The NODA also makes no mention of two other flawed "avoided cost" estimation methods used in the original proposed 316(b) rule, the "societal revealed preference" method and the "forage fish replacement cost" method. While PG&E NEG believes EPA's rejection of these methods is clear from their absence from the NODA, PG&E NEG is disappointed that EPA did not make this position explicit. It would be unfortunate if EPA's failure to do so were interpreted elsewhere as

supporting the continued use of these approaches. PG&E NEG requests that EPA specifically address this issue in the final rule.

29 This approach and its results are outlined in pages 13567-13575 of the Federal Register. Additional background information is contained in docket documents, including DCN 5-1010 (March 12,2003 Memorandum of Tudor et al. to 316(b) Record).

30 See French-McCay Comments, pp. 4-6.

31 See Section 3 16(b) Existing Facilities Case Studies, Chapter F3 (Brayton Point Case Study). EPA makes similar errors with respect to Pollock and other species. French-McCay Comments, pp. 5-6.

32 See 68 FR at 13569.

33 French-McCay Comments at pp. 6-8.

EPA Response

EPA does not use the Habitat-Based Replacement Cost (HRC) method in the benefits analysis for the final section 316(b) Phase II rule. However, EPA believes that the HRC method is a useful tool for comparing the cost of various technologies to prevent adverse environmental impacts, with the costs of offsetting adverse impacts not addressed by those technologies. EPA disagrees that the contents of the NODA indicate a change in EPA's position about the valid use of HRC.

In regards to the commenter's assertion that it is incorrect to assume that species abundance is a proxy for productivity, EPA notes that species abundance is a reasonable proxy for secondary productivity under the following conditions assumed by EPA and supported by the available data: the production to biomass ratio is 1; all of the annual production occurs during the time of sampling; and there is no turnover.

EPA relied on the judgment of local experts regarding preferred restoration alternatives. For further information on the biological foundations of the HRC, please refer to the document "Habitat-based Replacement Cost Method" (DCN #) and EPA's responses to comments 316bEFR.029.113 and 316bEFR.041.454.

Subject Matter Code 10.02.04.01

Peconic-based approach

Furthermore, EPA' s method for developing economic benefits values from habitat restoration contains invalid assumptions and arbitrary judgments at every step. The following summarizes a number of these errors:<FN 34>

EPA begins by using a survey-based valuation study of habitat restoration alternatives, conducted for the Peconic Estuary, as a source of per-household WTP values for habitat restoration. In doing so, EPA fundamentally misuses the Peconic Estuary study. As comments submitted by two of study's authors make clear, the express purpose of the study was to identify relative preferences among restoration alternatives, not absolute values.<FN 35> Although the methods used by the authors allowed for the derivation of dollar values, these values were found not to be robust -- indeed, the authors specifically cautioned in the published study against relying on these values.<FN 36> Significantly, the authors also found evidence that the dollar values reported "might not only be unreliable, but generally biased upwards " due to "symbolic" considerations which, for example, could lead some to express excessively high willingness to pay values for restoration out of a desire to "take action to help the environment."<FN 37>

EPA Response

For EPA's response regarding the soundness of value estimates from the Peconic study, please see the response to comment #316bEFR.304.002.

Comment ID 316bEFR.311.015

Subject Matter Code 10.02.04.01

Peconic-based approach

Author Name Mark V. Carney

Organization PG & E Energy Group

EPA next assumes that the values for eelgrass and wetlands it takes from the study can be treated as including the value that the respondents place on the ability of the habitats to increase fish and shellfish populations. Again, this assumption is one that the studies ' authors expressly reject as invalid. As the authors note, the questionnaire used in the study indicated "only in very general terms that eelgrass is a habitat for fish and shellfish. No quantitative information whatsoever was provided regarding the significance of eelgrass or wetlands as a habitat for fish and shellfish."<FN 38> Furthermore, wetlands were not even identified as fish habitat even in general terms. EPA's assumption therefore violates the fundamental requirement for sound stated preference surveys that, in order to be able to be able to express a valid opinion about value, respondents "must have available to them information about the commodity [fish and shellfish production] and its attributes that is sufficient to allow them to assign it a value."<FN 39> Because of this, the authors conclude "...it is not reasonable to treat the values given to the eelgrass and wetlands resources themselves as reflective of the values that would be placed on the production offish and shellfish.<FN 40>

Using these values, EPA makes wholly unjustified assumptions as to the proportion of non-use value ascribed to eelgrass and wetlands by study respondents that reflects the value of each type of habitat's fish production potential. For eelgrass, EPA assumes that all of the value is due to fish production. For wetlands, EPA assumes that one quarter of the value is due to fish production, despite the fact that respondents were not even told in the original study that wetlands served as habitat for fish. These assumptions are completely unsupported and arbitrary.

Subject Matter Code 10.02.04.01

Peconic-based approach

Author Name Mark V. Carney

Organization PG & E Energy Group

Having derived these purported per-household values of "fish production services," EPA then treats them as reflecting the non-use values placed on reductions of I&E. Although EPA characterizes this step as a "benefits transfer," EPA has in fact completely ignored fundamental criteria governing the use of benefits transfer methods, in particular the requirement of similarity between the circumstances of the original study and the study to which the benefits are transferred.<FN 41> The dissimilarities in this case are obvious and profound. There is simply no reason to believe that individuals' non-use values for the fish habitat services of wetlands and eelgrass - even if appropriately measured, which they most certainly were not in this case - are equivalent to the non-use value individuals would place on the fish themselves, or, more precisely, on reductions in the loss of fish due to I&E <FN 42>

Footnotes

41 Stavins Comments, III .

42 As the authors of the study note, EPA's application of the study further departs from the requirement of similarity by its failure to account for significant differences in the demographic characteristics of the populations of the source study -- the Peconic Bay Estuary -- and the areas to which EPA then applies the results. Opaluch & Grigalunas Comments, pp. 3-4.

EPA Response

For EPA's responses regarding the similarity of the study to the policy context, please see EPA's responses to comments #316bEFR.307.061, and #316bEFR.303.020.

Comment ID 316bEFR.311.017

Author Name Mark V. Carney

Organization PG & E Energy Group

Subject Matter Code 10.02.04.01

Peconic-based approach

The final step of the analysis requires EPA to determine the number of households to which its per-person "values" should apply. For the NODA, EPA chooses two populations: all households in counties abutting a given power plant and all households within 32.4 miles of a power plant. Obviously, the choice of the number of households is critical to the ultimate value EPA calculates. Yet EPA provides no rational explanation that could justify its choices. Instead, for this critical step EPA makes what is in effect an entirely arbitrary judgment-indeed a judgment that can only be arbitrary, since there is no basis on which the agency could possibly conclude that these entirely manufactured values are held by anybody.

EPA Response

The comment states that EPA has no basis to make a judgment of the affected population for its non-use benefit transfer. EPA disagrees. EPA believes that it has conservatively estimated the extent of the affected population in the study area based on households in counties abutting the affected water body, and households within 32.4 miles of the affected water body. The 32.4-mile figure was chosen based on results from the Rhode Island wetlands study. This study showed that Rhode Island residents who live in the most western parts of Rhode Island and as far as 32.4 miles from Narragansett Bay value wetland restoration in the Bay (see Chapter C6 the final Phase II Regional Studies Document, DCN #6-0003).

In the Peconic study, the survey was conducted only in the towns surrounding the Estuary, so it is impossible to determine from the survey results whether Long Island residents living at a distance from the Estuary would also value habitat improvements in the Estuary. However, evidence suggests that this is likely to be true. The Peconic study included a second survey of recreational users of the Estuary, which found that people traveled great distances to visit the Estuary and recreate there, indicating that these people would likely value the Estuary's habitats. They simply were not asked these questions, so the extent of the market for restoration and protection of the Peconic Estuary's services has not been conclusively determined.

The Agency also reviewed additional studies to identify the effect of distance on WTP for non-use values. Empirical evidence from economic literature suggests that EPA has chosen a conservative means of determining the affected population.

For example, a study by Pate and Loomis (1997) found that respondents outside the political jurisdiction in which a study site is located were also willing to ascribe stated preference values to the amenity being studied. The study was designed to determine the effect of distance on willingness to pay for public goods with large non-use values. Specifically, the study evaluated environmental programs designed to improve wetlands habitat and wildlife in the San Joaquin Valley. It compared WTP values for households residing in the San Joaquin Valley, California, to values for California households outside the Valley, and to households in Washington State, Oregon, and Nevada. The study found that WTP values for California residents outside the Valley were 97.7 percent of the

WTP of the Valley residents; WTP values for Oregon residents were approximately 27 percent of the WTP of the Valley residents. (The distances to these locations outside the valley exceed the 32.43-mile radius used in EPA's analysis.) (See DCN #6-2503 for detail).

A natural resource damage assessment study conducted by Schulze et al. (1995, DCN #5-1302) examined the effect of distance on household WTP to cleanup the Clark Fork River Basin in Montana, which had been polluted by hazardous waste from mining activities. The study surveyed Montana residents and asked their WTP for partial and complete cleanup of the site, which would result in improvements to surface water, groundwater, soil, vegetation, and wildlife. More specifically, the partial cleanup program, for example, would improve water quality, but trout populations would remain below normal, and about one-fourth of the habitat lost for wildlife species would be restored. The authors examined the effect of distance on WTP by grouping respondents based on the distance between their residences and the resource site. Respondents residing between 101 and 200 miles from the Clark Fork River Basin were willing to pay 49.7 percent of those respondents residing within 100 miles. The group of respondents residing more than 500 miles driving distance from the Clark Fork River Basin were willing to pay 18.5 percent of those within 100 miles. (See DCN #5-1302 for detail).

Peconic-based approach

In light of EPA's repeated disregard of economic principles in performing this "analysis," the values it produces simply cannot be taken seriously as estimates of the benefits associated with reductions in I&E. This is precisely the conclusion of the authors of the underlying study, who state unequivocally in their comments on the NODA that "...we believe that EPA 's use of the PES study is not a valid application of B-T [benefits transfer] and that the values calculated in the Tudor et al. memorandum can not be considered to accurately identify the benefits associated with EPA 'proposed cooling water intake technologies."<FN 43> PG&E NEG does not consider it coincidental the "values" that EPA derives from this approach are extraordinarily large, dwarfing the "use" values that EPA developed using traditional methods of economics analysis. Indeed, as UWAG notes, of EPA's overall estimates of the benefits of its supposed rule, over 97% are attributable to non-use benefits associated with the per-household method.<FN 44> It is profoundly unfortunate that EPA has found it necessary to resort to such a wholly invalid method to justify its proposed rule.

Footnotes

43 Opaluch & Grigalunas Comments, p. 4.

44 See UWAG Comments, X.E.4.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

RFC: Appropriateness of "significantly greater"

Cost Tests

In the NODA, EPA requests comment on whether it should further define the meaning of "significantly greater" as that term is used in two cost tests included in the proposed rule. These cost tests allow a facility to obtain a site-specific determination of technology if it can demonstrate that its costs are "significantly greater" than the costs estimated by EPA for the proposed rule or, alternatively, than the benefits to be achieved from compliance with the performance standards. PG&E NEG agrees with UWAG that a uniform interpretation of "significantly greater" is desirable as a means of providing consistency across states and EPA regions.<FN 45> PG&E NEG also agrees with UWAG's position that "significantly" should be interpreted in its scientific sense - as costs that are measurably greater than EPA's estimated compliance costs or, alternatively, than the estimated benefits, once uncertainties are taken into account.<FN 46> In this sense, the "significance" of greater costs will be determined by consideration of the precision of the estimates and of the magnitude of the measured difference between facility costs and EPA costs, or facility costs and estimated benefits.

RFC: Performance/effectiveness of restoration

Restoration Measures

The NODA proposes three new requirements for facilities seeking to use restoration measures in lieu of, or in addition to, technology to meet the performance standards. Specifically, EPA proposes that applicants be required to: (1) document the magnitude and sources of uncertainty in restoration proposals; (2) submit plans that use an adaptive management approach to monitor progress and make adjustments during the implementation phase; and (3) obtain peer review of their restoration proposals.<FN 47> PG&E NEG agrees with UWAG that each of the foregoing can, in appropriate circumstances, be a useful element in developing a restoration plan.<FN 48> At the same time, PG&E NEG is concerned that rigid application of these requirements could prevent many worthwhile restoration proposals from being implemented, especially if EPA insists on restoration measures replacing fish on a species-specific basis.

Footnotes

48 See UWAG Comments, 9 X.A.3.

EPA Response

EPA believes the three principles identified by the commenter are sufficiently helpful and important to include in the final rule as requirements. EPA believes the requirements, however, give permit applicants and permitting authorities flexibility to produce analyses commensurate with the level of complexity of a given restoration measure. The requirements are intended to reduce uncertainty associated with restoration measures and enhance their performance.

For a discussion of the use of out-of-kind restoration measures in the context of the final rule, see EPA's response to comment 316bEFR.206.055.

RFC: Performance/effectiveness of restoration

In order for restoration measures to result in increased production of a species, all the other requirements for increased production must also be present, such as sufficient sources of food, adequate water quality, etc. In other words, at the time the restoration is implemented, that species ' level of reproduction must be limited by habitat (which is the input being increased) and not by other factor.<FN 49> However, as a practical matter it is very difficult to determine in advance--or even during implementation--what factors are limiting the reproductive success of a particular species. As a result, there will often be very large uncertainties about the success of the restoration effort with respect to a single species; uncertainties that may be difficult even to adequately quantify. <FN 50> These uncertainties can undermine the possibility of obtaining meaningful peer review and cannot be resolved solely through use of adaptive management techniques.<FN 51>

In her comments, Deborah French-McKay notes that these uncertainties can be significantly reduced if EPA is flexible in its definition of acceptable restoration measures. In particular, uncertainty can be significantly reduced in many cases if reductions in fishing pressure and restocking programs are used as means of mitigating losses due to I&E.<FN 52> Such approaches are also much more likely to be successful, especially where fishing pressure is a dominant source of mortality. Uncertainty can also be reduced if fish are considered by trophic level, rather than on a species-specific basis.<FN 53> Considering restoration on an ecosystem level is already commonly done in the Natural Resources Damages context. Aggregated this way, it becomes possible to estimate, with reasonable precision, which restoration measures will result in production gains to the ecosystem, even if it remains impossible to be certain which species will experience those gains. Use of these methods is also likely to result in more effective peer review, as there is a greater knowledge base for using these methods and quantifying the uncertainties involved.<FN 54> Similar flexibility will be required in the use of adaptive management techniques. Understanding the changes that are occurring and adapting restoration activities appropriately would be very difficult, time-consuming, and in some cases virtually impossible -- especially if EPA were to insist on species-by-species replacement. A more realistic approach would be to develop specific goals about the scope and functionality of the project, perhaps through the use of performance standards, rather than to require a strict demonstration of the maintenance of the species. <FN 55>

EPA Response

For a discussion of the uncertainties associated with restoration measures, see EPA's response to comment 316bEFR206.055. EPA believes the use of adaptive management and peer review may not entirely eliminate these uncertainties but can help reduce them.

Because of the uncertainties associated with restoration measures, they may not be a feasible choice for every site.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

Any restoration measure must meet all of the requirements described in the final rule.

RFC: Proposed use of restoration measures

Author Name Mark V. Carney

Organization PG & E Energy Group

Ultimately, PG&E NEG believes that the goal of making effective restoration measures a viable alternative to technology will be best served if the three principles identified by EPA are incorporated as guidance, or factors to be considered, rather than as rigid rules. In appropriate cases, and coupled with the use of trophic levels to measure production gains, they can improve the reliability and effectiveness of restoration plans. Rigidly applied, they may serve as bars to the implementation of restoration projects that in reality will produce significant benefits.

EPA Response

EPA believes the three principles identified by the commenter are sufficiently helpful and important to include in the final rule as requirements. At the same time, however, the rule gives permit applicants and permitting authorities flexibility to produce analyses commensurate with the level of complexity of a given restoration measure. The requirements are intended to reduce uncertainty associated with restoration measures and enhance their performance.

Cooling system costs (e.g., dry, wet, recirculating)

EPA has missed an important opportunity in the NODA to correct fundamental errors in its original analyses so that they reflect sound science and to develop a final proposed rule that is technically feasible and justified on the basis of the record that has been developed. The limited improvements EPA has made in certain parts of its analysis are overwhelmed by the uncorrected errors that remain, and new errors introduced in the NODA, including:

- Clear errors in EPA's cost analysis, and in particular in the analysis of costs associated with the retrofit of cooling towers at existing facilities, resulting in substantial underestimates of the unacceptably high costs of this option;

EPA Response

The Agency has not based the final rule on closed-cycle, wet cooling technology retrofits. As such, the commenter's concerns have been met.

Benefit Estimation Methodology

EPA has missed an important opportunity in the NODA to correct fundamental errors in its original analyses so that they reflect sound science and to develop a final proposed rule that is technically feasible and justified on the basis of the record that has been developed. The limited improvements EPA has made in certain parts of its analysis are overwhelmed by the uncorrected errors that remain, and new errors introduced in the NODA, including:

EPA Response

The comment states that, while EPA's final rule analysis includes improvements, uncorrected errors remain. The comment does not specify these errors.

For EPA's responses to specific comments on commercial fishing methods please see response to comments # 316bEFR.323.016 and 316bEFR.005.029.

For EPA's responses to specific comments on recreational fishing methods presented in the NODA please see responses to comments # 316bEFR.041.452, comment #316bEFR.337.010, and comment #316bEFR.306.320.

For the final 316b rule analysis, EPA has not included quantitative measures of benefits associated with nonuse values due to uncertainty in monetizing non-use values for this rule. The Agency, however, has explored several approaches that indicate the potential for significant non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Valuing Forage Species (incl non-use and non-landed)

EPA has missed an important opportunity in the NODA to correct fundamental errors in its original analyses so that they reflect sound science and to develop a final proposed rule that is technically feasible and justified on the basis of the record that has been developed. The limited improvements EPA has made in certain parts of its analysis are overwhelmed by the uncorrected errors that remain, and new errors introduced in the NODA, including:

- An estimate of economic benefits dominated by grossly overstated non-use estimates of non-use values derived using a wholly invalid method -- one which the authors of the studies on which EPA relies have expressly rejected.

Given these serious flaws, EPA has not demonstrated that its proposed rule represents a valid application of the “best technology available’’ standard of Section 316(b) or a sound policy for addressing the environmental impact of cooling water intake structures.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN #6-0002).

EPA does not agree that the benefit transfer method is “wholly invalid.”

EPA has responded to concerns regarding the Agency’s non-use valuation methods in responses to a number of comments. For EPA’s benefit transfer approach, please see EPA’s response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA’s meta-analysis please see EPA’s responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA’s meta-analysis. For EPA’s response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Finally, the Agency notes that although two of the authors of the original studies on which EPA relied for this benefits transfer submitted comments on behalf of the regulated industry, two other investigators of the original studies (Dr. Marisa Mazzotta and Dr. Robert Johnston) served as EPA's consultants for the cost benefit analysis of the final Section 316(b) Phase II regulation.

RFC: Proposed use of restoration measures

Author Name Deborah French McKay

Organization Applied Science Associates, Inc.

Failure to Identify Appropriate Restoration/Enhancement Techniques that Provide Net Gains in Species Productivity: The preferred restoration alternatives for I&E species have not been based on a biological assessment of what is limiting to the populations and what action(s) could best enhance the production of the species in question. The choices appear to have been made from an a priori selection of desired habitat restoration alternatives (either saltmarsh or SAV) and whether a species is observed at any time in those habitats. While, for some I&E species, restoration of saltmarsh or SAV may be beneficial to its production, EPA has inappropriately estimated the net gain in production that would result from the restoration of specified amounts of this type of habitat. The life history of the I&E species needs to be researched carefully to identify the limiting factor(s) for the population during each life stage. The limiting factor is typically very different at different life stages. Thus, the restoration technique needs to be targeted to specific life stages and provide something that is limiting to the growth and survival of that life stage.

[The text above is from the summary on page 3. The text below can be found on pages 4-6 of the comment letter.]

Failure to Identify Appropriate Restoration/Enhancement Techniques that Provide Net Gains in Species Productivity

EPA asserts that it has chosen the preferred restoration alternative for offsetting I&E losses for those species included in the NODA (p. 13568, for the list of species considered p. 13550). However, to the contrary, the restoration alternatives suggested by EPA, coastal wetlands and eelgrass, will do little or nothing to increase production of several of the species considered. In order for the restoration technique to be of assistance to the particular species whose losses are being mitigated, the productivity of the species needs to be limited by something provided by the restoration project, such that there is a net gain in production. For example, if survival is controlled by predation, providing a refuge from predation would improve production. If however, food is more limiting to growth and survival, restoration that provides additional food or feeding habitat would be the appropriate choice to improve production. Thus, the life history of the I&E species needs to be researched carefully to identify the limiting factor(s) for the population during each life stage. The limiting factor(s) are typically very different at different life stages. Thus, the restoration technique needs to be targeted to specific life stages and provide something that is limiting to the growth and survival of that life stage.

Specifically, in the NODA and supporting document ("Estimating Total and Nonuse Values for Fish, Based on Habitat Values for Coastal Wetlands and Eelgrass (SAV)", DCN 5-1010), EPA has failed to identify appropriate restoration/enhancement techniques that would provide net gains in species productivity for winter flounder and pollock. As the amount of habitat needed to offset I&E losses is based on an inappropriate choice for winter flounder, the scales of habitat restoration used in the NODA analysis are unsubstantiated and overstated.

Winter flounder

EPA assumes winter flounder populations would be enhanced by tidal wetland restoration. However, as EPA itself acknowledges in the Section 316(b) Existing Facilities Benefits case Studies (Appendix A and in Chapter F3 of the Brayton Point case study), winter flounder do not prefer or rely on tidal wetlands (salt marshes) for completing their life cycle. The eggs, which are adhesive and demersal, are usually found on mud, sand or gravel bottom, with sand being the most common substrate (Pereira et al. 1999). Presence of vegetation may or may not be a factor in selection of spawning location. In Point Judith Pond, Rhode Island, the greatest concentration of eggs was found in the vicinity of a tidally submerged gravel bar with eggs clumped on gravel substrate or attached to fronds of algae (Crawford and Carey 1985; Pereira et al. 1999). Highest densities of newly settled winter flounder have been found on muddy substrates (Saucerman 1990; Howell and Molnar 1995; O'Connor 1997; Pereira et al. 1999). Larvae are often found near fine sand and gravel. There is also a high degree of variability in the habitat utilization of young-of-the-year (YOY, Goldberg et al. 2002). Some studies have found winter flounder YOY to be more abundant on unvegetated substrates (Sogard and Able 1991; Sogard 1992), while others have found them to occur in a variety of habitats, including seaweeds (Able et al. 1989), marsh creeks (Rountree and Able 1992) and to a lesser extent eelgrass (Goldberg et al. 2002). Adult winter flounder are found primarily on mud, sand, cobble, rocks or boulders (Pereira et al. 1999). Although winter flounder may be found in salt marshes, no stage of their life history appears to be linked specifically to salt marsh habitat. Therefore, the productivity of the species would be unlikely to exhibit significant changes due to salt marsh restoration. Thus, EPA's choice to restore tidal wetlands in order to mitigate winter flounder is inappropriate.

Winter flounder are limited in production by fishing, predation and other sources of mortality, not by availability of wetland habitat. Winter flounder age 3 and older are over-fished, and are limited by fishing mortality (NFSC 2003). Additionally, cormorants, jellyfish, and other predators have increased exponentially throughout northeast US waters over the last 20 years, which is undoubtedly reflected in higher mortality rates. Potentially, food resources could be limiting, particularly to younger stages. Thus, appropriate restoration techniques would need to decrease mortality, such as by reducing fishing pressure or predation, or provide food resources to increase growth. Provision of saltmarshes for winter flounder to inhabit, along with other more preferred habitats, would do nothing to increase winter flounder stocks. However, saltmarsh might increase food resources that indirectly increase survival and/or growth of winter flounder. In this case, the appropriate scale of restoration would be based on net gains due to increased food production, not abundance observed in saltmarshes, as proposed by EPA (see discussion below).

Pollock

EPA assumes pollock populations would be enhanced by eelgrass (SAV) restoration. However, pollock do not prefer or rely on SAV for completing their life cycle. Spawning occurs over hard substrate near coastal slopes and banks, and the eggs and larvae are pelagic and free floating, being found in depths of 50-250 m (Hardy 1978; Cargnelli et al. 1999; Collette and Klein-MacPhee 2001). Juveniles have been found over a variety of substrates, including sand, mud, or rocky bottom and vegetation (Hardy 1978). In southern New Jersey, YOY were prominent in spring collections in subtidal marsh creeks (Cargnelli et al. 1999), but have shown no sign of relying on eelgrass. Adult pollock are unselective of bottom type, and are often associated with sediments ranging from gravels to clay (Scott 1982; Cargnelli et al. 1999). The productivity of the species would be unlikely to exhibit significant changes due to SAV restoration. Thus, EPA's choice to restore SAV in order to mitigate pollock is inappropriate.

Other Species

Similar arguments could be made for other species, even if certain life stages inhabit tidal wetlands or SAV (as EPA has selected as the preferred alternative) at some time of the year. The observation of a species in a particular habitat does not infer that it is dependant on the habitat, or, more importantly, that the species' production will be enhanced by restoration of the habitat. The species' production may be limited by factors unrelated to habitat availability, such as over-fishing, conditions during over-wintering, predation, etc. If in fact, for example, a life stage is limited by food availability, and the restored habitat increases food available to the target species, then the restoration choice might be appropriate (although not necessarily the more efficient approach to enhance the target species). For example, bluefish do not prefer or rely on tidal wetlands, spending a large portion of the life cycle (i.e., as eggs, larvae, and adults) in the open ocean. Juveniles have been observed to feed on forage fish, which in turn are sometimes associated with wetlands (Fahay et al. 1999). Thus, there is a potential that wetlands would increase fish prey production and so food supply for bluefish. However, the net gain to bluefish production is not equivalent to the observed abundance of that species in or near wetlands.

EPA Response

In the HRC case studies presented at proposal, each species with quantified I&E losses was assigned to a restoration alternative from among the following categories: SAV restoration, tidal wetlands restoration, artificial reef creation, increase fish passages, improve water quality, and improve water quality/reduce fishing pressure. The assignment of each species reflected the consensus of a panel of local experts about which single action would most benefit the species in the general habitat where the I&E losses were being experienced.

For example, for the Brayton Point Station HRC analysis, the focus was on actions that could be taken in the waters of, and connected to Mt. Hope Bay and Narragansett Bay. These assignments were made recognizing that local fish populations could be experiencing population pressure from other sources (e.g., commercial fishing) and that some species could benefit from a range of actions. However, to complete the HRC scaling selection of a single, preferred restoration action was required.

With this focus on incorporating local knowledge and information, it is possible that species assignments to particular categories of restoration actions could contradict findings from other regions regarding species habitat use and preferences. However, selecting a preferred restoration alternative based on information on local habitat utilization and constraints is entirely appropriate and should be a component of any reasonable restoration efforts aimed at offsetting local impacts.

Finally, EPA disagrees with the commenter's concerns about some of the specific habitat assignments made by local experts. For example, EPA notes that the commenter recognizes that for winter flounder there is “a high degree of variability in the habitat utilization of young-of-the-year (YOY, Goldberg et al. 2002)”. The commenter also notes that YOY are also found in marsh creeks (Roundtree and Able, 1992). EPA believes that this demonstrates that emphasis should be placed on the habitat use of local populations.

Further, EPA disagrees with the commenter's objection to the selection of tidal restoration for winter flounder given the observation that winter flounder are found in sub-tidal creeks (i.e., marsh creeks) which are a feature tidal wetlands (personal communication K. Raposa, Narragansett Estuarine Research Reserve, 2001, DCN # 4-1763).

Use of Replacement Costs (HRC and hatchery-based)

Improper Use of Abundance data to Estimate Production: In the NODA examples, which are based on analyses in the proposed rule, EPA has failed to properly calculate the net production gained by habitat restoration/enhancement techniques. In particular, EPA incorrectly used abundance as a proxy for production. The correct methodology is to use production foregone on the loss side of the equation, and balance this with production gained by all age groups owing to the restoration. To quantify the net gain in production, EPA must develop estimates of the increased production rate in the restored habitat as compared to the habitat that previously existed, and also account for any losses of production due to the restoration activities themselves. This is normally done by population modeling, or at the ecosystem level using food web modeling. If EPA intends to perform the calculation on a species by species basis, it needs to develop population models for each species and identify the limiting factor(s) to each population. The restoration alternative would need to address the limiting factor(s) and ameliorate them. EPA has not performed such an analysis, and instead has incorrectly assumed that presence in the habitat infers limitation by that habitat, as well as that production gained is numerically equivalent to abundance measured by field samples. This use of abundance data is inappropriate and unreliable to estimate production.

[The text above is from the summary on page 3. The text below can be found on pages 7-8 of the comment letter.]

Improper Use of Abundance data to Estimate Production

While production is the appropriate scalar for measuring the gains of restoration, EPA has stated that data are lacking and so has used instead abundance estimates, corrected to age-one equivalents, as measures of production (p. 13569 of the NODA, as well as in Chapter F5-5 of the proposed rule). In other words, they have implicitly assumed both that the habitat is limiting to production and there is a 1:1 ratio between biomass and production (biomass being the standing stock or abundance of certain life stages at a given instant in time). Furthermore, EPA implicitly assumed that the standing stock is not turned over in time, and that those individuals observed at the sampling time are all the individuals that will be produced that year at that age sampled.

An analogy that illustrates the problem of using standing abundance as a proxy for production is as follows. If replacement income is sought for a person loosing his job, it is the annual salary that should be replaced. The quantity of dollars present in that person's wallet at any one time (when someone happened to query him) may be larger if their salary is larger, but there is not a one-to-one equivalence between his income and the amount in his wallet on a single day, or even with the average of what is in his wallet on a random sampling of days. Only if the person is paid his annual salary on one day of the year, if he places all of that salary in cash in his wallet, and if the sampling is made on the day he takes home his money, will the standing amount in this wallet be equivalent to annual salary.

Assuming that the habitat is in fact limiting to production of a species, the assumption of a production-to-biomass ratio of 1:1 is invalid for short-lived species that reproduce multiple times a year or at varying times during the year, such as for many of the forage fishes. Also, if a species has a protracted spawning period, such that individuals pass through a life stage using a particular habitat at varying times, the snap-shot standing abundance at any given time would not capture all the production in the habitat. If in fact the habitat were limiting to production, all life stages in the population use the same habitat, and the species spawns over a limited season, the standing abundance could be indicative of annual production of age-one equivalents. However, life histories of the species being considered are not this simple, making the assumption that production equals abundance invalid.

The details of the data used for estimating production from abundance for I&E species are not provided in the proposed rule documentation (nor in the NODA). Based on the standard life stage tables for the I&E species, it is apparent that abundance does not measure all the production for most (if not all) I&E species:

- The I&E species spawn over at least three months, and many species have more protracted spawning periods (Appendix A and Chapter F3 of the proposed rule). Thus, there is turn-over of individuals, with new individuals replacing those moving into older stages. The assumed age of the animals for the abundance data used has not been documented, and the uncertainty introduced by error in this assumption, as well as by the mortality rate estimate for the remainder of the first year of life, would be extremely large.

- Winter flounder do not preferentially use salt marshes as nursery grounds. Thus, the abundance observed in salt marshes is not indicative of production gained, as animals likely move in and out of the habitat sampled. Certainly the abundance in open water habitat is not indicative of production in tidal wetlands, as erroneously assumed by EPA.

- Forage fish such as stickleback, reproduce at varying times of the year, and predation rates are high, making a standing stock abundance at a single time a poor indicator of annual production.

The correct methodology is to use production foregone on the loss side of the equation, and balance this with production gained by all age groups owing to the restoration. If survival is increased from the sampled stage to age-one equivalents, or if production of older age classes is improved, the use of abundance corrected to age-one equivalents using the same survival rate as in less advantageous habitat provides an underestimate of the net gains of the restoration. While data are lacking in the form of production rate per unit area, estimations may be made using population modeling.

If young-of-the-year (YOY) abundance data are used to estimate age-one equivalent production per unit area of habitat, it is important to take into consideration the seasonal pattern of the species of spawning and development. It is not accurate to assume that abundance from any time of the year is indicative of production, because of the sampling of different age cohorts and potential turnover of individual over time. Again, the correct methodology is to estimate production over the life span of the individuals gained by the restoration.

Finally, it appears that EPA assumed that all the abundance observed in existing tidal wetlands and SAV would be a net gain in production if the habitat were created. In fact, the habitat would be an alteration of existing habitat, meaning that production associated with the habitat in its current form would be replaced by the new habitat's production. In the case of SAV, eelgrass would presumably be planted in unvegetated shallow waters. The tidal wetlands projects considered in the proposed rule were to alter Phragmites-dominated wetlands to Spartina-dominated saltmarsh. Because these types of habitat alterations would produce both losses and gains, they may not ultimately have the desired effect in enhancing the target species fish production, as I discussed in more detail in my 5 August 2003 letter commenting on the proposed 316(b) rule. This uncertainty needs to be considered by EPA.

EPA Response

Please see EPA's response to Comment 316bEFR.029.113 regarding EPA's assumption that abundance can be a reasonable proxy for production.

Use of Replacement Costs (HRC and hatchery-based)

Author Name Deborah French McKay

Organization Applied Science Associates, Inc.

Using the Maximum Acreage for Any Single Species Offsets Much More than the I&E Losses and Fails to Account for All Ecological Services Provided by Habitat Restoration/Enhancement Projects: EPA has proposed using the maximum calculated acreage required to offset a single species as the basis for the scale of restoration (p. 13569 of the NODA). This greatly over-compensates for other species losses, if one-for-one replacement in kind is required, and fails to recognize that most of the ecological services provided by I&E losses are as food to the marine food web. The purpose of habitat restoration/enhancement should be to provide a net improvement in fish production and not to offset each individual one-for-one with the same species affected by I&E. One-for-one replacement would only be warranted if the population is limited by the size of the spawning stock. If abundant eggs are produced by the spawning stock, such that the population is limited by other factors other than the supply of new eggs to the population, one-for-one replacement of that species is not needed.

[The text above is from the summary on page 3-4. The text below can be found on pages 8-9 of the comment letter.]

Using the Maximum Acreage for Any Single Species Offsets Much More than the I&E Losses and Fails to Account for All Ecological Services Provided by Habitat Restoration/Enhancement Projects

EPA has failed to account for the full range of ecological services provided by the proposed restoration techniques. EPA's approach begins from the assumption that all individuals need to be replaced in kind. However, a given restoration technique can provide many services, including increasing productivity of other species of similar ecological role to the target species. These services also mitigate the losses associated with I&E. As a result, EPA's approach would lead to significant overcompensation of the overall losses due to I&E.

Continuing with the winter flounder example: some of the services of winter flounder larvae are to become prey to larger organisms. Those larger organisms are flexible enough to eat other species of prey, as is the case for most marine predators. Thus, the prey service provided by (age-one) winter flounder can be replaced by production of another or several equivalent prey species. The replacement of winter flounder need only be enough to provide services unique to that species, i.e., larger winter flounder that survive the predation and fishing pressure and contribute to the next generation via reproduction. To the extent that a restoration plan is scaled to produce 100% of the winter flounder lost due to I&E, and also produces additional amounts of equivalent prey species, there will be overcompensation for the lost winter flounder.

The same point would be made for other species. Some of the services of the species and life stages entrained and impinged are to repopulate the local spawning and fishery stock of that species, while other individuals serve as prey to the food web. As most marine animals are opportunist feeders, replacement of similar sized fish prey would replace those ecological services. Thus, it may be argued that much (if not all) of the mitigation should be in the form of increased production of similar prey to those lost to I&E. This approach has been used in the restoration of many species injured by the North Cape oil spill in Rhode Island (French et al. 2001), and in other NRDA cases, as well as development mitigation projects in development projects.

The basic approach is to select a biological restoration or enhancement activity that will provide a net gain in terms of fish production, such as creating seagrass beds or wetlands (salt marsh) that provide habitat and food services to fish, such that there is a net increase in the total fish production of the ecosystem. Seagrass and wetlands have been shown to be more productive in terms of weight of fish produced per unit area than unstructured habitats. However, because some species prefer open bottom, while others prefer these structured habitats, the net fish production gain may not be of the same species as the losses. It may nonetheless be appropriate if it results in production of similar sized fish which provide ecological services to the food web, as well as other ecological and human (fishery) services, and so this is compensatory to the losses (French McCay et al. 2001).

EPA Response

The HRC analyses conducted for proposal are not used to estimate benefits for the final rule. Additional information on the HRC method and its uses is provided in the document entitled "Habitat-based Replacement Cost Method" (DCN #6-1003).

RFC: Performance/effectiveness of restoration

Author Name Deborah French McKay

Organization Applied Science Associates, Inc.

Documentation of Sources and Magnitude of Uncertainty: The use of restoration to mitigate some or all of I&E losses makes good biological and management sense. However, the replacement of specifically-identified species one-for-one and in-kind by habitat restoration would be difficult to quantify (because of the limits of biological knowledge on the species of concern) and highly uncertain. In view of this uncertainty, EPA should be clear in its allowance of flexibility in the choices of restoration options, including projects that (1) reduce mortality to fishing and other causes, (2) replace missing individuals using restocking techniques, or (3) provide equivalent ecological services. This flexibility should be provided in the case examples as well, so as not to provide a model for inappropriate restoration choices.

[The text above is from the summary on page 4. The text below can be found on pages 9-10 of the comment letter.]

Documentation of Sources and Magnitude of Uncertainty

The use of restoration to mitigate some or all of I&E losses (p. 13541-13543 of the Federal Register notice for the NODA) makes good biological and management sense and I am supportive of EPA's proposal in concept. However, the replacement of specifically-identified species one-for-one and in-kind by habitat restoration would be difficult to quantify (because of the limits of biological knowledge on the species of concern) and highly uncertain. As a result, EPA's new proposal that applicants must document the sources and magnitude of uncertainty, while an appropriate goal, is in practice likely only to be possible qualitatively, as anticipated by EPA on page 13542 of the NODA. It is very difficult to determine what is limiting a population, to link production to a specific habitat restoration approach, and to quantify the benefits to the species of a habitat restoration project. In the case of winter flounder, such documentation would be impossible to obtain if wetland restoration is used. Thus, EPA will need to be flexible in applying any such requirement and the considerations will need to be site- and species-specific.

Furthermore, in view of the uncertainty of habitat restoration in increasing fish production for specific target species, EPA should be clear in its allowance of flexibility in the choices of restoration options. In particular EPA should make clear that restoration options can include projects that (1) reduce mortality to fishing and other causes, (2) replace missing individuals using restocking techniques, or (3) provide equivalent ecological services.

As fishing mortality is high and limiting to many I&E species, it is more likely that addressing this major limitation to population size will be successful in increasing species production than habitat restoration. One way to reduce harvest is to provide alternatives for fishermen and consumers. This might involve stocking (or culture) of the same or alternative species or restoration to increase fish production generally, and thereby decrease fishing pressure on the target species of concern.

The use of appropriately designed restocking programs is more certain than habitat restoration when aiming at specific species. Restocking directly addresses the lost use as a fishery, which, for example, is a particular concern for winter flounder for which tidal wetland restoration would be of little use. In my previously-submitted comments on the proposed rule (dated 5 August, 2003), I have discussed use of and uncertainties of restocking and its potential as an alternative to restore I&E species. In addition, restocking might be implemented in conjunction with habitat enhancement to increase the production of the target species.

The use of a biological restoration or enhancement activity that will provide a net gain in terms of fish production generally, to offset I&E losses, was discussed in section 3 above. The fish and other biological production gained need not be entirely one-for-one in kind with I&E losses if the ecological and human services of the I&E individuals are replaced. Services of food production for predators, including humans, may be met with similar species that function in ecologically similar ways (e.g., are of the same trophic level). The documentation of uncertainty would be much more direct, involving the uncertainty of successful habitat restoration that would be expected to provide fish and invertebrate production. There is considerable established practice in the documentation of success for habitat production (e.g., for SAV see Fonseca et al. 1998).

EPA Response

EPA believes there are uncertainties associated with the design, implementation, performance and assessment of restoration measures. For a discussion of these uncertainties, see EPA's response to comment 316bEFR.206.055.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

For a discussion of the need for quantitative analysis in the restoration measure context, see EPA's response to comment 316bEFR.202.035.

EPA believes the requirements for restoration measures provide permitting authorities and permit applicants with flexibility. However, any restoration measure must meet all of the requirements described in the final rule.

Adaptive Management: While using an adaptive management plan for the restoration project's) is a worthy goal; in practice it will be very difficult. EPA should be flexible in its requirements for restoration options, monitoring and adaptive plans.

[The text above is from the summary on page 4. The text below can be found on pages 10-11 of the comment letter.]

Adaptive Management

While using an adaptive management plan for the restoration project's) is a worthy goal; in practice it will be very difficult, for many of the same reasons outlined in the foregoing sections. Having to show and quantify the benefits to individual I&E species, and adapt the plan as monitoring proceeds, will have many practical limitations and in some cases will be virtually impossible. Because of this, a strict application of adaptive management principles could prove highly discouraging to the use of restoration.

Each species would need to be studied and monitored in detail, including demonstration of the enhancement of species production over and above the baseline condition had the restoration not been performed. Thus, detailed understanding of changes in the populations would be required as fishing mortality and other ecologically-relevant changes ensued. The language EPA has suggested is somewhat vague on what would be required, perhaps appropriately so, but this will likely lead to protracted disagreements and may well discourage the use of restoration all together, which is not a desired result. It would be more realistic to be more specific in the goals of the project, such as to restore so many acres of habitat to a certain level of functionality, or to provide fish ladders with specific performance standards (etc.), than to require strict demonstration of the maintenance of a species in a water body at a level that would have been achieved under section 125.94.

EPA Response

EPA believes there are uncertainties associated with the design, implementation, performance and assessment of restoration measures. For a discussion of these uncertainties, see EPA's response to comment 316bEFR.206.055. The use of adaptive management is intended to help reduce uncertainties associated with restoration measures and enhance their overall productivity (see EPA's responses to comments 316bEFR.307.047 and 316bEFR.311.022).

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

EPA believes the requirements for restoration measures provide permitting authorities and permit applicants with flexibility. However, any restoration measure must meet all of the requirements described in the final rule.

RFC: Performance/effectiveness of restoration

Independent Peer Review: The use of peer reviewers is appropriate in principle. However, it is highly likely that the reviewers will comment that the project benefits are uncertain and they will not provide any easy answers for EPA, states and others involved in reviewing restoration proposals.

[The text above is from the summary on page 4. The text below can be found on page 11 of the comment letter.]

Use of Peer Review

The use of peer reviewers is appropriate in principle. However, if habitat restoration is proposed to offset specific species' lost production, it is highly likely that the reviewers will comment that the project benefits are very uncertain. The level of uncertainty may also result in outside reviewers being more influenced by their biases of what they would like to see happen, than what would be scientifically advisable. Reviewers would be more likely to agree with general rather than species-specific goals, for example to the concept that wetlands and SAV increase fish production in general as this is well accepted. In addition, consideration of the effects of restoration by trophic level, rather than by individual species -- an approach used in NRD restoration, as noted above -- may make peer review more effective. In any event, , peer review will not provide any easy answers for EPA, states and others involved in reviewing restoration proposals.

EPA Response

EPA believes there are uncertainties associated with the design, implementation, performance and assessment of restoration measures. For a discussion of these uncertainties, see EPA's response to comment 316bEFR.206.055. The use of peer review in intended to help reduce uncertainties associated with restoration measures and enhance their overall productivity (see EPA's responses to comments 316bEFR.307.047 and 316bEFR.311.022). Peer review provides a useful tool for bringing current and specialized expertise to bear on the use of a restoration measures. This is particularly important given the continued progress restoration science continues to make.

EPA believes restoration measures may not be appropriate for every site, in some cases because of uncertainties about the design, implementation, performance and/or assessment of the measures. EPA believes it is best for all parties to consider the uncertainties and discuss potential solutions before investing substantially in a particular restoration measure. This process is also important because of the potential limits, both practical and within the structure of the final rule, on the resources available for implementing restoration measures. This limit in the final rule is a function of a permit applicant's ability to apply for a site-specific performance standard should costs of compliance with the requirements of the final rule exceed the costs estimated by EPA.

In the final rule, the permitting authority has the flexibility of determining the necessity of independent peer review.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

EPA believes the requirements for restoration measures provide permitting authorities and permit applicants with flexibility. However, any restoration measure must meet all of the requirements described in the final rule.

RFC: Three-option framework for determining BTA

BTA Determination

We wish to reiterate our preference to a site-specific approach to implementing 316(b). The EPA's proposed process of determining BTA is flawed in that it appears to only allow for demonstration of BTA by meeting specific percentage reductions in fish impingement mortality and total entrainment numbers, or demonstration that costs of meeting that reduction would be significantly greater than its benefits. The process as proposed is inappropriately skewed toward the application of engineering controls for determining BTA. It still makes no allowance for a demonstration that the plants may have been historically operating for decades without a demonstrable adverse impact on populations of fish in the adjacent waterbodies. It also fails to recognize that certain plants may even have a positive effect on local and regional fish communities that is appreciated by the human population. Our plants, and others, have been extensively studied over the years. Those results have been scrutinized by regulators at the state and federal level as well as the lay public, as we described in our earlier response, and found acceptable.

Our studies, as have studies at other stations, have demonstrated that the plants have not caused adverse environmental impact (AEI) when judged in relation to the definition proposed by EPRI and UWAG: "adverse environmental impact is a reduction in one or more representative indicator species that 1) creates an unacceptable risk to a population's ability to sustain itself, to support reasonably anticipated commercial or recreational harvests, or to perform its normal ecological function and 2) is attributable to operation of the cooling water structure." We are dismayed that EPA did not define or address AEI in the NODA and we would hope that such a definition will appear in the final regulation. We would then expect that AEI would be used as the yardstick on a case by case basis to make the 316(b) determination.

EPA Response

EPA notes that the final rule includes a site-specific compliance alternative. Please refer to the preamble for more information.

EPA disagrees that the rule is "skewed toward the application of engineering controls for determining BTA." Under four of the five compliance alternatives in the final rule, a facility is potentially able to demonstrate that its existing intake technology meets the performance standards. As examples: 1) a facility with an existing closed-cycle cooling system meets the standards under the first alternative; 2) a facility demonstrates that its existing intake technology meets the standards under the second alternative; 3) a facility that has an existing approved technology and the appropriate set of site conditions meets the standards under the fourth alternative; and 4) a facility can seek a site-specific demonstration that its existing technologies meet the performance standards under the fifth compliance alternative.

However, EPA does not wish to imply that most or all facilities in the above scenarios will meet the performance standards. To the contrary, a goal of today’s rule is to set national minimum performance standards that reflect the best technology available for minimizing adverse environmental impacts. Given that previous determinations of best technology available were not made in reference to the national performance standards, EPA believes that the Director should not rely entirely on historical determinations. EPA believes that today's performance standards will promote more effective and consistent implementation of section 316(b) requirements, and ultimately minimize adverse environmental impacts associated with the use of cooling water intake structures by Phase II existing facilities.

Entrainment survival chapter

We also note with dismay that EPA still does not accept the principle of entrainment survival in its calculations despite numerous studies that prove that many organisms can successfully survive the entrainment process, just as many fish are known to survive impingement. In our opinion there is no rationale for ignoring the results of numerous entrainment survival studies that have been conducted at great expense to advance the knowledge base concerning power plant effects.

And we note that the principles of compensation and density dependence are still not recognized despite being recognized by the scientific community and intuitively obvious to nearly all except the staunchest opponents of power plants. These principles should also be incorporated into the final regulations.

As EPRI is submitting a rigorous defense of survival, compensation, and density dependence and other technical issues in their detailed comments, we will not address them further here. We have participated with EPRI in the preparation and review of their analyses, and support Peru's detailed comments. We also support the comments supplied by EEI and UWAG.

EPA Response

Please see response to comment 316bEFR.305.001 with regard to entrainment-based performance standards. Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis. Please see the response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule. Please see the response to comment 316bEFR.025.015 for the discussion regarding density dependent compensation.

Benefit Estimation Methodology

The calculation of the economic benefits and costs of applying BTA play a crucial role in whether or not existing facilities would qualify for site-specific BTA determinations. In addition, the manner in which the economic calculations are considered in the decision process is also critical to which technologies might be required for the site-specific cases. We remain concerned that EPA has employed inappropriate methodology and models in development of their economic criteria. For instance, EPA appears to have employed avoided costs as a measure of benefits, which assumes that individuals would voluntarily pay those replacement costs.

EPA Response

The avoided costs methods are not used in the cost benefit analysis for the final Section 316(b) Phase II rule. For EPA's response to comments on the HRC method, please see response to comment #316bEFR.005.035. In addition, EPA no longer uses hatchery costs to estimate impacts on forage species. Instead EPA translates foregone production among forage species into foregone production among harvested species that are impinged and entrained using an assumed trophic transfer ratio, and then translates foregone production among these harvested species to foregone yield. Further information on the methods EPA used to estimate forage losses is provided in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003). See Chapter A5: Methods Used to Evaluate I&E.

Valuing Forage Species (incl non-use and non-landed)

We particularly question non-use valuations and the assumptions behind them and do not believe them to be supported in the literature or in practice.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN #6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Comment ID 316bEFR.313.005

Author Name A. Christopher Gross

Organization KeySpan Corporation

Subject Matter Code 9.0

Costs

We also question the validity of using habitat replacement costs to measure benefits, but agree that habitat enhancement is a valuable tool that could be used to offset any demonstrated adverse impact of plant operation. In general, it seems basic economic principles have been misapplied or rigged to produce the desired result. It would seem to be more appropriate to apply actual costs of production lost against mitigation costs. And finally, we believe that EPA has seriously underestimated the costs of providing off-stream cooling (now apparently off the table, we are pleased to note) or other mitigative measures to plants located on saline waters. Once again, we will leave the detailed analyses and critique of the economic analyses to the comments that will be provided by EPRI, UWAG and EEI

EPA Response

Under the final rule, the Agency allows use of restoration measures to minimize or to help to minimize adverse environmental impacts deriving from impingement and entrainment of aquatic organisms.

Regarding the costs of providing "off-stream cooling", the Agency does not base the requirements of the final rule on closed-cycle recirculating wet cooling towers (referred to as "off-stream cooling" by the commenter). EPA notes that the commenter provides no evidence or any detailed discussion of how it believes the Agency has underestimated the costs of "other mitigative measures" for plants located on saline waters. The Agency believes that it has provided reasonable estimates for the difference in costs between fresh and saline waters for the mitigative technologies forming the basis of the final rule. See the Technical Development Document for detailed information related to the Agency's methodology for estimating the costs of mitigative technologies other than cooling towers and the incorporation of costs for plants located on saline waters.

While the Agency agrees that the HRC and hatchery costs are costs of replacement and not benefits, the Agency believes that understanding what it would cost residents in an area to replace CWIS losses could be a very useful tool in the regulatory process and also informs decisions on the use of restoration. The HRC like the HEA is a process that requires the analyst to systematically evaluate the losses caused by a CWIS, quantify them, and then consider the steps that would be necessary to replace these individuals and species. The species by species consideration of losses, even if not monetized, could be a useful tool in considering the environmental effect of CWIS losses. For further detail on the HRC method, please see EPA's response to Comment 316bEFR.005.035 and the document entitled "Habitat-based Replacement Cost Method" (Docket #6-1003).

Subject Matter Code 21.09

Permit applications/implementation schedule

Author Name A. Christopher Gross

Organization KeySpan Corporation

We are still unsure of the sequence and timing of activities required on the part of the applicant and the agency to demonstrate and determine BTA for a plant. We again submit that demonstrations of compliance should be triggered by incorporation of such a requirement in the NPDES permit renewal process. In other words, if the permit administrator or his designee, upon review of the applicant's renewal application, determines that the applicant's CWIS may not be BTA, the issue could be addressed through a formal process and, if necessary, the permit could be modified to include a condition that the applicant then demonstrate, through studies or other means, that the CWIS is BTA. Absent such a process, the applicant would have to presume that his CWIS might not meet the BTA standard and would preemptively, and perhaps unnecessarily, expend considerable time, effort and resources on a speculative assessment of risk. He might also have to initiate studies prior to the regulations becoming final in anticipation of providing a BTA demonstration at his next NPDES permit renewal application when, in hindsight, such actions may be determined to have not been necessary.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

EPA has also provided a tremendous degree of flexibility by offering four compliance alternatives and a site-specific determination of BTA with varying study requirements. Please see response to 316bEFR.034.005 for details.

Director's role in determining requirements

Author Name A. Christopher Gross

Organization KeySpan Corporation

We must assume that the proposed rules are intended to be implemented by EPA or designated representatives on a consistent national or regional basis. We are concerned that individual state permit administrators will not be constrained by the proposed rules but may use them as a stepping stone to ratchet up restrictions on an applicant. With deregulation of the industry this could put certain regions or companies or individual plants at a competitive disadvantage, which could ultimately create an adverse impact upon electric reliability and cost to the consumer. We urge that EPA require consistency of approach and evaluation on a national or at least regional scale. Failing such a leveling of the playing field, local regulators may advance individual agendas, which could cause excessive energy costs and diminish energy reliability without commensurate improvement to aquatic populations.

EPA Response

Please refer to EPA's response to comment 316bEFR.027.008.

Comment ID 316bEFR.313.008

Miscellaneous comment

We certainly appreciate the effort that EPA has put into producing the proposed regulations. However, the proposed regulations and information provided by the NODA document leave many questions unanswered and they still do not allow applicants to consider scientifically verified aspects of natural population dynamics such as entrainment survival and compensation. We respectfully submit that any regulation that will significantly affect the cost and reliability of electrical energy must incorporate the best scientific information available, not ignore it. We are concerned that the proposed regulation does not do so; instead, it will raise costs to achieve benefits that good science suggests will be illusory.

EPA Response

Please see response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality for the benefits analysis for this rule. Please see response to comment 316bEFR.025.015 for the discussion regarding density dependent compensation. Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analyses.

Streamlined Technology Option

ACC Supports The Identification Of Streamlined Or Preferred Technologies That Would Be Designated As the Best Technology Available For Certain Intakes

ACC concurs with EPA that the Comprehensive Demonstration Study required in the Phase II proposed definition could represent significant costs. Permittees should not be required to demonstrate that the Best Technology Available (BTA) is indeed BTA for each facility. Many of ACC's members have small intakes (< 50 MGD) on large rivers and estuaries and will therefore be primarily regulated under EPA's forthcoming Phase III rules. In these situations, the Comprehensive Demonstration Study could represent a significant portion of the total compliance cost to be borne by both small businesses and larger facilities in a competitive chemical manufacturing sector in the US. We recommend that EPA continue gathering data on the performance of cooling water intake structure (CWIS) technologies and determine whether a certain BTA exists that is capable of meeting the proposed impingement and entrainment reduction requirements.

With respect to BTA and streamlined alternatives, we maintain that EPA should consider design factors, aside from technologies, which may provide equivalent protection to the environment. Design factors could include intake placement, intake orientation relative to stream flow, intake velocities and stream velocities. For example, a facility cooling water intake flow that constitutes less than 10% of the stream flow, and has an acceptably low intake velocity, may not warrant the technologies required of larger intakes.

EPA Response

For the purpose of today's final rule, the performance standards set by EPA reflect best technology available (BTA). For an explanation of why the performance standards represent BTA, please see the final rule preamble section VII. 2. Because EPA has provided enormous flexibility for facilities in how they might opt to achieve BTA, EPA disagrees that permittees should not have to demonstrate BTA at their facilities. Furthermore, EPA has included the option of a Technology Installation and Operation Plan, by which a facility, with the approval of the Director, may demonstrate compliance with the rule by showing that it has installed, and is properly operating and maintaining protective technologies.

In response to the comment that EPA should consider design factors when establishing BTA and streamlined alternatives, EPA agrees. The structure of today's final rule considers factors such as waterbody type, capacity utilization rate, intake flow rate, ambient biological and physical conditions, cost, and existing technologies when establishing BTA for a given facility. Furthermore, EPA has provided any interested party the means to submit to the Director for approval an alternative approach for complying with today's rule. For additional details on the Approved Design and Construction Technology option (commonly referred to as the "streamlined technology"), please see the final rule § 125.99(b), and EPA's response to comment 316bEFR.306.062.

RFC: Three-option framework for determining BTA

EPA Should Give The Permittee The Greatest Possible Amount Of Flexibility To Meet The Regulations, So That Cost-Effective Solutions Can Be Implemented

EPA should not place constraints on the technology options a permittee can evaluate to meet the requirements of the regulations. If a site specific alternative shows that an existing intake has a minimal adverse environmental impact, the permittee should not be required to provide additional technology, regardless of the cost considerations. EPA should allow the greatest possible amount of flexibility to meet the regulations, so that cost-effective solutions can be implemented.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative. Please refer to the preamble for more information. With regard to the commenter's statement on "minimal adverse impact," EPA notes that the site-specific determination of best technology available would include a consideration for costs and benefits and if the facility was found to be employing the best technology available for minimizing AEI, then no further technologies would be required.

If the commenter was referring to a facility that purportedly has a history of minimal or no adverse environmental impact, then please refer to the response to comment 316bEFR.313.001 for more information on EPA's position on minimum impacts at existing facilities. EPA disagrees that a determination of whether an adverse environmental impact is occurring is a preliminary step in implementing 316(b).

RFC: Performance/effectiveness of restoration

Author Name Joe Mayhew & Tony Wagner

Organization American Chemistry Council

Independent Peer Review Will Add Unnecessary Expense And Delay

A peer review requirement for restoration projects will certainly increase the expense of restoration projects and most likely will delay implementation. In most cases it is likely that a permittee will propose a restoration plan developed with the aid of consultants or experts in the field. The requirements for restoration plans already contain safeguards to ensure that the project will achieve its goals. The Director should have the ability to review the restoration plan and approve or request additional information without an additional layer of review.

EPA Response

Under the final rule, the permitting authority has the flexibility to determine the need for independent peer review of a restoration measure. For additional discussion of peer review, see EPA's response to comment 316bEFR.312.006.

Organization American Chemistry Council

Subject Matter Code 7.02
Performance standards

Use Of A 3/8-Inch Mesh Size Traveling Screen As A Baseline Condition Is Inappropriate

ACC believes that EPA should not require 3/8-inch traveling screens as part of the baseline condition. A traveling screen is a sophisticated technology system that will reduce impingement/entrainment of fish on the intake screen. Facilities that already have this system should be entitled to take "credit" for this technology. The baseline condition should not consider components of the intake structure beyond a trash rack/bar screen.

EPA Response

EPA disagrees that the use of a 3/8-inch mesh screen as part of the baseline calculation is inappropriate. This allows a more consistent estimation of the organisms that are considered "entrainable" vs. "impingeable" by specifying a standard mesh size that can be related to the size of the organism that may potentially come in contact with the cooling water intake structure.

EPA disagrees that a traveling screen alone can be considered a "sophisticated" technology system with regard to reducing impingement mortality and entrainment. Entrainable organisms are generally smaller than 3/8 of an inch and would not be affected by a standard 3/8-inch traveling screen. Credit, as discussed by the commenter, would not apply. Similarly, impinged organisms typically need additional measures to ensure their safe return to the source water, such as lift buckets, fish return troughs, low-pressure spray washes, etc. EPA believes the calculation baseline presented in today's final rule is appropriate.

Performance standards

"As Built'' Approach To Determining Calculation Baseline

ACC supports the idea of flexibility in determining compliance with the rule's requirements. However, it is extremely difficult to quantitatively measure impingement in many situations. An example would be a submerged intake in a deep channel of a river. The theoretical baseline method will also be problematic. In these cases, 316(b) permitting requirements and compliance should continue to be determined on a case-by-case basis, at the discretion of the Director. ACC also supports the flexibility to allow a facility to use sampling data from other nearby facilities to calculate its baseline, assuming the data can be reasonably extrapolated to the facility (i.e., similar technology used, similar intake volumes, etc.).

EPA Response

Please see response to comment 316bEFR.314.005.

Comment ID 316bEFR.314.006

Author Name Joe Mayhew & Tony Wagner

Organization American Chemistry Council

Subject Matter Code 21.04

Determination of compliance

Options for Evaluating Compliance With Performance Standards

The options for evaluating compliance with the performance standards should be flexible and varied, taking into consideration percent intake of waterbody, location of intake on waterbody, type of waterbody, CWIS technology employed, etc. This approach would be consistent with the current NPDES program, where the amount of parameters and the frequency of monitoring vary based on the size of the discharge and the pollutants of concern. ACC believes that not all dischargers should have to evaluate compliance with performance standards based on the number of fish and larvae lost due to impingement and entrainment.

Once the technology has been shown to meet the performance requirements, the permittee should only have to demonstrate that the technology employed continues to operate effectively. For those permittees that must meet a performance standard, they should have the option to use either the enumeration of all fish, regardless of taxonomy or the representative species approach, using either absolute numbers, or wet or dry weight (biomass), to determine compliance with the impingement mortality and/or entrainment performance standards. Moribund fish should not be included in the calculation of compliance with the performance standard. For many species--shad for example--winter die offs of significant numbers of fish are common. At some facilities, these moribund fish may be the primary fish collected on the intake screens. Since the intake structure is not responsible for their deaths, ACC believes that these types of fish should not be included in the calculation of compliance of the performance standard.

For those facilities that must meet a performance standard, averaging periods for determining compliance with the performance standard should be as long as possible, i.e., the duration of the permit (5 years). This will reduce the variability caused by temporal and spatial abundance of organisms being impinged or entrained. Because of the inherent spatial and temporal variability of fish abundance, uncertainties around the effectiveness of technologies due to site-specific factors, and the inability to determine compliance with the performance standard over a short period of time, we maintain that it would be unreasonable to enforce the proposed performance standard during the first permit cycle. Facilities that do not achieve the performance standard at the end of their first permit cycle should be given the opportunity to use the collected data to modify their CWIS technology, or possibly re-evaluate their baseline calculation if it is based upon theoretical and not measured data. Facilities that implement CWIS technologies to reduce adverse environmental impacts should not be penalized until given the opportunity to optimize these technologies.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan. EPA also disagrees that a facility that is out of compliance should not be subject to enforcement actions.

Organization American Chemistry Council

ACC Supports Extensions Of Time For Facilities That Must Renew Their Permits Shortly After Promulgation Of The Phase II Rule

For permittees that have already applied for a permit renewal, and are thus in the period of agency review of the application, we believe the permittee should not have to redo its application due to the promulgation of the Phase II rule. In such a case, ACC recommends that the succeeding five-year permit term be the time in which the permittee must comply with the new rule.

Similarly, if the Phase II Rule is promulgated very near the time when a permittees renewal application is due (for example, between 365 and 180 days before its permit expires), we suggest that it would be counter productive to require the permittee to adjust its application process to the new rule. The practical difficulties in preparing a permit application, especially if biological monitoring is needed, should not be imposed until the succeeding permit term after the Phase II Rule becomes final.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

Permit applications/implementation schedule

Author Name Joe Mayhew & Tony Wagner

Organization American Chemistry Council

Once BTA Has Been Determined And No Significant Cooling Water Increases Occur, There Should Be No Further Need For A Section 316(b) Analysis

ACC believes that a Section 316(b) analysis should be a one-time only requirement. That is, once "best technology available" has been determined for a facility, installing and operating that technology should relieve the facility of further Section 316(b) reviews. The "location, design, construction, and capacity" of the cooling water intake structures are matters of design and construction, not operation. Congress could not have intended that facilities be in the business of redesigning, demolishing, and reconstructing their intake structures every five or ten years.

For each NPDES permit renewal cycle, a permittee could certify that there have been no changes that would affect the design of the intake structure. From this, the Director should then accept the original Section 316(b) analysis and BTA determination. However, ACC does support the need for a new Section 316(b) analysis if there have been significant changes in plant operations or the design of the intake structure that may lead to adverse changes to the aquatic populations.

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to comment 316bEFR 041.126.

Option 3--Site-specific determination

To reiterate previous UWAG, EEI and FPL comments, FPL would still prefer a fully site-specific approach to determining BTA for minimizing environmental impacts that might be attributed to power plant intake structures. This approach has been in effect since 1977 (EPA guidance) and has been extremely effective.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b) determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact at cooling water intake structures.

RFC: Proposed use of restoration measures

Author Name Ronald H. Hixs

Organization Florida Light and Power Company

Restoration

As in our original comments on the proposed Phase II rule, FPL applauds EPA for recognizing the benefits of voluntary restoration that a facility might employ in lieu of, or in conjunction with, technological approaches and voluntary operational restrictions. We would like to reiterate our comments on this very important issue.

EPA Response

For a discussion of the extent to which restoration measures are voluntary, see EPA's response to comment 316bEFR.060.022.

The final rule allows the use of restoration measures both in lieu of and as a supplement to design and construction technologies and/or operational measures.

Comment ID 316bEFR.315.007

Author Name Ronald H. Hixs

Organization Florida Light and Power Company

Subject Matter Code 11.0

Role of Restoration

FPL believes that restoration measures should be expanded to the largest extent possible and should make sense from an ecosystem standpoint and not be inhibited by political boundaries. For instance, mitigation or restoration that could be conducted in an estuary impacts numerous types of fish and shellfish that spend portions of their lives there. Many of these organisms later move to open ocean waters and can move up and down along the coastline.

EPA Response

For a discussion of the appropriate spatial scale on which to conduct restoration measures, see EPA's responses to comments 316bEFR.212.001 and 316bEFR.059.008.

Comment ID 316bEFR.315.008

Author Name Ronald H. Hixs

Organization Florida Light and Power Company

Subject Matter Code 11.08

RFC: Habitat conservation as part of restoration

FPL agrees that activities such as habitat conservation are an appropriate component of a facility's restoration efforts. Other appropriate components are activities such as stormwater management or connecting facilities using septic tanks located near a water body to a POTW. These activities don't directly replace organisms (like stocking) or sea grass (like restoration) but could play a major part in the recovery of an ecosystem.

EPA Response

Any restoration measure must meet all of the requirements described in the final rule.

For a discussion of the roles and responsibilities of the permitting authority in determining the appropriate level of performance to meet the requirements of the final, see EPA's response to comment 316bEFR.060.026.

For a discussion of ancillary benefits associated with restoration measures, see EPA's response to comment 316bEFR.032.011.

Comment ID 316bEFR.315.009

Author Name Ronald H. Hixs

Organization Florida Light and Power Company

Subject Matter Code 11.12

RFC: Restoration banking

FPL feels that innovation should be the driver and all reasonable approaches to restoration/mitigation should be considered. For instance, the development of mitigation banks, such as those allowed by the 404 program, could have a major positive impact on an aquatic ecosystem located next to them. This additional value could result in more banks being developed and therefore more restored habitat for all types of aquatic, as well as terrestrial, creatures.

EPA Response

In the final rule, EPA allows use of restoration to minimize or to help to minimize adverse environmental impacts that derive from impingement and entrainment of aquatic organisms. Restoration measures must meet the requirements described in the final rule.

For a discussion of trading programs, see the preamble to the final rule.

Comment ID 316bEFR.315.010

Subject Matter Code 11.06

RFC: Performance/effectiveness of restoration

Author Name Ronald H. Hixs

Organization Florida Light and Power Company

In the NODA, EPA states that it is considering requiring the following practices during the development of restoration projects:

- Documentation of sources and magnitude of uncertainty in expected restoration project performance

- Creation and implementation of an adaptive management plan

- Use of an independent peer review to evaluate restoration proposals

FPL agrees with UWAG that all of these approaches may be useful, depending on the nature and complexity of the proposed restoration measure. We also believe that the decision on whether or not to require these practices should be made by the permitting agency on a case-by-case basis, with these factors used as tools, rather than absolute requirements.

EPA Response

For a discussion of the usefulness and flexibility in the use of the practices described by the commenter, see EPA's response to comments 316bEFR.307.047 and 316bEFR.311.022.

Subject Matter Code 21.09

Permit applications/implementation schedule

Author Name Ronald H. Hixs

Organization Florida Light and Power Company

Compliance Timelines, Schedules and Determination

EPA has suggested two options for allowing additional time to facilities that are required to apply for a permit renewal soon after promulgation of this rule. The first requires the applicant to submit required studies, etc. within one year after their current permit expires. The second option allows information to be submitted two years after the original application was due (18 months after the permit expired). The second option might be acceptable for those facilities that have permits expiring the full year after the rule is promulgated, however some facilities will have permits expiring soon after the rule is effective. For this reason, a minimum of 3 years must be allowed from promulgation of the rule to the first full, "Comprehensive Demonstration Study" being required to be submitted. This time would allow a permittee to read and understand the new rule, budget appropriately, conduct studies, etc. This time frame does not take into account the amount of time a State might require for adopting the rule.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

Comment ID 316bEFR.315.012

Author Name Ronald H. Hixs

Organization Florida Light and Power Company

Subject Matter Code 16.01

RFC: Regulating limited capacity facilities

Determining Capacity Utilization Rates

FPL agrees with EPA that the new rule should only apply to the "steam electric part" of the facility when determining "capacity utilization rates".

However, EPA's proposed definition (as well as the concept) of "capacity utilization rate" may unfairly penalize some facilities. EPA's proposed definition of capacity utilization rate is,

"Capacity utilization rate means the ratio between the average annual net generation of the steam electric part of the facility (in MW) and the total net capacity of the steam electric part of the facility (in MW) multiplied by the number of available hours during a year. The average generation must be measured over a five year period (if available) of representative operating conditions."

The problem with this definition is the use of and possible definition of "available." As EPA notes in the proposed rule,

"The Agency's record demonstrates that facilities operating at capacity utilization factors of less than 15 percent are generally facilities of significant age, including the oldest facilities within the scope of the rule. Frequently, entities will refer to these facilities as peaker plants, though the definition extends to a broader range of facilities. These peaker plants are less efficient and more costly to operate than other facilities. Therefore, operating companies generally utilize them only when demand is highest and, therefore, economic conditions are favorable. Because these facilities operate only a fraction of the time compared to other facilities, such as base- load plants, the peaking plants achieve sizable flow reductions over their maximum design annual intake flows."

As noted above, a unit may not be operated for economic, maintenance or other reason (including permit driven operational limits). It doesn't seem important as to why the unit is or isn't operating, just the fact that it isn't operating reduces the flow, and thereby, impingement and entrainment. As these are generally older units, they may require extensive maintenance that may occur during periods where they wouldn't be operated for economic reasons. A unit under this scenario would be "penalized", as it wouldn't be "available" while on the outage. (This assumes "available" means physically capable of operating"). A facility with a "capacity utilization rate" of 15% would have that percentage increased to approximately 18% if you deducted two months of the year as being "not available" during to an outage, even though the unit actually operated the same amount of time as it would have without the outage.

The worst possible scenario would be a facility voluntarily accepting an operational limit so it can not exceed a 15% capacity factor (see definition of capacity factor below). It seems one could argue the unit is "not available" 85% of the time. If you subtract the hours the facility is not available (based on the EPA definition), you end up with a capacity utilization rate of 100%!

To simplify matters and not penalize certain facilities, FPL proposes that "capacity factor" as defined by the Energy Information Agency (under the Department of Energy - www.eia.doe.gov/cneaf/solar.renewables/rea_issues/glossary.html.) be for used in lieu of “capacity utilization rate”.

That definition of capacity factor is, as follows,

“Capacity Factor - The ratio of the electrical energy produced by a generating unit for the period of time considered to the electrical energy that could have been produced at continuous full-power operation during the same period.”

This definition gives you the same percentage you’d achieve if you eliminate the “available” portion of the capacity utilization rate” definition and eliminates the need to define “available” and track “available” hours.

EPA Response

This is a helpful and insightful comment. The Agency agrees that the term “available” was not appropriate for the case of the capacity utilization rate threshold. As such, the Agency has struck the term from the final rule definition of capacity utilization rate. However, the Agency cannot accept the definition verbatim as recommended by the commenter for the fact that it does not define the time period over which to measure the rate. The Energy Information Administration definition of capacity factor, as stated by the commenter, "gives you the same percentage you would achieve [with EPA's NODA definition] if you eliminate the "available" portion of the capacity utilization rate." Therefore, the Agency has ensured that the final rule definition is compatible with the suggested definition and that the term "available" is not included.

Author Name Daniel J. Orr

Organization Xcel Energy

Subject Matter Code 7.01

RFC: Three-option framework for determining BTA

According to the NODA it appears that EPA is analyzing two alternatives for § 316(b) regulations. Xcel Energy would support EPA's preferred option based on water body type and intake structure capacity over the less flexible and more costly waterbody/capacity-based option. EPA's own analysis for the NOPR revealed that the waterbody/capacity-based option would result in substantial net costs to society based on the required installation of recirculating cooling towers at numerous facilities. The results of the NODA analysis of that option estimated even more significant net social costs. The preferred option at least provides facilities some flexibility in meeting the performance standards and incorporates cost-cost and cost-benefits analyses to avoid excessive economic burdens for many facilities.

EPA Response

Please refer to the preamble for a discussion of the framework of today's rule.

EPA elected to not adopt any of the alternative technology-based options discussed in the proposed rule (67 FR 17154-17159) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

Please refer to the response to comment 316bEFR.005.020 for a discussion of the application of the cost-benefit test to assessing the value of alternative approaches.

Organization Xcel Energy

Subject Matter Code 10.07.02

RFC: Appropriateness of "significantly greater"

EPA requests comments on the use of "significantly greater than" as the trigger for the proposed "cost-cost" and "benefit-cost" test option for site specific review. EPA admits that their new methodology, in the NODA analysis, of applying the best performing technology in their technology cost modules rather than the traditional least cost technology results in greater cost conservatism than is typical of regulatory analyses. Given that the EPA's cost estimates are already overly conservative it is not appropriate to require that individual facility costs be "significantly greater than" EPA estimated costs to allow site-specific permitting. If facility costs are any greater than those estimated (or at most 10% higher than estimated) then site-specific permitting should be an option.

EPA Response

See responses to 316bEFR.337.021. See the preamble to the final rule for a discussion of the site-specific requirements of the final rule.

Comment ID 316bEFR.316.004

Subject Matter Code 7.04

Streamlined Technology Option

Author Name Daniel J. Orr

Organization Xcel Energy

Xcel Energy welcomes EPA's recognition that streamlining the permitting process is a benefit to both the regulated community and the regulating agencies in terms of costs and workloads. We encourage EPA to provide options for choosing from a suite of technologies that are presumed to meet the performance standards. Both of EPA's streamlining options should be incorporated allowing use of pre-approved technologies or use of innovative technologies that have been demonstrated effective at similar facilities. In no way should these streamlining options preclude a facility from using existing technology, operational measures, restoration, or combinations of the aforementioned to meet performance standards.

EPA Response

EPA appreciates Xcel Energy's support of EPA's Approved Design and Construction Technology option. Please refer to preamble section VIII.C.4., Approved Design and Construction, for EPA's position on using existing technology, operational measures, and/ or restoration measures combined with the Approved Design and Construction Technology (commonly referred to as the "streamlined technology" option) to meet performance standards.

Comment ID 316bEFR.316.005

Subject Matter Code 21.09

Permit applications/implementation schedule

Author Name Daniel J. Orr

Organization Xcel Energy

Xcel Energy questions how implementation of the § 316(b) regulations will occur and how compliance will be determined. In light of the lengthy pre-permitting study requirements, engineering analysis, and permit renewal submission requirements delaying the effective date of the new rule for at least two years after approval seems reasonable. We also support the use of compliance schedules in NPDES permits as a means of meeting the rule requirements.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion. See the preamble to the final rule for a discussion of compliance issues.

Comment ID 316bEFR.316.006

Subject Matter Code 21.04

Determination of compliance

Author Name Daniel J. Orr

Organization Xcel Energy

Compliance with the performance standards should be based on following all of the appropriate permitting procedures, installing the approved technology, and following approved O&M procedures not necessarily on meeting specific numeric impingement/entrainment reductions. If the properly installed and operated technologies fail to meet the standards it should not be considered a permit violation but rather require additional review and possible modifications still based on the appropriate cost-cost and cost-benefit analyses.

EPA Response

In today's final rule, EPA has included the Technology Installation and Operation Plan, as discussed in the final rule preamble. Facilities that prefer to comply using the Technology Installation and Operation Plan will not need to meet the numeric performance requirements. For a discussion of how compliance is to be determined, please see the preamble to the final rule and EPA's responses to comments 316bEFR.017.003 and 316bEFR.063.005. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Please see response to comment 316bEFR.019.014 for a discussion of site-specific study costs and considerations.

Costs

Xcel Energy still has significant concerns with EPA's analysis of the cost of compliance with the proposed regulation and notes that for the NODA the revised cost estimates are significantly higher than originally estimated.

EPA Response

The comment is unclear. It is not apparent whether the commenter believes costs are too high or low, or simply is concerned with the fact that the Agency revised its estimates between proposal and NODA. As such, the Agency cannot act upon the comment and differs to its substantial and detailed analysis of the compliance costs of the final rule, as outlined in the Technical Development Document and EBA for the final rule.

Burden to facilities (general)

Also it is unclear from the economic analysis whether EPA has analyzed what the impacts on costs will be of requiring all of these studies and technical construction work in a limited time period from an equally limited workforce.

EPA Response

The comment is unclear. The Agency notes that it integrated the projected compliance dates into its detailed economic market analysis and has provided for great flexibility in scheduling of rule compliance. For more information on ways of demonstrating compliance with this rule, see the preamble. For more information on the Agency's analysis of compliance years see Chapter B1 of the EBA for the final rule.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

In addition there is no discussion of the cumulative cost impacts, on the utility industry, of the proposed § 316(b) regulations in conjunction with other Agency regulatory initiatives including air, water, and waste programs.

EPA Response

EPA disagrees with this assertion. The IPM base case includes current federal and state air quality requirements, including future implementation of SO2 and NOx requirements of Title IV of the CAA and the NOx SIP call as implemented through a cap and trade program. It does not include programs that are still under consideration, such as the Clear Skies Initiative. EPA does not know – and cannot reasonably predict – the outcome of initiatives still under consideration; therefore, any cost estimates EPA might try to develop would be highly speculative and unhelpful. This practice of only including promulgated regulations is typical for energy market models and the Agency's analyses of Clean Water Act rules.

Other technology-based opt. under consideration

Xcel Energy adamantly opposes implementation of a nationwide one-technology fits all approach and also opposes any regulatory program that stipulates specific technology fixes without offering a range of technology options, modified operating procedures, and restoration alternatives to meet the performance standards.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161). Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to section VII.E of the preamble for more information on why EPA rejected this alternative.

Role of States and Tribes (alt./equiv. programs)

Of paramount importance is the need to retain the States' flexibility to implement the 316(b) Rule for specific waterbodies. The Clean Water Act and its implementing regulations include repeated expressions of Congressional intent to delegate broad discretion to the States to implement programs that protect the quality of our waters. The 316(b) Rule is among those provisions where Congress intended to provide the States with flexibility to address site-specific concerns while achieving the Clean Water Act's goal of protecting aquatic life in those waterbodies. As competitive suppliers of electricity to a deregulated marketplace, Midwest Generation supports the development of sound environmental regulatory programs that provide flexibility to enable affected facilities to meet the overall intent of the 316(b) rule through cost-effective, environmentally beneficial solutions that are based on site-specific circumstances. The 316(b) Rule for existing facilities can establish necessary standards to protect the environment, while still allowing each State to develop and implement its own policies and procedures to apply the 316(b) standards to specific waterbodies. The 316(b) Rule can and should address the States' need for flexibility in how the rule is applied in site-specific situations. In support of that goal, we offer the following additional comments.

EPA Response

EPA agrees that State programs should be able to address 316(b) issues. In today's final rule, State programs are eligible for approval based on meeting the requirements in 125.90(c). See response to 316bEFR.023.001 for additional discussion on State programs.

Author Name Basil G. Constantelos

Organization Midwest Generation EME, LLC

Subject Matter Code 3.01

Definition: Existing Facility

Facilities Affected:

The EPA states in the NODA that all Phase II facilities are subject to the requirements of the Phase II regulation, even if they do not currently generate electricity. This proposed broad scope of applicability of the 316(b) Rule will affect any facility which is currently in an extended shutdown. There are several merchant power plant units in the Midwest that have recently halted operations, due to the currently soft power market and rising costs of production. The intention is to return these units to service when and if the marketplace improves. As such, the units retain their NPDES-permit status and the ability to operate again in the future if needed. However, these units are physically laid up, to prevent corrosion and other fouling from occurring, and are not actively taking in water from, or discharging effluent to, a receiving stream. They are not having any environmental impact on the receiving stream, and certainly none that requires regulation under 316(b). Therefore, the 316(b) Phase II rule should not apply to these “shuttered” units until such time, if ever, the decision is made to bring these units back into service. To require such units to install impingement and entrainment controls when such controls may never be needed does not make good economic sense. It also does nothing to protect the environment. In addition, if a unit or facility is not currently in operation, it would be impossible to determine what its calculational baseline is, an essential determination for identifying the impingement and entrainment controls that the EPA is proposing to apply to these plants. The EPA’s comments in the NODA do not acknowledge this significant obstacle to compliance. It is another reason why the 316(b) Phase II Rule should not apply to non-operating plants or units.

EPA Response

"Shutdown" facilities may not meet the requirements of 125.91(a)(2), which requires that an existing facility uses or proposes to use cooling water intake structures with a total design intake flow of 50 MGD or more to withdraw cooling water from waters of the United States. Any such determination must be made on a case-by-case basis. An existing facility that does not meet 125.91(a)(2) is not subject to this rule.

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

Cost of Compliance Estimates

Midwest Generation appreciates the EPA's favorable response to the many comments submitted regarding how the Agency had underestimated the overall costs of installing and operating control technologies to respond to 316(b) requirements. Any retrofit to an existing facility is substantially more expensive than designing identical control equipment for installation at a new facility. There are very significant design and process changes required for existing facilities in many cases. These changes result not only in additional costs and downtime, but also have the potential to negatively impact the operational efficiency of the plant. For merchant plants in particular, the combined costs of procurement, installation and operation/maintenance of a control technology designed to meet the 316(b) performance standards cannot be passed on to the customers. Therefore, it is extremely critical that the Rule 316(b) compliance cost estimates accurately reflect the real-world situation and are not based on theoretical estimates for "model" facilities which do not bear any resemblance to the reality of a particular power plant's situation.

EPA Response

The commenter is mistaken when they assert that "theoretical estimates for 'model' facilities…do not bear any resemblance to the reality of a particular power plant's situation." The "model" facility costing is based on site-specific information obtained for particular power plants, and therefore it integrates real-world situations into the costing approach. The Agency believes that cost estimates for "model" facilities are reasonable when the costs estimates and technology decisions are based on the available site-specific engineering data for the existing facilities upon which the models are based. The Agency notes that the commenter has provided no contradictory evidence or comparative analysis of the Agency's "model" facility cost estimates and only provides generic, non-specific criticism that is unsubstantiated.

Comment ID 316bEFR.317.004

Subject Matter Code 9.0

Costs

Author Name Basil G. Constantelos

Organization Midwest Generation EME, LLC

While EPA has acknowledged that the original estimated cost of compliance was low, and has adjusted capital and O&M cost estimates upwards by 66% and 48%, respectively, we find that the revised cost estimates still do not capture the entire magnitude of the costs for the full implementation of the proposed 316(b) performance standards. The Agency has inappropriately relied upon case studies and information from only a small sampling of non-generic electrical generating plants. The EPA needs to broaden the representative nature and number of electrical generating plants on which it is relying in order to determine with a reasonable degree of reliability the estimated capital and O&M costs that will result from compliance with the proposed 316(b) performance standards.

EPA Response

The commenter possibly confuses the development of the performance standards or possibly the benefits assessment with that of the technology cost development by asserting that the costs development relied on "case studies and information from only a small sampling of non-generic electrical generating plants."

The Agency notes that it developed technology costs for the final rule based on implementation of 13 separate cooling water intake retrofit technologies. This is hardly a "small sampling" of technology case studies. The Agency relied upon the expertise of the manufacturers and installers of each particular technology in order to develop the costs for the variety of technologies considered for the final rule. The Agency obtained costs for generic electrical generating plants, but has not restricted the costs to only apply to just electrical generating plant intakes. The Agency father tailored the costs with site-specific variables and implemented the variety of technologies in such a way that utilized as much site-specific data as was available to the Agency. See response to comment 316b.EFR.317.008 for more discussion of the correlation between costs and performance standards.

Organization Midwest Generation EME, LLC

Subject Matter Code 9.04

Cooling system costs (e.g., dry, wet, recirculating)

Actual Cost and Timing Estimates for Required Controls

Midwest Generation encourages the Agency to carefully consider the recent submittals made by the Department of Energy (DOE) in October, 2002 and January, 2003 providing costs estimates for the retrofitting of wet cooling tower systems. In each case, the costs estimated by the Agency were found to be much lower than actual costs incurred by the subject facilities. In addition, the DOE estimated that three out of four facilities would likely require plume abatement technologies that could double the capital costs of the cooling tower portion of a retrofit project.

In the Midwest, where open cycle cooling is dominant, the prospect of having to install wet, closed cycle cooling, especially near large urban areas, is fraught with technological complexities and local regulatory obstacles. Consideration of site-specific factors, including plant location and configuration, available land, piping requirements, plume abatement needs and plant outage repercussions must be factored into the analysis of the feasibility of a complete retrofit to closed cycle cooling. All of these factors, by their very nature, will affect the feasibility and estimated time of completion of such a retrofit, should it be deemed necessary. (The same considerations would also be relevant for any other type of impingement/entrainment control technology that has the potential to significantly impact plant operations, such as installation of a new intake or fish return system, because they would require a period of extended shutdown of a plant).

Because the Agency does not have the available data to review the complete record for all such potential retrofit projects to determine the economic impacts, the 316(b) Rule should allow a facility to prepare and submit a project plan for its retrofit work to the State permitting authority for review and approval. Upon approval, the project plan would form the basis of a compliance schedule to be incorporated into the facility's NPDES permit as part of the permit renewal process. Realistically, the facility would also need an adequate amount of time (two to three years) to allow it to collect the required baseline data necessary for identifying the required control technology to achieve the performance standards adopted under 316(b). This information is critical to developing the project plan for retrofitting the existing system.

EPA Response

EPA first notes that the commenter misunderstands or misrepresents the nature of the cooling tower retrofit cost studies conducted (and shared with the Agency) by the U.S. Department of Energy. Contrary to what the commenter asserts, the cost studies do not reflect "actual costs incurred" for retrofit projects, but rather, prospective and predicted costs based on a hypothetical analysis. The Agency is aware of four actual cooling tower retrofit projects that have occurred. The Agency was able to obtain costs for two of these four retrofit projects. The costs of these projects are included in the record of the proposal rule at DCN 4-2526. Nonetheless, the Agency has reviewed the study presented by the U.S. Department of Energy relating to hypothetical potential retrofit projects. The Agency has reviewed the study (An Investigation Site-Specific Factors for Retrofitting Recirculating

Cooling Towers at Existing Power Plants, January 22, 2003)prepared on behalf of the Department of Energy and finds the principles and concepts behind the analysis to be sound.

EPA agrees that site-specific technological complexities and local regulatory obstacles of retrofitting open-cycle cooling to recirculating wet cooling could cause increases in costs of the technology beyond those estimated by EPA. This would serve to reinforce the Agency's decision to not base the final rule on cooling tower retrofit technologies.

For discussion of the Agency’s consideration of potential plant shutdowns for retrofit installation of new intakes or fish return systems, see the Technical Development Document.

The Agency has considered the schedule and time necessary to complete the baseline data for identifying the required control technology (which is analogous and/or similar to the Agency’s comprehensive demonstration study). For a discussion of timeframes, see the preamble to the final rule.

Organization Midwest Generation EME, LLC

Subject Matter Code 10.07.02

RFC: Appropriateness of "significantly greater"

Site-Specific Cost-Cost/Cost-Benefit Test Evaluation

In the current proposal, EPA provides an opportunity for a regulated entity to show that its site-specific costs of compliance are "significantly greater" than the Agency's estimates. However, the Agency does not provide any objective standard for determining whether or not the "significantly greater" requirement has been satisfied. This determination should be delegated to the individual State regulatory agencies to decide, based on their wealth of knowledge regarding state waterways and their unique biological characteristics, the facilities which utilize them for cooling and the State's own priorities regarding protection of their most important aquatic resources. For nearly thirty years, the States have applied sound science and judgment to site-specific data and conditions in order to implement section 316(b) standards. The States have shown that they have the ability and judgment to retain this role in the final 316(b) rule for existing facilities.

EPA Response

See responses to 316bEFR.006.003 and 018.009. EPA notes that in states authorized to implement the NPDES programs, the state Director will implement these requirements.

Comment ID 316bEFR.317.007

Subject Matter Code 10.02
Benefit Estimation Methodology

Author Name Basil G. Constantelos
Organization Midwest Generation EME, LLC

The same analysis and rationale applies for the calculation of environmental benefits to be gained by installation of a chosen technology. EPA makes gross assumptions that all impinged or entrained organisms have a comparable monetary or recreational “value”, which is extrapolated based on the broad assumptions used in calculating the number of organisms that are inadvertently removed from the system by power plant operations. Most of the data used in the Agency’s analysis is from coastal states or areas with known recreational or commercial potential. It is interesting to note, however, that the Agency admits that greater than 99% of all fish impinged have no recreational value. This being the case, it is unreasonable to attribute derived costs based instead on commercial or recreational species to all impingement/entrainment losses. This approach grossly overstates the alleged losses, as does the Agency’s attempt to assign “non-use” value to these species.

There is little impingement/entrainment and associated cost information for other waterbodies (especially fresh-water, by the Agency’s own admission) largely because the aquatic resources they contain are not necessarily directly equated with State revenue or personal/aesthetic enjoyment. As more fully discussed below, the State of Illinois is currently looking at methods to remove aquatic invasive species from its waterways in order to protect the unique ecosystem of the Great Lakes. The determination of what constitutes environmental “losses” and their valuation should properly be left to the States to determine, in conjunction with their natural resources agencies. This delegation of authority will allow the local permitting authority to rely on pre-existing data and other relevant and appropriate information to determine where best to invest the resources necessary to protect the most valued or sensitive aquatic populations in the State. Combined with accurate cost estimates for approved control technologies, this approach will allow a true comparison of compliance costs versus environmental benefits on a case-by-case basis.

EPA Response

The comment states that “EPA makes gross assumptions that all impinged or entrained organisms have a comparable monetary or recreational ‘value’.” This is correct with the exception that not all species may have 'comparable' value – EPA examined options for assigning values to all lost organisms. But, in the final rule, monetized benefits are based primarily on recreational and commercial caught fish. The comment also notes that “greater than 99% of all fish impinged have no recreational value.” From this, the comment concludes that EPA’s estimate of losses must be overstated. EPA does not agree that because organisms lost are not commercially or recreationally valuable they therefore have no value whatsoever. For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values in estimates of national benefits due to uncertainty in monetizing non-use values for this rule. The Agency, however, has explored several methods that indicate the potential for significant non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

The comment states that losses and their value should be determined by States, not by the EPA. EPA agrees that there is a role for States in ascertaining benefits in their waters and, therefore has authorized State directors to make site-specific determinations of BTA based on a consideration of costs and benefits.

For EPA's response to comments about using habitat values to estimate values for fish, please see the response to comment #316bEFR.307.061.

For EPA's response regarding comparisons of population demographics between the study region and policy region, please see the response to comment #316bEFR.304.004.

For EPA's response regarding the non-use meta-analysis, please see the response to comments #316bEFR.338.046 and #316bEFR.338.046.

Subject Matter Code 9.07
Cost Modules

Author Name Basil G. Constantelos
Organization Midwest Generation EME, LLC

Recommended Control Technologies

The revised cost estimates derived by EPA for all of the proposed control technologies are still too low, especially in relation to the worst-case, theoretical estimates of the environmental and economic benefits to be derived from application of these technologies to reduce impingement and entrainment to the required performance levels. EPA's desire to provide state regulatory agencies with a listing of standard, approved impingement and entrainment control technologies is commendable, but the usefulness of this "comprehensive" list, even when categorized by general waterbody type and facility design, is still very limited. There is no compelling evidence in the NODA documents showing that any treatment technology chosen will work equally well in all applications at all generating stations and result in attainment of the required performance standards. There are simply too many variables that must be taken into consideration. Site-specific conditions will dictate the efficiency of any chosen control technology. Significant variables, such as natural seasonal variability in receiving water flow regime, aquatic species cycling and variable facility operating modes, will drive the technological efficiencies of treatment options for each plant. No additional amount of data or studies will be able to establish that a particular technology can be applied uniformly, nationwide in a "one-size-fits-all" approach. Variability is a key biological characteristic and must be accounted for in any regulation that seeks to apply quantitative control criteria. Site-specific application of such control mechanisms, when warranted, is the only reasonable means by which the goals of the regulation will be realized without imposing substantial and avoidable adverse effects on the industry.

EPA Response

The Agency notes that it did not apply any of the 13 technologies forming the basis of the final rule in a "one-size-fits-all" approach, as the commenter asserts. The Agency agrees that no individual technology of the 13 forming the basis of the rule will work for all facilities complying with the final rule. However, due to the fact that the Agency examined and utilized a baker's dozen distinct technologies tailored to model site characteristics, the Agency has accounted for site-specific conditions that dictate technology efficacy. The Agency agrees that site-specific application of control mechanisms is the most reasonable means for realizing the performance targets of the final regulation. To ensure that the cost estimates developed by the Agency correlate well with the real-world application of the performance standards, the Agency has included a cost-cost test in the final rule. Therefore, if facilities can demonstrate to the satisfaction of the Director that they would incur significantly higher compliance expenditures than considered by the Agency for similar facilities to meet the requirements of the rule, then they would be eligible for to less stringent requirements. Therefore, the Agency, despite its model site-tailored costing approach, recognizes that its broad analysis of the vast number of plants within scope of the rule cannot predict seasonal variability and aquatic species cycling for all of the complying facilities. Should this dramatically affect costs for certain complying facilities, then the cost-cost test will provide a second chance for the facility and permit writer to rectify this site-specific condition. The Agency also points out that its approach to developing technology decisions for the NODA and final rule deviated from a more standard "least cost” approach, as might be found in an effluent guideline development. Instead, the Agency adopted a hybrid approach that incorporated the “best performing” technology in cases where significant uncertainty in site conditions existed in its data set. Therefore, the Agency, by default is approaching the costing effort with a degree of conservatism that inherently accounts for the variability described by the commenter.

Streamlined Technology Option

Streamlined Option

EPA has proposed a streamlined option whereby the Agency would certify that certain technologies, under certain conditions, meet the performance standards. The permittee could then simply choose one of the EPA-approved technologies appropriate for the conditions at the site and install it. Monitoring would be required to verify that required reductions in impingement and entrainment are achieved. While on the surface it appears that the Agency is accommodating the many requests made in the previous comment period to minimize the burdensome and costly monitoring required to determine which control technology may work best for each site, having a list of "pre-approved" technologies to choose from, without site-specific information is not a scientifically or economically sound approach for the industry. The chosen technology may or may not result in compliance with the performance standard, something that would not be realized until a facility already had expended a considerable amount of time and money on installation. Should subsequent performance monitoring indicate that the chosen technology does not meet the required reductions, the facility would be back to square one and required to install additional or substitute treatment technologies at significant costs to see if the performance limits can be met. Without an up-front agreement that installation of the Agency-certified technology is equivalent to compliance, regardless of actual performance, a facility would have little incentive to go with this approach. This option would instead only serve to minimize the Agency's regulatory burdens under 316(b) by eliminating the need for it to review baseline data or compliance plans. It does not address the already over-burdened workload of State regulatory agencies. Similarly, it also places a potentially significant burden on the regulated facility where the installed technology does not achieve the required performance limits. Instead of the proposed streamlined approach, Midwest Generation urges the Agency to adopt the suggestions herein for providing the necessary flexibility to the States to address the site-specific needs of many electrical plants. This alternative approach will achieve the same performance goals but at far less risk of expending unnecessary and duplicative compliance costs.

EPA Response

EPA acknowledges that not every facility will opt for the Approved Design and Construction Technology Option(s) for a variety of reasons. EPA believes based upon the data it has reviewed, that the Preapproved Technology Option should meet the performance standards in most cases for those facilities that qualify for that option. The facilities that do choose the Preapproved Technology Option will benefit by having greatly reduced permit application requirements; therefore, EPA disagrees that there is no incentive to go with that approach. EPA has designed the final rule so that facilities have numerous options by which they may comply with the final rule, including site-specific determinations of best technology available. In addition, EPA has provided permittees with the Technology Installation and Operation Plan, which allows any facility, with the approval of the Director, to demonstrate compliance with today's requirements based on showing that it has installed and is properly operating and maintaining protective technologies. Finally, EPA believes that it is the burden of the facility to achieve compliance. If the permitting Director determines at any point that additional technologies or operational measures are necessary in order for a facility to meet the performance standards, it will be the facility's responsibility to accommodate the requirements. The facility may also seek a site-specific determination of best technology available based on cost-cost or cost-benefit considerations.

Source data used by EPA

Author Name Basil G. Constantelos

Organization Midwest Generation EME, LLC

Inadequate Representation of Midwestern Plants in the NODA Information

Midwest Generation commends EPA on the time and effort expended to obtain additional technical, biological and economic data to test the original assumptions made in the proposed rule. A broad perspective is essential in order to capture the magnitude of variability of facility operations and impacts. Since the 316(b) issue is in essence a site-specific one, in that it is impossible to assume that all plants affect all source water bodies in the same exact manner, we are encouraged that more site-specific information has been included in the NODA.

That being said, we are greatly concerned by the fact that the majority of the site-specific cases, studies and technical information comes from steam-electric generating facilities located on either the East or West coasts. There is very little representation of the Midwestern or Southern States in any of the NODA materials. While it is true that the coastal regions are those that have largely already dealt with 316(b) issues in the past, on a State-specific level, and therefore have the information on technological control methods, applications and monitoring, it is also true that these facilities are adjacent to much more sensitive waterbodies that may require the additional protections afforded by 316(b) controls. Both coasts have considerable recreational and commercial fisheries, which necessitate that power plants provide adequate technology-based solutions to minimize negative, population-level impacts to important aquatic species. Estuaries, in particular, are extremely vulnerable and should be afforded adequate protection to prevent population-level impacts. In this respect, 316(b) requirements have already successfully been implemented in the coastal States , based on the original 1977 guidance document. Applying this regulation uniformly across the country is not a practical or prudent approach, for reasons illustrated in the sections below.

EPA Response

EPA reviewed as many site-specific studies as possible; studies from the East and West coasts simply happened to be available in greater quantity to EPA. It is possible that permitting authorities on the coasts were more active in requiring and collecting studies from their permittees than those in the Midwest. Nevertheless, EPA reviewed studies and literature from all over the U.S., and believes that the standards set by today's rule are both appropriate and achievable nation-wide. Furthermore, the commenter did not provide any additional studies for EPA to review. Finally, EPA did consider waterbody type when designing the rule, and has established more protective requirements (reduction in both impingement and entrainment) in waterbodies it considers most sensitive, including estuaries.

Source data used by EPA

Midwestern Experience with 316(b) Issues

In contrast to many of the facilities located in coastal States, there is very little current impingement or entrainment data available for most existing facilities in the Midwestern States, particularly Illinois. The limited number of baseline studies available (that were done up to twenty to thirty years ago at some sites) have shown that station operations were not the cause of significant adverse impacts on the aquatic communities in the adjacent waterways. Monitoring data subsequently collected by State natural resource agencies mirrored this conclusion to a large extent. Where impacts were noted or expected, control technologies have already been employed as part of overall plant operations. The remaining facilities have either been deemed to be in compliance with the 316(b) regulations or final judgment was deferred by the regulating agency in deference to more pressing environmental issues. In some cases, as is true with several of Midwest Generation's facilities located on heavily industrialized waterways, no 316(b) demonstration was ever required by the Agency. The water quality and aquatic life of almost all of Illinois' waterways on which Midwest Generation plants are located have greatly improved in recent years. All of this progress has been made with the continued operation of Midwest Generation's open cycle power plants. The State has recognized these improvements and, in general, is in agreement that intake impacts of the open-cycle steam-electric generating facilities in Illinois are not considered to be significant in the context of population-level aquatic communities.

EPA Response

EPA disagrees that facilities with cooling water intake structures are not responsible for adverse environmental impacts. For EPA's position on adverse environmental impact associated with cooling water intake structures, please refer to the preamble section IV, Environmental Impacts Associated With Cooling Water Intake Structures.

Non-aquatic impacts

Aquatic Invasive Species Control

There has been a continuing joint effort by the International Joint Commission, U.S. Fish and Wildlife Service, U.S. Army Corps of Engineers, Illinois Department of Natural Resources and other aligned groups to create a barrier zone in the Chicago Sanitary and Ship Canal which would be made devoid of, and impassible to, all aquatic life (through chemical, physical or other means). The purpose of this barrier is to prevent the migration of aquatic invasive species into or out of the adjacent waterway systems, which include Lake Michigan. The current exotic invaders, the Asian Carp (silver, black and bighead), have the ability to decimate the aquatic ecosystem of Lake Michigan and the rest of the Great Lakes. Infiltration of these species also would destroy the popular sport fishing industry that has taken the States so long to build in these waterbodies. Other invasives, which have been inadvertently introduced into the Great Lakes via ballast water and/or accidental or deliberate releases, travel the course of the Chicago waterway system down to the Mississippi River basin, where they out-compete sensitive, threatened and/or endangered native species for available food and habitat. The City of Chicago recently held an Aquatic Invasive Species Summit to gather worldwide experts to permanently address this problem. One of the potential solutions coming out of the summit was to utilize power plant intakes and discharges, combined with other methods, to effect some control over the migration of aquatic nuisance species though the waterway leading to and from Lake Michigan. Midwest Generation has several open cycle power plants strategically located on this particular waterway (the Chicago Sanitary and Ship Canal and adjoining Chicago River and Lower Des Plaines Rivers) that could potentially assist in the invasive species control efforts. However, all of these facilities are subject to the proposed 316(b) rule, which would require the protection of the very species that the State and federal natural resources agencies seek to destroy. Imposing protections which may actually bolster the populations of these aquatic invasive species in the waterway could serve to further jeopardize the existence of more sensitive, ecologically-valued species in both the Great Lakes and the Mississippi River systems.

Under the proposed regulations, it makes no sense for these particular Midwest Generation power plants to be required to install control technology to minimize impingement and entrainment down to the proposed performance standards when State and federal agencies are simultaneously taking steps to create a “dead zone” in this waterway to eliminate invasive species and, regrettably, the limited number of non-invasive species that travel through this same waterway. The cost of adding any new control technology under such circumstances is clearly unnecessary and actually works against the nuisance species control efforts. In the absence of a “valued” aquatic community that is intended to be protected under section 316(b), the proposed 316(b) rule imposes additional regulatory and financial burdens without realizing any additional environmental protection whatsoever.

The above example is yet another justification of the need for site-specific applicability considerations to be included in the 316(b) regulations for them to have any true environmental benefit on a State or regional basis. Exemptions must exist to cover such unique circumstances. These exemptions should be left to the State regulatory agencies to dispense, with adequate justification.

Organization Midwest Generation EME, LLC

Subject Matter Code 6.03

Impacts of CWIS on impaired waterbodies

Waterbody-Specific Protection is Warranted

Equal protection is not required for every waterbody in Illinois, as evidenced by the fact that a significant portion of the waterways located in the Chicago area are designated as Secondary Contact and Indigenous Aquatic Life waters, due to their inability to meet the fishable / swimmable" standards required by the Clean Water Act. These waterways have been either created or significantly altered by human disturbances for more than one hundred years, and function largely as conveyances for treated effluents and barge transport, while still supporting a fair assemblage of aquatic organisms which are suited to this particular environment. The types of species expected to be entrained and/or impinged by power plants on these waterways are largely rough, low quality fish such as common carp, buffalo and gizzard shad, in addition to the invasive species noted above. These species are not "valued" (within the meaning of EPA's economic analysis) and do not warrant the same kind of protection as more desirable or ecologically important species, such as game fish, threatened or endangered species or other species important to the support of the food chain and/or recreational industry in any particular waterway. State natural resources management agencies have long been allowed to give greater protection to those waterbodies which can support the greatest diversity of quality aquatic species. This is another important example of why flexibility is required to allow the States to direct their limited resources to the protection of the most ecologically important waterways. The proposed 316(b) rule, as presently written, will result in the broad application of uniform controls for waterbodies without the necessary consideration of whether a comparable environmental benefit is attainable.

EPA Response

In order for species to coexist in a given area and utilize the same resources, they must occupy a separate and distinct niche. EPA believes all species native to a given waterbody warrant the same level of protection. Although the author may consider common carp, buffalo and gizzard shad to be "rough, low quality fish", their presence in the waterbody indicates they do occupy a distinct niche and contribute to the food chain in the ecosystem. That said, EPA believes today's final rule allows ample flexibility for the States to set their own priorities.

RFC: Entrainment vs. entrainment mortality

Entrainment Survival

Recent data has been submitted to EPA regarding entrainment survival. This data shows that entrainment survival is a site-specific, and sometimes species-specific occurrence. Because the Agency contends that this data is highly variable and unpredictable, it refuses to use it in its estimates of national benefits to be derived under the 316(b) Rule. While we are encouraged that EPA is going to initiate a formal peer review of its analysis of this data, we are disturbed by the fact that the Agency does not view this data as being relevant and important in the context of site-specific situations. In reality, the variable and unpredictable nature of entrainment survival is the primary indicator that entrainment (as well as impingement) is a truly site-specific phenomenon. The variability should not be discounted as not being sufficiently uniform to use in a national application. Indeed, the Agency should recognize that the data variability is a persuasive reason to maintain site-specific flexibility in demonstrating whether entrainment and/or impingement impacts are negatively affecting the aquatic communities in the receiving stream.

EPA Response

Please see the response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule. Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis.

RFC: Should EPA include impingement trading?

Further, species-specific survival data from other power plants in the same region should be allowed to be referenced by other sites to gain entrainment “credits” to be applied to the baseline assessment, while still allowing a facility to do its own survivability studies to gain additional credits. This would allow facilities in the same ecoregion to rely on existing data to supplement any site-specific studies needed.

EPA Response

Please see response to comment 316bEFR.034.027 regarding the role of trading in today's final rule.

RFC: Entrainment vs. entrainment mortality

The data presented to the Agency in the NODA is important because it shows that site-specific factors are critical in assessing entrainment losses. EPA should not impose a global approach on what should be a regional process. Sites with data to show entrainment survival (or with resource information for similar waterbodies within the same region) should be given credits towards meeting the performance standards. Similarly, if it can be shown that entrained (or impinged) organisms belong to a group identified as nuisance or invasive species by the State, credits should be given to the facility to offset selected control technology or performance standard requirements. These matters can appropriately be addressed between the regulated entity and the State permitting/natural resources authority as part of a compliance plan incorporated into the regulated entity's NPDES permit.

EPA Response

Please see response to comment 316bEFR.305.001 with regard to entrainment-based performance standards. Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis.

EPA methods: age 1 equiv, yield, prod foregone

Impingement Age Class

Based on comments received, EPA has revised its impingement loss estimates to include other fish age classes beyond the age 1 class assumed in the original analysis. While the Agency's effort to improve the estimation methodology is appreciated, the shift in the predominant assumed impingement age class is in the wrong direction. The Agency has suggested that it revise its impingement costs based on a more natural age distribution, with heavier emphasis on the inclusion of older age groups, to provide a normal distribution of life stages impacted by impingement. However, the reality is that most impinged species are young-of-year (YOY), age 0 fish, and not older individuals beyond the age 1 class. Impingement studies done at several power plants in the Midwest have all shown that a majority of all impinged fish are age 0. YOY fish are those most likely to be impinged since their smaller size and limited ability to swim away from a current can result in increased impingement numbers. YOY fish, in general, have a mortality rate of close to 95%, even if they are not impinged. This is likely the reason why impingement (and entrainment) is not a problem affecting overall fish populations in the Midwest. The fish being impinged or entrained would be taken out of the system in any case, due to either predation or mortality from other causes. Larger fish, while sometimes found on traveling screens, likely represent dead or dying (moribund) specimens that have been affected by other stressors and can no longer effectively avoid the intake current. Including higher age class fish in the Agency's impingement analysis will greatly bias the economics in favor of tighter controls due to the assumed taking of more harvestable (and hence, more "valued") fish. It is hoped that the Agency will take this information under advisement when reviewing impingement estimates and develop more realistic population-level impacts that more accurately account for the ages of impinged fish and the resultant decrease in the potential economic and environmental effects.

EPA Response

The commenter expresses concern about EPA's assumptions about the age distributions of impinged fish. EPA has revised its assumptions in a manner that acknowledges that YOY may be predominant among impinged fishes, as described in the EPA response to Comment 316bEFR.029.105.

Organization Midwest Generation EME, LLC

Subject Matter Code 21.04

Determination of compliance

Moribund Fish

As the Agency has suggested in the NODA, moribund fish should not be included in compliance accounting. This is essential, because a great proportion of impinged fish (especially those other than YOY) are already stressed or distressed before they become impinged. They would have died whether or not they became impinged. This factor must be considered in any valid evaluation of the effects of impingement on the overall fish community, as well as in any economic evaluations.

EPA Response

Please refer to EPA's response to comment 316bEFR.306.116 for a discussion of EPA's approach to the exclusion of naturally moribund or dead organisms from determining compliance.

Organization Midwest Generation EME, LLC

Subject Matter Code 6.04
Impacts of CWIS at ecosystem level (popn. vs. indiv.)

Population-Based Approach

To emphasize a point made throughout our comments, EPA needs to consider impacts on a species-specific fish population, and not individual organisms, to determine whether impingement or entrainment is having a negative effect on the aquatic community. EPA also wrongly continues to assess the 316(b) economic benefits and losses on a "per-fish" basis, regardless of the species. This is clearly not appropriate. It only serves to enhance the purported ecological benefits of imposing 316(b) requirements on all power plant discharges. The ecological "value" is in the population of a given fish species, not in individual organisms. Natural compensation exists within any given biological population, which ensures species survival, even at the expense of losing considerable numbers of individual organisms to predation, natural mortality, or other causes. The loss of individual organisms should not be considered adverse unless it can be directly tied to a population-level effect. If no adverse impacts from impingement/entrainment are noted in a State-valued fish population at a given facility, then there should be no need to effect costly control mechanisms which would result in no significant environmental benefit.

EPA Response

Please see response to comment 316bEFR.207.015 for the discussion regarding impacts of cooling water intake structures at the individual versus population level. Please see the response to comment 316bEFR.025.015 for the discussion regarding density dependent compensation.

RFC: Performance/effectiveness of restoration

Author Name Basil G. Constantelos

Organization Midwest Generation EME, LLC

Restoration Projects

EPA is requiring more quantitative criteria to determine the overall success of any mitigation project undertaken in whole or partial fulfillment of the 316(b) requirements. We understand this is an effort to ensure that the project, as designed, will result in the desired outcome. However, the project should be viewed as a best-effort on the part of the regulated entity. The regulated entity should not be penalized if a well-designed project does not perform as intended, due to circumstances beyond the immediate control of the permittee. Midwest Generation generally supports the restoration project concept, which by its very nature is a site-specific/State-specific issue. We would be very willing to work with the appropriate State agencies to develop a workable plan. However, one issue of concern is what the required baseline objectives of any mitigation plan would be and how likely it is that these objectives could be achieved in a particular, site-specific situation. Should the requirements for a “successful mitigation project” be too difficult to achieve (or difficult to measure), the benefits of this option to meet the 316(b) objectives would be effectively negated.

EPA Response

EPA believes there are uncertainties associated with the design, implementation, performance, and assessment of restoration measures. For a discussion of these uncertainties, see EPA's responses to comments 316bEFR.206.055 and 316bEFR.312.006.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

For a discussion of the need for quantitative analysis in the restoration measure context, see EPA's response to comment 316bEFR.202.035.

EPA believes the requirements for restoration measures provide permitting authorities and permit applicants with flexibility. However, any restoration measure must meet all of the requirements described in the final rule.

Author Name Basil G. Constantelos

Organization Midwest Generation EME, LLC

Subject Matter Code 21.04

Determination of compliance

As-Built Approach

While Midwest Generation is largely in favor of minimizing the burdens associated with baseline monitoring and the subsequent analysis of appropriate control measures, where required, we have some reservations regarding what is termed by the Agency as the "as-built" approach. This approach would save monitoring time and money up-front, but may leave the facility with an already-installed technology that does not meet the required performance criteria. This does not appear to be the best course of action for any facility, as site-specific factors should rightly dictate the choice of control technology, not vice-versa. This approach also would not be applicable to impingement, because there is no way to estimate the percentage or species composition of organisms impinged without doing pre-control technology counts.

Pre-control technology installation entrainment monitoring is expensive, but it would be the option of choice for Midwest Generation. This is true for all of our affected sites, since we do not have any recent data to determine what the current entrainment or impingement rates are. We need this information to determine what type of control or operational technologies would be the most cost-effective to achieve the performance standards, (contingent upon agreement with the State that controls are required). It is likely that several seasons of data would be needed to determine representative impingement and entrainment estimates. Depending on the results of these studies, it should be up to the State regulatory agency to propose appropriate reduction goals (if deemed necessary, dependent on waterbody and species involved) and work with the permittee to incorporate the installation and subsequent monitoring of the required control technology(is) into the NPDES permit in a compliance schedule.

EPA Response

EPA agrees that the "As-Built" approach is an acceptable method for establishing the calculation baseline. Therefore, a facility may choose to use the current level of impingement mortality and entrainment as the calculation baseline (see EPA's definition of calculation baseline at § 125.93). EPA acknowledges that the studies in the Comprehensive Demonstration Study may be lengthy in some cases. Please see EPA's response to comments 316bEFR.034.066 and 316bEFR.002.021 and the preamble to the final rule for a discussion of timing.

Comment ID 316bEFR.317.022

Author Name Basil G. Constantelos

Organization Midwest Generation EME, LLC

Subject Matter Code 21.04

Determination of compliance

Representative Species Approach

This option would require the permittee to identify representative important/indicator species (RIS), instead of considering all species present at the cooling water intake structure. The list may be developed with the input of the local permitting authority and State natural resources agencies. Midwest Generation is clearly in favor of the Representative Important Species (RIS) approach in determining compliance with the performance standards. As stated throughout our comments, we believe it is critical for 316(b) to be applied on a site-specific basis, with greater protection given to those waterbodies and species which are the most sensitive and/or the most important commercially or recreationally to the State. This perspective absolutely requires that compliance be dictated by assessment of impacts on specific species found to be important to the State/local regulatory authority.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Comment ID 316bEFR.317.023

Subject Matter Code 21.04
Determination of compliance

Author Name Basil G. Constantelos
Organization Midwest Generation EME, LLC

Compliance Determination

The assessment of compliance with impingement / entrainment reduction requirements should be determined through the identification and enumeration of individual RIS species. While it may not be possible to attain a uniform reduction for each individual RIS, compliance should be assessed based on achieving the required reduction on an average basis for all RIS species based on a reasonable period (e.g. a two to three years) for evaluation.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Comment ID 316bEFR.317.024

Organization Midwest Generation EME, LLC

Subject Matter Code 21.09

Permit applications/implementation schedule

Compliance Schedules

EPA is appropriately considering extending the compliance deadline for the 316(b) Rule beyond the effective date of the Rule. Given the extensive scope and magnitude of the compliance requirements imposed by the 316(b) Rule, a regulated entity will need sufficient time to review and evaluate the site specific situation of each of its affected facilities, determine the scope of required monitoring to gather pertinent information for selecting an effective control technology, completing the necessary engineering and economic studies to support that selection, and to work with State regulatory agencies to determine the appropriate and necessary compliance schedule under the final 316(b) Rule.

We understand that the Agency is considering (1) allowing an applicant whose permit must be renewed in the first year following promulgation to submit application materials one year after the current permit expires and (2) allowing a two-year extension in the deadline for submitting application materials. However, neither of these options allows sufficient time for the collection of the data necessary to determine the control technologies to comply with the established performance criteria. A minimum of two to three years of seasonal data are recommended for impingement and entrainment in order to determine what the calculational baseline is with a reasonable degree of assurance that the baseline is representative of actual conditions. Midwest Generation does not have current data for any of our facilities, since most were never required to perform any 316(b) related evaluations in the past. From the above guidance regarding the compilation of biological data, we would require at least two to three years for data collection and analysis at each of our facilities before we would have sufficient data on which to prepare the application materials to be submitted to the State. In light of the site-specific issues related to several of our plants in the Chicago Area Waterways (as discussed in Section 4c above), we do not believe that it is prudent to embark on a sampling program before the final rule is issued. It is our hope that a mutually agreed-upon compliance solution for these facilities will be developed, based on State natural resources agency priorities.

In addition, all of Midwest Generation's affected facilities will be in the midst of their 5-year permit renewal cycle when the 316(b) Phase II rules become final. It will be impossible to collect data, analyze compliance options and propose effective control technologies prior to the renewal deadline. It is also reasonable for the Agency to provide adequate time to allow Midwest Generation, and other dischargers in a similar situation, to seek guidance on the compliance implications of Rule 316(b) for each of its facilities with the Illinois EPA prior to initiating any biological, engineering or economic studies. This will allow Midwest Generation to ensure that the studies it performs will generate the data necessary to achieve compliance with the 316(b) Rule, as deemed appropriate by the State. In addition, the workload imposed by the proposed calculational baseline monitoring is not currently being adequately responded to by local biological contractor personnel, who are already overburdened with existing work. The 316(b) rule monitoring requirements, if imposed in a unilateral manner, will result in the increased need for biological consultants and contractors whom have not had a large presence, especially in the Midwestern states, for many years. Therefore, the only workable solution is to include a reasonable compliance schedule into the reissued NPDES permit that will allow for the timely completion of each step of the 316(b) determination process, as defined by the State regulatory agency. This will ensure that compliance controls are implemented, where warranted, within the following 5 to 10 years (depending on final control technology chosen) for each affected site. Considering that the Agency has only recently taken steps to finalize the 316(b) rules, which have existed as guidance since 1977, the comparatively minimal additional time needed to implement the proposed compliance schedule should be acceptable to the EPA, State regulators and the regulated community, as well as environmental interest groups.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

See also response to comment 316bEFR.034.005 for a discussion of the many streamlining efficiencies added to reduce burden in today's final rule.

Author Name Basil G. Constantelos

Organization Midwest Generation EME, LLC

Subject Matter Code 21.05

Role of States and Tribes (alt./equiv. programs)

Midwestern States' 316(b) Experience:

Based on the most recent DOE EIA 767 data (2001), the State of Wisconsin has 28 plants with open-cycle cooling out of 32 fossil-fueled steam-electric generating units (87.5%). In Illinois, 32 out of 47 fossil-fueled steam electric generating units are operated with open-cycle cooling (68%). In these instances, the States have determined the appropriate controls on those facilities located on sensitive waterbodies in response to actual or anticipated adverse impacts. In developing the proposed 316(b) rule for existing facilities, Midwest Generation encourages EPA to build on the solid foundation created by years of State experience with site-specific decision-making under section 316(b) of the Clean Water Act. For nearly thirty years, the States have been allowed to apply sound science and judgment to site-specific data and conditions in order to implement section 316(b) standards. The current Illinois methodology reflects a holistic approach to assessing how to ensure the environmental protection required by the 316(b) rule in site-specific situations. It is not prudent to ignore an established and reliable performance record showing that no adverse environmental impact exists when considering how to protect the environment in the future.

The States are already empowered to take a comprehensive look at adverse environmental impacts. When the States consider the impact of a discharge on individual organisms, they also evaluate that impact in relationship to the overall health of the affected population in, and the water quality of, the waterbody. This holistic approach enables a State to improve its assessment of what is happening in the waters where cooling water intakes are located. Cross-media environmental impacts generally also have been considered by the States when making the appropriate technology choices for minimizing the entrainment and impingement of fish. Consequently, the States have been able to achieve the primary intent of section 316(b) without compromising other environmental priorities. Many States have a well-established approach to evaluating technology choices that consider cost-effective alternatives for achieving positive environmental outcomes. This is especially important because of the huge cost differential between certain technologies and correspondingly different levels of environmental benefits. The States' goal has been, and continues to be, to ensure the protection of the environment based on the application of sound science and engineering, while avoiding the imposition of unwarranted financial burdens on regulated facilities. Because both water and fisheries quality are site-specific factors, and the design, location, and circumstances of each power plant are unique, a site specific decision framework is the best approach to achieving the most cost-effective and environmentally beneficial outcome.

EPA Response

EPA agrees that States may be best positioned to address site-specific concerns at facilities within the State and has included a provision to approve existing State programs in today's final rule at 125.90(c). See also 125.94(e). Please see response to comment 316bEFR.025.017 for additional discussion.

Comment ID 316bEFR.317.026

Author Name Basil G. Constantelos
Organization Midwest Generation EME, LLC

Subject Matter Code 7.01.03
Option 3--Site-specific determination

This is another important example of why flexibility is required to allow the States to direct their limited resources to the protection of the most ecologically important waterways. The proposed 316(b) rule, as presently written, will result in the broad application of uniform controls for waterbodies without the necessary consideration of whether a comparable environmental benefit is attainable.

States should be allowed to determine the overall quality of a particular waterbody, based on current 305(b) report data, and to rely on this determination to support the imposition of 316(b) requirements that are necessary to improve the indigenous fish community. If factors other than power plant operations are influencing the overall quality and biological potential of the system, then States should be empowered to make the determination that 316(b) requirements would not result in any overall improvement to the physical, chemical or biological quality of the receiving water. This determination should be accepted by U.S. EPA and documented in a given facility's NPDES permit in lieu of the imposition of unwarranted 316(b) BTA controls and/or study requirements. The State's determination would remain in effect until significant changes occur either in the waterbody or in the facilities' operations which warrant a re-evaluation of the 316(b) determination for the facility.

EPA Response

A facility may choose to seek a site-specific determination of BTA using the cost-benefit test. Please see the preamble to the final rule for further discussion.

Subject Matter Code 7.01.03

Option 3--Site-specific determination

Midwest Generation believes that the ultimate decisions made by the EPA in this rulemaking have the potential to adversely affect energy costs and supply in our region of the country while not achieving a commensurate environmental benefit. These potential adverse effects are significant and may not be justified or necessary for each regulated facility and/or the associated waterbody. Accordingly, Midwest Generation urges the EPA to devise a workable, site-specific approach that gives to the States the necessary flexibility to make sound choices that reflect and account for the complexities of the issues involved.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees that the final rule will have adverse effects on the energy supply and cost, and also disagrees that the rule will result in minimal environmental benefit. Please refer to sections XI and XII of the preamble to the final rule, as well as the Economic and Benefits Analysis (DCN 6-0002) and the Regional Studies document (DCN 6-0003) in the docket for the final rule.

Great Lakes

Therefore, EPA's reliance on the operational or technological control data from the coastal States to determine potential Rule 316(b) impacts to the Midwest Region is inappropriate. The waterways within the Midwest itself are extremely variable in both natural biotic integrity as well as their recreational/commercial potential. The Great Lakes are our most valuable aquatic resource and provide opportunities for recreational fishing and some commercial harvesting. However, they are not truly representative of the remainder of the waterways in this region, which vary from ephemeral streams to urban canals designed and built to convey treated effluents and commercial navigation. Thus, EPA's proposal to use the 1995 Michigan Recreational Anglers survey as the basis for the economic model for Midwestern States is not appropriate for anything but the Great Lakes themselves, and even then, this data should be viewed with caution as it primarily targets recreationally important species, rather than the entire aquatic community (some of which are undesirable or nuisance species).

EPA Response

EPA agrees with the commenter that the Great Lakes are "our most valuable aquatic resource" and that they are not representative of other waterbodies in the Midwest Region. EPA did not use the 1995 Michigan Recreational Anglers survey as the basis for the economic model for Midwestern States. For the final Section 316(b) rule, these data were used for estimating recreational fishing benefits for the Great Lakes region only. See Chapter G 4 of the Regional Analysis Document for the Phase 2 rule (DCN #6-0003). Other waterbodies within the Midwest were included in the Inland Region in the regional case study analysis.

Response to Public Comment

Subject Matter Code 2.04.04

Use cost-benefit tests

In the Federal Register notice, EPA proposed the following objectionable provisions: first, EPA proposes a new, and wholly unauthorized, cost-based approach that would be used by EPA and industry in determining allowable technologies for Phase II facilities with regard to cooling water intake structures.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Comment ID 316bEFR.318.002

Author Name Patrick C. Lynch

Organization State of Rhode Island Office of Attorney General

Subject Matter Code 2.04.06

Restoration measures in place of technologies

Second EPA proposes that Phase II existing facilities may suggest to implement restoration measures "in lieu of' design and construction or operational methods to meet the performance standards in § 125.94(b) a proposal, which provides zero "minimization of adverse environmental impact" as is required by §316(b)-or site specific requirements imposed under §125.94(c), which would be an extremely resource intensive and unduly burdensome approach for the states.

EPA Response

EPA recognizes that restoration projects do not directly address impingement and entrainment of individual aquatic organisms by cooling water intake structures. Successful restoration measures, however, do help to minimize the impacts that derive from the impingement and entrainment of individual aquatic organisms by cooling water intake structures, thereby accomplishing the specific purpose of section 316(b).

Use cost-benefit tests

EPA DOES NOT HAVE THE AUTHORITY TO CONSIDER COSTS UNDER SECTION 316(b) OF THE FEDERAL CLEAN WATER ACT.

The federal Clean Water Act (hereinafter “CWA”), §316(b) specifically requires that: “any standard established pursuant to section 1311 of this title or section 1316 of this title and applicable to a point source shall require that the location, design, capacity, of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact” (emphasis added). Id at §316(b), 33 U.S.C. §1326.

In the recent case, Whitman v. American Trucking Association. Inc.. et al., 531 U.S. 457, 121 S.Ct. 903 (2001), the United States Supreme Court considered the question of whether the Administrator of the Environmental Protection Agency may consider the costs of implementation in setting the national ambient air quality standards (NAAQS) under Section 109(b)(1) of the Clean Air Act (CAA). In considering this issue, the United States Supreme Court ruled: “the Clean Air Act (CAA) bars the Environmental Protection Agency (EPA) from considering implementation costs in the process of setting national ambient air quality standards (NAAQS)” (emphasis added). Id at 471, 121 S.Ct. 903, 911. The Unites States Supreme Court was unequivocal in its language, “to prevail in their present challenge, respondents must show a textual commitment of authority to the EPA to consider costs in setting NAAQS under §109(b)(1).... Congress — it does not hide elephants in mouseholes.” Id at 466, 121 S.Ct. 903, 908, quoting MCI Telecommunications Corp.. v. American Telephone & Telegraph Co.. 512 U.S. 218, 231, 114 S.Ct. 2223, 129 L.Ed.2d 182 (1994).

For the sake of guidance to EPA in any finalization of a proposed “cost-based” approach under CWA §316(b), it is important to note that the United States Supreme Court acknowledged in American Trucking that while there may have been other standards within the federal Clean Air Act that authorized the consideration of costs, the authorizing language must be section specific, stating with respect to the federal Clean Air Act: “the Act contains no explicit permission for Agency to consider costs as to those standards. Clean Air Act, § 108(a)(2), 109(b)(1), as amended, 42 U.S.C.A. § 7408(a)(2), 7409(b)(1)” (emphasis added). American Trucking, supra at 466; See also “Other provisions explicitly permitted or required economic costs to be taken into account in implementing the air quality standards. Section 111(b)(1)(B), for example, commanded the Administrator to set “standards of performance” for certain new sources of emissions that as specified in § 111(a)(1) were to “reflec[t] the degree of emission limitation achievable through the application of the best system of emission reduction which (taking into account the cost of achieving such reduction) the Administrator determines has been adequately demonstrated.” Id at 467, 121 S.Ct. 903, 909. See also General Motors Corp. v. United States, 496 U.S. 530, 538, 541, 110 S.Ct. 2528, 110 L.Ed.2d 480(1990)(refusing to infer in certain provisions of the CAA deadlines and enforcement limitations that had been expressly imposed elsewhere).

While it is true, therefore, that specific sections of the CWA authorize EPA to consider costs as they pertain to unique technology-based standards, CWA §316(b) does not make any mention, let alone establish “explicit permission” for EPA to consider costs. Further, even if EPA could successfully assert that the reference in CWA §316(b) to “any standard established pursuant to section 1311 of this title or section 1316 of this title...” grants to it the authority to consider costs when determining “the best technology available for minimizing adverse environmental impacts,” such an authorization would not justify the cost-based approach adopted by EPA as section 1311 sets forth a technology standard that is quite unique from the standard established under CWA §316(b) and as section 1316 applies only to new sources. See CWA § 301(b)(1)(A) (requiring the application of best practicable control technology currently available; see also CWA §304(b)(2)(B) (requiring cost of achieving effluent reduction to be taken into account in determining best measures and practices available to comply with subsection (b)(2) of section 1311....); see also CWA §306(b)(1)(B) (requiring that for new sources the Administrator take into consideration the cost of achieving such effluent reduction....).

Finally, with respect to EPA’s proposed adoption of a cost-based approach under 316(b), any distinction that can be drawn between technology-based standards and health-based standards is entirely irrelevant to a statutory construction argument. In American Trucking, the United States Supreme Court did not make a distinction between health based standards and technology based standards, but rather found that where the statute did not explicitly authorize EPA to consider costs, EPA was barred from doing so regardless of the type of standard they were considering. Id at 466. The court further held that: “That factor [of cost] is both so indirectly related to public health and so full of potential for canceling the conclusions drawn from direct health effects that it would surely have been expressly give.” Id at 468. Likewise, the factor of cost is so indirectly related to “minimizing adverse environmental impact” that surely it would have been expressly given in CWA §316(b).

For the above-referenced reasons EPA’s proposed rule allows for the consideration of costs in direct contradiction of the United States Supreme Court’s recent decision and outside the scope of its delegated legislative authority.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Subject Matter Code 2.04.06

Restoration measures in place of technologies

EPA DOES NOT HAVE THE AUTHORITY TO ACCEPT PROPOSALS OF RESTORATION IN LIEU OF DESIGN MEASURES TO MEET PERFORMANCE STANDARDS OR SITE-SPECIFIC REOUIREMENTS.

Allowing restoration “in lieu of" design measures to meet performance standards is not contemplated by CWA §316(b). The goal of CWA §316(b) is to use the best technology available to “minimize adverse environmental impacts” (emphasis added).

Logic and the historical practices of EPA involving the enforcement of other environmental programs requires that the above-quoted language be interpreted in a way that would require facilities to use technology to avoid impacts in the first instance, and minimize impacts in the final instance. Mitigation, in the form of restoration, would seem to be a last resort not contemplated by the language of CWA §316(b) and imposed only in conjunction with technologies designed to prevent impacts in the first instance. Moreover, the language of CWA §316(b) suggests that the technology related to the “location, design, capacity, and construction of cooling water intake structures” will be the method by which adverse environmental impacts are minimized. The language does not include “restoration projects.”

Secondly, allowing a facility to propose site-specific requirements to meet performance standards would be unduly burdensome to the state.

Even assuming that authorized restoration projects are allowable within the meaning of CWA §316(b), and would, in fact, minimize adverse environmental impact, the determination of appropriate restoration projects populations requires a comprehensive, and resource intensive assessment of complicated biological interactions in the relevant water body. Furthermore, the proposed rule does not provide any standards to guide permit writers in this assessment, and EPA has acknowledged the difficulty of determining the effects of restoration measures on waterbodies. 66 FR at 65,314. In practice, state, permitting authorities will be required to consider proposed site-specific requirements, which will unduly burden the resources of the states.

EPA Response

For a discussion of EPA’s authority to include restoration measures as an aspect of cooling water intake structure design technology in today’s rule, see the preamble to the final rule.

Subject Matter Code 21.05

Role of States and Tribes (alt./equiv. programs)

THE RIGHTS OF THE STATES TO IMPOSE MORE STRINGENT LIMITATIONS THAN THE FEDERAL GOVERNMENT HAS BEEN EXPRESSLY RESERVED IN THE LANGUAGE OF THE CLEAN WATER ACT.

The State of Rhode Island supports EPA in its reaffirmation of the states' rights to impose more stringent limitations than the federal government for the purpose of protecting state water quality. See 40 C.F.R. § 125.84(e).

The language of 40 C.F.R. § 125.84(e) is supported by provisions relating to state law and authority in the federal Clean Water Act. Specifically, CWA §401(d), 33 U.S.C. § 1341(d) provides in part that: "Any certification provided under this section shall. . .assure that any applicant for a Federal license or permit will comply with.. .any other appropriate requirement of State law set forth in such certification, and shall become of condition on any Federal license or permit subject to the provisions of this section." Id. Further, CWA §510 states in relevant part: ". . .nothing in this chapter shall (1) preclude or deny the right of any State or political subdivision thereof or interstate agency to adopt or enforce .. .(B) any requirement respecting the control or abatement of pollution, . . .or other limitation, ... or (2) be construed as impairing or in any manner affecting any right or jurisdiction of the States with the respect to the waters ... of such States." (emphasis added) Id.

The aforementioned provisions of the CWA are consistent with the goals of the CWA as identified in CWA §101, and make clear that states' authority to impose more stringent water quality limitations was preserved by Congress.

The State of Rhode Island would encourage EPA to maintain § 125.84(e) as written.

EPA Response

EPA has included provision 125.90(d) and 125.94(e) to preserve a State's right to develop more stringent standards.

Comment ID 316bEFR.318.007

Organization Mercatus Center at George Mason University

EPA's Estimation of Nonuse Values of Impinged and Entrained Fish

In the proposed rule published on April 9, 2002, EPA used a "50 percent rule" to estimate the nonuse value of fish impinged or entrained by cooling intakes (the 50 percent rule estimates the nonuse value as 50 percent of the use value). However, in response to comments, EPA presents new values for nonuse benefits in this NODA based on a "benefits transfer" approach.<FN 5> As noted above, benefits transfer is "the practice of transferring existing estimates of non-market values from the context of study to a new context."<FN 6> In this case, the existing study EPA used is a contingent valuation (CV) survey conducted of the value of eelgrass and wetlands in the Peconic Estuary on the East End of Long Island.

This comment focuses on the nonuse value estimates provided in the NODA. The NODA also provides estimates of the benefits to commercial fishing and recreational fishing attributable to the proposed rule. While recreational fishing values are not as readily measured as commercial fishing values, which rely on direct market prices, they are more reliably estimated from indirect methods than nonuse values. We do not address EPA's estimates of recreational benefits here.

A Lack of Understanding of the Role of Prices

The first problem in the NODA does not recognize the role of prices. For example, in calculating the value of fish lost to impingement and entrainment, EPA uses a measure it describes as "total yield" and "production foregone." "Total yield" is an estimate of "direct losses of harvested species as well as the yield of harvested species that is lost due to losses of forage species.<FN 7> "Production forgone" is estimated by using "trophic structure and trophic transfer efficiency to estimate the harvested species that is lost because of the loss of forage species to impingement and entrainment."<FN 8> While it is not clear how EPA uses "total yield," and "production foregone" in the calculations, it is clear that assigning prices to these metrics is problematic.

Prices are not static values that reflect only the value of the good in question. Rather, they are dynamic values that change as people's perceptions change about the value of the inputs to the good, the scarcity of the good, and the value of substitutes to that good. By assigning a price to either "total yield" or "production foregone," EPA conflates the value of the good (the fish), with the value of the inputs to the good (the forage fish). While this alone would not invalidate the study, these types of problems are compounded throughout the analysis, resulting in a nonuse value for fish that has no basis in the real world.

8 68 Fed. Reg. at 13,546.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

EPA agrees that prices can depend on perceptions about inputs, scarcity, and substitutes. This is true for all goods, not only fish. For fish, inputs include habitat and other organisms (including but not limited to forage fish); scarcity depends on the status of the stock; and substitutes are other fish. EPA assigns values to the total estimated number of fish lost due to I&E, based on commercial and recreational values for those fish. These fish include recreationally and commercially valuable species as well as forage fish that are inputs to these species through the food web. Through their value for recreational and commercial species, people indicate their value for the inputs to those species, just as the price of a loaf of bread includes the value of all of the inputs used to make the bread. EPA uses standard methods of fisheries valuation found in any resource economics textbook.

Subject Matter Code 10.02.04

Valuing Forage Species (incl non-use and non-landed)

Benefit Transfer Approach

Any benefits transfer approach rests on a number of assumptions and estimates, and EPA's study is no different. The first assumption is that the values from the Peconic Estuary survey of preservation/restoration of eelgrass and wetlands can be transferred to provide useful information about the valuation of fish.<FN 9> This assumption alone is questionable.

The Peconic study was a contingent choice survey conducted "to estimate the relative preferences of residents and second homeowners" on the East End of Long Island.<FN 10> The study asked respondents to choose between bundles of "goods" comprising "physical, environmental, aesthetic, and/or monetary dimensions."<FN 11> One problem with transferring the results from this study is that the contingent choice survey estimated a value for habitat. In the NODA, EPA used the estimating of the values of habitat as a way of valuing how much people value fish. However, if there is a nonuse value for the fish impinged and entrained in cooling intakes, that value is for the fish themselves, not for the habitat the fish live in. EPA's study is a study of nonuse benefits about fish that get entrained and impinged. The relevant value is the nonuse value of the fish, not the habitat.

The EPA's approach estimates the amount of wetland that could hypothetically produce the habitat services necessary for the fish hypothetically impinged or entrained, and then uses information from people's hypothetical willingness to pay for the fish production services of that habitat. Each hypothetical estimate further detaches the final estimate from any mooring connected with actual values. Each estimate, assumption, and hypothetical weakens the explanatory power of the final valuation.

In the NODA, EPA "solicits comments on whether [this] benefits transfer approach provides a more comprehensive value that address all impingement and entrainment losses."<FN 12> Due to the number of assumptions and hypotheticals involved in this approach, there is little reason to believe that the approach provides more or less of a comprehensive value of impingement and entrainment losses than the arbitrary 50 percent method. The real question is if the benefit transfer approach as applied here provides any information at all.

Peconic-based approach

Author Name Mercatus Center at George Mason University

Organization Mercatus Center at George Mason University

The Peconic Study

To develop willingness-to-pay (WTP) nonuse values, the NODA relies on “Measuring Public Values and Priorities for Natural Resources: An Application to the Peconic Estuary System,” a dissertation paper by Marisa J. Mazzotta. This paper is not available online in the EPA’s docket, and we were unable to find it online at all. Since we do not have a copy of the study<FN 13> we assume it is not peer reviewed.

Many questions are raised by the study. The first and most obvious is that the study was conducted in the area surrounding Peconic Estuary: Southhold, Riverhead, Southampton, Easthampton, and Shelter Island.<FN 14> These areas are in Suffolk County, New York. Median household income in Suffolk County $65,288, while the median household income in the rest of New York is $43,393.<FN 15> Not only is the Peconic Estuary more wealthy, “the study found that the survey sample population was better educated and had higher incomes that the population of the area.”<FN 16> This forced the study’s author to adjust the values “to be representative of the general population of the East End in terms of education and income.”< FN 17> It is not known how the study’s author would know and understand the relative preferences of the survey respondents compared to the general population. Also the study’s author had to estimate and adjust for people who lived in the area year-round, compared to seasonal residents.<FN 18> It is also not known how the study’s author could know and understand the relative preferences between year-round residents and seasonal residents to produce.

Another problem with the Peconic study is that, from the information we have, the survey did not ask how much respondents were willing to pay, but rather if each household on the East End of Long Island should pay either $0 for habitat or $50. There are several problems with this for EPA’s purposes. First, it is not a measure of stated WTP, but rather a response to a binary question regarding what others should pay. Second, respondents have no expectation that they will actually be asked to pay the $50 as a result of their response. Third, though the EPA claims the Peconic study provides marginal cost information, individuals were not asked about the marginal cost of habitat, but rather whether they thought that each household should pay a certain amount for a certain amount of wetland.<FN 19> Inferences of people’s marginal preferences may be possible in economics text books, but it is far more difficult, and maybe impossible to derive a valid demand function from people’s responses to a survey of this design.

To use the information from the Peconic study, EPA adjusted the values estimated for wetlands because the wetlands values “reflect all ecological services provided by the wetlands, not just fish and shellfish habitat.”<FN 20> To do this, EPA used another stated preference study to estimate the value people assign to the ecological services for fish and shellfish habitat provided by wetlands.<FN 21> Put in other way, EPA had to conduct benefits transfer within another benefits transfer to arrive at values for its study.

In the NODA, EPA requests comment on its methodology of assigning a share of WTP to “fish production services” for each habitat type.<FN 22> As noted above, there are so many estimates, including estimates within estimates within estimates, it is questionable that any useful value could be derived from this analysis. The real question is, “Is there a connection between these hypothetical values and any values in the real world?” There is no reason to believe that there is a connection. In fact, as will be shown in the next section, because the values in EPA’s analysis are so detached from people’s actual preference, they provide no useful information.

EPA Response

EPA disagrees that a dissertation paper by Marisa Mazzotta is not included in the docket (see DCN #5-1284) and that it is not peer-reviewed. First, the dissertation paper was reviewed by the dissertation committee, whose members include researchers with exemplary reputations and records. Second, a number of peer-reviewed publications were based on this study. For example:

(1) Johnston, R.J., J.J. Opaluch, T.A. Grigalunas, and M.J. Mazzotta. 2001. Estimating Amenity Benefits of Coastal Farmland. Growth and Change. 32(summer): 305-325. (DCN #5-1276)

(2)Johnston, R.J., T.A. Grigalunas, J.J. Opaluch, J. Diamantedes, and M. Mazzotta. 2002. Valuing Estuarine Resource Services Using Economic and Ecological Models: The Peconic Estuary System Study. Coastal Management 30(1): 47-66. (DCN #5-1275)

For EPA’s response regarding demographic differences between the Peconic study area and the policy area, and how adjustments were made for differences in demographics between the survey population and general population, please see response to comment #316bEFR.304.004.

Regarding the Peconic survey itself, the comment reflects an incorrect understanding of the survey and of the contingent choice survey method. The survey did not ask if each household should pay $0 or $50 for habitat. The survey included sixty different questions with different combinations of resource changes and prices, with five questions in each of twelve survey booklet versions. Prices included in the survey ranged from $0 for the “no new action” option to $500, and prices of $50, $100, $200, $300 and $500 were included in the different questions and versions. The questions were developed using a standard fractional factorial plan to allow for statistical estimation of values per acre of the resources included in the survey.

In terms of the connection between hypothetical values and real-world values, non-use (referred to as “passive use”) values are accepted as part of damages caused by oil and chemical spills and Superfund sites, under the Oil Pollution Act and CERCLA. NOAA convened a blue-ribbon panel of economists and survey researchers, including several Nobel laureates, to debate the merits of measuring and including non-use values in NRDA. The panel concluded that these values exist, can be measured, and should be included in damage assessments. As the only generally accepted way to estimate these values is by the use of hypothetical (contingent valuation) surveys, legal precedent has confirmed that there is, in fact, a connection between hypothetical values and values in the real world. In addition, a number empirical studies have compared hypothetical payments to real money payments and shown a correlation between these values.

Valuing Forage Species (incl non-use and non-landed)

EPA's Estimates are Implausible

After numerous estimates, assumptions, and extrapolations, EPA concludes that in the North Atlantic region, the annual nonuse value of fish lost from impingement and entrainment is between $76 million and $140 million a year.<FN 23> This is in stark contrast to commercial fishing's estimated losses of a mere $282,339 per year.<FN 24> In other words the annual value lost nonuse benefits from impingement and entrainment in the North Atlantic is 270 to 500 times greater than the lost benefits to commercial users.<FN 25> To evaluate the validity of these estimates, these numbers need some context.

One way to compare the validity of these estimates is to evaluate them on a per pound basis. According to table X-6, X-7, X-8, and X-9, the total yield per year in the North Atlantic region lost to impingement and entrainment is 1.24 million pounds of fish. This translates to a nonuse value of between $61 and $113 per pound. In comparison, the estimated commercial losses are only $1.12 per pound. This means that EPA estimates the nonuse value of fish to be 54 to 100 times greater than their commercial value. The implication of this is that fish are worth 54 to 100 times more to people if they are left in the water than if a commercial fisherman catches them for human consumption.

This gigantic discrepancy between the estimated nonuse value of the fish and the commercial (or consumption) value begs the question, "why do we still have commercial fishing?" If Americans really value knowing that fish are swimming free so much more than they value eating fish, why do we pay commercial fishermen to catch them for our consumption? If the values EPA produced are truly people's "willingness to pay" for the nonuse value they place on the fish, then why don't people organize, raise money, and buy out the fishermen? Obviously there are some organizing costs to such an endeavor, but the possible societal benefits are enormous. In fact, the societal benefits are so enormous that EPA's estimate of nonuse value could be overstated by an entire order of magnitude, and nonuse values would still dwarf use values. If nonuse values were anywhere near the estimate the EPA provides, we have to assume that environmental groups would organize to collect money and buy out commercial fishing.

To further put the EPA's estimate in perspective, according to the National Marine Fisheries service, in 2001, commercial fishermen landed 9.5 billion pounds of fish. The value of these fish is $3.3 billion. Applying the same benefits transfer approach EPA used here to all fish taken by commercial fisherman, the nonuse value of the 9.5 billion pounds of fish landed may be worth between $580 billion and $1 trillion. Therefore, according to the EPA's logic and estimates, commercial fishing costs the nation between $500 billion and $1 trillion a year – almost 5 to 10 percent of GDP!

Footnotes

23 68 Fed. Reg. At 13,577. EPA estimates that a portion of these losses would be avoided with the proposed rule, resulting in benefits of between $14 million and $27 million per year.

24 68 Fed. Reg. At 13,558

25 See 68 Fed. Reg. At 13,577, table X-44

EPA Response

The comment's first point is that lost nonuse benefits in the North Atlantic are 270-500 times greater than lost benefits to commercial users. This does not take into account a number of factors, one of which is the number of people who benefit from commercial fishing (the commercial anglers) is much smaller than the number of people who receive non-use values. Additionally, fisheries are renewable, open-access resources, which makes comparison of benefits to commercial anglers to benefits to the general public much more complicated than implied by the comment. This is discussed in more detail below.

The comment goes on to compare values per pound for non-use values and for fish commercially caught. Again, the comment misses the complexity of the issue. By definition, non-use values are not connected to use of a resource. They are expressions of peoples' values for the resource in its undisturbed natural state. It is unlikely that people think in terms of values per pound when evaluating their non-use values for wild creatures. Instead, they think of the creatures themselves, or the ecosystem. Therefore it does not make sense to evaluate the validity of non-use values in terms of value per pound. A single whale would likely have a very small value per pound in terms of nonuse value, possibly lower than the price per pound for whale products in countries where it is legal to trade in whale products. Yet, there is a ban on killing whales in the U.S., based on the fact that people hold non-use values for these creatures. If we simply compared the market value of whale products to nonuse value per pound, it would probably make sense to kill off and sell whales. At the other extreme, a well-known and often-referenced study estimated the nonuse value of the striped shiner, a very small fish with no commercial or recreational value. The values per pound for striped shiners are likely larger than the value per pound for whales, and are infinitely larger than the commercial value, which is zero, illustrating the irrelevance of thinking of nonuse values in terms of value per pound. There is absolutely no theoretical connection between non-use values of fish or other wild creatures and commercial market prices of fish or other wild creatures.

The commenter wonders, if non-use values of fish are greater than commercial values, "why do we still have commercial fishing?" The comment neglects to consider certain key points that are standard to fisheries economics and management. First, fish are an open-access resource, often resulting in overfishing in unregulated fisheries, as fishers extract all of the resource rents from the fishery. In the United States, fisheries have been regulated under the Magnuson Act since 1976. The National Marine Fisheries Service receives over $600 million per year to manage marine fisheries in the United States, with the expressly stated goal of achieving the maximum sustainable yield for each managed fishery. The maximum sustainable yield is the maximum allowable catch that allows the stock size to remain constant over time. Therefore, because fish are a renewable resource, fish can be caught in quantities up to the maximum sustainable yield without affecting the total stock, thus allowing fish to continue swimming free in the sea, and allowing for other values, including non-use values. Therefore, it is absolutely possible for Americans to both value fish swimming free, and at the same time to value eating and catching fish. It is irrelevant to argue how much commercial fishing costs the nation without evaluating the sustainable yield status of all fisheries first. If fisheries are managed optimally, then commercial fishing provides additional benefits to the nation, above and beyond non-use and recreational use values. If fisheries are not managed in a sustainable manner, it is entirely possible that commercial fishing costs the nation large amounts in lost values of our shared natural capital. However, the figures presented in the comment are not relevant, as they do not consider the degree to which fisheries are managed in a sustainable manner in the U.S.

Perhaps a market-based analogy will clarify this point. A person may have a certain amount of savings, or financial capital, invested in interest-bearing accounts, stocks or elsewhere. This financial capital earns a return on investment that can be spent without affecting the capital stock. If the capital stock is managed properly, the individual can live off of the returns, thus enjoying both the returns to capital, analogous to fish caught recreationally and commercially in a well-managed fishery, and the capital stock itself, analogous to the fish stock. However, if management produces insufficient returns, the individual may deplete his or her capital stock. Similarly, I&E effects of power plants may deplete fishery stocks, thus reducing the public's overall natural capital, and reducing total benefits available to the public from the fish.

The comment goes on to ask why people do not organize, raise money, and buy out the fishermen. In fact, the American people do this, through the National Marine Fisheries Service, which has boat buyout programs in some fisheries and regions. If people did not believe this program is worthwhile, they would lobby for its elimination. Environmental groups such as the Conservation Law Foundation support these and other programs. In May, 2000 CLF, on behalf of its members, sued NMFS to press for more stringent fisheries regulation.

Valuing Forage Species (incl non-use and non-landed)

Nonuse Values, Contingent Valuation, and Benefits Transfer

This section attempts to address how EPA could derive such implausible results from its analysis. It examines the nature of nonuse values, and the use of contingent valuation methods to measure them. It also briefly addresses the appropriate use of benefit transfer methods.

The nature of nonuse values

"Nonuse" values are alleged to derive from the mere existence of something; in this case, common species of fish. Some economists view nonuse values as a form of externality that must be addressed by government action, while others question their existence.<FN 26> There are several conceptual problems inherent in nonuse values.<FN 27> First, it can be difficult to distinguish true nonuse values from values that do involve the use or potential use of a resource, particularly unique resources, such as the Grand Canyon or Alaskan wilderness, which are often used to illustrate the concept of nonuse values. Though you may not currently visit the Grand Canyon, you may place a value on its continued existence in pristine condition so that your children or grandchildren can enjoy it ("bequest value"), so you could visit it if you chose to ("option value") or so you can see photographs and nature videos of it ("indirect use value").<FN 28> These are all values that derive from potential or indirect use, and are not true nonuse values.

Weikard,<FN 29> for example, distinguishes real nonuse values from these other values based on potential use and altruism, and attempts a theoretical proof to show that individuals would not be willing to sacrifice use values to receive nonuse values. He argues that the concept of nonuse or existence value is inconsistent with generally accepted economic principles.

Boudreaux, Meiners & Zywicki raise related concerns, though they do not deny the existence of nonuse values.

"Although everyone experiences subjective utility gains and losses that do not correspond to market money values, the fact that subjective utility exists in humans does not justify government policy geared to that dimension. Of course, government policy and the law, if they are to serve useful social functions, must be geared to measures of human welfare. But because subjective utility is unmeasurable, government cannot be charged with the task of maximizing utility." (p. 793)

This recognition that nonuse values reflect subjective utility gains and are therefore not measurable or comparable across individuals is important. Though generally discussed in the context of environmental amenities, nonuse values exist for innumerable things. Some individuals may gain nonuse values from the knowledge that the Alaskan wilderness is untouched by oil drilling, while others may gain nonuse values from the knowledge that oil wells exist to provide jobs for Alaskan workers and national security. Some individuals may assign nonuse values to knowing people attend church regularly, while others may gain nonuse values from knowing others engage in hedonistic behavior. The question then becomes, if nonuse values are to be included in government decisions, on whose values should government reallocation of resources be based?

EPA Response

EPA concurs that the estimation of nonuse values is an extremely challenging, complex, and controversial matter. See response to comment 316bEFR.306.105 for further discussion of the feasibility of doing original state preference analysis.

Please also note that for the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. See Chapters A12, Non-use Meta-analysis Methodology, and A9, Economic Benefit Categories and Valuation Methods of the final Phase II Regional Studies Document (DCN # XX). Please see Chapter D1 of the final Phase II EBA document regarding break-even analysis.

Stated preference (Contingent Valuation)

Contingent Valuation

Since there is no market in incremental changes in subjective individual utility, proponents of including nonuse values in government decision calculus turn to stated preference or “contingent valuation” (CV) surveys. Recent draft guidelines for regulatory analysis prepared by the Office of Management and Budget raise concerns about CV surveys, noting “the reliance of these methods on stated preferences regarding hypothetical scenarios and the complexities of the goods being valued by this technique raise issues about its accuracy in estimating willingness to pay compared to methods based on (indirect) revealed preferences.”<FN 30>

Despite concerns about its accuracy, the draft guidelines conclude that CV may be the only method available to estimate “nonuse” values, and do not dismiss CV as a tool. Instead, they state that “value estimates derived from contingent-valuation studies require greater analytical care than studies based on observable behavior,” and proceed to enumerate “best practices” for conducting CV. The best practices for conducting CV surveys address sampling, survey instrument design, transparency and replicability of results.

However, Boudreaux et al show that the practical problems of CV cannot be resolved with better surveys because the technique itself is conceptually flawed.

The questionable results [recognized by OMB and others] are merely the manifestation of greater underlying and incurable problems that render contingent valuation studies generally—and attempts to discern existence value particularly—useless and unreliable. The problem confronting designers of contingent valuation studies is at the conceptual and theoretical level, not at the merely practical level of implementation. Contingent valuation studies are inconsistent with the fundamental Contingent valuation studies are inconsistent with the fundamental principles of economic choice under conditions of scarcity and budget constraints and rest on a superficial understanding of the role played by dollar prices in a dynamic economy. (p. 776)

Values emerge, not as conscious, intentional decisions, but as the unintended and undesigned results of decentralized market activity. People do not have a single value for an environmental amenity, but rather schedules of different dollar figures dependent upon a nearly infinite variety of variables. As a result, Boudreaux et al conclude that stated market values are not acceptable surrogates for market prices.

Kahneman, Ritov, and Schkade have also examined CV methods and results to understand what stated preferences actually express.<FN 31> They find that willingness to pay estimates derived from CV studies, though denominated in dollars, “are better viewed as expressions of attitudes than as indications of economic preferences,” and that “the anomalies of CV are inevitable manifestations of known characteristics of attitudes and attitude expressions.” (p. 204) They find that stated preferences derived from CV studies are analogous to juries' punitive damage awards, and are not consistent with economists' rational models.

Both jury awards and CV results seem to reveal a prescriptive notion of what should be, divorced from actual behavior or revealed preferences. But how much weight should these prescriptive notions carry in designing government policy?

Boudreaux et. al. point out,

In market transactions, we can assume that all individual trades increase individual utility, because the occurrence of the trade itself suggests that the individual values the good received more highly than the good surrendered. Thus, it is only through the process of actual exchange of one good for another that we can know for sure that an individual values one option over another… Divorced from the discipline of making actual choices, the hypothetical choices presented by contingent valuation have little value. (p. 785)

Kahneman et al and Boudreaux et al, through very different paths, reach the conclusion that stated preferences divorced from any expectation of actually having to pay the stated values, are not accurate proxies for revealed economic preferences. The similarities Kahneman et al find between jurors and CV respondents suggests that, like jurors determining civil damage awards, CV respondents view the values they assign as imposing costs on someone other than themselves. They know they will never have to pay the values they profess to place on different amenities. Thus, these responses do not comply with the key concept of opportunity cost articulated in the guidelines – they do not "measure what individuals are willing to forgo to enjoy a particular benefit." Indeed, it strikes us as unrealistic to think that individuals would give up more than a small amount of income or other use value in exchange for a nonuse value. Indeed, as discussed above, the implications of the NODA—that nonuse values of the common fish saved from harm by the proposal dwarf the commercial or recreational value of the fish— is completely implausible. It is equally unrealistic to assume that it is in society's interests to pursue government policies that would divert society's scarce resources based on these subjective, stated preferences.

EPA Response

EPA acknowledges that there are many debates within the economics and related professions regarding the best way to design and implement a stated preference (SP) survey instrument, and that there is also some debate on how reliable the findings would be from such an effort. Overall, however, well conceived and designed SP research has provided useful and credible results in many areas. The SP approach is widely recognized and accepted, if the application is done well. Please see response to comment 316bEFR.306.105 for additional information and discussion.

Benefits transfer

In its draft guidelines, OMB recognizes that it is not always possible to conduct an original study to estimate non-market benefits attributable to regulatory activity. It notes that although "benefit transfer," a method that applies existing estimates to a new context, "offers a quick, low cost approach for establishing values for goods and attributes of goods, you should consider it as a last resort option. Several studies have documented difficulties in applying benefit transfer methods."<FN 32> The draft guidelines go on to list the conditions under which benefit transfer is appropriate and when it is not.

We have endorsed the draft guidelines on this point.<FN 33> However, as discussed above, EPA's use of the benefit transfer method in this case, relying on a survey of willingness to pay for wetlands habitat to measure the value of fish in open waters, appears to defy most if not all of the conditions set forth in the draft guidelines.

Valuing Forage Species (incl non-use and non-landed)

Conclusions and Recommendations

EPA's efforts to place values on the nonuse benefits attributable to reducing fish losses due to entrainment and impingement at power facility cooling water intakes illustrates the problems with attempting to capture subjective utility measures in policy decisions. EPA estimates that the commercial value (or value to American consumers) of the proposed regulations is $80,000 per year. It estimates the recreational fishing value at another $880,000 per year. In contrast, it values the nonuse benefits of the proposed regulations at between $14,170,000 and 26,870,000. On a per-pound basis, the nonuse values of the common fish examined in the NODA are 54 to 100 times greater than actual use values. This is implausible.

EPA's results suggest that every fish consumed actually costs Americans much more in nonuse values than it provides in consumption value. As noted above, the implication of this result is that Americans could experience benefits of between $500 billion and $1 trillion per year, simply by not eating fish. Preferences revealed by the fact that Americans do eat fish shows the impossibility of the benefit estimates presented in the NODA.

Relying on stated preferences regarding hypothetical scenarios is widely recognized to be less reliable than relying on methods based on revealed preferences. In this NODA, EPA compounds the problems inherent in stated preference surveys by attempting to transfer the results of a CV study designed to value wetland habitat to estimate the benefits of common fish species. EPA appears to have gotten caught up in the complicated exercise of adjusting, extrapolating, and transferring, and not stopped to conduct a reality check on the plausibility of the results.

EPA should reconsider its approach to estimating benefits for this rule. The values attributable to commercial fishing (and corresponding consumption) are observable through market transactions and should be included. The values associated with recreational fishing are less easy to estimate, because they involve assumptions about the relationship between number of fish and recreational enjoyment, however, with care they should also be included. The nonuse values of the fish, however, involve subjective utility changes and are not measurable or comparable across individuals. While individuals may experience subjective utility gains from knowing that fish are not entrained or impinged, this does not justify regulation that imposes real opportunity costs. If forced to actually pay for the costs of regulation, it is simply implausible that people would be willing to give up a significant amount of private economic goods in exchange for pure nonuse value of fish.<FN 34>

Footnotes

34 Boudreaux et al defer to Adam Smith, who illustrated the concept two centuries ago with a hypothetical earthquake in China that killed millions. While a European would express sincere regrets about the plight of the dead, his concern would pale in comparison to a comparatively trivial misfortune of his own. Adam Smith, The Theory of Moral Sentiments, referenced in Boudreaux et al. (p. 774).

EPA Response

The comment states that attempting to measure non-use values is problematic because they represent subjective utility. EPA does not agree. Please see EPA's response to comment #316bEFR.319.005 regarding subjective utility.

The comment states that it is implausible for non-use values to exceed commercial values by a large amount. EPA does not agree. There is no theoretical connection between total commercial values and total non-use values. See EPA's response to comment #316bEFR.319.004 regarding comparing commercial and recreation values to non-use values. As elaborated in the reply to #316bEFR.319.004, the fact that Americans eat fish does not mean that non-use benefits from fish are implausible.

For details regarding EPA's benefit transfer approach, presented in the Notice of Data Availability (see 67 FR 38752), please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services.

The comment states that it is "implausible that people would be willing to give up a significant amount of private economic goods in exchange for pure nonuse value of fish." However, the comment does not refer to any empirical evidence for this statement, but is simply expressing an opinion. Numerous studies and evidence show that people are, in fact, willing to give up private economic goods in exchange for non-use values of fish and many other natural resources. See Freeman (2003) as one source of references to studies that have found positive and significant non-use values.

It is not unreasonable to expect that aggregate non-use values for the resources affected by the 316b regulation are much greater than aggregate use values because the number of individuals who directly use the resources (i.e., commercial and recreational fisherman) is much smaller than those who do not.

For example, assume that there are 10,000 people living near a CWIS, and 100 of these people are fisherman. Also assume that these 100 people have a use value of $10 per year from fishing and a non-use value of $5. Non-use value consists of existence and bequest values. Existence value is the value that individuals may hold for simply knowing that a particular good exists regardless of their present or expected use. Bequest value exists when someone gains utility through the knowledge that an amenity will be available for others (family or future generations) in the future.

The nonusers in the community, the other 9,900 people, by definition have zero use value. They may still have a nonuse value. Assume again that these people have a lower nonuse value than people using the resource, or $2.50 per year. This means that the total use value is equal to $1,000 ($10 x 100). The nonuse value for users equals $500 ($5 x 100), and the nonuse value for nonusers is $24,750 ($2.50 x 9,900).

The ratio of nonuse to use for users is 0.5 (there is no ratio for nonusers as you cannot divide by zero). The ratio of aggregate non-use value to aggregate use value is, however, much greater ($25,750 /$1,000) because the number of people who hold non-use values is much greater than the number of people who directly use the affected resources. In fact, for some resources such as endangered species this ratio is infinite, because use value for such species is zero.

General statement of support

The PFBC staff has reviewed the Notice of Proposed Regulations to Establish Requirements for Cooling Water Intake Structures for Phase II Existing Facilities. We understand that EPA is reopening the comment period on all aspects of the April 9, 2002 proposal. Our comments are organized according to the April 9, 2002 proposal and the March 10, 2003 Notice of Data Availability (NODA). In general, the staff supports this initiative as we believe the proposed regulations will serve to significantly reduce fish losses related to impingement and entrainment at cooling water intakes in Pennsylvania.

EPA Response

EPA notes the comment. No response necessary.

Subject Matter Code 6.04

Impacts of CWIS at ecosystem level (popn. vs. indiv.)

Page 17137 – The document states that EPA is concerned with ecosystem-level impacts of impingement and entrainment. The PFBC shares these concerns, but is also concerned with the loss of individual organisms caused by impingement and entrainment. Fish protection measures should take both ecosystem level and individual fish losses into account. We believe that total prevention of impingement and entrainment should be pursued. However, often this is impractical or infeasible. In such cases, restoration measures should be based on restoring the fishery by taking into consideration the replacement costs of individual fish as well as ecosystem level considerations (e.g. production foregone), and the restoration of recreational values that have been lost. This is similar to the approach used in Natural Resource Damage Assessments under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) and the Oil Pollution Act (OPA). We note that the proposed rule does address these issues, which we believe is a major improvement in how Section 316(b) will be implemented in the future. Every effort should be made to make the public trust resources whole when dealing with fish mortality from impingement and entrainment. This has not been the case historically, at least in Pennsylvania.

EPA Response

EPA agrees with this commenter and believes that the provisions in today's final rule will reduce the loss of the large number of organisms killed as a result of impingement and entrainment by cooling water intake structures. Please see the response to comment 316bEFR.025.018. As suggested by the author of this comment, EPA agrees that permitting authorities should take into account not only the individual replacement costs of a fish but also ecosystem level considerations such as production foregone and lost recreational values, into account when determining whether restoration projects will result in comparable performance with the requirements of today's final rule. Please see the preamble of the final rule for the discussion on restoration.

RFC: Regulating limited capacity facilities

Page 17141 – EPA is proposing that facilities that operate at less than 15 percent capacity would be required to implement impingement control technology only (with no entrainment control technology). Regardless of the form of the final rule, we believe that mitigation should be required for all entrainment or impingement losses.

EPA Response

The Agency disagrees with the comment. See response to comment 316b.EFR.330.032 for more discussion of EPA's decision to include a capacity utilization rate threshold in the final rule. See also the preamble to the final rule.

Option 2--Implement performance requirements

Page 17143 – EPA solicits comment on whether the proposed regulation should specify that proper design, installation, operation, and maintenance should satisfy the terms of the NPDES permit, until the permit is reissued pursuant to a revised Design and Construction Technology Plan. We believe this should be the case only if restoration measures are determined on a basis that is retroactive to the time of the original permit.

EPA Response

EPA has included in today's final rule several alternatives for achieving compliance, including demonstrating compliance with a Technology Installation and Operation Plan in place of achieving the numeric performance requirements. Please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Subject Matter Code 11.01

RFC: Proposed use of restoration measures

Page 17146; What is the role of restoration? – Every effort should be made in the proposed rule to allow the greatest possible flexibility in designing and implementing restoration programs. We recommend inclusion of an alternatives analysis requirement for restoration, with the highest priority given to restoration actions on-site, but also including other options, which may be directed at the watershed level, with the lowest priority given to off-site mitigation. Similarly, highest priority should be directed at restoring the same species or group of species impacted, but flexibility should be provided to direct restoration to other species or even broader ecosystem level benefits. Such an approach will permit creative solutions to these resource impacts, which for the most part are not currently being addressed, at least in Pennsylvania.

EPA Response

EPA believes the requirements for restoration measures in the final rule provide permitting authorities and permit applicants with a significant amount of flexibility. For a discussion of the permitting authority's role in determining suitable restoration measures, see EPA's response to comment 316bEFR.212.001.

For a discussion of the appropriate scale on which to conduct restoration, see EPA's response to comment 316bEFR.212.011. EPA does not want to preclude use of restoration measures that can accomplish the environmental objectives of the final rule through an alternatives analysis. However, the alternatives analysis suggested by the commenter could be useful for assessing restoration measure alternatives.

For a discussion of the use of out-of-kind restoration in the final rule, see EPA's response to comment 316bEFR.206.055.

RFC: Consultation with wildlife agencies

Page 17146 – The PFBC is the "state fish management agency" in the Commonwealth of Pennsylvania. The PFBC is authorized to protect, conserve and enhance fish and other aquatic life in Pennsylvania and encourage, promote, and develop recreational fishing and boating interests. As the agency responsible for managing the resources that are most significantly impacted by impingement and entrainment, we believe that we should play a very significant role in consultation related to restoration measures designed to influence these resources. The state and federal fish and wildlife agencies should be included in the rule as agencies that must be consulted in the development of restoration measures. The agencies should be given the authority to veto measures ruled inconsistent with the proper management of the resources they are mandated to protect.

EPA Response

Permit applicants must consult with Federal, State, and Tribal fish and wildlife management agencies with responsibility for fisheries and wildlife potentially affected by a permit applicant's cooling water intake structure in order to determine the species of concern to be addressed in the Restoration Plan. Permit applicant's must also submit a summary of any past or ongoing consultation with appropriate Federal, State, and Tribal fish and wildlife agencies on the use of restoration measures, including a copy of any written comments received as a result of such consultations. The requirements for these interactions are described in the final rule.

The responsibility to authorize restoration measures in the context of the final rule belongs to the permitting authority. For a discussion of the roles and responsibilities of the permitting authority, see EPA's response to comment 316bEFR.060.026. The permitting authority should take into serious consideration, however, the views and advice of other Federal, State, and Tribal fish and wildlife management agencies because of their expertise and responsibilities in fish and wildlife management. Moreover, this final rule does not modify any other state or federal law or requirement that can be applied independent of this final rule.

Subject Matter Code 11.07

RFC: Restoration above BTA level

Page 17147 – We agree strongly with the proposal to require an over-design of restoration measures as a built-in margin of safety. This is a common practice related to wetland restoration activities associated with Section 404 of the Clean Water Act and it makes sense here as well, given the many uncertainties associated with restoration measures. The “margin of safety” could perhaps be tailored to the sensitivity of the affected resource, especially if the measures to be implemented are relatively inexpensive in relation to the benefits to the applicant of not implementing more costly control technologies.

EPA Response

For a discussion of the roles and responsibilities of the permitting authority in determining the appropriate level of performance to satisfy the requirements of the final rule, see EPA's responses to comments 316bEFR.060.026 and 316bEFR.212.001.

Subject Matter Code 12.02

RFC: Monitoring frequencies

Page 17149; minimum frequencies for impingement and entrainment monitoring – Monitoring frequencies should be established to address the inherent variability (as determined by a pilot test or previous study at the site) in the rates of impingement and entrainment rates at a particular facility. Standard statistical procedures can be followed to establish sample sizes needed to establish appropriate levels of precision in the estimates (e.g., 95% confidence intervals within 15-25 % of the mean). Sampling frequency should likewise be determined so that the accuracy of the estimates will be reasonable. Because impingement and entrainment rates can vary greatly with season of the year, monitoring should be of sufficient frequency to allow precise estimates within each season, month or biweekly period, as appropriate for the specific fish community that is being impacted.

Subject Matter Code 15.02

RFC: States to demonstrate comparable env. perf.?

Page 17152 – We do not believe that states should be given the latitude to provide less protection than would be achieved under Sec. 125.94. Of course, it should be up to the states to decide if they want to provide more control.

EPA Response

Today's final rule allows States and Tribes to demonstrate alternative regulatory requirements (§ 125.90(c)) that will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment in the performance standards. Additionally, § 125.90(d) states that nothing in today's rule precludes a State or interstate Agency from adopting or enforcing any requirement that is not less stringent than those required by Federal law. However, providing less protection is not an option with regard to alternative regulatory requirements.

UWAG definition of "adverse environmental impact"

We disagree strongly with the definition of an adverse impact proposed by UWAG. The UWAG definition is very subjective, and we believe designed to result in unnecessary ambiguity in dealing with what is in our opinion a fairly straightforward issue, i.e., if fish are killed, and technology measures to prevent these mortalities are for some reason infeasible, then the resource and the users of that resource should be made whole by way of appropriate levels of mitigation.

EPA Response

EPA agrees with this commenter. Please see the response to comment 316bEFR.002.019 for the discussion on the definitions EPA rejected for adverse environmental impact in this rulemaking.

RFC: Use of previous demonstration studies

Page 17165 – We believe that the final rule should permit the use of a previous 316(b) demonstration only in the case when there has been no change to the biota of the water in question or to the facility. This is very unlikely to be the case in Pennsylvania, where most 316(b) demonstrations were conducted over 20-25 years ago. Perhaps the best way to address this is to only permit previous demonstrations to be adequate if they were done within the last five-year period and there has been no documented change in the fishery or the operation or design of the facility.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule; however, existing data that is reflective of current conditions may be used to support the required studies. Please see response to comment 316bEFR.040.001 for details.

Comment ID 316bEFR.320.035

Author Name John A. Arway

Organization Pennsylvania Fish and Boat Commission (PFBC)

Subject Matter Code 21.04

Determination of compliance

Page 13582 – We believe the “all species approach” or perhaps a hybrid of the “all species approach” and the “representative species approach” to determine compliance with impingement and entrainment performance standards would be appropriate. The hybrid approach we would recommend is that the compliance be measured for all species in total but also include certain highly important species as determined by the federal, state, and tribal fish and wildlife management agencies. In other words, this approach would require X% reduction in mortality for all species combined with the option for X% reduction in mortality for certain individual species as determined by the agencies. The number of species selected should be at the discretion of the agencies. Regardless of the option used, however, restoration should be provided to address any remaining losses. We recommend that compliance monitoring be based on numbers of organisms and not biomass.

EPA Response

In today’s final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA’s response to comment 316bEFR.017.003. For EPA’s explanation of EPA’s monitoring requirements, please refer to EPA’s response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Author Name John A. Arway

Organization Pennsylvania Fish and Boat Commission (PFBC)

Subject Matter Code 21.04

Determination of compliance

Page 13583 – We believe that the permittees should not be responsible for moribund organisms that are impinged. To reduce ambiguity, we recommend that this be limited to organisms that are already dead at the time of impingement, and not to organisms "previously injured," as this necessitates the need to determine the extent of the injury, the definition of this condition, etc. Also, it is often very difficult to collect individuals in baseline studies without injuring or even killing them. Removing only fish that have obviously been dead (e.g., those discolored or in some degree of decay) is the most reasonable way to deal with this issue, especially since previous comments accompanying this proposed rule suggest that in many occasions, entrainment is underestimated.

EPA Response

Please see EPA's response to comment 316bEFR.306.116 for EPA's position on accounting for naturally dead or moribund organisms.

Permit applications/implementation schedule

Page 13585 – We recommend that detailed re-assessments be required every 5 years, with the option to extend this to a longer period (e.g., 10 years) if agreeable to the Director, in consultation with the federal, state, and tribal fish and wildlife agencies, based on information that conditions have remained substantially unchanged at the facility since the initial evaluation. We believe that the proposed language under Sec. 125.95(a) is generally acceptable. However, this should include additional language that specifies specifically how a determination will be made that conditions have remained unchanged, i.e., the language should stipulate that a null hypothesis of “there has been no change in X condition at this facility,” be developed and the appropriate statistical tests and specific criteria for testing this hypothesis be established as part of the initial permit.

EPA Response

EPA agrees that permits should be re-evaluated every five years and has included a provision in today’s final rule whereby the facility may receive reduced information collection requirements if conditions (such as biological, chemical, or physical) at the cooling water intake structure and waterbody remain substantially unchanged since the last permit issuance (see 125.95(a)(3)). See response to comment 316bEFR.034.005 for a discussion.

Regional Benefits Approach

EPA identifies its regional approach to developing benefits estimates and then presents its estimates for only two of the eight regions. When will EPA present its methodology and use benefits for the other regions? Will interested parties be given an opportunity to comment on these benefit analyses?

EPA Response

EPA's methods for the other regions were the same as those presented in the NODA for two regions. Please see responses to Comment 316bEFR.041.041 and Comment 316bEFR041.037. Results are presented in EPA's final analysis for the section 316b Phase II rule (DCN #6-0003).

Regional Benefits Approach

Author Name Robert H. Reider

Organization The Detroit Edison Company

EPA is proposing combining similar species into family groups or groups used by NMFS for landings data (page 13545). Species should be combined according to their taxonomic classification and not by their common names. Ex: two widespread species whose distributions overlap, the trout-perch (Percopis omiscomaycus) is in the Order Percopsiformes which is unrelated to the Order Perciformes to which belongs the logperch (Percina caprodes). (These two species were erroneously combined in at least one of the case studies.)

EPA Response

EPA agrees with the commenter, and made every effort to ensure that species groupings were biologically appropriate. EPA also carefully reviewed the species groupings proposed in the NODA (Federal Register: 68 FR 13522-13587) and revised them as needed to more accurately reflect biologically meaningful associations.

EPA methods: age 1 equiv, yield, prod foregone

EPA states that data collected at the Salem and Millstone facilities indicate that individuals older than age 1 were collected and that EPA's assumption that all impinged fish were age 1 resulted in an underestimate (page 13546). While this may be true for these two facilities, it is certainly not true for all facilities. As stated in the comments on the Monroe case study, for several of the major species the majority of the impinged fish were less than one year old.

EPA Response

Please see response to Comment 316bEFR.029.105 concerning EPA's assumptions about the age distribution of impinged fish for its final analysis for the Phase 2 rule.

Valuing Forage Species (incl non-use and non-landed)

EPA provided no explanation as to how it arrived at the 99.92 percent value for "unvalued" fish in the Great Lake case study indicated in the footnote on page 13567.

EPA Response

The percentage of impinged and entrained fish that are unvalued is calculated as the total number of age 1 equivalent fish lost to the commercial or recreational harvest divided by the total number of age 1 fish lost to I&E. Updated estimates of the percentage of unvalued fish in each region are provided in the EBA for the final Section 316(b) Phase II rule (DCN #6-0002).

Comment ID 316bEFR.321.007

Author Name Robert H. Reider

Organization The Detroit Edison Company

Subject Matter Code 10.02.04

Valuing Forage Species (incl non-use and non-landed)

EPA's literature review of nonuse and use values references appears to consist primarily of surface water valuation studies rather than fish studies.

EPA Response

EPA agrees that the available primary studies included in the NODA do not (in general) value fish directly. The selected studies estimate willingness-to-pay for improvements to aquatic habitat that directly benefit fish populations. The policy context, however, calls for willingness-to-pay to prevent the loss of fish directly. The two are strongly correlated, but not identical. This divergence is imposed by the available meta-data. For EPA's response to comments on applicability of the surface water valuation studies to the analysis of non-use benefits of the 316(b) regulation, please see comment #316bEFR.338.046.

Cooling system costs (e.g., dry, wet, recirculating)

Net Installation Downtime for Compliance Technologies Other Than Recirculating Cooling Towers.

In the analysis supporting the proposed rule, EPA assumed that compliance technologies other than cooling towers would not require facility downtime for installation. 68 Fed. Reg. 13,525. In the NODA, EPA reversed this assumption. EPA now expects downtimes of between two and eight weeks for the installation of various non-recirculating cooling tower compliance technologies. While Georgia Power appreciates EPA's revision of this assumption and recognizes it to be a positive step, EPA must recognize that under certain circumstances, based on the characteristics of a particular facility, the downtime could exceed eight weeks.

EPA Response

The Agency has further revised the net downtime estimates for non-cooling tower technologies for the final rule. For a few situations, the Agency has estimated net downtimes approaching 11 weeks. As such, the general comment has been met, though based on much more specific and detailed research by the Agency. See the discussion of the specific technology cost modules in the Technical Development Document for the final rule.

Cost Modules

Technology Costs Modules.

EPA developed a new approach to determining compliance costs that include a broader range of compliance technologies than it used for calculating compliance costs for the proposed rule requirements. 68 Fed. Reg. 13, 526-27. At the time the rule was initially proposed, EPA based its cost analysis primarily on the addition of fine-mesh traveling screens with fish handling systems. EPA, through the NODA, has added explicit cost modules for a much broader array of compliance activities that EPA believes will ensure compliance with the proposed performance standards. The revised and new technology modules analyzed by EPA include the following: (1) addition of fish handling and return system to an existing traveling screen system; (2) addition of fine-mesh screens (both with and without fish handling and return system) to an existing traveling screen system; (3) addition of a new, larger intake in front of an existing intake screen system; (4) addition of passive fine-mesh screen system (cylindrical wedgewire) near shoreline; (5) addition of a fish net barrier system; (6) addition of an aquatic filter barrier system; (7) relocation of an existing intake to a submerged offshore location (with velocity cap inlet, passive fine-mesh screen inlet, or onshore traveling screens); (8) addition of a velocity cap inlet to an existing offshore intake; (9) addition of passive fine-mesh screen to an existing offshore intake; (10) addition or modification of a shoreline-based traveling screen for an offshore intake system; and (11) addition of dual-entry, single-exit traveling screens (with fine-mesh) to a shoreline intake system. Georgia Power supports the expanded list of compliance technologies. Georgia Power encourages EPA to add as many of these technologies as possible to the proposed streamlined technology option. Georgia Power is concerned, however, that the expanded list of compliance technologies may result in resistance to restoration options. EPA should make it clear that the availability of compliance technologies should not impact a permittee’s choice of proposing restoration measures.

EPA Response

EPA has added as many of the candidate best technologies available as possible to the streamlined technology option, as the commenter recommends. The Agency has also has clarified that restoration measures, though not preferable to technologies in the cases where technologies are feasible, may be used in addition to or in lieu of design and construction technologies and operation measures.

Subject Matter Code 7.04

Streamlined Technology Option

Streamlined Technology Option for Certain Locations.

In response to comments that the proposed Comprehensive Demonstration Study requirements would impose too great a burden on permit applicants, EPA is considering two variations of a streamlined compliance option. 68 Fed. Reg. 13,539 - 41. Under the first variation, EPA would evaluate the effectiveness of specific technologies with respect to the performance standards. If EPA identifies technologies that are sufficiently protective under certain conditions, EPA would promulgate regulations that allow for their use as a means of compliance.

Under this streamlined option, the permittee would have to provide documentation that it meets the applicable conditions and that, once installed, the facility will properly operate and maintain the technology. Georgia Power supports this option; however, Georgia Power urges EPA to specify that the permittee need only "substantially meet" the applicable conditions. Because monitoring would be required, as necessary, to verify that the technology is in fact achieving an acceptable level of performance, Georgia Power does not believe it is critical that all conditions be specifically met. To the extent that monitoring reveals a deficiency, the permittee can then be required to make appropriate adjustments.

Under the second variation of the streamlined option, the Phase II regulations would establish the criteria and process for approving cooling water intake structure control technologies. Under this option, the rule would define the criteria that a control technology must meet to be approved, and the process for approval. Georgia Power also supports this option. Indeed, Georgia Power strongly encourages EPA to not only approve both streamlined options, but to also allow States to create other streamlined options consistent with their State programs.

EPA Response

EPA disagrees that the permittee should only be required to "substantially meet" the applicable conditions to qualify for the Approved Design and Construction Technology Option. It should be stated, however, that whether a facility does meet the applicable conditions will be determined by the various State permitting Directors. If a facility can prove that it meets the specifications for the option, it is likely that the Director will approve that method of compliance. With regard to allowing States to create additional streamlined options, EPA agrees. As stated in § 125.99(2)(b), "…any other interested person may submit a request to the Director that a technology be approved in accordance with the compliance alternative in § 125.94(a)(4)." This could apply to a permitting Director as well as to a facility operator, or other interested party. In addition, States have the option to demonstrate that their programs will achieve environmental results equivalent to those results that will be seen through the implementation of today's final rule. In both ways, EPA is demonstrating support for States that have made or desire to enhance efforts towards creating 316(b) programs.

RFC: Appropriateness of "significantly greater"

Definition of "Significantly Greater."

EPA seeks comments on whether it should adopt a quantitative definition of "significantly greater," and if so, what specific ratio would be appropriate. 68 Fed. Reg. 13541. For several reasons, we believe this term is better left defined by the States. First, because Section 316(b) has been applied and implemented in a variety of ways by the States over the last 30 years, the States are in a much better position to determine what amount over a 1:1 ratio is "significantly greater" to justify a site-specific standard. For instance, a particular State's historical approach to addressing 316(b) and the resources used in addressing the related issues may inform a State's thinking on how much additional resources are justifiable. In some cases, depending on the types of aquatic species that are at risk, a particular State may want added assurance that harm is minimized. Second, given the lack of economic justification for a "significantly greater" standard (we believe that any amount over the EPA estimates, for example, should qualify a permittee for a site-specific standard), it makes sense to allow the States to come up with their own rationale for justifying any amount over a 1:1 ratio. Third, EPA has revised the capital and operation and maintenance costs for several compliance technologies. Overall, for the preferred option, the cost updates reflect a 66% increase in the total capital costs and a 48% increase in the operation and maintenance costs. These increases reflect better information as a basis for EPA's estimates. In many cases, these increases will make it more difficult for industry to pursue, unjustifiably, a site-specific standard. However, and even more importantly, these updated and purportedly more accurate estimates will provide States with good baseline numbers to serve as guidance in evaluating how much more would constitute "significantly greater." To the extent that EPA has confidence in its estimates, EPA should trust the States to determine how much more it should cost a permittee before a site-specific standard is justified.

EPA Response

Supports rule. No response necessary.

RFC: Entrainment vs. entrainment mortality

Entrainment Survival.

Georgia Power urges EPA to allow use of entrainment survival data for purposes of establishing compliance with the entrainment performance standard. 68 Fed. Reg. 13541. There is simply no rational basis to reject the use of credible scientific evidence of entrainment survival, where available. Georgia Power believes that the details of establishing the extent of entrainment mortality at a particular facility should be worked out between the permit writer and the permittee.

EPA Response

Please see response to comment 316bEFR.305.001 with regard to entrainment-based performance standards.

Comment ID 316bEFR.322.006

Author Name Mike Wilder or Nancy Gilbreath

Organization Georgia Power Company

Subject Matter Code 11.06

RFC: Performance/effectiveness of restoration

Measuring the Success of Restoration.

Georgia Power commends EPA for proposing the use of restoration as a mechanism for achieving compliance with the performance standards. The restoration option provides an abundance of room for creativity and flexibility, especially with respect to focusing resources on a precise problem. Further, it enables State agencies to work closely with permittees in determining how best to effectively and efficiently address entrainment and/or impingement. It also provides new opportunities for communities to get involved in identifying projects that may provide significant benefits to communities as a whole. Georgia Power, therefore, urges EPA to not be too prescriptive in setting forth methods of determining the success of restoration projects. The appropriate metrics or methodologies for making this determination should be left up to the State agencies with the most knowledge of the affected waterbodies and the relevant aquatic communities.

EPA Response

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

EPA believes the requirements for restoration measures provide permitting authorities and permit applicants with flexibility. However, any restoration measure must meet all of the requirements described in the final rule.

Author Name Mike Wilder or Nancy Gilbreath

Organization Georgia Power Company

Subject Matter Code 21.04

Determination of compliance

Implementation and Other Regulatory Refinements.

Calculation Baseline. Under the proposed rule, EPA defined the "calculation baseline" as "an estimate of impingement mortality and entrainment that would occur at your site assuming you had a shoreline cooling water intake structure with an intake capacity commensurate with a once-through cooling water system and with no impingement and/or entrainment reduction controls." Based on comments that the proposed definition is too vague, EPA is considering adding certain specifications to the definition and seeks comments on these refinements and other considerations. See 68 Fed. Reg. 13580. Georgia Power is very comfortable with EPA's proposed definition without additional specificity.

EPA Response

For a discussion of the definition of calculation baseline, see the preamble to the final rule.

Subject Matter Code 21.04

Determination of compliance

Author Name Mike Wilder or Nancy Gilbreath

Organization Georgia Power Company

Options for Evaluating Compliance with the Performance Standards.

EPA is evaluating two basic options for determining compliance with the proposed performance standards (i.e., the percent reduction): (Option 1) consideration of all fish and shellfish species that have the potential to be impinged or entrained; or, (Option 2) consideration of fish and shellfish from only a subset of species determined to be representative of all the species that have the potential to be impinged or entrained. 68 Fed. Reg. 13, 581 - 13,584. For either approach, species impinged or entrained may be measured by counting the total number of individual fish or shellfish, or by weighing the total wet or dry biomass of organisms. Georgia Power believes that the only practical way to implement Option 1, the all species approach, would be to use the total number or the total biomass of the species without regard to their taxonomic grouping. The total biomass approach would be more straightforward and workable. At the very least, EPA should preserve the options (both the all species and representative species approach) for the States to decide which methodology would be preferred based on the waterbody and other factors the States deem relevant.

With respect to the representative species approach, to the extent that EPA includes language requiring permittees to develop a list of “critical aquatic organisms” for agency review, Georgia Power urges EPA to provide a “consulting” role for the State agency rather than a “concurring” role. Also, EPA presents two options for making the compliance determination using “critical aquatic organisms.” Georgia Power urges EPA to focus on the first option which would be to determine compliance based on a “total enumeration of individuals from all of the listed critical aquatic organism species,” rather than a separate analysis for each species. See 68 Fed. Reg. 13,583 Col. 2.

EPA Response

In today’s final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA’s response to comment 316bEFR.017.003. For EPA’s explanation of EPA’s monitoring requirements, please refer to EPA’s response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Permit applications/implementation schedule

Compliance Timeline and Schedules.

EPA requests comments on whether the final rule should allow facilities required to apply for a permit renewal shortly after promulgation of the Phase II rule additional time to complete the studies associated with submitting a permit application. 68 Fed. Reg. 13, 584 Col. 2 - 13,586 Col. 2. The bigger issue is EPA's overall approach to scheduling compliance with the final rule. EPA should make it clear that the actual performance standards themselves will not become effective when the rule is finalized. The performance standards themselves (or site-specific standard, to the extent one is sought) become effective in accordance with the appropriate NPDES permit conditions subsequent to submission of all necessary information and demonstration studies. Furthermore, Georgia Power anticipates that it will take approximately four years to complete a typical comprehensive demonstration study. This includes time to hire consultants, consult with State agencies, compile data, draft and finalize reports. Accordingly, Georgia Power respectfully requests that EPA grant all permittees whose permits will expire within the first four years after the rule is finalized a categorical four year extension to submit the initial 316(b) comprehensive demonstration study and associated information.

EPA Response

EPA agrees with this comment and has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

Comment ID 316bEFR.322.011

Author Name Mike Wilder or Nancy Gilbreath

Organization Georgia Power Company

Subject Matter Code 21.01.04

Comprehensive demonstration study (7 parts)

Georgia Power is concerned that the proposed rule could be interpreted to require both entrainment and impingement characterization even when the permittee would not be required to reduce entrainment (such as in a lake or reservoir). Georgia Power urges EPA to clarify that entrainment characterization studies are not required where the permittee is only required to reduce impingement.

EPA Response

In today's final rule, EPA has clarified which facilities will be subject to impingement mortality standards only, and which facilities will be subject to both impingement mortality and entrainment standards. Please refer to § 125.94(b)(1)-(3) (National Performance Standards) for explicit instruction on which performance standards are required for each facility type.

RFC: State or Tribal alts. achieve comparable perf.

We noted that the State of Maryland believes that our existing 316(b) CWIS regulations have been and continue to be protective of the environment and the State's natural resources. For this reason, we suggested that the Phase II rule include the option of a State's existing regulations being accepted as satisfying 316(b) requirements,

EPA Response

Today's final rule maintains the prerogative of a permitted State to demonstrate to the Administrator it has adopted alternative requirements that will result in reductions in impingement mortality and entrainment within a watershed comparable to those that would be achieved under § 125.94. This alternative recognizes the successful achievements of many states in regulating environmental impacts associated with cooling water intakes.

Subject Matter Code 6.04

Impacts of CWIS at ecosystem level (popn. vs. indiv.)

We strongly supported a site-specific approach for determining BTA to minimize Adverse Environmental Impacts (AEI). We also stated our belief that AEI should be considered at the species or ecosystem-effects levels and not simply on the basis of the numbers of organisms entrained and impinged.

EPA Response

Today's final rule allows for site-specific determinations of the best technology available for minimizing adverse environmental impact. It is unclear what the commenter means by species and ecosystem-effects levels. The requirements in today's rule are based on reducing the number of organisms impinged and entrained in order to protect species and eliminate ecosystem-wide effects. Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision to not define adverse environmental impact in today's final rule.

Comprehensive demonstration study (7 parts)

Comprehensive Demonstration Study (VII.B: 13539)

In our August 5, 2002 letter, we commented that the plans for any comprehensive demonstration study (CDS) should be reviewed and approved by the Director prior to initiation because a State's site-specific knowledge is likely to be needed to ensure that the study will produce the information necessary for making a permitting decision. We agree that a CDS may require substantial effort on the part of a licensee and thus support the idea of providing a stream-lined alternative that applicants might follow, which would reduce the burden on both the permittee as well as the state regulatory agencies. With regard to the two stream-lining options described, they both appear to be reasonable, but we would favor the second, since it would give the State flexibility and discretion in making site-specific evaluations and decisions. It would, however, place a greater burden on the State than would the first alternative, where EPA would specify an acceptable technology and the State would merely have to confirm that the applicant was going to install that technology. Thus, from a nation-wide perspective, it may be best to include both of those streamlining options in the final rule.

We do have concerns about the ability to make precise technology efficacy determinations that would serve as a basis for establishing decision criteria that may be used by Directors. Our knowledge of the existing body of literature on technology effectiveness suggests that there is a high degree of variability in results of the many studies that have been performed, and there are no studies that have integrated all of these data and established quantitatively and conclusively all of the factors affecting performance and relative contribution of each of those factors to the variability observed. In the absence of such an assessment and with the likelihood that such an analysis may not be possible, any performance criteria that may be established would have to encompass the uncertainty documented in the literature. That is, a range of efficiency would have to be provided rather than a single value (e.g., 55% to 85% reduction in entrainment, rather than 70% reduction in entrainment). Because it will not be possible to precisely define technology efficiencies, the second streamlining option, in which Directors would have the flexibility to make reasoned decisions, may be the best streamlining option.

EPA Response

EPA agrees that it should include both of the approved design and construction ("streamlined") technology alternatives, and has done so in today's final rule at § 125.99. EPA also agrees that ranges of efficiency should be provided as opposed to a single value. In today's final rule, EPA has set ranges of performance standards for both impingement mortality and entrainment. Furthermore, EPA believes that any performance within specified ranges (80-95%; 60-90%) should count as compliance. EPA opted for performance ranges instead of specific compliance thresholds to allow both the permittee and the permitting authority a certain degree of flexibility in meeting the obligations under the final Phase II rule.

RFC: Appropriateness of "significantly greater"

Definition of "Significantly Greater" vs. "Wholly out of Proportion" (VII: 13541)

As we stated in our August 5, 2002 letter, Maryland concurs with EPA's decision to utilize a "significantly greater" cost test in this Phase II rule. We agree that, for existing facilities, cost of retrofit relative to the benefits gained should be a major factor to be considered in determining BTA. We also do not disagree that new facilities should be held to a cost higher standard ("wholly out of proportion") for the reasons presented in the NODA. Maryland has used a quantitative definition of "significantly greater" in its existing CWIS regulations. For mitigation of impingement losses, the additional costs to install and operate CWIS modifications over a 5-year period are not required to exceed 5 times the estimated value of impingement loss (COMAR 26.08.03.05D). Entrainment losses have no specific cost test in current regulations. However, mitigation of entrainment losses is required (by installing and operating functional modifications to the CWIS) if there is a statistically measurable effect beyond the legal mixing zone, on a spawning or nursery area of consequence for Representative Important Species (COMAR 26.08.03.05E).

Since EPA has proposed specific performance measures which do not include measurement of adverse environmental impact, it may be more difficult to craft a reasonable and precise definition of "significantly greater". We suggest that if EPA is to attempt such a definition, that considerable research may be necessary to adequately demonstrate that it is reasonable. This is not likely possible before the deadline for the new rule, and thus we believe that EPA should not provide any quantification of "significantly greater" and leave this determination to the discretion of the Director, who is likely to be most familiar with the circumstances at a specific facility within his jurisdiction.

EPA Response

Supports rule. No response necessary.

Assumptions about I&E survival

Assumption of Entrainment Survival (IX.A: 13541)

EPA seeks comment on their assumption of 0% survival of entrained organisms and on whether entrainment mortality and survival should be accounted for in their benefits assessment. The agency also seeks input on the design and implementation of entrainment and mortality studies. Maryland has shared the concerns expressed by EPA concerning the wide range of entrainment mortality and survival values that have been documented in the literature and the uncertainty associated with such values. Because of these concerns, in our 316(b) evaluations of most power plants in Maryland in the late 1970s and early 1980s we also assumed 0% survival in assessing whether entrainment losses were having a significant effect on spawning and nursery areas of consequence. All these assessments were conducted nearly 20 years ago, such that we have not had cause to reassess our acceptance of that assumption. Given the difficulties in conducting studies that would precisely document the percentage of entrained organisms that would survive after their discharge into the receiving waters, we would be reluctant to depart from our assumption of 0% survival. However, we are aware of study technologies, such as the larval table, that have been developed to provide the most accurate assessment possible of entrainment survival and mortality. We are also aware of literature that suggests that the eggs and larvae of some species, such as striped bass, may be quite hardy and may exhibit significant survival after entrainment. For these reasons, we would suggest to EPA that the assumption of 0% survival be required, unless an applicant can provide results of very rigorous and scientifically valid studies that conclusively prove otherwise. Thus, we support EPA's suggestion of specifying data quality objectives with very high technical standards that would have to be met by any applicant who chooses to challenge the 0% survival standard. Given the site-specific nature of entrainment effects, we believe that it is appropriate to require that such an applicant conduct site-specific studies supported by literature findings.

EPA Response

EPA agrees with this commenter today's final rule requires the assumption of zero percent entrainment survival for determinations of compliance with the requirements of the rule. In the case of site-specific benefits analyses, entrainment studies may be incorporated; however, they must first be approved by the permitting authority. Please see the response to comment 316bEFR.305.001 for the discussion regarding the inclusion of entrainment survival estimates in site-specific benefit analyses. Please see the response to comment 316bEFR.305.001 regarding entrainment-based performance standards.

Please see the response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule. Please see the chapter, Entrainment Survival, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule.

RFC: Performance/effectiveness of restoration

Uncertainty in Restoration Project Performance (IX.B.1-2: 13541-13542)

Maryland agrees that there can be great uncertainty in the benefits of restoration projects and that an adaptive management plan can be one way to ensure that ecosystem benefits anticipated from restoration projects implemented as mitigation are achieved and meet the objectives established for those projects. However, we are concerned that this approach can result in potentially opened-ended costs to a permittee which may be unreasonable, particularly if very comprehensive and precise restoration objectives are not established at the onset of the project. Should EPA choose to include adaptive management of restoration projects in the new rule, we suggest that the agency also include very specific guidance on how to establish quantitative, measurable restoration objectives, and include a cost factor or some sort of monetary cap on expenditures to limit exposure of a permittee to unlimited costs to comply.

EPA Response

EPA believes there are uncertainties associated with the design, implementation, performance and assessment of restoration measures. For a discussion of these uncertainties, see EPA's response to comment 316bEFR.206.055. The use of adaptive management is intended to help reduce uncertainties associated with restoration measures and enhance their overall productivity (see EPA's responses to comments 316bEFR.307.047 and 316bEFR.311.022).

For a discussion of limits on the resources expended on restoration measures, see EPA's response to comment 316bEFR.312.006.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

EPA believes the requirements for restoration measures provide permitting authorities and permit applicants with flexibility. However, any restoration measure must meet all of the requirements described in the final rule.

RFC: Performance/effectiveness of restoration

Peer Review of Restoration Projects (IX:B.3: 13542-13543)

Maryland believes a peer-review requirement potentially has merit. Although it may increase costs and delays in the permitting process, the benefit in a more cost-effective and efficient restoration project is likely to be outweighed by the initially higher cost and time to conduct the peer-review. However, we know from experience that a selection of peer reviewers with absolutely no biases or preferences is extremely difficult, and it is likely that an applicant as well as all stakeholders with interest in a facility would seek to have significant influence on the selection of the peer review panel. EPA should consider specifying in the rule some process for selection of unbiased reviewers, including, perhaps, the use of independent organizations such as the National Academy of Sciences to identify potential peer reviewers.

EPA Response

For a discussion of the use of peer review, see EPA's response to comment 316bEFR.312.006. As described in the final rule, peer reviewers are chosen through consultation between the permitting authority and permit applicant. Every effort should be made to select unbiased reviewers.

Cooling system costs (e.g., dry, wet, recirculating)

As a general matter, EPA's approach to analyzing cost impacts has emphasized conservatism, i.e., ensuring that cost impacts of compliance are not understated. ("EPA has approached the compliance costing effort with great conservatism.") (p. FR 13527). For example, the analysis selects best performing rather than the least cost measure that achieves compliance. The EPA's conservatism is appropriate and helps address concerns regarding uncertainty.

EPA Response

The Agency appreciates the commenter's understanding for the approach to conservative estimates of costs (i.e., that the costs help address concerns regarding uncertainty of technology performance, as EPA stated in 68 FR 13527).

Cooling system costs (e.g., dry, wet, recirculating)

Installation downtime. EPA has revised its downtime assumptions for retrofit closed-cycle cooling systems to up to seven months for nuclear plants and four weeks for non-nuclear plants. (FR 13525) Such downtimes are likely to be coordinated with other scheduled outages, such as refueling outage for a nuclear plant. Hence, the analysis should ensure that only "incremental" downtime is included in the analysis.

EPA Response

The Agency points out that the downtime estimates analyzed for both the proposal, NODA, and final rule were “incremental” downtimes. The Agency referred to them as “net construction downtimes,” perhaps that is where the confusion lies with the comment. Therefore, the comment only reiterates the analysis conducted by the Agency and does not contradict its approach to downtimes.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

Author Name Richard I. McLean & J. James Dieter

Organization Maryland Department of Natural Resources and Maryland Department of the Environment

Installation downtime for IPM. Installation downtime could be an important cost for a nuclear plant if seven months (or at least several months) of replacement power is, in fact, required as suggested in the NODA. The problem is that it is unclear whether this is adequately captured in the IPM analysis. The IPM analysis shown in the NODA is for the year 2010, and is intended to be a representative post compliance year. The results for this year appear to exclude the downtime costs needed for installation of the compliance equipment since installation (and therefore downtime), assumed to occur prior to 2010. Thus, results for 2010 may not accurately represent all costs incurred. This is a limitation of the IPM modeling.

EPA Response

EPA agrees that the effect of downtimes is not captured in the results for 2010. However, for both the NODA and the final rule, EPA analyzed modeling results for 2008 to capture market-level impacts during the technology installation period. For the NODA, EPA analyzed the market-level impact at 2008 for two options: the NODA preferred option and the waterbody/capacity-based option. For the final rule, EPA also analyzed the market-level impact at 2008 of the final regulation. These analyses did not show significant impacts as a result of the Phase II rule during the installation period. See also DCNs 5-3002, 5-3121, and 6-0002.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

IPM Net Income Analysis. The IPM model runs calculate the impact on (pre-tax) net income by NERC region. (For example, see Exhibits 1 and 2 of the NODA.) This presentation appears to overlook the fact that most NERC regions are dominated by generation-owning utilities subject to full cost of service regulation (the major exceptions being MAAC, ERCOT and NPCC). By definition, captive retail customers must pay the full cost of compliance, and therefore there can be no adverse pre-tax income effect for regulated plants. In fact, cost of service utilities will receive an increase in pre-tax income as customers provide utilities with a return on investment associated with the compliance retrofits. It should be noted that Exhibit 1 presents an estimate of change in wholesale price per mWh, but this may be meaningful (in terms of consumer impacts) only in "retail access" regions.

EPA Response

EPA agrees with this comment. EPA notes that for regulatory analyses conducted for the EPA, the IPM model generally uses assumptions that reflect wholesale competition occurring throughout the electric power industry.

Capacity Utilization Measure. We agree with the suggestion in the NODA that capacity utilization (for purposes of the 15 percent threshold estimate) is better obtained from the IPM model (using only steam generation) rather than historical data. This is due in part to the substantial increase in new merchant plant capacity (mostly gas combined cycle) which tends to drive down capacity factors for existing (less efficient) gas and oil units.

EPA Response

EPA agrees with this comment.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

Non-IPM cost impacts - annualization. The NODA (FR 13534) identifies "annualized costs" of compliance of $265 million under the preferred compliance option and about $800 million for the alternative water body/capacity-based option. However, the annualization calculation method is not discussed in the NODA. The proper annualization calculation will depend on the assumed remaining life of the Phase II facility. Some of these facilities have operated for decades and in most cases do not have announced retirement dates. (nuclear plants, of course, have approved operating license dates.) Given the uncertainty over power plant remaining life, it may be appropriate for EPA to employ range of annualization factors to capture uncertainty over remaining life.

EPA Response

EPA notes that the methodology of annualization was described in Chapter B1 of the Economic and Benefits Analysis in support of the proposed rule (DCN 4-0002). Since the methodology did not change between the proposed rule and the NODA, this methodology was not re-published in the NODA.

Conceptually, EPA agrees with the statement that proper annualization will depend on the assumed remaining life of Phase II facilities. However, EPA notes that the concept of a fixed, limited remaining operating life is generally not applicable to non-nuclear facilities. Component replacement and repowering are common with the consequence of significant extension of the expected useful life of electric generating units. As a result, while individual parts of the generating system have a finite life, the overall facility and surrounding infrastructure need not be viewed in this way. While it is true that nuclear plants have approved operating license dates, this does not mean that they will cease operation at the end of their license term. In fact, given their low operating costs and efficiency, many nuclear plants are expected to renew their operating licenses beyond their current expiration date. Finally, EPA notes that for the final rule, all technology costs were annualized over a 10-year period, which is less likely to exceed the remaining life than the 30-year period for cooling towers. As a result, EPA believes that its annualization methodology used for the final rule is based on appropriate assumptions.

Economic impacts on consumers/households

Cost of Compliance Per Household. The calculations of electric rate impacts appear reasonable subject to the simplifying assumption that all compliance costs incurred by generating facilities ultimately flow through to end use customers. This assumption probably is reasonable in most cases. However, in reporting the cost per household, it appears that the reported impact reflects only a household's utility bill. Households also will incur costs assigned to industrial and commercial electric customers who will flow such costs through to households in the prices of products they sell. That is, it is reasonable to assume that businesses will not absorb their now higher electric bills but will include those added costs in their product prices. Thus, the final per household impact shown on Exhibit 12 is probably substantially understated because the product price effects are omitted.

EPA Response

EPA performed a sensitivity analysis assuming that 100% of compliance costs are passed through to residential customers. This analysis provides a ceiling of the potential effects on residential customers. Please refer to response to comment 316bEFR.072.208 for a discussion of this analysis.

Commercial Fishing Benefits

Commercial. As discussed in the NOPR, the proper measure of commercial fisheries economic benefits from compliance is the sum of changes in producer and consumer surplus. The NODA also correctly states that consumer surplus does not change if compliance has no net impact on dockside fish prices. Presumably, the price change would occur only if compliance meaningfully affects overall market supply for a given fish species.

EPA appears to propose using a rule-of-thumb of 0 to 40 percent of the change in gross revenue to estimate producer plus consumer surplus. We understand that practical considerations may support this simplified approach, although the NODA does not make clear how the point value within this range will be selected. The NODA (FR 13548) also claims this to be conservative "because it does not account for shifts in marginal cost curves." We are puzzled by that assertion and believe that the percentage of gross revenue implicitly does, in fact, reflect improved fishing productivity (i.e., the same quantity with less effort or more quantity with the same effort), and therefore shifts in marginal cost curves.

Recreational. The NODA suggests that greater fish stocks due to compliance will improve the recreational fishing experience and therefore angler benefits, and that this qualitative improvement also may increase the number of person fishing days. While these concepts appear reasonable, we believe that their validity should be very rigorously documented in the docket, to show that this assumed behavior of recreational fishermen can be documented to occur nationwide for all fisheries. Past work by PPRP on recreational benefits has measured local or statewide economic activity benefits, e.g., local job creation and income gains from expanding the recreational fishing industry. While such employment gains may not be meaningful for a nationwide study, they can be important for localized studies.

EPA Response

For response to comments regarding commercial fishing benefits for final rule, see response to comment 316bEFR.005.029. For detail on EPA's approach to estimating recreational fishing benefits for the final 316(b) rule, see Chapters A11, Estimating Benefits with a Random Utility Model, and Chapter 4, RUM Analysis, in Parts B through H in the final Phase II Regional Studies Document (DCN #6-0003). EPA did not include a quantitative measure of secondary economic benefits (e.g., local job creation and income gains) from an increase in recreational fishing activities in the cost benefit analysis for the final Section 316(b) Phase II rule due to data limitations and because it is sometimes difficult to determine if these impacts are transfers. This omission is unlikely to have a significant effect on the final benefits estimates because the estimated percentage increase in the number of fishing days due reduced impingement and entrainment is small. The Agency, however, assessed this benefit category qualitatively. See Chapter A9, Economic Benefit Categories and Valuation Methods, in the final Phase II Regional Studies Document (DCN #6-0003).

Subject Matter Code 10.02
Benefit Estimation Methodology

Author Name Richard I. McLean & J. James Dieter

Organization Maryland Department of Natural Resources and Maryland Department of the Environment

Discounting. We agree that discounting is appropriate if (and to the extent) there is a significant and identifiable lag between compliance and resultant increase in the fisheries stocks. The NODA does not fully explain the magnitude of this lag. The NODA asserts that "non use" benefits should not be subject to discounting but does not adequately defend that decision. EPA should further explain or document the reason for exempting non-use benefit estimates from
discounting.

EPA Response

Information on the methods EPA used to estimate the time lag between compliance and resultant increase in the fisheries stocks is provided in the Regional Study Document prepared for the analysis for the final Phase II rule. See Chapter A14 (DCN #6-0003). See also response to comment 316bEFR.005.029 for discussion about lags and discounting.

EPA does not estimate nonuse benefit in the analysis of the final rule. However, EPA has explored methods for valuing nonuse benefits and finds potential for significant nonuse benefits to exist. For a discussion of EPA's exploration of methodology for non-use benefits see Chapter A12 in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003).

Organization Maryland Department of Natural Resources and Maryland Department of the Environment

Subject Matter Code 10.02.04

Valuing Forage Species (incl non-use and non-landed)

Non-Use Benefits. We also note that “non-use” benefits comprise a large proportion of the total benefits estimated by EPA. The valuation of “non-use” benefits remains a controversial topic with results that are often debatable. While we do not offer a technical assessment of the methods used by EPA to develop their “non-use” benefits, we hope that others commenting on the NODA will provide the level of detailed scrutiny that will ensure that those estimates are valid and based on widely accepted methods. It would also be valuable to have those estimates reflect the uncertainty often associated with estimates of “non-use” benefits.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN #6-0002).

EPA has responded to concerns regarding the Agency’s non-use valuation methods in responses to a number of comments. For EPA’s benefit transfer approach, please see EPA’s response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA’s meta-analysis please see EPA’s responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA’s meta-analysis. For EPA’s response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Determination of compliance

Definition and Methods Associated with Calculation Baseline (XI.A: 13580-13581)

Defining a calculation baseline as being the effects of a facility with a shoreline intake and no entrainment or impingement controls is problematic, since this suggests an open pipe with no screen at all, an unrealistic assumption. In such a situation, everything withdrawn from the source water body would be entrained and there would be no impingement (disregarding as a practical matter that a plant could not operate long in this mode due to intake clogging). This is why we suggested in our August 5, 2002 comments that EPA should consider specifying the mesh size that would represent the standard for distinguishing between entrainment and impingement. The third specification in the NODA on this point (traveling screens with 3/8 in. mesh) provides this definition.

However, the first two definitions of calculation baseline that EPA is considering would not apply to facilities with an intake canal. It is difficult to see how one could calculate what the hypothetical E&I impacts would be in these or other cases if they instead had a shoreline intake. Our Maryland experience has shown that intake canals and intake embayments are often attractive to fish and result in enhancement of impingement rates. We see no means of estimating what impingement would have been in the absence of such structures. It would be even more difficult to estimate these theoretical losses if the screen were angled with currents or near the water surface vs. deeper in the water column.

The fourth specification is still vague in that it is not clear if a standard traveling screen of 3/8 mesh would be considered baseline or not. Such a screen is primarily used to prevent debris from entering the intake system; it has the incidental effect of reducing entrainment but potentially increasing impingement (by definition, in the third suggested specification). Thus it is not clear how these issues would be resolved, if this suite of options were included in the design specifications in the new rule.

An "As Built" approach to estimate the calculation baseline may be appropriate, if this definition means that the facility would estimate E&I impacts based on its technology, practices and operating procedures that were employed for normal plant operation in the absence of any specific effort or requirement to reduce E&I impacts. This would avoid the difficulty of whether traveling screens reduce E&I impacts even though that was not their original purpose. However, in this instance, if the facility happens to have been constructed and operated such that the amount of impingement and/or entrainment was low at the initiation of its operation, a requirement that it be reduced by another large percentage would be very unreasonable. We also remain concerned that the compliance standard is specified without regard to the level of impact to the fish populations or community.

We don't feel it is appropriate in most cases to allow facilities to define the calculation baseline using data from other facilities, since that information is likely to be very site-specific. The only exception might be for facilities of similar design located within the same local water body and in fairly close proximity. For example, in Maryland, this exception might apply to Baltimore Harbor facilities with similar intake designs.

Clearly, it is easier to critique potential approaches to this issue that to provide concrete positive suggestions. We believe that if a baseline is to be included in the final rule, it would have to be based on a combination of all the possible approaches described, but ultimately have to be based on what has been observed at a facility over the time it has been operating, within the context of what has been observed at other similar facilities. For example, at Chalk Point, which has an intake canal, the installation of a double barrier net reduced impingement by about 90% from the level observed prior to installation of barrier nets. We believe that such a reduction would be sufficient to document that the existing CWIS at Chalk Point is in compliance with the new rule, regardless of the absolute magnitude (and composition) of the numbers of organisms currently impinged. Conversely, for a facility such as Dickerson station on the Potomac River, where impingement is extremely low, it would make no sense to require CWIS modifications to reduce already low impingement to even lower levels. These examples point out the difficulty in establishing a single baseline estimation approach, and suggest that allowing broad discretion to the Director in establishing baseline may be the most appropriate way to address this issue.

EPA Response

As discussed in the NODA, EPA considered many suggestions for the approach to determining the calculation baseline, and has clarified its definition of calculation baseline in today's final rule (see §125.93). For additional explanation of EPA's definition of calculation baseline, please refer to EPA's response to comment 316bEFR.034.013. EPA agrees that the "As-Built" approach is an acceptable method for establishing the calculation baseline. Therefore, a facility may choose to use the current level of impingement mortality and entrainment as the calculation baseline (see EPA's definition of calculation baseline at § 125.93). With regard to using data from other facilities when determining the calculation baseline, please see EPA's response to comment 316bEFR.343.011.

Subject Matter Code 21.04

Determination of compliance

Determination of Compliance with Performance Standards; Representative Species (XI.B: 13581 - 13583)

We believe it is appropriate to develop quantitative estimates of all organisms (excluding phytoplankton and zooplankton) entrained and impinged. This would be accomplished through a statistically rigorous study design sufficient to allow quantification of total impingement with good levels of precision (e.g., in circumstances where organisms have very "patchy" distributions and sample variability is high, more samples would be required than in situations where distributions are more uniform). Organisms should be identified to the lowest taxonomic level feasible, and quantitative estimates of annual entrainment and impingement estimated. For impinged fish and shellfish (e.g., crabs, shrimp), organisms should also be quantified in size classes. However, we see no particular value in documenting total biomass of entrained or impinged organisms. The species- and size-specific data is what is required to evaluate potential ecosystem effects, and biomass estimates can be derived from those data. For impingement, properly designed mortality/survival studies should be conducted, with the primary interest being the number of organisms killed by impingement, not the number impinged. Also, applicants should be allowed to exclude moribund individuals from their counts (although the numbers of moribound organisms should be reported), so long as there are very specific and definitive
criteria provided for establishing that organisms are moribund.

We don't believe that the use of Representative Important Species (RIS) is applicable for the new rule as has been proposed by EPA, since the rule assumes that the amount of organisms entrained and impinged is the impact of the CWIS. The RIS concept would only be applicable if the intent of the rule was to evaluate whether there were effects on ecosystems or communities. Because of the site-specific constraints on sampling methods, EPA should only offer guidance on sampling objectives, and not include detailed sampling requirements. For the same reasons, compliance should be measured on a facility-specific basis.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Permit applications/implementation schedule

Timing of Phase II rule and NPDES permit renewals (XI.C: 13584-13585)

Maryland agrees that facilities with permits expiring soon after the effective date of the Phase II rule should be given more time to understand and implement the regulation, including the study requirements. Allowing a two-year extension from the date of the final rule for permits expiring within two years of the rule would be a reasonable approach. The regulation should also specifically allow the expiring permits to be reissued at expiration but with a reopener for permit modification for the Phase II rule deadlines.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion. See also response to comment 316bEFR.320.038.

Permit applications/implementation schedule

Author Name Richard I. McLean & J. James Dieter

Organization Maryland Department of Natural Resources and Maryland Department of the Environment

Information to be Required at Subsequent Permit Renewals (XI.C: 13586)

In comments on proposal, Maryland stated that it may be reasonable to require a detailed 316(b) reassessment perhaps only every third permit renewal, unless there is reason to believe there is a substantial change in the affected ecosystem or that plant operations are likely to be causing some significant impact. EPA's suggested regulatory language in the NODA at 125.95(a) meets our suggestion in this regard, although we suggest further guidance on this issue perhaps in a later document.

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to 316bEFR 041.126 for a discussion.

Permit applications/implementation schedule

Information for Compliance with Phase II Rule (XI.C: 13586)

As we stated with regard to the Comprehensive Demonstration Study, it appears reasonable to establish specific time frames for demonstration of compliance, but, given the substantial uncertainties that surround environmental studies, it is also reasonable to provide substantial flexibility to Director in enforcing compliance with those time frames. EPA could provide specific guidance to the Directors so that a reasonable justification is provided for allowing varying timeframes for compliance depending on site-specific circumstances

RFC: Proposed use of restoration measures

Author Name James R. Wright

Organization Tennesse Valley Authority

The Tennessee Valley Authority (TVA), a resource development agency and public (federal) power producer, is submitting the attached two reports into the record in support of EPA's proposal to maintain restoration as a regulatory option under rules pursuant to Section 316(b) of the Act. TVA takes pride in its multipurpose operation of the Tennessee River reservoir system and encompassing ecosystems, stewarding, them in a manner to protect or enhance water quality and aquatic life, recreation, and sustainable development, in addition to providing power production, navigation, and flood control.

The 2 reports are (1) John Sevier Aquatic Biological Program, Paddlefish Stocking and Assessment, Report for 1994; and (2) Aquatic Biological Program for John Sevier Fossil Plant, Walleye Stocking and Assessment Report, 1995. In 1995, TVA provided the Tennessee Wildlife Resources Agency (TWRA) with 5 new rearing ponds, to integrate into its fish propagation, stocking, and management programs, and in which to propagate appropriate fish species for introduction into the Cherokee Reservoir and the Holston River (on which the plant is located). TWRA has and will continue to manage the rearing facilities and stocking programs as it sees fit.

General statement of support

The New Regulation Continues to Have Many Favorable Features

EPA is to be commended for the considerable effort that has been put toward this regulation. There are a number of positive elements in the rule that we endorse and hope will be part of the final requirements. Among the provisions that will improve the overall 316(b) processes are:

- Cost and benefit tests to determine technology suitability;

- The option to use voluntary environmental restoration and enhancement measures to satisfy compliance requirements;

- The use of a 'baseline' intake condition with no controls from which compliance is determined; and

- Allowances for plants with low utilization.

We appreciate that EPA has seriously considered the comments from the regulated community and recognized that the proposed rule needs further refinements. It is also good that the entire slate of issues in the proposed rule remains open for additional comments.

EPA Response

EPA notes the comment. No response necessary.

RFC: Definition of "adverse environmental impact"

However, despite the extensive work and many new considerations offered in the NODA, we continue to be frustrated by the vagueness and absence of clear guidance in this rulemaking. Too many important provisions are still subjective, open for interpretation or simply not addressed.

Science and the Basis for the New Regulation

The Regulation Needs a Definition of 'Adverse Environmental Impact' - It seems clear that the final rule will not attempt to define 'adverse environmental impact'. We continue to believe this is an unfortunate lapse of regulatory oversight. The statutory language is clear. To have a rule that is based on the concept, repeatedly references it, purports to reduce it yet refuses to define it will not serve the process well.

Rather than focus on reducing an absolute number of organisms, EPA should recognize the importance of population-level impacts and accept that, as a matter of basic biology, (sometimes large) losses occur naturally with little or no effect on the health of aquatic populations. In its comments on the proposed Phase II rule, UWAG recommended the following definition:

"Adverse environmental impact is a reduction in one or more representative indicator species that [1] creates an unacceptable risk to the population's ability to sustain itself, to support reasonably anticipated commercial and recreational harvests, or to perform its normal ecological function and [2] is attributable to the operation of the cooling water intake structure."

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

Comment ID 316bEFR.325.003

Subject Matter Code 7.01.03

Option 3--Site-specific determination

Author Name Kenneth S. Johnson

Organization Constellation Generation Group

The New Rule Should Encourage Site-Specific Regulation of Cooling Water Intake Systems – We strongly urge EPA to craft a rule that accepts the site-specific aspects of power plants, their cooling systems, the source water bodies, the surrounding environments and the affected populations of aquatic organisms. All of these factors intuitively argue for greater consideration of a site-specific application of this rule and less uniform, one-size-fits-all alternatives. The original 1977 guidance and regulations required site-specific considerations. There is no sound scientific or technical basis to change EPA's or Congress's 30-year record that promotes site-specific regulation of cooling water intake systems.

There are other reasons to support a site-specific approach to regulating cooling water intake structures:

Entrainment and impingement are largely determined by factors that vary from site to site. Just because the proposed rule distinguishes certain water body types, it does not mean that everything after that is the same and amenable to one type of solution. Power plants are still different, as are water bodies and their surrounding landscapes. In fact, one might suggest that no two plant sites are the same. Every locality has its distinctive environmental characteristics, independent of the facility. Aquatic populations vary and the technologies and control options that are feasible will not perform the same way in certain environments.

Prior (site-specific) determinations should be considered. Also, if there are data that already show there is so little entrainment or impingement that the community is not affected or the economic impact is exceeded by the cost of a comprehensive study, there should be no need for further evaluation.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b) determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact at cooling water intake structures.

A goal of today's rule is to set national minimum performance standards that reflect the best technology available for minimizing adverse environmental impacts. Given that previous determinations of best technology available were not made in reference to the national performance standards, EPA believes that the Director should not rely entirely on historical determinations. EPA believes that these national requirements will promote more effective and consistent implementation of section 316(b) requirements, and ultimately minimize adverse environmental impacts associated with the use of cooling water intake structures by Phase II existing facilities.

Subject Matter Code 7.02.03
Technology Efficacy Database

Author Name Kenneth S. Johnson
Organization Constellation Generation Group

In the NODA @ P. 13539, EPA requests comment on the documents in the “Technology Efficacy Database”, a collection of 148 references on the performance of the recommended intake control technologies. To quote from the FR notice,

“EPA requests comment on whether these data are of sufficient quantity and quality to support the determination that the proposed performance standards are best technology available and that the existing facilities can meet these standards by implementing design and construction technologies either singly or in conjunction with other design and construction technologies (including operational and restoration measures).”

At this time, we do not believe that enough of the proposed intake technologies have demonstrated experience at the operating plant level or under sufficiently representative hydrologic conditions. Until more experience is available to support BTA decisions, it may be premature to suggest that some technologies will meet the performance standards…especially if non-compliance is to be based on strict percent reduction requirements.

Also, while relevant historical and operations experience from other plants has value, we do not want to facilitate hasty decisions or encourage challenges based on a simplistic justification that would be as follows:

“This plant is on an estuary…it installed fine mesh screens and restored a wetland…you are on an estuary…you should do the same.”

Experiences elsewhere are worthwhile but technology determinations are another of the many factors that clearly argue for site-specific determinations.

EPA Response

Please see response to comment 316bEFR.074.005.

EPA notes that many of the studies reviewed during the development of this rule were not analyses of “out-of-the-box” technologies. That is, many of the installations of the various technologies were modified or adjusted to better suit the unique conditions, species, and configurations present at the facility. A key factor in the long-term success of a particular technology is the monitoring, maintenance and adjustments made during the course of its deployment.

Proposed standards for Great Lakes

Author Name Kenneth S. Johnson

Organization Constellation Generation Group

The Great Lakes and Estuaries Do Not Require More Regulation Based on Sensitivity to Cooling System Impacts – The Great Lakes are unique but that does not make them uniquely sensitive. Great Lakes fisheries are highly managed and consist largely of introduced and stocked species. The life history characteristics of the Great Lakes commercial and recreational fish of concern are not put at risk by power plant operations.

Similarly, burgeoning human development and the fishing pressures on the abundant populations of commercial and recreational species have impacted estuaries. That many estuaries continue to be productive in spite of over-fishing, pollution and habitat degradation suggests resilience more than sensitivity. It also suggests that, if the overall health or 'sensitivity' of certain, important waters are at issue, the EPA should place as much attention on more obvious threats to the sustainability of important species. Habitat losses, competition from introduced species, non-point source runoff and over-fishing all contribute [to a greater degree] to the loss of commercial and recreational species.

EPA Response

Please refer to the response to comment 316bEFR.025.013 for a discussion of the Great Lakes as sensitive waterbodies and the presence of introduced and nuisance species.

EPA acknowledges that other factors such as overfishing or declining water quality may also affect fish populations. However, these factors do not diminish the increased potential for adverse environmental impact from cooling water intake structures in tidal rivers and estuaries.

RFC: Proposed use of restoration measures

Implementation of the New Regulation

Allowing Restoration and Environmental Enhancements is Good Policy – Mitigation can be a cost-effective way to offset the impacts of cooling water intake systems and a most reasonable alternative to many technologies. Congress has consistently promoted creation and restoration of wetlands in a number of laws. EPA should not accept the Riverkeeper position that restoration measures are "wholly unrelated" to intake structure technologies and therefore cannot be BTA. The State of Maryland has included mitigation measures as part of 316(b) settlement decisions and we hope the new national guidance will continue to encourage that option. The voluntary option should remain in the final regulation.

EPA Response

In the final rule, EPA allows use of restoration measures to minimize or to help to minimize the adverse environmental impacts that derive from the impingement and entrainment of aquatic organisms. For a discussion of EPA's authority to include restoration measures as a compliance option in the final rule, see the preamble to the final rule.

Comment ID 316bEFR.325.008

Subject Matter Code 11.06

RFC: Performance/effectiveness of restoration

Author Name Kenneth S. Johnson

Organization Constellation Generation Group

The NODA (@ p. 13542) requests comment on additional proposed requirements for the use of restoration measures.

- Documentation of sources and magnitude of uncertainty in expected restoration project performance;

- Creation and implementation of an adaptive management plan; and

- Use of an independent peer review to evaluate restoration proposals.

We agree with UWAG's recommendations on the requirements. All three can be useful to evaluate and endorse a proposed measure but the degree to which each requirement is applied should depend on the specific project. Based on the environment and experience, some activities certainly have less uncertainty and should need less scrutiny.

EPA Response

EPA believes there are uncertainties associated with the design, implementation, performance and assessment of restoration measures. For a discussion of these uncertainties, see EPA's response to comment 316bEFR.206.055. The practices mentioned by the commenter are intended to help reduce uncertainties associated with restoration measures and enhance their overall performance (see EPA's responses to comments 316bEFR.307.047 and 316bEFR.311.022).

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

EPA believes the requirements for restoration measures provide permitting authorities and permit applicants with flexibility. However, any restoration measure must meet all of the requirements described in the final rule.

Permit applications/implementation schedule

Utilities Need Clear Guidance Regarding the Effective Date and Implementation Requirements of the Rule – While we are certain this concern was a high priority comment in many of the responses to the proposed rule, the NODA seems to have done little to lessen the vagueness that detracts from the proposal in so many important places. This is a complex matter that requires the kind of guidance that EPA produced in 1977. We suggest that uniform approaches to this very site-specific activity are not possible without more comprehensive guidance.

CEG has a total of six facilities that would be regulated under this proposal. One nuclear facility has an NPDES permits that expires in December 2004. If the complete application package is due to the permitting agency 180 days before the permit expires (May, 2004), it is most unreasonable to expect to have all the elements of the Comprehensive Demonstration Study completed in time. We will have known the final regulatory requirements for only three months. EPA misses the point when they justify the 180-day requirement (68 FR 13584). This is not about the time that permit writers need to review such complex and extensive submittals. It is about the time the applicants need to prepare the package. In fact, the expanded submittal that permit renewals will become might argue for even more time to review the substantial additional material…after all, most states require the 180-day lead time already and have much less to address (by comparison).

Our concern is about the time we will need to develop the application package with all the elements that the Comprehensive Demonstration Study requires. Sufficient time must be allowed to bring together the necessary information. More important than that, the application must be prepared with the understanding that comes from the final rules. It is unreasonable and unfair to expect the commitment of resources that would be required to prepare the next round of Phase II permit renewal applications before we know what the final requirements will be. (See more under the 'Compliance' headings below)

EPA Response

Comment ID 316bEFR.325.010

Author Name Kenneth S. Johnson

Organization Constellation Generation Group

Subject Matter Code 21.04

Determination of compliance

The Rule Needs a Better Definition of 'Calculation Baseline' and Guidance on How it is Determined - We agree with UWAG's recommendations to factor full operation conditions into a fair baseline characterization. We particularly agree that the process should be consistent with the same, overly-conservative assumptions EPA uses to estimate CWIS impacts and benefits – all fish are alive and in good health when impinged and there is zero survival. To be consistent, the baseline assessment should apply the same assumptions.

We appreciate that there will be a hypothetical, rudimentary basis to which the proposed performance standards will be applied. However, there must be acknowledgement that many cooling water intake systems have always had features that are improvements on (or just different from) the 'baseline' condition. Apart from operational considerations, we still need guidance on how we are expected to factor biological phenomena and all the structural differences that most intakes have into an assessment of a condition that never existed before. EPA (and UWAG, for that matter) continues to address what the 'baseline' intake should look like and we suggest the greater uncertainty is how we determine the entrainment and impingement at such a facility.

EPA Response

As discussed in the NODA, EPA considered many suggestions for the approach to determining the calculation baseline, and has clarified its definition of calculation baseline in today's final rule (see §125.93). For additional explanation of EPA's definition of calculation baseline, please refer to EPA's response to comment 316bEFR.034.013.

Comment ID 316bEFR.325.011

Author Name Kenneth S. Johnson

Organization Constellation Generation Group

Subject Matter Code 21.04

Determination of compliance

Determining Compliance – CEG agrees with UWAG and strongly suggests that the final rule clearly indicates what constitutes compliance with the numerical performance standards. If we complete the demonstration study and install the technology specified in the NPDES permit, we should be considered in full 'compliance'. If monitoring shows that the measures have not actually achieved the required reductions in impingement and/or entrainment, the facility should not be in violation and be penalized. The facility should be expected to evaluate and commit to additional measures to meet the performance standards.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan. EPA disagrees that a facility that is out of compliance should not be subject to enforcement actions.

Comment ID 316bEFR.325.012

Subject Matter Code 21.09

Permit applications/implementation schedule

Author Name Kenneth S. Johnson

Organization Constellation Generation Group

In the NODA @ p. 13585, there is some worrisome language that suggests perpetual reconsideration of 316(b) issues and compliance with every NPDES permit renewal. If a facility has installed and operates technologies that monitoring shows meet the new performance standards, the issue should be closed. The plant has met the BTA standard or its equivalent under the site-specific determinations. To recommend that each renewal application include information that demonstrates that conditions have not changed suggests that facilities may have to monitor constantly in order to have this information. This should not be necessary if the accepted technology has demonstrated that it meets the performance standard.

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to 316bEFR 041.126 for a discussion.

Comment ID 316bEFR.325.013

Subject Matter Code 21.03
Monitoring requirements

Author Name Kenneth S. Johnson
Organization Constellation Generation Group

This same difficulty arises on p. 13586 with the issue of how much time a facility needs to come into compliance. If compliance is NOT just having BTA that is installed/operated/maintained but monitoring that demonstrates that it meets the percent reduction standards, we may have to monitor routinely…as we do for effluent limits. The Clean Water Act enforcement framework has fines for daily non-compliance. If we cannot show we are in compliance every day, how will we counter accusations that we are not? This is another reason why, once monitoring demonstrates that the performance standards are met, the issue should be closed.

EPA Response

Please see EPA's response to comment 316bEFR.021.007.

Comment ID 316bEFR.325.014

Subject Matter Code 21.09

Permit applications/implementation schedule

Author Name Kenneth S. Johnson

Organization Constellation Generation Group

Finally, EPA has some suggestions @ p. 13584 to address the considerable feedback it got regarding how applicants will be able to get the substantial permit application package together when it is due in 2004, shortly after the rule becomes final. We would agree to at least a one-year delay and two years if new biological studies would have to be conducted. We continue to believe that an easy way to cleanly resolve this question would be to make compliance start with a renewed permit that specifically requires all the elements of compliance in the new five-year term. Field studies, economic assessments, technology selection, approvals, installation and compliance monitoring can all be done with the applicants and permit writers having the advantage of knowing the final requirements [and having a guidance manual and training available].

One option we do not want is a 'Compliance Schedule' (p. 13584)…if that approach implies that the facility is not in compliance with the regulations. While EPA describes a process that is attractive and innocent enough, with the permit writer preparing a "reasonable" schedule that "will ensure the facility is brought expeditiously towards compliance", we do not want any presumption that our facilities are out of compliance now. With the understanding that considerable time will be needed to do all that is required, EPA should call the approach an "Implementation Schedule" and make it clear that the facility is not in a state of non-compliance during this intermediate stage.

EPA Response

See response to comment 316bEFR.025.019.

Comment ID 316bEFR.325.015

Author Name Kenneth S. Johnson

Organization Constellation Generation Group

Subject Matter Code 21.04

Determination of compliance

Impingement of Moribund Organisms Must be Factored Into the Impact Assessment – There is no doubt that certain environments can produce conditions that result in mass mortalities of aquatic organisms. Cold shocks in winter and the presence or sudden movement of low oxygen water in the summer have caused fish kills in the vicinity of the Calvert Cliffs Nuclear Power Plant on the Chesapeake Bay. Such conditions have killed or irreversibly weakened thousands of vulnerable fish, which are essentially collected by the plant's intake system. If this happens during impingement sampling, the numbers collected can be overwhelming. However, since impingement monitoring is a sub-sampling process and the numbers are extrapolated to the longer period of plant operation, these episodic events can yield huge estimates of impinged organisms. The final guidance for determining impingement impacts must factor in the obvious influence of episodic events where dead fish are drawn into the plant intakes. Guidance should allow for the development of scientific methods that document such episodes (and ultimately discount this site-specific phenomenon from the impact assessment).

EPA Response

For EPA's position on the factoring of naturally dead or moribund organisms, please see EPA's response to comment 316bEFR.306.116.

Comment ID 316bEFR.325.016

Subject Matter Code 12.03

RFC: Entrainment vs. entrainment mortality

Author Name Kenneth S. Johnson

Organization Constellation Generation Group

The Final Regulation Should Allow Entrainment Survival to Determine Compliance With the Performance Standard – As with impingement, the performance standard for entrainment should be mortality. Mortality is what constitutes the adverse impact…and it can be argued that planktonic organisms that are killed are not as lost to the food web they support, as other parts of the system would be. Also, it seems EPA is going to rather extreme lengths to criticize the body of work on entrainment survival. While many of the utility studies are dated and some methodologies may not be exquisite, one is still left to wonder why EPA does not apply the same level of scrutiny to the studies that support its initiatives.

The assumption of 100 percent mortality is too conservative and is inconsistent with the proposed impingement standard. Also, there are considerations that should be factored into any given facility's impact assessment. If we understand that entrainment mortality is a combination of three primary factors – exposure to heat, biocides and physical stresses, there are site-specific issues to consider. Biocide use is infrequent. Most entrained organisms are not exposed to the chemicals. Some plants have very efficient or substantial condensers and do not reject as much heat to the cooling water. The maximum temperature increase at the Calvert Cliffs Nuclear Power Plant is 12°F, not a significant thermal shock to many organisms. Finally, while certain groups of organisms may be vulnerable to the physical stresses of entrainment, others are not. The foregoing simply supports what many studies have demonstrated…sometimes, a significant number of entrained organisms survive. We need a regulatory framework that honestly assesses impacts and has a valid basis for evaluating the controls that may be required.

EPA Response

Please see response to comment 316bEFR.305.001 with regard to entrainment-based performance standards. Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis.

Subject Matter Code 7.04

Streamlined Technology Option

We Support the Streamlined Technology Option – At 68 FR 13,539, EPA suggests that the burdens of the Comprehensive Demonstration Study might be reduced if a facility in the appropriate water body agrees to install a control technology that has a confirmed history of meeting the proposed performance standards in that type of aquatic environment. Although the proposed example will not apply to any CEG facility, we support the Streamlined Technology Option and any other provisions that will (with sufficient scientific justification) lead to expeditious agreement on compliance without protracted monitoring and reporting.

EPA Response

EPA appreciates Constellation Generation Group's support of EPA's Approved Design and Construction Technology option.

RFC: Appropriateness of "significantly greater"

We Still Need a Better Definition of 'Significantly Greater' – The cost/benefit tests that make economic feasibility a part of BTA selection are one of the most important features of the proposed rule and CEG strongly supports their retention in the regulatory process. However, as we noted in our comments for the 2002 Phase II rule, such a subjective term is not the way to go. 'Significantly greater' is too vague, and clearly needs clarification…preferably as a measurable or quantifiable expression. Otherwise, we face different interpretations across the country and the potential for regulators to say, "the difference is not significant enough."

Permit applications/implementation schedule

Author Name Jay Hudson

Organization Santee Cooper (South Carolina Public Service Authority)

With a projected promulgation date of February 16, 2004, for the Phase II Existing Facilities 316(b) Rule, as EPA discusses in the Compliance Schedule section beginning at page 13525, Santee Cooper believes it would be virtually impossible for facilities to meet EPA's early compliance date indicated as 2005.

The NPDES permit renewal (or modification) application must be submitted at least 180 days before the permit expires. Since the Proposal For Information Collection requires the state Director's approval before the waterbody sampling can begin, we believe permittees will need to submit their proposal to the Director not later than one year before the permit expiration date.

Permittees seeking modifications or renewals will need to ensure enough lead time is scheduled to accomplish their sampling in time to prepare and submit the Comprehensive Demonstration Study, which must include their Impingement Mortality and Entrainment Characterization Study and the Design and Construction Technology Plan. Should the presence, absence, or abundance of representative indicator species be seasonally dependent, as EPA generally recognizes<FN 1> , the permittee's proposal may need to be sent in 15 to 18 months before the expiration date.

From a business perspective, it would not be prudent to initiate any of these activities until the final rule has been analyzed. Assuming up to 8 weeks may be required to analyze the final rule and prepare the Proposal For Information Collection, state Directors are not likely to receive a Proposal For Information Collection before April 2004. Assuming another 30 to 60 days are consumed before the Director's approval is returned, the permittee would not be able to start his impingement and entrainment characterization study earlier than May or June 2004. May or June may be too late in the year to collect data for significant migratory species, so the permittee would have to wait until the spring of 2005 to accomplish the sampling. In this case, permittees whose permits would be expiring or needing modification during 2004 or early 2005 certainly would not be able to comply.

Should some permittees receive the Director's approval in time to proceed and result in the NPDES permit being issued during 2005, additional time would be needed to implement and verify the project. Implementation would likely include obtaining state and federal construction in navigable waters permits, construction of the technology, and performance verification.

We believe a hypothetical date of February 16, 2005 (one year after the projected promulgation date for the final rule) is an optimistic date to assume an NPDES permit could be issued in the above scenario. However, using this date as the "issued date" would leave approximately 10 ½ months to obtain permits, construct, and verify the efficacy of the selected technology.

Santee Cooper estimates that it would take at least 4 to 6 months of this time to obtain the state and federal permits for construction in navigable waters and another 1 to 2 months for construction. Then, the permittee would have approximately 2 ½ to 5 months during the end of 2005 to verify the efficacy and prepare the verification study. This timeframe may not accommodate performing the study within the season for certain migratory species. Thus, we believe the EPA's projected early compliance date of 2005 is very optimistic and demonstrates the need for a compliance schedule.

Footnotes

1 At page 13582, the EPA states "An important consideration in evaluating entrainment is the element of time, i.e., the density of entrainable organisms will fluctuate"

Permit applications/implementation schedule

Author Name Jay Hudson

Organization Santee Cooper (South Carolina Public Service Authority)

At page 13585, the EPA requests comment whether the final rule should allow facilities required to apply for a permit renewal shortly after promulgation of the Phase II rule additional time to complete the studies associated with submitting a permit application. As Santee Cooper noted in comment number 2 above, we believe EPA should allow facilities submitting a permit application, whether for renewal or for modification, additional time to complete the studies. Thus, Santee Cooper believes any provisions that result in the final rule for facilities applying for permit renewals should also be applicable to any facility needing to apply for a permit modification.

Santee Cooper prefers the EPA's second option noted on page 13585 which allows a two-year extension in the deadline for submitting Phase II application materials. For the reasons cited in comment number 2 above, we do not believe one year of additional time, as the EPA's first option allows, is sufficient.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

Organization Santee Cooper (South Carolina Public Service Authority)

Subject Matter Code 21.01.04

Comprehensive demonstration study (7 parts)

At page 13585, the EPA is soliciting comments on the relaxation of application requirements in subsequent permit renewals for facilities that have previously implemented the Phase II regulations. In particular, the EPA notes "Determinations of unchanged conditions may rely upon demonstrations that there is no statistically significant changes in impingement and entrainment at the facility or in the densities of the organisms in the vicinity of the cooling water intake structures." EPA's proposed regulatory language, also at page 13585 and which states, "if conditions at your facility and in the waterbody remain unchanged since your previous application," incorporates this precept by providing that Directors may approve a permittees's request for reduced information to be submitted in their permit application.

Santee Cooper commends the EPA's approach to relax the subsequent permit application requirements which allows applicants to update only the key parts of the application that reflect changes. However, we believe this language could potentially create some "Catch 22" scenarios that would penalize permittees.

For example, it is Santee Cooper's view that the water quality of any waterbody is dynamic with respect to time and may be impacted by many factors<FN 2> , both natural and anthropogenic. Permittees should not be penalized for changed conditions in the waterbody except to the extent they caused the changed water quality conditions.

We also believe it is reasonable to assume that certain permanent <FN 3> facilities, which are properly operated and maintained throughout their life, are likely to continue to operate within or very near their design performance specifications. It is our opinion that impingement reductions of 80-95% and/or entrainment reductions of 60-90% which are verified during the initial compliance with the Phase II rule should result in a significant population improvement to the species within the waterbody over time.

Therefore, it is our view that requirements to perform additional studies to determine if population densities have increased, with an associated potential requirement to ratchet down the previously verified impingement and entrainment reductions, would be punitive. Such requirements would constitute penalizing the permittee for achieving a compounding of benefits that resulted due to the permittee's initial implementation of the Phase II rule.

Therefore, in fairness, Santee Cooper believes permittees that properly operate and maintain "permanent" intake structure facilities, such as those mentioned above, in accordance with the conditions that demonstrated compliance with the Phase II rule should also be deemed to meet the "determination of unchanged conditions" requirement that warrants the relaxed submittal requirements.

Santee Cooper suggests the following language at 125.94(a):

“Those applicants seeking permit renewals or modifications which have previously implemented the Phase II regulations by installing ‘permanent’ technology(ies) and which have also demonstrated compliance through verification monitoring and received the Director’s approval for BTA determination are deemed in compliance with the performance standards and need not resubmit any of the Comprehensive Demonstration Study data previously submitted. Instead, these applicants must submit a certification statement that the previously installed BTA facilities are being maintained and operated in accordance with the terms and conditions previously approved by the Director.”

We do not believe the EPA would not have to develop a list of approved “permanent” facilities, because state Directors would have knowledge of the installed technology and have sufficient data in each facility’s NPDES file to confirm the performance on that technology on a site specific basis.

Footnotes

2 Some factors that have the potential to impact the population density of organisms could include climactic factors, such as droughts, or other anthropogenic factors, such as, but not limited to, new water withdrawers, new wastewater dischargers, changed land uses adjacent to the waterbody, or environmental incidences, none of which may or may not be attributable to the permitted facility.

3 Some potential “permanent” facilities could include structural modifications such as new or modified intake screens, angled bars or louvers, or even new wirewound screens, etc. Gunderbooms or accoustic fish deterrent systems, for example, which may be subject to clogging or electronic failures, etc., probably should not be considered “permanent” facilities.

EPA Response

EPA appreciates Santee Cooper’s support of EPA’s efforts to minimize burden associated with the permit application process. EPA disagrees, however, that a facility should not have to take changes in their facility’s source waterbody into account when determining compliance, or that a facility should be allowed to maintain a technology regardless of the waterbody conditions. The facility should keep in mind, however, that “representative of current conditions” refers to conditions expected over the course of one year. Therefore, unusual peaks or declines in ambient fish densities would not be considered “representative.”

Organization Santee Cooper (South Carolina Public Service Authority)

Subject Matter Code 21.09

Permit applications/implementation schedule

At page 15384, the EPA is soliciting comments on a compliance schedule that would allow a permittee some specific time to come into compliance with the rule. Santee Cooper recognizes the EPA's uncertainty on the appropriate averaging time for verification monitoring. The final decision on which averaging time is appropriate needs to be factored into the permittee's compliance schedule. Santee Cooper believes it would be appropriate to extend the compliance schedule commensurate with the extension in the averaging time for each year beyond one year.

Santee Cooper believes there are circumstances where it may be highly appropriate to extend the compliance schedule into the second round of permitting depending upon the compliance option proposed by the permittee. For example, if the permittee chooses a restoration option, then additional time may be required to measure the success of the restoration.

EPA Response

EPA has clarified timing requirements for the submittal of required studies. See response to comment 316bEFR.034.066 for a discussion. In today's final rule, EPA has left the determination of appropriate averaging time to the Director. The facility could outline an averaging time in its Proposal for Information Collection for review and approval by the Director. See also the preamble to the final rule for a discussion of issues relating to compliance.

Subject Matter Code 21.02

Director's role in determining requirements

On page 15386, the EPA is soliciting comments on how Directors will determine if a facility is in compliance with the requirements of the proposed rule, as well as the time frames for permittees to come into compliance. Santee Cooper agrees with other commenters that existing facilities should not be subject to immediate enforcement actions in the first permit term for failing to meet the proposed performance ranges.

Therefore, we believe the EPA should not specify a definite compliance schedule that should be applied across the board on a national basis in the federal regulation. Santee Cooper believes the Directors should have the discretion to establish appropriate compliance schedules according each permittee's site-specific case. We believe the Director's would be more intimately familiar with the circumstances and potential site specific difficulties encountered by the permittee than EPA and would need the latitude to make such determinations.

EPA Response

For a discussion of timeframe for submitting information under this rule, please see § 125.95(a) and the accompanying preamble text. For a discussion of demonstrating compliance using a Technology Installation and Operation Plan, see § 125.94(d), § 125.95(b)(4) and accompanying preamble text.

Proposed standards for lakes and reservoirs

As fully described in the TXU comments submitted for the Phase II regulations, we believe that southern reservoirs, especially those in Texas, are much different from those chosen as examples in the proposed regulations. Probably the greatest concern for TXU is that none of the various cooling water intake structure technologies discussed or described by the agency have ever been applied successfully in typical Texas reservoirs. The Company is also of the opinion that, based on our intimate knowledge of Texas reservoirs, these same cooling water intake structure technologies are not appropriate and/or will not function effectively. The phrase “not function effectively” means that the technologies will either have a significantly negative impact on the operation of the facility or will not achieve the desired goals for impingement or other measurements.

EPA Response

Please refer to the response to comment 316bEFR.041.551 for a discussion of the biology of reservoirs.

EPA disagrees that all intake technologies are not appropriate or will not function effectively. EPA does agree that some technologies may not be effective at some facilities. However, the final rule does not specify any single technology, thereby providing each facility the flexibility to select the most effective technology for its intake structures. Please refer to section VII of the preamble for a discussion of the basis for the performance standards in the final rule.

Alternative site-specific requirements

If TXU is correct in its assessment of the technologies, implementation of the proposed regulation will be very difficult for both the agency and the affected sites. For that, and the other reasons discussed above, TXU believes that the greatest flexibility possible should be provided to both the agency and the permittee to adjust for the regional biological, hydrological, physical, and climatic differences. TXU endorses those concepts offered in the NODA that provide both the agency and the regulated community the ability to customize these regulations to each situation. This is especially true for those dealing with restoration, the "Calculated Baseline" (and the use of data from other facilities), the use of "Representative Species", removal of moribund organisms, and the use of compliance schedules.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

For information on the role of restoration, please refer to sections VII and VIII in the preamble to the final rule.

For information about the calculation baseline, please refer to § 125.93 and the preamble to the final rule.

For information about representative species, timeframes, and moribund organisms, please refer to section IX of the preamble to the final rule.

Cooling system costs (e.g., dry, wet, recirculating)

Author Name Paul L. Zweiacker

Organization TXU Business Serves obo TXU Energy Company LLC

TXU is also extremely concerned about the economics of these proposals. Although the NODA does correct some of the economic misconceptions found in the original proposal, the agency's improved methodologies still grossly underestimated the cost and significantly overestimated the benefits. The agency must take into consideration the tremendous cost and risk associated with the application of the cooling water intake structure technologies that are untested and unproven in different waterbodies and regions.

EPA Response

The Agency notes that the comment provides no specific examples nor any data to support the commenter's statement that the costs and benefits are overstated. Without further specific reference, the Agency cannot further act on the comment except to counter the assertion that "cost and risk associated with the application of the cooling water intake structure" have been incorporated. See the Technical Development document for the Agency's approach to cost analysis supporting the final rule. Additionally, see the efficacy discussion in the Technical Development Document for a discussion of the demonstrated cases of the cooling water intake structures in different waterbodies and regions.

Option 3--Site-specific determination

Author Name Quinlan J. Shea

Organization Edison Electric Institute

EEI Strongly Supports Inclusion of Site-Specific Elements in Any Final § 316(b) Rule

In our August 2, 2002 comments on EPA's April 2002 NOPR, both EEI and the Utility Water Act Group of which we are a member noted that implementation of § 316(b) of the Clean Water Act inherently involves some site-specific analysis. In determining whether an existing cooling water intake structure is having adverse environmental impact, and if so in identifying the best technology available for addressing that impact, State water quality agencies need to consider the nature of the water body, the cooling water intake structure, and the biota involved.

Therefore, we are pleased that EPA has tried to include some consideration of these types of factors in its proposed rule. We also are pleased that EPA has included provisions in the proposed rule allowing adjustments to be made in the measures required for a given facility if the costs of those measures exceed their benefits or the costs that EPA anticipated. EEI strongly encourages EPA to retain these and other site-specific elements in any final rule, and to ensure that the State agencies can implement the rule reasonably in light of the circumstances at each facility.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Subject Matter Code 21.01.04
Comprehensive demonstration study (7 parts)

EEI also encourages EPA to clarify that facilities whose cooling water intake structures have only minor impingement and entrainment effects do not need to undertake costly new studies or adopt costly new technology, operational, or other measures. For example, if prior or current studies of a particular intake structure show that the numbers of organisms entrained or impinged or the effects of the entrainment or impingement are small, EPA should have a de minimis exception to costly new measures that might otherwise be required.

EPA Response

Please see EPA's response to comment 316bEFR.041.007, for a discussion of what would be required of facilities that demonstrate impingement mortality and entrainment rates lower than the performance standards set by today's final rule.

Facility & firm-level costs/Econ. Practicability

First, based on EPA's revised cost estimates in the NODA, the cost of the water body/ capacity-based option has increased significantly, and that option would impose net social costs in excess of its benefits.

EPA Response

This comment supports EPA's decision not to promulgate a rule based on the waterbody/capacity-based option.

Comment ID 316bEFR.328.004

Subject Matter Code 7.01.03

Option 3--Site-specific determination

Author Name Quinlan J. Shea

Organization Edison Electric Institute

Second, the approach EPA has proposed in the NOPR was a credible attempt to balance the need for administrative simplicity with the realization that site-specific factors can have a major impact on the reasonableness of the standards at any given facility. The consideration of site-specific factors is embodied in three provisions of the proposed rule.

- Performance-based standards allow facilities to choose the most cost-effective means of meeting the standards – provided there is more than one way of achieving the target reductions in impingement and entrainment.

- The "cost-cost" test allows facilities to meet less stringent performance requirements if the costs of meeting the performance standards at a particular facility are significantly greater than the costs envisioned by EPA in establishing the standards. This test recognizes that site-specific technical factors may make the installation of controls to meet the performance standards at a specific location sufficiently expensive that those controls no longer represent a reasonable regulatory approach.

- The benefit-cost test allows facility owners to meet alternative standards if the benefits of meeting the performance standards of the rule are significantly less than the costs of achieving those standards, or stated another way if the costs are significantly greater than the anticipated benefits. This test recognizes that site-specific biological factors may limit the value of potential improvements at a given site and allows a facility to take a more reasonable approach in such circumstances.

The provision of reasonable site-specific safety valves in the rule is a minimum requirement of any rule that the electric utility industry can find acceptable. Moreover, such safety valves avoid perverse regulatory outcomes and should be desired by the regulators and the public as well.

We are encouraged that EPA's proposed rule recognizes the site-specific nature of the cooling water intake structure issue, provides several compliance options based on benefit-cost analysis, and, most importantly, rejects any mandate for the retrofit of costly and potentially inefficient closed-cycle cooling towers that would affect 40 percent of the nation's total installed electric generating capacity.

Moreover, we agree with EPA that the Phase II rule should allow voluntary use of "restoration" measures as a voluntary option to technology and operational measures, so long as the restoration measures are reasonably related to the losses caused by intake structures. Voluntary restoration increases the flexibility of the rule and makes it possible to produce benefits that may last even beyond the life of the regulated facility.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to section VII.E of the preamble for more information on why EPA rejected this alternative.

For information on the role of restoration, please refer to sections VII and VIII in the preamble to the final rule.

RFC: Test: benefits should justify the costs

EPA Should Further Refine the Cost Tests

EPA should modify the "cost-cost" and "benefit-cost" tests so that any cost greater than the anticipated cost or benefits allows site-specific modifications. This would more fully maximize societal benefits and better reflect EPA's economic analyses, by not imposing greater costs than the costs EPA has considered in promulgating the proposed rule and by not imposing costs that exceed benefits

EPA Response

See the preamble for a discussion of the cost tests and site-specific compliance alternative.

For EPA's response to comments on application of the cost-benefit test to assessing the value of alternative CWIS technologies, please see comment #316bEFR.005.020.

Comment ID 316bEFR.328.006

Author Name Quinlan J. Shea
Organization Edison Electric Institute

Subject Matter Code 7.04
Streamlined Technology Option

EEI Supports Additional Streamlining Efforts

EEI appreciates EPA's movement toward identifying technologies that can be presumed to meet performance standards under specific sets of conditions. Specifically, EPA is proposing to allow use of wedge-wire screens as a pre-approved technology and to allow States or EPA to identify additional technology that could be used in specified circumstances. While the cost-cost and benefit-cost tests still are necessary to ensure that the costs of the proposed rule are kept within reasonable bounds, any identification of "pre-approved" technologies, if carefully done, can help reduce costs to permittees and permitting authorities alike.

In allowing use of pre-approved technology, EPA needs to take care to preserve the option for permit applicants to rely on existing technology, operational, and restoration measures, or to propose necessary additional such measures, without the pre-approved technology constraining those options. Further, EPA needs to avoid a "one size fits all" approach in allowing the use of pre-approved technology. As already stated, the 316(b) issue requires careful consideration of site-specific factors. Having an array of pre-approved options can help streamline the permitting process, but it should NOT compromise the ability of an applicant to explore alternatives that best suit its facility's circumstances.

EPA Response

EPA appreciates Edison Electric Institute's support of EPA's Approved Design and Construction Technology option. EPA agrees that existing technology, operational and restoration measures may be used by a facility to comply with today's final rule. In response to the comment that EPA needs to avoid a "one size fits all" approach in allowing the use of pre-approved technology, EPA believes that it has built tremendous flexibility into the Approved Design and Construction Technology Option, and expects that this will encourage and support innovation by industry and State Agencies (see § 125.99(2)(b)).

Comment ID 316bEFR.328.007

Author Name Quinlan J. Shea

Organization Edison Electric Institute

Subject Matter Code 21.09

Permit applications/implementation schedule

EEI Also Supports Reasonable Transition and Compliance Provisions

EEI continues to support transition and compliance provisions for the Phase II rule's requirements. It will take time for facility owners to gather new information required by the rule, examine the options at their facilities for complying with the new rule, and implement any changes that may be necessary in technology, operations, or restoration programs already in place. Similarly, it will take time for State permit writers, in issuing National Pollutant Discharge Elimination System (NPDES) permits under § 402 of the Clean Water Act, to review permit applications submitted to comply with the new rule and to make informed decisions about the appropriate course of action. EPA needs to reflect and allow for this in any final rule.

In addition, the effectiveness of the technology, operational, and restoration measures that EPA has evaluated and States and facility owners will use to reduce impingement and entrainment mortality at cooling water intake structures is likely to vary depending on the circumstances at each facility and each site. Therefore, EPA needs to allow facilities and permit writers to make best informed judgments in issuing permits, recognizing that some permit requirements may need to be adjusted when permits come up for renewal to achieve the desired reductions in mortality. The implementation of new measures in conformance with general time frames specified in a permit should constitute compliance, even if it turns out that additional measures may be needed ultimately to achieve mortality reduction goals or other numeric standards.

EPA seems to recognize some of our concerns in this area, by proposing use of "compliance schedules" that would allow new technology, operating, and restoration measures to be implemented over some period of time. However, we are concerned that EPA has not provided enough flexibility for permit writers to provide sufficient time for the new measures to be implemented, much less for the information gathering and analysis that will precede issuance of permits. EPA needs explicitly to allow permit writers to establish reasonable time lines and milestones in NPDES permits, even spanning multiple permit time periods if necessary to allow adequate time to gather and evaluate the necessary information and to implement any new measures that may be necessary and appropriate.

In addition, we are concerned that failure to achieve the rule's performance standards will be treated as non-compliance despite the best efforts of facility owners and permit writers to achieve those standards. Provided that a facility owner and permit writer have examined whether additional measures are needed at a particular cooling water intake structure in accordance with the rule's framework, if technology, operating, or other measures required by the permit are installed and operated consistent with the permit, failure to meet the proposed rule's numerical impingement and entrainment reduction standards should not constitute a violation of the rule. Instead the permit should be reviewed at renewal to require any additional measures necessary to meet the numerical requirements – based on the full array of technology, operational, and restoration options available to any other facility and consistent with the site-specific principles of the proposed rule, including the cost-cost and benefit-cost tests.

EPA Response

See response to comment 316bEFR.025.019.

EPA has also added many efficiencies to today's final rule since the proposal and NODA to provide options for streamlining application requirements and speeding permitting. See response to comment 316bEFR.034.005 for details.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

EEI is Still Concerned About EPA's Cost Estimates and Market Impact Analysis

The attached document "Analysis of Economic and Market Impacts of the Proposed Phase II 316(b) Regulations" looks at EPA's revised cost estimates and analysis in greater detail. EEI's reactions to the revised analysis are mixed. On the one hand, the engineering costs and national costs are more reasonably estimated. On the other hand, economic and market impact analyses remain fundamentally flawed.

EPA has made an attempt in the new analysis to address some of the issues we raised in our comments on the proposed rule. However, significant methodological issues remain that appear to skew the results of the analysis in a way that could misrepresent the actual impacts of the rule on the utility industry.

EPA's reevaluation of the costs of its proposed alternative and the water body/ capacity-based alternative has resulted in significant increases in the estimates of the cost of the proposed rule. The capital cost estimate for the proposed alternative increased by 66 percent, and the estimate of operations and maintenance costs increased by 48 percent. For the water body/ capacity-based alternative, the capital and operation and maintenance cost estimates increased by 40 percent and decreased by 13 percent respectively.

Some of these increases reflect new information collected by the agency with respect to technology cost as well as a response to other changes such as increased installation downtimes that were consistent with the comments filed by EEI and others in response to the NOPR. However, some of these cost increases reflect a change in the methodology EPA used to select applicable technologies for each facility. EPA intentionally uses a conservative methodology – estimating the costs of over compliance by selecting the most effective technology at each facility – to estimate the costs of the rule.

While EPA has not redone its nationwide benefit-cost analysis of the proposed rule in light of the new cost information, EPA has conducted two regional case studies using the new information. Those studies suggest that the cost of the proposed rule could significantly exceed its benefits. Furthermore, there are substantial questions about EPA's benefit estimates, including non-use benefits that we believe EPA has grossly and inappropriately estimated, as we will discuss in the next section of these comments.

Therefore, EPA needs to avoid adding any new requirements to the proposed rule that would increase the cost of the rule, for example by requiring greater use of cooling towers, or by forcing use of measures whose costs would exceed anticipated benefits or costs at particular facilities (i.e. by removing the site-specific benefit-cost and cost-cost tests). Furthermore, the increase in the cost estimates means that the costs of the water body/ capacity-based option even more greatly exceed its anticipated benefits than EPA estimated in the NOPR. So that option would be even less justified under the new cost estimates.

While EPA's new costing methodology may provide a general idea of national costs, we were not able to obtain the facility-specific assumptions used to generate this estimate. Therefore, we cannot comment fully on whether technology-selection assumptions are reasonable. Moreover, it would be inappropriate for EPA to share this cost information with other regulators for any purpose, in particular for use as the starting point in developing permit requirements.

In addition, the economic and market impact conclusions drawn from this national cost estimate remain fundamentally flawed. EPA continues to use the cost-to-revenue test, the average cost per household, the average electricity price impacts, and the IPM model to evaluate market impacts. EEI raised serious concerns about these methods in response to the NOPR, and EPA has done nothing to address these concerns.

Upon closer review of the IPM model, it is clear that the structure of the model is simply not conducive to evaluating the impacts of the Phase II requirements. The IPM methodology and choice of assumptions minimize the impact of § 316(b) compliance costs.

- The IPM model's estimates of market-clearing prices are based on variable costs, of which 85 percent are fuel costs that do not change under the preferred option.

- EPA's engineering cost estimates for § 316(b) compliance allocate operational and maintenance (O&M) costs as fixed rather than variable costs. But in the IPM model, changes in fixed costs do not drive changes in market-clearing prices.

- The model assumes 100 percent market competition. Yet a large number of States continue to regulate electricity prices on a cost-of-service basis, which would allow the fully amortized cost of § 316(b) to be reflected in prices.

- The model underestimates the potential for plant closures because it does not consider the recovery of embedded capital costs.

Thus, while the IPM model may have value in analyzing alternative air emission scenarios, it is ill suited to evaluating the impacts of this regulation.

In addition, before any conclusion can be made on whether or not the requirements of the rule are justified, EPA must still address one key issue regarding the impacts of the rule on the electric utility industry. EPA needs to address the cumulative impact of air and water requirements on the electric utility generating sector.

EPA's IPM analysis looks at the requirements of this rule in isolation, not accounting for the requirements of the President's Clear Skies Initiative. However, since Clear Skies is Administration policy, it should be in the baseline of any analysis run to evaluate the post-regulatory health of the industry. Failure to include the costs associated with the Clear Skies requirements gives an incomplete and potentially misleading picture of the post-regulatory world. EPA should provide this additional analysis for review prior to promulgation of a final rule.

EPA Response

The commenter makes several points:

(1) The commenter claims that EPA has grossly and inappropriately estimated non-use benefits. EPA RESPONSE: Please refer to the response to comment 316bEFR.328.010 in subject matter code 10.02.04.

(2) The commenter states that "EPA needs to avoid adding any new requirements to the proposed rule that would increase the cost of the rule, for example by requiring greater use of cooling towers, or by forcing use of measures whose costs would exceed anticipated benefits or costs at particular facilities (i.e. by removing the site-specific benefit-cost and cost-cost tests). EPA RESPONSE: EPA notes that the final rule does not require the installation of cooling towers. In addition, the final rule still contains the benefit-cost and cost-cost tests.

(3) The commenter states that "it would be inappropriate for EPA to share this cost information with other regulators for any purpose, in particular for use as the starting point in developing permit requirements. EPA RESPONSE: EPA will not share confidential business information with anybody not authorized to view such information.

(4) The commenter reiterates concerns voiced in comments on the proposed rule about EPA's economic impact methods. EPA RESPONSE: Please refer to the following comment responses:
The Cost-To-Revenue Test (CRT): 316bEFR.072.206 (subject matter code 9.01)
Average Household Impact: 316bEFR.072.207 (subject matter code 9.02)
The IPM: 316bEFR.072.209 (subject matter code 9.03)

In addition, the commenter makes several points about EPA's IPM analysis. For a response to these comments, please refer to comments 316bEFR.328.024 and 316bEFR.328.025 (subject matter code 9.03).

Finally, the commenter argues that EPA needs to address the cumulative impact of air and water requirements on the electric utility generating sector, in particular the President's Clear Skies Initiative. For a response to this comment, please refer to comment 316bEFR.316.009 in subject matter code 9.03.

Assumptions about I&E survival

EPA overstates the impacts of cooling water intake structures

Of greater concern are the methodologies that EPA uses to value the benefits of the rule. There are a number of technical concerns and internal inconsistencies in how EPA estimated recreational benefits in different regions of the country. We also direct you to the work submitted in conjunction with the comments filed by the Utility Water Act Group (UWAG) that raises serious concerns with the estimation of the projected losses due to entrainment and impingement. This work suggests that EPA has grossly overstated the environmental impacts of impingement and entrainment at Phase II facilities.

In addition, EPA's analysis continues to ignore the basic question of whether impingement and entrainment in cooling water intake structures, in fact, causes an "adverse environmental impact." The analysis ignores three important factors in computing the potential impact of impingement and entrainment.

- The analysis continues to assume that entrainment survival is zero. While there is no single number that can be supported to replace this assumption in all cases, the evidence shows that the assumption of zero survival is definitely false. Therefore, estimates of entrainment mortality will be overstated.

- The analysis does not place impingement and entrainment losses in their larger biological context. Experience with cooling water intake structures over the past several decades has shown that impingement and entrainment losses attributable to these structures often are relatively minor when compared with natural losses, and that fisheries typically thrive despite relatively high natural losses in all life stages. Thus, the impact of impingement and entrainment losses on the overall fishery may be relatively minor, if any.

- The analysis also ignores important compensation responses in natural systems. Many of the species entrained or impinged in cooling water intake structures have very high juvenile mortality rates and have reproduction rates that take this into account. It is not clear that the relatively low levels of additional mortality have any impact on the development or abundance of these organisms at all.

However, all of these significant concerns pale in comparison with the implications of EPA's fundamentally flawed attempt to calculate non-use values.

EPA Response

Please see the response to comment 316bEFR.306.506 for the discussion regarding EPA's assumption of 100 percent entrainment mortality in the benefits analysis for this rule. Please see the chapter, Entrainment Survival, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule.

Please see the response to comment 316bEFR.025.015 for the discussion regarding density dependent compensation.

EPA did not use calculations of non-use value in today's final rule.

Valuing Forage Species (incl non-use and non-landed)

EPA's methodology for estimating non-use values is fundamentally flawed

While the existence of non-use values may be theoretically sound, the accurate quantification of such values is fraught with difficulty. Non-use values are the values that persons place on a particular good even if they have not used the good and do not ever intend to use the good.

The clearest examples of non-use values are those dealing with the existence value of unique or spectacular resources. For example, one may place a value on preserving the grandeur of the Grand Canyon even if one never expects to go there. Likewise, one may place a value on the preservation of an endangered species even if that species is of no benefit to that person in any other way. Such values can be real and significant – especially if large proportions of the population share the values.

However, the likelihood that non-use values are significant diminishes greatly when we begin to discuss the value of easily replaceable and non-unique resources. While a person may be willing to pay five dollars for a cup of designer coffee across the street from their office, the value they place on knowing that a virtually identical cup is available at that same moment on the West Coast is likely to be at or near zero.

Unfortunately, EPA's preamble indicates that it does not understand the nature of non-use values. EPA cites as the primary non-use values the uncalculated value of unharvested commercial and recreational fish and losses of forage fish. But in fact, these resources are use values that EPA has already considered as part of its benefit calculations:

- Trophic transfer of forage to harvested species is a key input into EPA's model of commercial and recreational losses.

- Commercial and recreational landings are a function of the total population – including non-landed fish – therefore, EPA's estimate already places a value on these non-landed fish.

In addition, things that affect current or future use, such as one's potential desire to go fishing next year, are not non-use values and have likely been accounted for in the analysis already used to estimate use value. Moreover, while non-use values can vary to some extent based on proximity, the degree of locational variation that EPA has observed suggests that the values on which EPA is relying have a significant use component.

Despite not properly defining what it is trying to measure and ensuring that it is measuring non-use benefits rather than duplicating use benefits already estimated, EPA attempts to use a stated-preference or contingent-valuation study to generate an estimate of non-use benefits. Contingent-valuation studies are done by creating surveys that ask people what they would be willing to pay for some hard-to-value good. This generates a willingness-to-pretend-to-pay estimate that is only as good as the survey used to generate it and that generally measures both use and non-use benefits without distinguishing them.

The use of stated preference methods to estimate values is controversial. Even proponents of this methodology caution that studies need to be done with great care to avoid the common biases that result from this methodology. Stated preference studies are often difficult to administer correctly and are seldom done well enough to provide a reliable answer to the actual question that is being asked in a particular study. Moreover, EPA's attempts in the context of the proposed rule to transfer values from one stated-preference study (loss of habitat) to infer values of a resource that was not specifically addressed in the original survey (loss of fish due to impingement mortality or entrainment) is highly inappropriate and stretches the credibility of the estimates beyond reasonable bounds.

A full discussion of the methodological shortcomings of EPA's benefits estimation approach is contained in comments filed by UWAG and others. These EEI comments merely draw your attention to the fact that the EPA's conclusions about the non-use benefits of fish, shellfish, and for that matter, wetlands, are grossly inconsistent with both observed behavior and reasonable economic analysis.

EPA Response

The first point made by the comment is that accurate quantification of non-use values is difficult. For this reason, for the final 316b rule analysis, EPA has not included quantitative measures of nonuse values. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN #6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Valuing Forage Species (incl non-use and non-landed)

EPA's conclusions with respect to non-use value are inconsistent with observed behavior

EPA estimates the annual non-use values of baseline losses in the North Atlantic Region at between $76 and $482 million for a loss of 284 million pounds of biological production. This translates to a non-use value of between $0.27 and $1.70 per pound of lost fish. While these numbers may not seem high, one needs to put this in the context of the fact that the average gross value per pound of fish landed (commercially) is $0.33 per pound. This puts the non-use value significantly above the use value of the resource in all but EPA's lowest bound case – an outcome inconsistent with sound economic theory.

Likewise, wetlands restoration is valued between $6,000 and $20,000 per acre per year, to say nothing of the $46,000 per acre per year value placed on planting submerged vegetation. This is well above any reasonable cost estimate for wetlands restoration activities. Since there are no market barriers preventing individuals from pooling their resources to undertake such projects, the fact that widespread voluntary restoration is not taking place is a clear indication that EPA's estimate is not consistent with observed behavior and, therefore, is invalid.

Moreover, EPA's methodology makes no distinction between fish taken by cooling water intake structures and those lost in any other way. If the values implied by EPA's methodology apply uniformly across the country, the social loss associated with our $3 billion dollar fishing industry is between $2.5 and $16 billion. This conclusion is not credible.

EPA's conclusions do a great disservice to the public and make the benefit-cost test overly complicated to implement at best and meaningless at worst. Intuition suggests that the real non-use values for any entrainment and impingement losses are likely to be small to negligible. Little would be lost by ignoring them entirely in both the analysis supporting the rule and in any demonstration required under a benefit-cost test.

At the very least, EPA's methodology needs to undergo serious peer review to help correct the misapplication of stated preference methodologies.

EPA Response

The comment compares non-use values to commercial values for fish and states that the results are inconsistent with economic theory. EPA disagrees. There is no clear theoretical connection between commercial use values and non-use values. For EPA's detailed response to this point, please see the response to comment #316bEFR.319.004.

The comment's second point is that benefits of wetlands and eelgrass restoration are well above costs, and that "the fact that widespread voluntary restoration is not taking place" indicates that EPA's estimate is not consistent with observed behavior. In fact, voluntary restoration is common. In Rhode

Island alone, Save the Bay, a single organization, transplanted over 21,000 eelgrass plants in Narragansett Bay in 2002, using 212 volunteers. Save the Bay's spokesperson announced "… we were able to transplant sixty percent of an acre of Bay bottom with eelgrass, which was an amazing amount of work." Thus, 212 volunteers assisted in attempting to restore less than one acre of eelgrass (www.savebay.org/aboutus/2002/6_14_02.htm) (DCN #6-3259). Nationally, a group called Restore America's Estuaries, founded in 1995, is "an alliance of eleven regional, nonprofit, non-governmental organizations all working towards restoring estuarine habitats. … Collectively, the RAE organizations, working in partnership with others, have restored over 25,000 acres of estuary habitat. They are dedicated to reclaiming one million acres by the year 2010. (www.savebay.org/bayissues/rae.htm)" (DCN #6-3260).

Furthermore, as reported in the National Estuary Program Newsletter, Coastlines: "Mark Fonseca of the NOAA National Ocean Service Laboratory notes that, based on successful Federal Court cases in which he has been involved, adult-shoot planting efforts [for eelgrass] can cost $41,836 per acre (in 1996 dollars)." (http://www.epa.gov/nep/coastlines/feb01/sowingseeds.html) (DCN #6-3261).

The next comment, that "intuition suggests" negligible non-use values, is an opinion that is not backed up with empirical evidence. EPA has provided empirical evidence that non-use values for the resources of estuaries are in fact significant. For EPA's response to comments regarding evidence for non-use values for temporary losses to common species, please see the response to comment #316bEFR.306.302.

Option 3--Site-specific determination

EEI continues to support site-specific measures for implementing § 316(b) of the Clean Water Act. To the extent it includes such measures, we guardedly support EPA's proposed alternative as a means of providing a simple to administer – yet flexible when necessary – means of implementing the requirements of § 316(b). However, the key to our support remains the availability of reasonable economic and energy impact analyses, and realistic safety valves to avoid blind implementation of technological solutions that do not result in net improvements to society.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Comment ID 316bEFR.328.013

Author Name Quinlan J. Shea

Organization Edison Electric Institute

Subject Matter Code 7.02

Performance standards

We clearly oppose EPA mandating uniform use of cooling towers or any other particular technology, operating measures, or other measures. We also strongly prefer EPA's proposed rule over the water body/ capacity-based option discussed in the NODA. EPA's NODA resolves some of our issues with the proposed rule and its analysis, but the NODA raises a new set of issues that must be addressed.

EPA Response

Today's rule does not require any facility to retrofit its cooling system to include closed-cycle cooling (cooling towers), although EPA notes that this option remains available to any Phase II facility in order to satisfy the requirements of the regulation. If a facility were to adopt closed-cycle cooling (compliance alternative 1), they would be exempt from many of the additional elements required of facilities opting for one of the other compliance alternatives. EPA also notes, however, that today's rule preserves each State's right to adopt or enforce more stringent requirements.

EBA related comments

Author Name Quinlan J. Shea

Organization Edison Electric Institute

EPA needs to provide a realistic post-regulatory picture of the health of the electricity generating sector. This must include a combined analysis of the impacts of water and air requirements.

EPA Response

EPA notes that its IPM market modeling analyses did provide a realistic post-regulatory picture of the health of the electricity generating sector. The IPM base case includes current federal and state air quality requirements, including future implementation of SO2 and NOx requirements of Title IV of the CAA and the NOx SIP call as implemented through a cap and trade program. It does not include programs that are still under consideration. EPA does not know – and cannot reasonably predict – the outcome of initiatives still under consideration; therefore, any cost estimates EPA might try to develop would be highly speculative and unhelpful. This practice of only including promulgated regulations is typical for energy market models and the Agency's analyses of Clean Water Act rules.

Subject Matter Code 10.02.04

Valuing Forage Species (incl non-use and non-landed)

EPA must also discard the results of its incredible analysis of non-use benefits. We recommend that EPA not waste further effort trying to estimate the non-use benefits because they are likely to be quite small and so would not materially change the relative attractiveness of the regulatory options EPA has evaluated. If however, the agency wishes to continue to pursue quantification of these benefits, EPA must seek external peer review on any future attempts to use this type of analysis. EEI is prepared to help EPA in this effort.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values at the national level. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including peer-reviewed meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN #6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services.

For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis.

For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Subject Matter Code 9.03
Mkt-level impacts/Reliability/EO 13211: Energy Effects

Scope of Analysis

This analysis addresses the economic and market impacts of the proposed Clean Water Act § 316(b) Phase II Existing Facility Regulations (Proposed Rule) (67 Fed.Reg. 17122) based upon the information provided in EPA's March 19, 2003 Notice of Data Availability (NODA) (68 Fed. Reg. 13522). It specifically examines the methodologies and assumptions used by EPA in estimating economic impact to electricity consumers and electric power sector investors. The analysis focuses on the cost estimates for EPA's "preferred option," although the methodological issues also apply to EPA's "waterbody/capacity" based option.

National Cost Estimate Assumptions

In the NODA, EPA revised its estimate of the national cost of compliance to $416 million (net present value), an increase of 49% above the estimate at the time of proposal. The increase in the national cost estimate appears to be due to two factors:

- EPA adopted more conservative assumptions regarding the appropriate compliance measures for the 551 in-scope facilities (e.g., the adoption of "best performing technology" rather than the most cost effective technology).

- EPA performed a more rigorous analysis of facility-by-facility compliance assumptions, utilizing a set of 11 technology costing modules. The modules used in the NODA analysis incorporate revised cost assumptions regarding capital and operating and maintenance (O&M) costs and net installation downtime. For the preferred option, total capital costs increased by 66% compared to the initial analysis, and total O&M costs increased by 48%.

The analysis in this paper used the revised national cost estimates in the NODA as a given. It is expected that other commenters will address specific issues regarding the engineering cost estimates. Also, this analysis accepted the EPA assumptions regarding the application of best performing technology at individual facilities. The assumption of best performing technology has potential implications for the determination of cost effectiveness and the selection of a cost baseline for purposes of the cost-cost test. These issues are addressed elsewhere in the industry's comments.

Summary of Conclusions Regarding Economic and Market Impacts

The cost of compliance is borne by either electricity consumers (in the form of higher prices) or electric industry shareholders (in the form of lower share prices, lower dividends, or both). In the case of not-for-profit consumer-owned and governmentally-owned utilities, costs are reflected in higher electricity rates, reductions in ancillary services, or increased taxes.

The NODA presents four alternative approaches for estimating the economic and market impacts of the proposal. All four approaches show no significant adverse economic or market impact. These approaches have substantially different and, in some cases, conflicting methodologies. All four have serious underlying flaws that undermine the validity of the reported results.

- The cost-to-revenue (CTR) test is not a useful metric because it does not provide a direct measure of impacts on either consumers or producers. It should be dropped, or at least modified to measure impact on net revenue.

- The average household impact measure is misleading because of the averaging methodology and should be dropped.

- The average electricity price impact also is misleading because of the averaging methodology and should be dropped.

- The electricity market impacts (based on the IPM model analysis) are significantly underestimated because the model does not adequately capture the effects of compliance costs on market prices. The model structure and the choice of assumptions tend to minimize impacts.

TABLE 1. Summary Analysis of EPA Economic/Market Impact Analysis.
[See hardcopy]

Some of these issues are not new. They were raised in the comments provided on the proposed rule but not addressed in the NODA. A summary of the issues raised with the proposed rule that were not included (or partly addressed) in the NODA are shown in Table 2.

TABLE 2. Summary of NODA Adjustments in Response to Comments.

Executive Orders (except EO 13211)

Significance of Economic and Market Impact Analysis in Assessing the Value of the Proposed Rule

Under E.O. 12866, EPA is required to consider the estimated total costs and benefits of its proposal. In the NODA, as in the proposed rule, EPA used estimated national compliance costs as a measure of the total cost to society.

While the impact on electricity producers, consumers, and electric power industry investors is important, it is not the appropriate criterion for determining whether the rule will produce net positive societal benefits. The estimates of economic and market impacts are not benefit/cost analyses, but instead are measures of "affordability." EPA's presentation of analyses of affordability creates a false impression that, if the proposal appears affordable, it must be cost-beneficial. But "affordability" is not a metric for measuring benefit-cost, nor is it endorsed (or even mentioned) in either E.O. 12866 or other statutes addressing regulatory analyses, such as the Regulatory Flexibility Act or the Small Business Regulatory Enforcement Fairness Act.

The question that an affordability test seeks to answer is, "Can the nation, industry, or consumer segment afford to absorb the costs of compliance with the rule?" From a benefit-cost standpoint, this question has no value. The theoretical cost maximum that a company, nation, or consumer base can shoulder does not provide any information about whether or not they should be asked to do so. In a functioning market, almost any increase in price will result in a new equilibrium point reflecting consumer adjustments. For example, many U.S. consumers probably could "afford" a doubling of the electricity price. Demand for electricity would decrease, alternative forms of energy would gain in popularity, and consumers would adjust to the new price reality, though the price increase clearly would affect consumer pocket books, and more poorer consumers could be unable to afford to pay for basic needs. It is highly unlikely, however, that the nation would be better off as a result of a regulatory change with this result. Similarly, the ability of firms to "afford" the increase in operating costs resulting from compliance is an irrelevant metric when assessing whether or not an industry or a nation benefits or suffers as a result of the regulation.

It is precisely for this reason that E.O. 12866, the Federal guidance on cost-benefit analysis, recommends the use of net present value (NPV) whenever possible. If the NPV of a regulation is negative then it does not matter if it is "affordable" to one or more segments of the population or industry – the agency should not promulgate the rule. For these reasons, even if the CTR, average household impact, and average electricity price analyses were done correctly, they would still fail to provide a meaningful assessment of the benefit-cost wisdom of promulgating the regulation. In addition to this point, the following sections provide detailed discussions of the methodological flaws inherent in each affordability analytical method.

EPA Response

EPA has coordinated with OIRA in accordance with Executive Order 12866 and will complete any associated docketing requirements. EPA’s final decisions with respect to this rule were made pursuant to, and consistent with the Clean Water Act. EPA has complied with all Administrative Procedure Act requirements regarding ex parte contacts during an informal rulemaking.

Analysis of the Cost-to-Revenue Test (CTR)

The CTR compares both average and maximum annual costs per facility against the facility's (and firm's) gross revenue. EPA estimated the CTR at both the firm level and the individual facility level. The firm-level CTR for the preferred option ranged from 0.00% to 7.36%. The facility-level CTR for the preferred option ranged from 0.01% to 102.6%. A detailed breakdown of the EPA estimates is shown in Tables 3 and 4 below, taken from the March 12, 2003 memo to the record from EPA:

TABLE 3. Firm-Level Cost-to-Revenue Measure by Entity Type for the Preferred Option.
[See hardcopy]

TABLE 4. Facility-Level Cost-to-Revenue Measure for the Preferred Option.
[See hardcopy]

The CTR data reveal several anomalies:

- Surprisingly, the CTR estimates in the NODA show fewer facilities and firms with a CTR greater than 3.0%, even though the NODA analysis is based upon higher cost estimates.

- The CTR data show several facilities with very high CTR values. For example, one investor-owned oil/gas steam generating facility shows a CTR of 102.6%, (i.e., the annualized compliance costs are slightly greater than the facility's gross revenues), yet that facility is not indicated for closure in the plant closure analysis.

- The maximum CTR value for nuclear facilities is only 3.1%, yet one nuclear facility is identified for closure in the IPM modeling analysis.

- Two governmentally-owned facilities have CTRs of 22.8% and 62.9%, yet neither is identified for closure, and neither appears to have affected the market-clearing prices in the IPM analysis.

The comparison of the data, however, is a secondary issue. The principal issue is methodological – the CTR methodology is not a meaningful measure of economic viability or lack thereof. Commodity industries – including the electric power industry – are generally characterized by low profit margins earned on high volumes of transactions. This means that while gross revenues can be quite large, the net revenues are frequently a small percentage of gross revenues. In electric power, these margins are generally predicted to shrink even further in the wake of expanding deregulation. For example, as shown in Table 5, the ratio of net income to gross sales revenues for the investor-owned utility industry is about 10% and decreasing. It is possible that a facility or firm with a low estimated CTR may actually have negative net revenues after application of the requirements. This would likely result in the facility's closure. This example further demonstrates why CTR is not a valid indicator.

TABLE 5. Revenue and Expense Statistics for Major U.S. Investor-Owned Electric Utilities.

[See hardcopy]

A more appropriate measure of the economic impact of the proposed rule on firms and facilities would be to analyze the impact on each regulated entity's net revenues, with consideration of the portion if any of increased costs that can be recovered through higher revenues. EPA should evaluate the effect of the proposed rule by calculating the ratio of the discounted present value of the marginal cost of compliance to the discounted present value of expected net revenues. Similarly, the regulations for economic analysis in E.O. 12866 state that net present value is the preferred method of evaluating the costs and benefits of regulatory actions.

While estimates of net revenues are readily available for investor-owned utilities, municipally-owned utilities and electric cooperatives have different measures of net "revenue." For example, municipal utilities do not report net revenue, but instead apply a portion of their gross revenues in the form of provision of services and payments to the community, including donations to the general fund, no-cost provision of power, free communication services, funding of shared resources, and other contributions. The aggregate values of these services and payments are readily available as a matter of public record through city budgets and as recorded in their financial statements. Similar information is available on the use of net proceeds by cooperatives. The use of NPV in the analyses is important because, if the utilities cannot pass through the costs of compliance with 316(b) regulations, they will have to make reductions in their contributions of net proceeds for other purposes.

In addition to considering the impact on net revenues, EPA also should perform a more detailed analysis of the cost impacts of the proposal on different segments of the industry. EPA should therefore compare the NPV ratios of discrete groupings of facilities to assess the possibility of competitive harm. These groups should be delineated by factors such as:

- Size

- Location

- Customer Base

Only by determining the reductions in NPVs (as a result of compliance) of the facilities in each group can the agency determine the actual economic impact on firms and facilities resulting from the rule.

EPA Response

The commenter makes three points in this comment:

(1) The cost-to-revenue results of the NODA preferred analysis reveal several anomalies compared to the results at proposal.
i. "Surprisingly, the CTR estimates in the NODA show fewer facilities and firms with a CTR greater than 3.0%, even though the NODA analysis is based upon higher cost estimates." EPA response: EPA agrees that based on the NODA analysis, 5 fewer facilities have a CTR greater than 30%. It should be noted, however, that the changes in the CTR are not only a function of different cost

estimates but also of different revenue estimates. As documented in the NODA (68 FR 13528), EPA's revenue estimates at proposal omitted revenues from non-steam generators at Phase II facilities. This omission was corrected for the NODA analysis and the analysis for the final rule. For facilities with non-steam generators, accounting for all of the facility's revenues, in some cases, lead to a lower CTR despite higher compliance costs.

ii. "The CTR data show several facilities with very high CTR values. For example, one investor-owned oil/gas steam generating facility shows a CTR of 102.6%, (i.e., the annualized compliance costs are slightly greater than the facility's gross revenues), yet that facility is not indicated for closure in the plant closure analysis." EPA response: EPA notes that in the IPM, a facility's decision on whether to close or remain in operation is not based on the profitability of one year alone. The model determines the net present value (NPV) of future operations for each facility. If this value is positive, the facility remains in operation, even if there is a loss in any one year. The facility cited by the commenter is an example of this algorithm. If 2010 revenues were used instead of 2008 ones, the CTR of this facility would be less than 4%. This is the case because this facility realized capacity revenues in 2010 but not in 2008 (due to a change in excess capacity in the region).

iii. "The maximum CTR value for nuclear facilities is only 3.1%, yet one nuclear facility is identified for closure in the IPM modeling analysis." EPA response: As argued by the commenter himself, the CTR is not (and was not intended to be) a predictor for facility closures. Even if compliance costs represent a relatively small percentage of revenues, it is possible that a facility is modeled to close if, as a result of this additional cost, the facility's NPV of future operations becomes negative.

iv. "Two governmentally-owned facilities have CTRs of 22.8% and 62.9%, yet neither is identified for closure, and neither appears to have affected the market-clearing prices in the IPM analysis." EPA response: EPA notes that the two facilities referenced by the commenter have generating capacities of less than 30 MW each. As a result, their contribution to the electricity supply in their respective regions is insufficient to influence the market-clearing prices.

(2) "The cost-to-revenue test is not a meaningful measure of economic viability or lack thereof." The commenter states that "A more appropriate measure of the economic impact of the proposed rule on firms and facilities would be to analyze the impact on each regulated entity's net revenues, with consideration of the portion if any of increased costs that can be recovered through higher revenues." EPA response: Please refer to the response to comment 316bEFR.072.206 in subject matter code 9.01.

(3) EPA should perform a more detailed analysis of the cost impacts on different segments of the industry. EPA response: Please refer to the response to comment 316bEFR.072.206 in subject matter code 9.01.

Economic impacts on consumers/households

Estimates of Average Household Cost Impacts

As another method of assessing the economic impact of the rule, EPA estimated the average energy price increase per household resulting from compliance with the proposed regulatory requirements. The calculated annual cost per residential consumer ranges from $0.55 in NERC region ASCC to $5.69 in NERC region HI.

EPA evaluated the annual cost per household by multiplying the average annual compliance cost per MWh of sales by the average annual electricity sales per household. Both input variables were calculated by NERC region according to the following methods:

- Average Annual Compliance Cost per MWh of Sales = Total electricity sales divided by total pre-tax compliance costs. EPA compiled the total electricity sales from the 2000 Form EIA-861 data base and used utility-level sales aggregated by region.

- Average Annual Electricity Sales per Household = MWh of residential sales divided by the number of households. The raw data also came from Form EIA-861.

Presenting an average cost per household, when a significant portion of the households are unaffected by the proposal, is not a meaningful metric. This approach is warranted only in those instances where the entire population is homogenous with respect to the impact of costs – that is, in those cases where each household can reasonably be expected to see increases in costs as a result of rule. That is not the case in the context of this rulemaking.

- EPA states that only 13% of existing facilities (representing 50% of electricity generation) are in-scope facilities under the proposed rule. However, the cost of compliance for the in-scope facilities is averaged over total electricity sales from all facilities.

- The use of regional averages masks the variation of impact at the local level. For example, rural populations or those served by government-owned facilities might face a significant increase in the cost of electricity, but that effect would be masked by using the average cost over an entire NERC region.

EPA should eliminate this analysis altogether. The inclusion of unaffected households in the averaging methodology creates an erroneous impression that the cost impact is smaller than it is, while masking the true impacts on sensitive subpopulations. Both the Unfunded Mandates Reform Act and E.O. 12866 specifically require that the effects of a proposed regulation on sensitive subpopulations be considered. This is impossible when the costs are calculated only as a population-wide average.

Economic impacts on consumers/households

Average Electricity Price Impacts Analysis

In order to assess the potential effects of the regulation on electricity prices, EPA compared the average compliance cost per KWh of sales against baseline electricity prices. EPA used the total electricity sales and the consumer prices from the Annual Energy Outlook (AEO) 2002. The analysis assumes that industry passes the full cost of compliance through to consumers. In addition, the agency assumes that all sectors -- residential, commercial, industrial, and transportation -- bear an equal share of the increase per MWh of purchased electricity.

EPA estimates that the additional costs of compliance resulting from the preferred option will raise the price of electricity:

- 0.14% for Residential

- 0.15% for Commercial

- 0.25% for Industrial

- 0.15% for Transportation

Several problems exist with this analysis. First, the estimates do not provide an accurate picture of the compliance impact because the costs of compliance are averaged against total sales, including sales from facilities that are not in-scope.

Second, by averaging across entire NERC regions, the EPA analytical approach makes it impossible to assess the impacts on cost-sensitive subpopulations. Both UMRA and E.O. 12866 specifically direct the agency to consider these vulnerable groups.

Finally, it is unrealistic to assume that cost is allocated uniformly across customer classes. In a relatively competitive power market, different types of consumers have different power requirements and vastly different elasticities of demand. This can result in some groups paying a proportionately larger share of the rate increases than others. For example, EIA projections in Table 6 show that average prices for customer classes do not change in equal amounts. There is no basis for assuming that certain action, such as 316(b) compliance, will have equal impacts among customer classes. In view of these problems, EPA should eliminate this analysis altogether.

TABLE 6. Projected End Use Prices by Customer Class.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

Analysis of IPM Modeling Issues

The Integrated Planning Model (IPM) is a dynamic linear programming model of the electric power sector. The IPM is used by government agencies and the private sector to conduct assessments of capacity planning, environmental policy analysis and compliance planning. The IPM analysis supporting the proposed regulations utilized a modified version of the EPA Base Case 2000.

A detailed description of the model and its main assumptions can be found in various documents published by EPA. This discussion focuses on several issues with IPM that lead to a significant underestimate in the electricity market impact of the proposed 316(b) regulations. The issues stem from a combination of the methodology of the IPM model itself and the choice of assumptions – all of which seem chosen to minimize impacts. There are five general issue areas, which we will now discuss.

The IPM Structure Does Not Adequately Capture the Impacts of 316(b) Compliance Costs

IPM is designed to depict production activity in fully deregulated wholesale electricity markets, not in retail markets. Two key methodological features of IPM are its assumption of "perfect competition" and "perfect foresight." In IPM, the dispatching of electricity is based on the variable cost of generation. In the absence of any operating constraints, units with the lowest variable cost generate first. The marginal generation unit, i.e., the power plant that generates the last unit of electricity, sets the wholesale energy price.

The model also uses physical constraints in certain instances to influence the dispatch order. For example, IPM uses "turndown constraints" to prevent baseload units from cycling (i.e., switching on and off). This is especially important for nuclear and large coal-fired baseload plants, which, when operating, are run steady–state at or near full capacity.

While this methodological approach may be based on sound economic theory, it is unlikely to show any increases in market-clearing prices due to 316(b) regulations except in cases where the variable costs of compliance actions represent a significant proportion of variable costs in the model. Furthermore, the IPM model fails to recognize that the costs of complying with 316(b) will be borne by consumers and investors. Instead, the model suggests that these costs simply fade into the background because they do not affect market clearing prices. This is simply unrealistic.

The 551 in-scope facilities subject to Phase II 316(b) regulations are mostly fossil steam and nuclear facilities. These facilities typically have relatively low variable costs, and are dispatched early in the generation mix. The cost of compliance of the preferred option would not, except in a few circumstances, increase the variable cost of generation to the point where these units would become the highest cost unit and thus increase the market-clearing price. For this to occur, the increase in variable costs – due to variable O&M and fuel costs associated with any energy penalty – would have to exceed the current differential in variable costs between coal and nuclear plants and oil and natural gas steam plants and gas-fired combustion turbines, which in most cases are the highest variable cost facilities.

Moreover, since many coal and nuclear facilities are likely to be subject to “turndown constraints” in the IPM model, they would not affect the IPM calculation of market clearing price in any event.

In the NODA, EPA provides revised engineering estimates of the capital and O&M costs for various 316(b) compliance options. In developing the IPM model inputs, EPA estimated that, with two exceptions, the fixed O&M cost component would be 40-100% of total O&M costs, depending upon compliance technology. Thus variable O&M costs – which affect market-clearing prices in the IPM model – comprised 0-60% of total O&M costs for the 316(b) compliance options. A comparison of the model results between the base case and the preferred option case shows essentially no change in variable O&M costs. The analysis also shows that the effects of variable O&M costs in the model represent only 14% of total variable costs. The comparison of total variable costs is shown in Table 7 below.

TABLE 7. Comparison of National Total Variable Costs in IPM Model Run for 2010.
[See hardcopy]

The variable O&M costs resulting from 316(b) compliance are extremely small, which, in turn, drives the model output that shows no change in the market-clearing price. For example, the projected national average variable production cost in 2010 is essentially unchanged between the base case and the preferred option.

This is not to suggest that EPA’s assumptions on the relative projection of fixed and variable O&M costs are flawed. The analysis of EPA’s engineering cost estimates of O&M costs is beyond the scope of this paper. What it does indicate is that an IPM modeling analysis of EPA’s 316(b) options, assuming a 100% competitive wholesale electricity market, and assuming no energy penalty and relatively small variable O&M costs, is not the appropriate method for estimating market impacts.

A further illustration of the lack of sensitivity of IPM to 316(b) costs can be illustrated by comparing the IPM results with the CTR analysis. The CTR analysis shows 41 facilities (7.4% of the total in-scope facilities) with a CTR greater than 3%. Yet, the IPM results show no increase of market-clearing prices commensurate with this level. The model apparently assumes that these costs are absorbed within the producers’ surplus, i.e., net revenues. Yet, 17 of the 41 affected facilities are governmentally-owned, and another 3 are cooperatives. These 20 facilities (half of those with CTRs above 3%) do not have net revenues that can absorb 316(b) compliance costs.

If 316(b) compliance costs exert little effect on the IPM market-clearing prices, then what does account for changes in IPM projections of market-clearing prices? In the NODA, EPA notes that the IPM results for 2010 show that energy prices per MWh decrease in three NERC regions: MAAC, MAIN and SPP. If the model runs were reflecting only changes in 316(b) compliance, this result is anomalous. Further analysis of the model runs suggests that the changes are due to other factors such as differences in the mix of new generation additions and retrofit upgrades. Thus, the model is showing the effect of alternative investment decisions in new or upgraded capacity that are not the direct result of 316(b) compliance, but rather some form of secondary response. And these results are based on the premise of a fully deregulated wholesale electricity market functioning under perfect competition.

In reality, the cost of retrofits at Phase II facilities to meet new regulations will have significant impacts on wholesale and retail prices. A total of 25 states currently regulate retail electricity prices on a cost-of-service basis. Another 18 states plus the District of Colombia permit varying levels of retail competition. Vermont has pending restructuring legislation, California has suspended restructuring, and the remaining 5 states are taking a "wait and see" approach by actively delaying moves toward competition. Table 8 shows the state-by-state information.

TABLE 8. Status of Adoption of Retail Competition in States <FN2>
[See hardcopy]

While the extent of wholesale price regulation is much smaller, many of the existing facilities subject to the proposed 316(b) regulations are still in cost-of-service operation.

All states that allow retail competition incorporate a cost-of-service component. In even the most competitive states, retail consumers ultimately have the option to purchase cost-of-service power, which is intended to set a benchmark for all utilities in the market. The IPM model does not capture the current dynamic of a market that is partly competitive and partly cost-of-service. As a result, the modeling outcomes are seriously flawed.

In conclusion, the methodological structure of the IPM is not conducive to the type of analysis of the proposed 316(b) regulations for which it was used. The specific conclusions can be summarized as follows.

(a) The model structure does not adequately consider the types of 316(b) compliance costs. Thus, changes in 316(b) compliance costs have little or no effect on IPM calculations of market-clearing prices.

- IPM estimates of market-clearing prices are determined by the facility with the highest variable cost. The 551 in-scope facilities typically have relatively low variable costs and thus do not affect market clearing price calculations.

- The variable cost component of the IPM model consists primarily of fuel costs, which are critical to the analysis of air emissions control options, but not to 316(b) compliance options. For example, IPM model data for the preferred option show over 85% of variable costs are comprised of fuel costs. Furthermore, EPA's analysis of the preferred option assumes no change to fuel costs.

- The EPA engineering cost estimates for 316(b) compliance costs allocate total O&M costs between fixed O&M and variable O&M costs, but the allocation is weighted heavily to the fixed O&M cost component. Changes in fixed O&M costs do not drive changes in market clearing prices under the IPM analysis.

(b) Because the model is dynamic in nature, the model results reflect other investment changes that may be secondary but not the primary result of 316(b) compliance actions.

- Changes in market-clearing prices, such as cases where prices decline, appear to be due to other factors, such as different mixes of new and retrofit capacity investment rather than 316(b) compliance.

(c) The model does not address the price impacts from facilities still subject to cost-of-service regulation.

- A large number of states continue to regulate electricity prices on a cost-of-service basis, which would allow the fully amortized cost of 316(b) compliance to be reflected in changes in prices.

- The model appears to treat electricity dispatch, pricing, and financing for cooperatively-owned and governmentally-owned utilities in the same manner as for investor-owned utilities.

Because the IPM was designed as a flexible analytical tool that focuses on the analysis of air emission control scenarios, it does not appear to provide a good analytic framework for analyzing the impacts of the proposed 316(b) regulations.

EPA Response

EPA disagrees with the comment that the IPM structure does not adequately capture the impacts of 316(b) compliance costs. The commenter's argument rests on the suggestion that the IPM "is unlikely to show any increases in market-clearing prices due to 316(b) regulations except in cases where the variable costs of compliance actions represent a significant proportion of variable costs in the model. Furthermore, the IPM model fails to recognize that the costs of complying with 316(b) will be borne by consumers and investors. Instead, the model suggests that these costs simply fade into the background because they do not affect market clearing prices."

EPA disagrees fundamentally with the validity of the commenter's argument. Dispatch and market-clearing prices are a function of variable costs. As a result, only variable costs should drive unit dispatch and market-clearing prices. The argument that there is something wrong with the structure of the IPM, or that it is inappropriate for assessing the effects of the 316(b) regulation, just because the final Phase II rule does not contain significant variable costs, is invalid. If the variable cost differential between facilities subject to the final rule and other facilities is great enough as to not change the dispatch order, then the final rule should not lead to increases in prices. Furthermore, the suggestion, that just because the modeling results do not show any price increases, the compliance costs "fade into the background" is unfounded. The IPM considers all cost increases as a result of the final rule. Even if they do not affect market-clearing prices, they are taken into account in the long-term operating decisions of each affected facility. And, patently, compliance costs do not "fade into the background" in the IPM analysis. Compliance costs are explicitly recognized and accounted for in the IPM system: to a limited extent, they are passed through as increases in prices to consumers; in other, more common, circumstances, they manifest as reductions in the net income of the complying entities and are explicitly accounted for in the 316(b) impact analysis in terms of these financial impacts. They don't "fade into the background."

For a response on potential impacts on governmentally-owned facilities, please refer to comment 316bEFR.028.008 in subject matter code 22.03.

The commenter further notes that changes in market-clearing prices that are not the direct result of 316(b) compliance costs are anomalous. EPA disagrees with this assertion. The IPM is an integrated market model that takes into account the direct and indirect effects of a policy option. One of the indirect effects the IPM models is the need for new additions in response to other changes in the market. EPA disagrees with the commenter's assertion that such a comprehensive treatment of potential regulatory effects is a flaw.

With respect to the comment that the IPM analysis is flawed because it does not account for facilities still subject to cost-of-service regulation, EPA notes that in terms of industry impacts, the assumption of full competition is conservative. While some facilities might be able to pass on some of their costs, this will be less possible in many regions where competition has already taken hold. In addition, the ability to partially or fully pass on costs to consumers also means that there will be fewer impacts on the facilities themselves, including fewer closures and less loss in net income. In short, the presence of cost-of-service regulation reduces the potential financial burden on complying entities; in contrast, the assumption of full deregulation increases the likelihood of finding a material financial burden on complying entities.

Finally, EPA notes that the IPM is a peer-reviewed, OMB-approved model. The commenter themselves conducted an analysis of the proposed rule using a different model. Interestingly, despite highly conservative assumptions (including grossly overstated compliance costs), the re-analysis did not produce results that were materially different from EPA's analysis. (See response to comment 316bEFR.072.101 in subject matter code 9.03.) EPA therefore notes that any alleged flaws of the IPM, which EPA does not acknowledge, did not materially affect the results of this analysis.

The IPM Analysis Underestimates Potential Plant Closures

In the analysis of the preferred option, the IPM analysis projects the closure of one nuclear facility representing 434 MW of capacity. The IPM allows for the retirement of plants, as well as retrofits, repowering, and, in the case of nuclear facilities, relicensing. Each of these options is represented in IPM as "model plants," and the options available for each facility, such as retrofit or retirement, are pre-defined. However, the algorithm in the model to determine if a retirement option should be triggered due to 316(b) compliance costs has not been described in the NODA Docket. The algorithm and the choice of assumptions can significantly alter the results of the closure analysis.

There are several methodological issues that would lead to underestimates. The first issue is the IPM treatment of embedded costs. The IPM model documentation indicates that the model only considers new capital costs that may be incurred during the model run period. The model does not consider recovery of the historic embedded costs of generating facilities. Thus, it would appear that the IPM algorithm for estimating plant closures only considers whether the facility can recover new capital costs within the revenues realized at the projected market clearing price. In reality, facility owners would consider whether the facility can recover the combined total of both its embedded and future costs in deciding whether to close a facility. A consideration of the combined total would lead to more plant closures than merely considering future capital costs only.

The second issue relates to how the IPM was used to model the capital costs for 316(b) compliance. Typically, the up-front capital costs for compliance are provided as model inputs. The model then translates these costs into a series of annualized charges, using the following assumptions <FN 1>:

- Initial capital investment is converted into an annualized capital outlay stream at a capital charge of 12%.

- The book life and debt life of generating unit investments are assumed to be 30 years.

- The period used in calculating levelized annual outlays is either the book life of the investment or the years remaining in the model planning horizon, whichever is shorter.

- NPV is estimated using a discount rate of 5.34%.

However, it appears that EPA modified the standard IPM model set up. The Economic and Benefits Analysis states that the IPM used two single up-front cost values for 316(b) compliance, one for technologies with a useful life of 10 years, and another for technologies with a useful life of 30 years. For the preferred option, all compliance technologies had a useful life of 10 years. However, there is no indication that replacement capital costs were considered over the span of the IPM model run, i.e., to 2030. Since EPA used a relatively low discount rate of 5.34%, replacement costs 10 years in the future would exert some influence on net present values.

Finally, there appears to be some uncertainty as to how the IPM modeled the capital costs of 316(b) compliance. While the discussion of capital costs describes the 316(b) capital costs as input to the capital cost variable, the discussion of model outputs describes annualized capital costs as being included in the reported model results for fixed O&M costs. At a minimum, the differences in these descriptions are confusing. More importantly, however, they may reflect that the costs were treated differently in the model.

These three factors – embedded costs, useful lives and replacement costs, and assignment of costs within the model – would affect the model estimates of plant closures.

In addition, the assumption of a capital charge rate of 12% is significantly less than the current cost of capital for the electric utility. The 12% rate is based on an assumption that the compliance measures are a retrofit to existing units and are financed on the strength of the parent company's balance sheets. The 12% rate also assumes that the environmental retrofit has a 30-year book life and a 30-year debt life. These assumptions are extremely low in the current financial environment for electric generators, and they will result in much less predicted impact on annualized costs. By comparison, in comments provided on the proposed rule, OnLocation, Inc., a contractor to the Edison Electric Institute, performed an alternative modeling analysis, using the POEMS model that utilized a 20% capital charge rate. The POEMS model is an electricity market model developed by the Department of Energy, and used extensively in modeling alternative electricity policy scenarios. Adjusting the IPM results for a higher capital charge would increase the model's projection of plant closures, because the annualized costs would be higher. This was shown in the POEMS modeling results at the time of the 316(b) proposal.

EPA Response

The commenter argues that three factors affect the model estimates of plant closures:

(1) Embedded costs: EPA disagrees that IPM's treatment of embedded costs is inappropriate and will cause underestimation of facility closures. The decision of whether or not to incur compliance costs and continue operation of the affected facility depends on the discounted present value of future cash flows from the facility – specifically, whether the discounted net present value of the facility, before payments to capital, will remain positive. This concept of business decision-making is a fundamental and universally accepted element of financial analysis. The IPM analysis properly embodies this concept.

(2) Useful lives and replacement costs: EPA notes that replacement costs are captured in its analyses. As documented in chapter B3 of the EBA, capital costs are modeled as annual fixed O&M costs. By annualizing them over the 10-year period of the technology's useful life, the analysis explicitly considers the need for technology replacement.

(3) Assignment of costs within the model: The commenter states there is confusion over how capital costs were treated because the discussion describes 316(b) capital costs as input to the capital cost variable. EPA notes that the commenter did not carefully read the documentation. Chapter B3, as

published for the NODA, states that "Capital cost inputs into the IPM are expressed as a fixed O&M cost, in dollars per KW of capacity." (See DCN 5-3002.)

Finally, the commenter states that the capital charge rate of 12% is too low. The commenter cites a different model, POEMS, that uses a capital charge rate of 20%. Without commenting on the reasonableness of the POEMS capital charge rate, EPA notes that the IPM rate reflects a real (i.e., adjusted for inflation), after-tax weighted average cost of capital and that the IPM rate concept has been reviewed and approved by EPA and OMB in a range of regulatory studies.

EPA notes that the commenter's own re-analysis of the proposed rule, which used the POEMS model, did not produce results that were materially different from EPA's analysis. See response to comment 316bEFR.072.101 in subject matter code 9.03.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

The IPM Analysis Uses Outdated Projections of Demand Growth and Natural Gas Prices That Underestimate Compliance Costs

The IPM analysis underestimates demand growth because it relies upon the EIA reference case projection in AEO 2001, and it reduces the projected demand by the estimated electricity savings from the EPA and DOE Climate Change Action Plan (CCAP) voluntary programs to reduce greenhouse gas emissions.

The lower level of projected electricity demand underestimates 316(b) compliance cost in three ways: (1) it reduces the level of new capacity additions, which, in turn, lowers the market-clearing prices for new generation additions; (2) it enables more oil/gas steam electric facilities to operate at less than 15% capacity utilization, enabling them to quality for less stringent compliance requirements; and (3) it fails to consider the impact of the proposed "generation caps" on electricity price behavior during peak periods.

A comparison of several key assumptions is shown in Table 9 below. It shows that IPM's projected electricity sales are 5.9% below current forecasts. Furthermore, it shows that the fuel price projection used in IPM is almost 15% lower than current projections. Since the market-clearing pricing algorithm is heavily influenced by fuel prices, lower fuel price projections will result in lower market-clearing prices.

Table 9. Comparisons of IPM and Current AEO Projections.
[See hardcopy]

The sensitivity of the IPM to changes in electricity demand projections and fuel prices can be illustrated by comparing the model results from the two baseline model runs: the base case for the preferred option, which uses the EPA demand and fuel price assumptions, and the base case for the waterbody/capacity based option, which uses the higher AEO 2001 assumptions. The differences, by NERC region, are shown in Table 10.

TABLE 10. Changes in IPM Baseline Price Projection EPA Base Case 2000 vs AEO 2001.
[See hardcopy]

The comparison shows that:

- Capacity prices ($/ KW-yr) are higher in 6 of 9 NERC region with comparable data. Four regions show increases above 2%, one region (SPP) shows an increase of 8.6% and another region (WSCC) has an increase of 64.8%.

- Energy prices are higher in 9 of the 10 NERC regions. Five regions have energy price increases greater than 5%, with one region (ECAR) showing an increase of 10.1%.

Both of these cases are base cases – i.e., without the effect of 316(b) regulations. The EPA base case was used to model the EPA preferred option for 316(b) regulations, and the AEO 2001 base case was used to model the waterbody/capacity based option. The modeling results for the two 316(b) options show little or no change relative to their respective base cases. Thus, even in the waterbody/capacity based option model run, which were based upon the higher demand and fuel price assumptions, there was little market effect.

By looking at all four model runs, it becomes clear that the IPM model is sensitive to changes in electricity demand and fuel prices, but is not sensitive to 316(b) compliance costs. A possible explanation for this anomaly is that the costs for 316(b) compliance options were assigned to fixed O&M costs, rather than capital charges and variable O&M costs. Such an allocation would minimize the effects on model results. However, since this level of detail was redacted in the IPM files placed in the NODA, it is not possible to fully examine this possibility.

The NODA discusses the fact that the IPM results project that 75 facilities would have a capacity utilization rate of less than 15%. This projection is much higher than actual historical data complied by EIA. If the IPM model were run with a higher demand projection, the utilization rate for a number of these facilities would increase above 15% thereby triggering the more stringent 316(b) requirements, and the results would show fewer facilities falling below the 15% threshold.

Finally, the NODA discusses the use of a "generation cap" that would ensure that facilities that qualify for less stringent 316(b) requirements based on a low utilization rate would actually operate at less than the 15% utilization level. However, a "generation cap" was not modeled in the IPM analysis. While the concept of a threshold based on 15% utilization is a flexible and cost effective approach, establishing a hard cap on generation could have significant adverse market impacts. For example, the generation cap could be reached in instances of peak demand (such as during extended summer heat waves) or during times of major unplanned outages. Not only would prices be at a peak during these times, but also, as past events have shown, electricity prices can be bid up to levels significantly above marginal production costs. Generating facilities would need to have flexibility to respond to these types of situation. While the 15% threshold concept has merit, the market implications of adopting a hard and fast generation cap could be significant and should be analyzed further.

EPA Response

EPA notes that the analyses using the two different electricity demand assumptions did not show materially different results. EPA further notes that even a highly conservative re-analysis of the proposed rule, conducted by the commenter himself, did not produce any results that were materially different from EPA's. This re-analysis included a sensitivity analysis that assigned high per MW costs to all facilities, including those with capacity utilization rates below 15% and those that already meet the requirements of the Phase II rule. Again, even this highly overstated cost assumption did not produce results materially different from EPA's. As a result, EPA concludes that the different assumptions outlined by the commenter would not change EPA's decisions with respect to this final rule. See response to comment 316bEFR.072.101 in subject matter code 9.03.

Finally, EPA notes that the commenter's assertion that a generation cap was not modeled by IPM is incorrect.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

EPA's Approach for Estimating the Costs of Installation Outages in the IPM Model Is Flawed

In the NODA, EPA acknowledged that the initial IPM analysis of installation outages was flawed. The NODA provides a new analysis based upon a different approach.

The challenges associated with modeling facility outages appear to be due to basic limitations in the IPM model, not due to any specific assumptions. The IPM is run for only a few selected years (the "model run years"). The results of the model run years are then "mapped" to other years over a multi-year period (typically 3-6 years) that spans the model run year. Typically, the costs of compliance that may occur over the "mapped years" are aggregated into the "model run year." The results are then re-allocated back over the mapped years. As described by EPA Economic and Benefits Analysis Report:

The model assumes that capital investment decisions are only implemented during run years. Each model run year is mapped to several calendar years such that changes in variable costs, available capacity, and demand for electricity in the years between the run years are partially captured in the results for each new model year.

A detailed assessment of the accuracy of this mapping process is beyond the scope of this analysis. However, as EPA stated in the NODA, the mapping process may have the effect of overestimating the price effects of installation outages because the process maps the effects of outages in the model run year to each of the mapped years. However, EPA's proposed solution to the problem is also flawed. EPA's revised IPM run averages the installation outages over the number of mapped years, and only uses the annual average value (and not the total value) in the model run year.

The market impact of installation outages is a one-time perturbation in generating capacity, that can occur in warm weather months (peak summer or "shoulder" spring and fall seasons). It is not appropriate to treat this type of event as multi-year annual average. A proper assessment of the impact requires an analysis relative to peak load periods under varying assumptions of the probability of multiple simultaneous occurrences of installation downtimes among in-scope facilities. Averaging the effect among multiple facilities over a multi-year period virtually assures that the model will not identify any market impact.

EPA Response

EPA acknowledges the fact that its analyses average the outage time over the seven months of the non-summer season. However, EPA believes that despite this assumption, the short-term effects of the final rule on energy supply, reliability, or energy prices will be minimal. EPA examined the capacity of facilities projected to have downtimes under the final rule, by compliance year and NERC region. For each NERC region, EPA then compared the maximum projected downtime capacity in the year for which the maximum downtime capacity occurs to the total capacity of the region in 2008 (the model run year that represents the compliance years). This analysis found that the highest percentage of capacity projected to experience downtime in any one year, in any one region would be 10.1 percent (4.9 GW out of 49.1 GW, in FRCC, in 2009). Three facilities account for the 4.9 GW: two of these facilities have estimated downtimes of two weeks while one has an estimated downtime of three weeks. For five other regions, the estimated maximum percentage of downtime in any one year is greater than 3.0 percent. In each case, at least three facilities account for the downtime capacity, which provides the opportunity to schedule unit outages in non-overlapping periods and thus reduce the potential capacity loss during any scheduled outage period. It can be expected that facilities would work within the outage management frameworks provided by their reliability coordinating councils to schedule their outages to minimize system reliability issues. EPA therefore believes that short-term effects of downtimes as a result of the final rule will be minimal. EPA also notes that facilities have some flexibility in when to comply and might decide to comply during an earlier year to avoid overlap of downtimes with other facilities.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

Lack of Consideration of the Administration's Clear Skies Proposal, When Combined With the Phase II 316(b) Regulations, Ignores Potentially Significant Interactive Cost Impacts to In-Scope Facilities

The IPM is primarily intended for use in modeling air quality regulations. In fact, it is detailed and flexible when used for that purpose. However, the EPA Base Case 2000, which is the starting point for the 316(b) modeling scenarios, takes into account only those Federal and state air emission laws and regulations where provisions "were either in effect or enacted and clearly delineated." The modeling analysis includes the NOx SIP call, but excludes the new National Ambient Air Quality Standards (NAAQS) from ozone and fine particulates, Maximum Achievable Control Technology (MACT) standard for mercury, and revisions to SIPs to address regional haze. The Base Case does include the EPA Climate Change Action Plan, even through the plan has no statutory or regulatory basis, has not been fully funded by Congress, and has been superseded by the President's February 14, 2002 Climate Change Initiative. Most importantly, IPM does not consider the cumulative impact of the Administration's Clear Skies initiatives and Phase II 316(b) regulations.

The Clear Skies Initiative is the most aggressive action ever proposed to reduce air emissions from power plants. The proposal has been fully delineated and has already been extensively modeled by EPA using IPM.

The milestones for Clear Skies reductions begin in 2008 and extend through 2020. EPA expects the initiatives will result in significant over-compliance in the early years because sources are allowed to bank excess emissions reductions and use them later. Thus, a substantial level of activity to implement Clear Skies will occur in the same timeframe as Phase II 316(b) regulations implementation. For example, an unpublished analysis of compliance with Clear Skies, compiled by the Electric Power Research Institute (EPRI), showed that one-half to two-thirds of the fossil steam units that were analyzed for air emissions controls have cooling systems that would be subject to the Phase II 316(b) regulations. Comparable details from EPA's IPM analysis of Clear Skies and the IPM analysis of 316(b) have not been made public.

Implementation of Clear Skies will increase both the fixed and variable costs of fossil fuel generating facilities. Many facilities will have higher variable costs, raising their relative cost in the dispatch process modeled by IPM. With the additional impact of 316(b) regulations, it is likely that a number of these facilities would affect the market-clearing price. In addition, the fossil fuel generating units will have installation downtimes and energy penalties associated with Clear Skies implementation. These will interact with similar impacts from 316(b) implementation. It is unlikely that the impacts are simply additive. A new modeling analysis that combines both requirements is needed to determine both the cumulative and interactive effects.

In short, the IPM analysis of the proposed Phase II 316(b) regulations should be combined with the IPM analysis of the Clear Skies Initiative. Both proposals are sufficiently well-defined to support such an analysis, and since both represent Administration policy, it would be appropriate to consider the cumulative effects as part of the analysis of costs as required under Executive Order No. 12866.

EPA Response

EPA disagrees with the comment that it should have included the Clear Skies Initiative in its IPM analysis. The IPM base case includes current federal and state air quality requirements, as known at the time the model version was developed, including future implementation of SO_2 and NOx requirements of Title IV of the CAA and the NOx SIP call as implemented through a cap and trade program. It does not include programs that are still under consideration, such as the Clear Skies Initiative cited by the commenter. EPA does not know – and cannot reasonably predict – the outcome of initiatives still under consideration; therefore, any cost estimates EPA might try to develop would be highly speculative and unhelpful. This practice of only including promulgated regulations is typical for energy market models and the Agency's analyses of Clean Water Act rules.

In its recent notice of data availability (NODA),<FN 2> the EPA has dealt with some of the data gaps that plagued the original proposal. The level of protection afforded to waterbodies has not improved, however. In fact, the NODA gives the impression that EPA will retreat even further from its obligation to issue regulations which "require that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact."<FN 3>

We once again strongly urge the EPA to fulfill its statutory responsibility by selecting the "all closed-cycle option" as the Best Technology Available (BTA). A rule that requires closed-cycle cooling or its functional equivalent in terms of cooling water intake capacity would provide much greater protection against adverse environmental impact than would the EPA's preferred option. We also take this opportunity to reiterate that the EPA has overstated the potential impact the "all closed-cycle option" would have on energy reliability. Recent analysis of the energy sector confirms that which we told the Agency last summer: the amount of electric generating capacity that EPA estimates would be retired if closed-cycle cooling was required at all Phase II facilities is but a tiny fraction of the amount by which the EPA has underestimated long-term total generating capacity. Finally, we submit for the EPA's consideration a recent report prepared by the Clean Air Task Force and the Land and Water Fund of the Rockies that details the harm caused by power plants to water resources in the Western United States. Our report, The Last Straw: Water Use by Power Plants in the Arid West, provides additional evidence that the EPA needs to adopt a CWIS rule that is more protective than the option it currently prefers.<FN 4>

Performance standards

EPA Must Adopt a CWIS Standard that Truly Minimizes Adverse Environmental Impact

For the reasons set forth in our August 2002 comments,<FN 5> the EPA's preferred Phase II CWIS standard fails to reflect the best technology available for minimizing adverse environmental impact. The EPA is required by law to ensure that "[a]ny standard established pursuant to [Clean Water Act limitations on effluent and thermal discharge] and applicable to a point source shall require that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact."<FN 6> To fulfill its mandate, the EPA must select the available CWIS technology that will best protect aquatic organisms from impingement and entrainment. The Agency has instead indicated it prefers an option – a hodgepodge of compliance methods and various standards based on the perceived sensitivity of the source waterbody<FN 7> – that is patently less protective than the "all closed-cycle option."

The all closed-cycle option would be more effective than the EPA's preferred option at protecting the quality of our rivers, lakes, estuaries, and bays. A Phase II rule that requires closed-cycle cooling or its functional equivalent would ensure that intake capacity levels at existing facilities are reduced by 96% when compared with once-through cooling systems.<FN 8> Mortality from impingement and entrainment would decline by as much as 98%<FN 9> – a significant improvement over the preferred approach, which would require that facilities reduce impingement mortality by 80% and entrainment mortality by 60%.<FN 10> Congress directed the EPA to regulate CWIS by mandating the best technology available for minimizing adverse environmental impact. The all closed-cycle option is clearly better than the EPA's preferred option at achieving that directive, and it is readily available and affordable. Accordingly, the EPA should select the all closed-cycle option as the CWIS standard for Phase II facilities.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

The All Closed-Cycle Option Would Have an Insignificant Impact on Energy Reliability

In our August 2002 comments, we pointed out that the projected market impact of a rule that mandates closed-cycle cooling is miniscule. According to the EPA's projections, only 6560 MW would be closed if the Agency adopted an all closed-cycle rule.<FN 11> That lost capacity would be less than one percent of total generating capacity, an amount the Agency has characterized as "insignificant."<FN 12> We also explained how the IPM 2000 – the model used by the EPA to project the market impacts of the various regulatory options – dramatically underestimates the amount of new generating capacity that is currently under development. As a consequence, the EPA's market impact projections for the all closed-cycle option, which were negligible to begin with, were in fact exaggerated.<FN 13> Finally, our comments demonstrated that the amount by which the EPA underestimated long-term total generating capacity dwarfs the amount of electric generating capacity that the Agency estimates will be retired under the all closed-cycle option.<FN 14>

Several of these findings relied on an analysis of the April 2002 update of the RDI NEWGen database, a proprietary database that contains detailed information on the status of new plant development projects across the country. The database is updated monthly and provides the most timely and accurate method of tracking actual power plant development. By analyzing data from the April 2002 update of the RDI NewGen database and taking into account various project and business criteria, the Clean Air Task Force and our consultants were able to assess the likelihood that power plant development projects across the country will be completed. Based on that assessment, were able to confidently project capacity additions through 2006.

Using the February 2003 update to the RDI NEWGen database, the Clean Air Task Force and our partners have reanalyzed the likely scale of future additions to the United State's electric generating capacity.<FN 15> We found that almost 130,000 MW of new capacity has come online since the beginning of 2000, with more 70,000 MW of capacity currently under construction.<FN 16> An additional 40,000 MW of additional capacity is under development and is likely to go online by the end of 2007.<FN 17> Regional power market reserve margins – a leading indicator of energy reliability – have greatly improved since 1999 and will continue to improve through 2007 in most regions.<FN 18>

Based on our reanalysis of the RDI NEWGEN data, we are able to reaffirm the position we took in our August 2002 comments. The amount of generating capacity that EPA predicts would be lost under an all closed-cycle rule (6560 MW) remains insignificant when considered against the abundance of new capacity that is coming online. Moreover, the Agency's lost capacity estimate is only a fraction of the amount by which the EPA, using IPM 2000, has underestimated future generating capacity additions.<FN 19>

Footnotes

11 Id. at 17188, Exhibit 13 (April 9, 2002).

12 Id. at 17186 (in its description of market impacts associated with the waterbody/capacity-based option, the EPA describes relative larger capacity closures of 1.1% and 1.3% as “an insignificant percentage of total baseline capacity”).

13 CATF CWIS Comments 2002, supra note 1, at 13-15.

14 Id. at 15-18.

15 See Clean Air Task Force, Electric Power Generation Update: Preliminary Results (April 2003) (“CATF April 2003 PowerGen Update”). The update is attached to these comments as Appendix 3. As with our analysis of the April 2002 update, the future capacity forecast assumes many active capacity development projects will be delayed or abandoned due to regulatory or market factors.

16 Id. at 8.

17 Id.

18 Id. at 19.

19 For example, the EPA’s revised market projections suggest that under the base case scenario, a total of 100,634 MW of additional capacity will come online by 2010 (79,683 MW of new additional capacity and 20,951 MW of additional repowering capacity). EPA, Section 316(b) Phase II Economic Benefits Analysis – Chapter B3: Electricity Market Model Analysis B3-12 (NODA Version – March 12, 2003). According to our conservative analysis of recent RDI NEWGen data, however, 113,947 MW of new capacity will be developed by 2007. CATF April 2003 PowerGen Update, supra note 15, at 8. Thus, the amount of new capacity that RDI NEWGen data indicates will come online in the next four years is greater than the amount that EPA projects will come online in the next seven years.

Recent Report Underscores the Need for a More Protective Cooling Water Standard

Phase II facilities actively contribute to water scarcity in the Western United States. Existing fossil fuel-fired power plants in the Interior West withdraw well over 200 billion gallons of water per year – enough to accommodate the municipal water needs of almost four million people.<FN 20> New power plants currently under development will exacerbate the problem by withdrawing an additional forty-two billon gallons each year.<FN 21> Most of the water withdrawn by these facilities is used for cooling purposes.<FN 22>

The Clean Air Task Force and the Land and Water Fund of the Rockies recently published The Last Straw: Water Use by Power Plants in the Arid West. The report is included in these comments at Appendix 2. The Last Straw "examines the close relationships between power generation and water, including water use effects on competing uses, water quality and power system reliability."<FN 23> The report finds that coal-fired power plants in particular can significantly impact water resources in the Interior West, especially in overused water basins and in times of drought. "Despite the potential water savings associated with other means of power generation, many older generating units are still in operation today, and coal-fired power plants continue to be the dominant power source in the Interior West."<FN 24>

EPA has the opportunity and the responsibility to limit the impact that these facilities have on Western water resources by selecting the all closed-cycle option as BTA for Phase II facilities. Most of the fossil fuel-fired power plants in the Interior West already use closed-cycle cooling – evidence that closed-cycle cooling is an effective, affordable, and available option for Western power plants.<FN 25> A CWIS standard that requires closed-cycle cooling at all Phase II facilities would protect vulnerable Western water resources by drastically reducing the adverse environmental impact caused by those generators that continue to utilize outdated once-through cooling systems.

Footnotes

20 The Last Straw, supra note 4, at 1. The Interior West consists of Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, Utah, and Wyoming.

EPA Response

EPA agrees with the commenter that water use issues are of concern, especially in areas where limited supplies may be under additional stress. EPA notes that today's rule recognizes the ability of a State to adopt or enforce more stringent requirements.

Comment ID 316bEFR.329.005

Subject Matter Code 7.02

Performance standards

Author Name Johnathan F. Lewis

Organization Clean Air Task Force

In our previous comments, we argued that in order to discharge its statutory duty, the EPA must require that Phase II facilities use closed-cycle cooling or its functional equivalent. Closed-cycle cooling is simply more effective than the various proposed stratagems at minimizing the adverse environmental impact of CWIS. In addition, we argued that the significant environmental advantages associated with a rule that requires closed-cycle cooling could be achieved without threatening the supply or reliability of electricity around the country.

Those comments remain true. The EPA is still incapable of demonstrating that its preferred approach would do a better job of minimizing adverse environmental impact than would a closed-cycle cooling rule. Nor has the EPA been able to show that the closed-cycle option should be precluded on the basis of cost – a factor which the Agency is not even authorized to consider.<FN 26> The EPA's proposed Phase II CWIS rule is an inadequate response to a serious problem. Accordingly, we once again urge the Agency to adopt the all closed-cycle option as BTA for existing power plants.

Benefits of reduced intake capacity

Best Technology Available for Cooing Water Intakes

Closed-cycle recirculating cooling systems (evaporative cooling towers) are the best technology because they reduce impingement and entrainment of all species by approximately 95%. EPA proposes that instead of closed-cycle cooling, facilities may use other technologies that reduce entrainment by 60-90% and reduce impingement by 80-95% from the calculation baseline. In this section we examine several technical issues related to best technology available and EPA's performance standards: (a) the relationship between intake flow and impingement and entrainment; (b) EPA's concept and definition of the "Calculation Baseline"; (c) the extent to which available intake screening and fish diversion technologies can achieve 60-90% and 80-95% reductions; and (d) the reasonableness of EPA's assumption of 100% mortality of entrained organisms.

EPA Response

EPA disagrees that evaporative cooling towers reduce entrainment by 95 percent for all waterbodies. This statement is somewhat misleading when comparing to the Agency's entrainment standards of 60 to 90 percent for all waterbodies. See response to comment 316b.EFR.330.006 and 316b.EFR.404.034.

The Relationship Between Intake Flow And Impingement And Entrainment:

Introduction

In this note we discuss the role of intake velocity in determining the number of fish sucked into a power station intake. In our previous analysis we have produced predictive regression models that relate the number of fish impinged to the volume of water pumped rather than the velocity. Below we first examine the statistical basis for these regression models in more detail and place confidence limits on the regression equations produced. This more refined statistical analysis demonstrates the validity of our previous work ands shows that the volume pumped is a good predictor of total impingement.

Further, we examine intake velocity data and show that in many cases fish will be caught even if the velocities are set at the lower end of the practical limits. This is important because the argument that if the designed intake velocity is set low fish will be able to escape seems to have a logical basis. Put simply, if a fish can swim against the intake water flow then it should be able to escape and thus the rate of impingement will not depend on the volume but rather the velocity. Our use of volume was based on the observation that in practice, no direct-cooled large power plants have intake velocities sufficiently low to allow all sizes of fish to escape. Further, most fish are small and as the swimming speeds of fish are determined by their size (length) and the maximum intake velocities in almost all cases are above the sustainable swimming speed of small fish. The result is that the total number of fish caught is relatively insensitive to differences in average intake velocity.

Finally we will explain below that a key reason why intake velocities cannot in practice be used to predict fish ingress is because velocities usually vary through time and frequently vary spatially across the intake. Without extensive site measurements of flow it is simply not possible to predict what the intake velocities experienced by the fish actually are. A particular point to note is that taking the volume pumped and dividing it by the cross-sectional area of the intake calculates the nominal intake velocity. As will be shown below such an approach takes no account of the water velocity caused by tidal currents etc. It gives no idea of the maximum intake velocity, it is the maximum velocity which must be below the swimming speed of the fish if impingement is to be avoided.

The relationship between volume pumped and the number of fish impinged

The basic regression results previously presented are shown in the Figure below. Three regressions linking the number of fish impinged were calculated, (1) all plants. (2) Marine and Estuarine and (3) freshwater excluding Great Lakes. These will be considered in turn below and the full statistical analysis and confidence intervals calculated.

Overview of I & E effects on organisms

The relationship between volume pumped and the number of fish entrained

Annual entrainment of fish in for US power plant cooling water systems was estimated using the same approach to that developed above for impingement (See Section 1.1.2).

Predicting entrainment

Two key aspects that affect the number of young fish killed by entrainment are location and size of the intake. It is apparent that, within single water body, the larger the volume pumped the larger the number of organisms that will be entrained. The locality and nature of a water body will influence the abundance of fish eggs and larvae. It is clear that some localities are particularly favoured as spawning grounds whilst other regions, such as highly turbid waters in muddy estuaries, are not. After investigation of the various options source waters were classified into (1) freshwaters of all types and (2) marine and estuarine.

Table 1. The number of fish entrained al freshwater and marine power plants in the USA
[See hardcopy for table]

Entrainment flow relationship for freshwaters

Annual entrainment estimates were collected from the literature for 14 power plants drawing their cooling water from freshwaters including the Great Lakes (Table 1). To be included in the analysis entrainment data had to be collected over at least one year to ensure full seasonal coverage. Using regression analysis the best fit to a simple function gave the equation:

En= 2E+07 V^0.1924

where En is the number of fish entrained per year and V the volume extracted in cubic feet per second. This equation and the entrainment data are plotted in Figure 1.

Figure 1. Total entrainment for freshwater stations in the US.
[See hardcopy for table]

Entrainment flow relationship for oceans and estuaries

Annual entrainment estimates were collected from the literature for 15 power plants drawing their cooling water from estuarine or marine waters (Table 1). To be included in the analysis entrainment data had to be collected over at least one year to ensure full seasonal coverage. Using regression analysis the best fit to the combined marine and estuarine data gave the equation:

En = 457475 V^1.1405

where En is the number of fish entrained per year and V the volume extracted in cubic feet per second.

This equation and the entrainment data are plotted in Figure 2.

Figure 2. Total annual entrainment for marine and estuarine stations in the US.
[See hardcopy for table]

Overview of I & E effects on organisms

The Approach Velocities at intakes

The water velocity ahead of the primary (coarse) screening systems of a water intake structure is termed the approach velocity. A more precise definition for the present purpose is the maximum velocity in an intake system against which fish must swim to escape. To ensure that fish can escape, the approach velocity must therefore be kept below the maximum sustainable swimming speeds of the fish.

The swimming speed required for escape, depends on the orientation of the fish. If the screen is not aligned normal to the flow and the velocity is close to the maximum sustainable swimming speed, fish are often observed to swim ahead of the screen, in a direction perpendicular to the screen face (Sonnichsen et al., 1973; Arnold, 1974). This indicates that the fish are orientating to the face of the screen rather than the hydraulic streamlines. A similar behaviour has been observed in fishing gear research amongst flatfish herded by the sweeps and bridles of a trawl (Main and Sangster, 1981). It is generally agreed, therefore, that the design velocity for fish escape should be computed as the velocity vector normal to the bars of an intake and not along the streamline, unless these happen to be perpendicular to the trash-rack face.

Design values for approach velocities have been adopted by various agencies with a view to fish exclusion. Schuler and Larson (1975) cite a design velocity of 76 cm/s for the Southern California Edison Company's (SCEC) offshore intake structures, but from their own experimental trials recommended a modified design value of 46 cm/s for SCEC's San Onofre Nuclear Generating Station. Other utilities in the USA have adopted design values as low as 15-30 cm/s (Sonnichsen et al., 1973). While these are all standards defined almost 30 years ago the age of much direct-cooled plant makes it likely that they were designed using 1970s/1980s specifications.

In Britain Mawer (1982) specifies a peripheral velocity at the capped offshore structure “in the order of 50 cm/s” to enable fish to escape.

It must be borne in mind that other factors influence the choice of approach velocity, for example the necessity to prevent sedimentation in waters with a high silt burden, and the higher cost of the larger structure required to maintain low approach velocities. The final design velocity therefore reflects an optimization of all the salient factors, of which fish exclusion is only one; its importance will depend upon the significance of the locality to fisheries.

EPA Response

EPA appreciates the data provided by the commenter and notes the inclusion, under compliance alternative 1, for a facility subject to impingement mortality performance standards to maintain a through-screen velocity of 0.5 feet per second (fps), thus triggering reduced Comprehensive

Demonstration Study requirements. For further discussion of this alternative, please see the preamble to today's rule.

Fish Escape

It is generally accepted that if the flow is sufficiently low for the fish to swim away then they will not be entrained or impinged. Below we discuss what
velocities will allow fish to escape. However, it should always be remembered that large fish which almost certainly did have the power to escape are frequently
caught on screens indicating that swimming ability is not the only factor determining the rate of impingement.

To ascertain approach velocities from which fish can escape, it is necessary to consider first the species present in the locality and then the size distributions present. From this information, swimming performance data can be used to predict the proportion of fish vulnerable at any given water temperature. For all species, the probability of escape is lowest when waters are coldest. Where significant seasonal variations occur due to age-selective migrations or growth, separate length distribution and temperature values can be applied for each season.

Velocity Characteristics of Water Intakes

Onshore and shoreline intakes

An onshore intake is defined as one where the water is abstracted without the need for an offshore pipeline and intake structure. Where the marginal water is shallow, water is normally taken via a deep canal, or directly through a sea wall or river bank where the marginal water is deep. The second type is known as a 'shoreline' intake.

A typical onshore intake layout is shown below.

(See 1.1.6. For Missing Diagram)

Water enters via an orifice in a vertical wall. The opening is normally protected by a coarse screen or 'trash rack' of vertical steel bars fixed at circa 15 cm centres. Beyond this is a traveling band or drum screen which removes entrained fish and debris. While it has been shown that live fish released behind the coarse screens into the screenwell area can escape from the system, the hazards of turbulence in the screenwells and of sometimes toxicity due to chlorine injected to prevent bio-fouling render this opportunity unlikely as a general rule. The design expectation should therefore be that fish are enabled to escape before passing through the coarse screens.

The vertical openings of onshore intake designs lend themselves to fish escape since the water currents are predominantly horizontal at the coarse screens. The main consideration for fish escape is therefore that the approach velocity at that point, under all operating conditions, is kept within the swimming speed ranges of the fish. It is preferable that a uniform velocity profile be achieved across the face of the screens but, .if not, that the conditions for fish escape are met at the maximum velocity value.

A difficulty of some canalized onshore intake designs is that the point of maximum approach velocity in the canal is at some distance ahead of the coarse screens and not at the screen face. As a consequence, by the time fish come into contact with the coarse screens and attempt to escape, poorer swimmers become trapped within the system.

A further aspect of great importance is that in tidal waters fish move off the mudflats as the tide drops. To do this they follow the current. If they are in the vicinity of an intake they will follow the water into the intake. Thus their normal behaviour can cause them to move into danger.

Offshore intakes

Offshore intakes vary widely in design, but generally comprise an offshore structure connected by a sub-sea tunnel to the shoreline. Older designs, are open-topped and have strong vertical draw-down currents, whereas more recent designs have capped intakes with a more horizontal flow pattern (see below). Capped intakes may reduce fish ingress but blocking the top of an intake without due regard to the flow pattern is not sufficient to guarantee fish protection. As a simple criterion for a fish protecting intake, Schuler and Larson (1975) proposed that “to create the desired uniformity in entrance velocity and to increase the time for reaction (of fish) to the flow, the cap and lip of the riser must extend horizontally from the riser body 1.5 times the height of the opening” (see below). There are, however, reasons unrelated to fish protection for adopting capped intake designs. Goldring (1984) showed that capped intakes have superior characteristics for selective withdrawal of cooler water in thermally stratified environments - another example of how intake design must reflect a variety of requirements.

(See Figure1 in 1.1.6)

The horizontal flow pattern around an offshore structure is just as important as it is for onshore intakes. In still water, inflow is uniform around the structure and
streamlines are normal to the trash-rack bars. In a tidal cross-flow, the distribution becomes biased, with most of the water entering close to the upstream radial axis where the approach velocity is consequently higher.

HORIZONTAL DISTRIBUTION OF STREAMLINES AND WATER VELOCITY AROUND A CIRCULAR CAPPED INTAKE STRUCTURE IN A TIDAL CROSSFLOW.

Intake flow - 13.7 m3 s-1, tidal velocity of 50 cm s-1, velocity values shown are as measured at mid-intake level along the direction of streamlines at the periphery of the intake structure. Values in parentheses are vectors normal to the periphery. All values are in units of cm s-1. [Based on trials with a 1/50 scale model.

It would be expected from this that catch rate at an offshore structure sited in a tidal stream would tend to be maximal around mid-flood and mid-ebb, and minimal around the slack water period. This has indeed been shown to be the case.

In hydraulic model tests carried out at CERL using a capped, circular intake with a nominal approach velocity (flow/screen area) of 25 cm s-1, the measured peak velocity in a simulated 50 cm s-1 tidal crossflow was 70 cm s-1. As a principle, it is not possible to achieve maximum approach velocities of less
than the tidal cross-flow velocity using a circular intake structure.

The above point has great importance, for it effectively states that irrespective of the velocity that would be generated in still water, in flowing water an offshore intake will have a maximum approach velocity determined by the tidal velocity. As the tidal velocity is frequently greater than the sustainable swimming speed of fish this means that they will be vulnerable to capture no matter how low the nominal intake velocity is.

EPA Response

EPA acknowledges this comment and notes that these are the types of important issues that must be considered when selecting the best technology for a particular site to meet the requirements set in today's final rule.

Benefits of reduced intake capacity

Effect of reducing intake flows by 95%

Reducing the cooling water flow at a facility can produce a larger decrease in impingement than a simple percentage decrease in flow would indicate. The reduced velocities around the intake would mean many more young fish would be able to escape, and the reduced volumes would make effective protection methods such as wedge wire screens possible.

For entrainment, where the organisms are more passive, the relationship will be more linear, with a reduction in cooling water usage producing a similar reduction in impingement. The reduced flow will again make effective protective technologies possible.

EPA Response

First, the Agency notes that the reduction of intake flows due to adoption of recirculating cooling towers leads to a 95 percent intake flow reduction only in freshwater environments where entrainment is not as dramatic an issue as in marine environments. In marine environments, the reduction in flow due to cooling tower installations generally results in flow reductions in the range of 85 to 92 percent. As such, the commenter's basis of assumption for the 95 reduction may be misleading. See response to comment 316b.EFR.404.034.

Regarding intake velocity and impingement. The median intake velocity of intakes within the scope of this final rule is 1.5 ft / sec. This level of velocity is near to the reasonable range of acceptable levels for ensuring survival of impinged organisms for both modified ristroph traveling screens and wedgewire screens. The Agency has found that a significant number of facilities will be able to comply with impingement reduction requirements with their existing traveling screens and relatively simple modifications to these. This is due in large part to the moderate intake velocities of these existing intakes. For other intakes, where the velocity is above approximately 1 ft / sec, the Agency expects and predicts costs for significant changes to the intake in order to overcome the elevated velocity level. These means are discussed in detail in the Technical Development Document. In some cases the changes may involve enlarging the intake to lower the intake velocity, moving the intake slightly or dramatically and simultaneously enlarging the intake, adding barrier net systems that inherently operate at extremely low through-velocity, or installing velocity caps (that rely on a fish's ability to sense and avoid certain velocity vectors). As such, the Agency has accounted for reductions in impingement as required by the rule. Should facilities choose to also incorporate voluntary intermittent flow reduction as a means to meeting various standards, these would be acceptable means in the Agency's view. Therefore, the Agency believes that it is promulgating a rule that will dramatically reduce impingement of aquatic organisms over the absence of the rule.

Regarding entrainment performance of flow reduction, the Agency notes that the comment is only a general statement and does not assert a position in relation to the Agency's final rule requirements.

For further information relating to the basis for the final rule's requirements for entrainment reduction see the efficacy discussion included in the Technical Development Document.

Calculation Baseline

Introduction

The EPA wishes to impose a reduction in impingement and entrainment at all power plants in the US. One obstacle to applying this reduction fairly comes from the need to recognise the technologies already installed at the facilities - it is unfair if a plant with good intake protection is forced to reduce its entrainment by the same amount as a facility with no protection. To this end, the EPA has come up with the concept of a calculation baseline station.

The calculation baseline station is a theoretical station that is built on the same site as the real station. It has set features that are defined below:

Calculation baseline means an estimate of impingement mortality and entrainment that would occur at your site assuming (1) the cooling water system has been designed as a once-through system; (2) the opening of the cooling water intake structure is located at, and the face of the standard 38-inch mesh traveling screen is oriented parallel to, the shoreline near the surface of the source water body; and (3) the baseline practices and procedures are those that the facility would maintain in the absence of any operational controls, including flow or velocity reductions, implemented in whole or in part for the purposes of reducing impingement mortality and entrainment.' (from National Pollutant Discharge Elimination System—Proposed Regulations To Establish Requirements for Cooling Water Intake Structures at Phase II Existing Facilities; Notice of Data Availability)

We will examine each part of this process in turn.

- Baseline cooling water intake structure is located at, and the screen face is parallel to, the shoreline.

This baseline is calculated to allow for stations with good intake designs, for example having an angled screen or an offshore intake. Offshore intakes are expensive structures and are only used where there is an engineering advantage. They are often the only solution for areas with large variations in water level caused by tides, seasonal low levels or flow, or drawdown. It is certainly feasible for offshore intakes to catch as many, if not more, fish than an onshore intake, particularly in marine environments.

New wording could possibly be - Baseline cooling water intake structure is located with the greatest engineering advantage, with the most cost-effective screening fitted.

- Baseline cooling water intake structure opening is located at or near the surface of the source water body.

Withdrawing water from lower in the water column is not unusual. This is done for a number of sound engineering reasons, chiefly getting the coldest water to the condensers, and maintaining cooling water flow when the water level drops. The intake structures of power plants are designed to allow the facility to operate at full capacity when the water level is as low as it can feasibly get. For example, in the marine environment the intake will be designed to cope with the lowest possible tide in combination with high atmospheric pressure; a facility using lake water for cooling must be able to cope with drought and drawdown. The intake often is placed 3 ft or so below this level. It seems generous to allow a reduction for this factor, that in most cases is done to allow the continued operation of the facility in any conditions.

New wording could possibly be - Baseline cooling water intake structure opening is located at the depth which good engineering practice demands.

- Baseline cooling water intake structure has a traveling screen with the standard 3/8 inch mesh size commonly used to keep condensers free
from debris.

This is sensible as it allows a standard split to be made between impingeable and entrainable organisms.

- Baseline practices and procedures are those that the facility would maintain in the absence of any operational controls implemented in whole or in part for the purpose of reducing impingement mortality and entrainment.

This is fair, as any restriction imposed for the facility to reduce impingement and entrainment is already potentially costing the plant in terms of electrical production.

Performance standards

Calculating the catch of the baseline

This is probably the most difficult part of this method. Even calculating the baseline figures from a station where data exist will be difficult. The variations caused by small changes of station configuration are very difficult to quantify. For example, recalculating the number of organisms entrained by an existing offshore intake to estimate catches at a hypothetical inshore intake requires considerable background knowledge. Information on where fish live in the area, whether the intake is on a migration route for a fish species, the distribution of larval fish between the inshore and offshore areas and many other factors would need consideration before a realistic conversion could be made.

Estimating the numbers and species of fish impinged or entrained on two facilities close to each other, on the same water body and in similar environments may be possible. However, it would only be a very approximate figure, and the EPA would probably need to add a large safety factor to ensure that I & E were not underestimated. Suggestions have been made to allow data from plants on different water bodies to be used. In our opinion, this is very problematical as, as stated above, minor variations can have very large effects on the potential for I & E.

Data from power plants need to be considered with some care. Take, for example, the situation of a power plant working in an area with a depleted natural population of fish. The population may have been reduced by many years of heavy I & E by the power plant, or by pollution or other environmental factors, but the result will almost certainly be that the power plant records fairly low levels of I & E. If the hypothetical baseline calculations were made assuming an environment with a healthy fish population, the existing plant might appear to have a good (i.e. low) level of I & E, and thus avoid the requirement for reduction. In fact, in terms of proportion of the total population entrained/impinged, the existing station could be performing as badly or worse than the hypothetical baseline station in a healthy environment.

For this reason, it would be desirable to be able to apply some kind of scaling (for example, % of total population impinged, or number impinged per 100,000 population) to existing and extrapolated I & E data, rather than using raw numbers. However, it is appreciated that in practice this may be difficult or impossible to achieve.

The suggestion to use “as built” approach.

In this approach the facility must either use historical entrainment data for the site or collect new data by sampling in front of the intake. This has several advantages in terms of simplicity. The lack of reliance on a hypothetical baseline would make the process more robust, but would involve a considerable amount of data collection, and consequent costs.

Source data used by EPA

Screen And Fish Diversion Technologies To Reduce Impingement And Entrainment

The new database provided by the EPA does not materially improve the knowledge on these different technologies. Some are studies of well-known methodologies (traveling screens etc) others are of very experimental technologies.

One of the most obvious facts to come from the new data is that most of the technologies produce large between-sites and between-species variations in reduction of I&E. It is therefore impossible to produce a meaningful average figure for the decrease due to a particular technology. The only exception is the effect of reducing the total amount of cooling water used as a facility. This will produce a reduction in the I&E of all species.

EPA Response

EPA agrees that the technologies available to minimize impingement mortality and entrainment caused by cooling water intake structures will demonstrate a range of efficacies affected by physical and biological conditions at a given site. For this reason, EPA has set requirements that facilities must achieve, using whatever combinations of design and construction technologies, operational measures, and restoration measures are necessary to do so. EPA believes that the requirements represent the best, economically achievable, technology available for minimizing adverse environmental impact for Phase II facilities, considered as a group, although site-specific options are also available. EPA has also provided a compliance option that rewards facilities that have reduced flow commensurate with closed-cycle cooling, to be automatically considered in compliance with today's final rule.

Available I&E technologies

Modified traveling screens - 'Ristroph Screens'

Efficacy of Cooling Water Intake Technologies Chapter 3 adequately summarises the effectiveness of Ristroph screens and fish return systems to reduce fish impingement mortality. The report notes that their effectiveness is highly variable but that at least a 70-80% reduction in impingement can be achieved over conventional traveling screens. In practice this figure is probably higher than will actually be achieved, for two reasons. First, it will depend on the species mix at the particular site and, as will be discussed below, some species of fish are much more easily hurt than others. Second, the need to fit modified screens into existing intake structures may result in less effective performance.

The actual reduction that can be achieved will depend on the dominant species for the locality. Generally clupeid fish are by far the most abundant species and these are particularly vulnerable to damage following contact with surfaces. Further, there are likely to be considerable differences in survival between clupeid species e.g. survival values quoted in chapter 3 show bay anchovy 20-72%; herring 78-82%; alewife 15-44%.

Table 2. 8 hr survival rates for Indian Point (Fletcher, 1990)
[See hardcopy]

Table 2 suggests that an intake situated in waters where alewife were one of the most abundant species caught would be unlikely to achieve 70% reduction in average impingement mortality. The effect of the species mix on the average survival that can be achieved in practice can be appreciated from a consideration of the data for Salem. Bay anchovy are by far the most abundant species impinged and on average represent about 50% of all impinged individuals. The next most abundant species is weakfish, which contributes about 22% of all individuals impinged. Thus these species, with recorded survivals at Salem for bay anchovy of 20 - 72% and weakfish of 18 - 88%, represent about 72% of all impinged fish, and will effectively determine the average survival. It is clear that this value is unlikely to reach 70% and could on occasions be much lower.

An additional factor reducing the likelihood of 70 to 80% survival rates is that the data presented in Table 14 above are 8 hr survival rates, and may not be of sufficient duration to predict the long-term survival of fish. It has been found that stressed and damaged fish can take a number of days to die. There is also the problem with all fish return systems that exhausted, disorientated and damaged individuals can be picked off by predators on their return to the main water body.

Further doubt on the effectiveness of screens with modified Ristroph features comes from studies undertaken at Roseton units 1 & 2. This site has six conventional screens and two modified dual-flow screens. One of the modified screens also has a flow straightening device. Testing of the dual flow screens found that while post impingement survival rates were higher than at the conventional screens, they were not as high as those observed at the Indian Point or Arthur Kill intakes. It was suggested that this was linked to the pattern and magnitude of the water velocity close to the screens.

Velocities were increased because the modified screens had a reduced filtering area. This was the inevitable outcome of fitting modified screens without major structural alteration to the intake system (DEIS for Bowline Point, Indian Point & Roseton GS, VIII-29).

Cylindrical wedgewire screens

Wedgewire screens have a proven ability to reduce both impingement and entrainment mortality at low volume intakes (1 to 50 MGD). Their effectiveness is related to (1) the slot width, (2) through-slot velocity, (3) existence and strength of ambient cross flow to carry organisms away from the screen, (4) the amount of biofouling and (5) the amount of ambient debris. As the EPA note, they are an unproven technology for protecting once-through intakes that typically pump volumes in excess of 100 MGD. As will be discussed below, the effectiveness of wedgewire screens is linked to water velocity across the screen and this has not been quoted in the EPA discussion of effectiveness.

Wedgewire screens with slots widths of 5 to 10 mm have been used to effectively eliminate impingement at freshwater cooling water intakes. They have not been used at marine or estuarine facilities probably because of fears that biofouling and screen blockage would lead to operational problems. Small-scale trials of Johnson wedgewire screens at Fawley, England in the 1980s showed that standard steel wedge-wire screens developed a fouling community (Bamber and Turnpenny, 1986). Even a Johnson 715 alloy (70% Cu: 30% Ni) screen that leached copper and thus poisoned organisms that had settled, experienced some fouling.

To reduce entrainment of fish eggs and larvae appreciably the screen slot widths need to be in the range 0.5 to 3.0 mm. Weisberg et al. (1984) & (1987) found that a 3 mm slit width excluded about 50% of bay anchovy and naked goby larvae in the 5 to 6 mm long size class. A 1 mm slot width gave almost complete exclusion of bay anchovy greater than 8 mm in length and naked goby greater than 7 mm long. To give good protection to the very small larvae a slot width of 0.5 mm is required.

A 0.5 mm slot width will only be highly effective for larval exclusion when used with a suitable intake velocity. At a velocity of 7.5 cm/s this width will exclude larvae less than 6 mm in length. However, at a velocity of 15.0 cm/s (0.5 fps) about 60% of larvae less than 7.0 mm in length were entrained.

The reduction of egg entrainment is related to the size of the egg. However, eggs are not rigid and eggs greater than 0.5 mm in diameter will pass across a 0.5 mm slot. Data on the entrainment of marine fish eggs via a 0.5 mm slot width screen with a velocity of 7.5 cm/s are presented in Table 3.

Table 3. Entrainment of marine fish eggs via a 0.5 mm slot width screen with a velocity of 7.5 cm/s (Sunset Energy Facility proposal for Brooklyn New York)
[See hardcopy]

A species of particular importance in many estuaries is the striped bass. This species has a relatively large egg (2.4 to 3.9 mm diameter) and thus egg entrainment would almost certainly be eliminated by slot widths in the range 0.5 to 1.0 mm. However the striped bass yolk sac larvae range in length from 2 to 7 mm which would suggest that some young larvae would be entrained with even a 0.5 mm slot width, and very limited protection would be offered by a width > 1.0 mm.

It is clear that the reduction in entrainment possible using wedgewire screens will be determined primarily by the slot width, the water velocity across the screen and the mix of species present at the particular locality. The performance values quoted in Chapter 3 – 'Efficacy of cooling water intake structure technologies' indicate exclusion efficiencies of eggs and larvae at or above 90% for a 1 mm screen width (Logan 90%; Seminole 99% reduction; Chalk Point 90%). In localities where the eggs of fish such as the bay anchovy are present, or yolk-sac striped bass are abundant, a 1 mm screen width would not be able to achieve this level of efficiency with any realistic intake velocity. Further, in fully marine localities there are species with egg diameters well below 1 mm. It is therefore unlikely that 90% exclusion could be achieved by a 1 mm screen width at many estuarine sites. At marine sites this level of exclusion would be even more unlikely to be achieved because of the presence of even smaller eggs and larvae and the probability of biofouling.

A more realistic appraisal of the level of entrainment exclusion that could be achieved with a velocity of 7.5 cm/s across the screen would be in the order of 90% for a 1 mm screen width in flowing rivers, 90% for a 0.5 mm screen width in lakes and 80-85% for estuarine sites with a 0.5 mm screen width. There are no data upon which to base an assessment for an intake situated on the ocean, but it would likely be below that for an estuarine intake because of the small size of some marine fish eggs and larvae and problems of screen blockage. Biofouling at ocean and lower estuarine sites is likely to be an insuperable problem which at best would result in regions of high cross screen velocities. It should be noted that in some localities, such as bays and inlets with small tidal ranges there may be insufficient cross-flows to sweep debris and impinged organisms off the screen surface.

Fine mesh traveling screens

The incidence of entrainment can be greatly reduced by the use of 1 to 0.5 mm mesh traveling screens. However, this does not mean that the mortality of young fish is proportionately reduced as the eggs and early stages are now liable to impingement damage. The EPA Chapter 3 discussion may give a misleading impression of the effectiveness of these devices by quoting the reduction in entrainment rather than the increase in survival. Survival on such screens is highly species-specific with clupeid and other pelagic fish such as bay anchovy and Alosa species having low survival. Taft et al. (1981) report laboratory studies of the effects of impingement on fine mesh screens for the larval stages of striped bass, winter flounder, alewife, yellow perch, walleye, channel catfish and bluegill. Survival was highly variable and dependent on water velocity across the screen and the duration of impingement. The highly species-specific nature of survival of impinged larvae was also noted by McLaren & Tuttle (1999).

Fletcher (1990) also noted that the mortality on fine mesh screens is related to the amount of debris retained by the screen. This would suggest that fine mesh screens would not be effective in all waters. Fletcher (1992) reports a study of the effectiveness of fine mesh screens to reduce losses of early life stages of striped bass. The results showed that survival was influenced by mesh size, water velocity and exposure time. It was concluded that impingement resulted in high mortality for young larvae and many larvae that initially survived impingement subsequently died. The results suggested that striped bass up to 8.4 mm long are too delicate to survive impingement.

Given the high maintenance of fine screens together with the known high impingement mortalities of many species these devices cannot be considered a useful protective measure.

Barrier nets

Under appropriate conditions barrier nets can be effective devices to reduce fish impingement. To be effective there must be limited debris in the water, a low incidence of biofouling, relatively low water velocities and sheltered conditions with low wave action, low current velocities, etc. The last of these requirements excludes their use at open water ocean sites. In estuarine conditions the EPA assessments exaggerate their effectiveness. The following is described for the barrier net deployment at Bowline Point GS on the Hudson Estuary.

"The Bowline Point Station (New York) has an approximately 150-foot barrier net in a v-shape around the intake structure. Testing during 1976 through 1985 showed that the net effectively reduces white perch and striped bass impingement by 91 percent. Based on tests of a "fine" mesh net (3.0 mm) in 1993 and 1994, researchers found that it could be used to generally prevent entrainment. Unfortunately, species' abundances were too low to determine the specific biological effectiveness."

This account gives the impression that the 3 mm net was useful for reducing entrainment. In fact as Lawler, Matusky & Skelly Engineers (1997) report in 1993 the net clogged with fine suspended silt and sank. In 1994, even when the net was sprayed to remove clogging it fouled with the algae Ectocarpus causing two of the support piles to snap and the evaluation to end. They concluded that 3 mm barrier nets can only be considered an experimental device.

The available data would suggest that barrier nets can be effective at reducing impingement mortality at intakes situated in lakes and sheltered waters. Fine barrier nets capable of reducing entrainment have not been successful at estuarine sites and Chapter 3 gives a misleading impression of the effectiveness of the 3 mm net at Bowline Point.

Microfiltration

The only microfiltration system considered is the Gunderboom and the report makes clear that the only data available comes from the observations at Lovett GS. It is concluded that 'Entrainment reductions up to 82 percent were observed for eggs and larvae and these levels have been maintained for extended month-to-month periods during 1999 through 2001.

This statement is a clear exaggeration of the observed effectiveness of the Gunderboom at Lovett GS. Overtopping, tunneling and rips have been observed during testing. For example, in the Lovett evaluation report for 1999 it is stated that "the divers documented a substantial gap along the bottom of the boom. The gap extended along the bottom of the boom for approximately 3 m and ranged in depth from 0.5 to 0.6 m".

Figure 3. The ratio of entrained larvae and eggs at Unit 3 and Unit 4 of Lovett during trials of the Gunderboom.
[See hardcopy]

It is clear in Figure 3 of the Lovett 2000 report (above) that there was a gradual increase in entrainment through time. Further, there was also a series of events between May and August 2000 that resulted in short-term total failures. The efficiency of the Gunderboom was assessed by comparing the level of entrainment at unit 3 (protected by a Gunderboom) to that at unit 4 (unprotected). Thus a ratio above 1 for the number of fish entrained at unit 3 to unit 4 shows that the boom was offering no protection. To achieve 82% effectiveness or better the ratio would need to be smaller than 0.18. As shown in the figure below this level of efficiency was only achieved for a short period during May 2000. It is therefore incorrect to conclude that it was achieved for extended month-to-month periods during 1999 through 2001. In fact from late July 2000 the Gunderboom was completely ineffective at reducing entrainment.

Louver

Chapter 3 concludes that "Overall, the above data indicate that louvers can be highly effective (70+ percent) in diverting fish from potential impingement. Latent mortality is a concern, especially where fragile species are present."

Louver systems have been studied at hydroelectric facilities with migratory species in rivers; they have been little studied at steam generating plant and require further large-scale evaluation before the view that they are highly effective or capable of preventing more than 70% of potential impingement can be accepted.

Angled screens

Chapter 3 concludes "Similar to louvers, angled screens show potential to minimize impingement by greater than 80 to 90 percent." This conclusion may give a misleading impression of the proven ability of such systems. There is no evidence that such high levels of impingement reduction would be achieved in practice.

Velocity caps

To claim that velocity caps have been successful in minimizing impingement is an exaggeration. They have been found to reduce impingement by 50 to 80% when compared with an unprotected intake. However, it should be noted that this reduction is usually only observed for pelagic species. Other fish and crustaceans may still be caught in large numbers.

Porous dikes

Chapter 3 gives a fair summary of the present state of knowledge.

Behavioural barriers

The EPA conclude that "Many studies have been conducted and reports prepared on the application of behavioral devices to control I&E, see EPRI 2000. For the most part, these studies have either been inconclusive or shown no tangible reduction in impingement or entrainment." This is certainly a fair assessment of the situation and we know of situations where sound deterrent systems have actually increased impingement. It is therefore rather surprising to read in the final sentence that "Overall, the Agency expects that behavioral systems would be used in conjunction with other technologies to reduce I&E and perhaps targeted towards an individual species (e.g., alewife)." This would suggest behavioral barriers could be usefully implemented. Except perhaps in the case of alewife there is little evidence that such systems reduce impingement and there is no evidence that they reduce entrainment at all.

Other technological alternatives

The heading holds a number of techniques that might be considered simple good practise rather than fish protection technologies.

The fitting of variable speed pumps can reduce the amount of water consumed compared with one-speed pumps and can therefore result in a reduction in the quantity of life entrained and impinged. However, the effectiveness will depend on the coincidence in time of the periods when the young fish are most abundant, the plant has the highest demand for electricity and the source water is warmest. In practice, for some localities the proportional reduction in fish killed will be less than the reduction in the volume pumped because demand, water temperature and young fish abundance all peak during the summer. Therefore the 10-30 % reduction claimed may not be achieved in practice and is more likely to be at the lower end of the estimate.

Continuous screen operation is probably useful as it reduces fish exhaustion prior to their return.

EPA Response

Assumptions about I&E survival

Entrainment Survival

Current Position

It has generally been accepted that the only safe assumption for the mortality of fish entrained in the cooling water flow is 100%. This is the view expressed by the EPA in the new 316b regulations; we support that view and present our reasons for believing that 100% mortality is the only reasonable assumption.

Evidence for the assumption of 100% mortality

Survival of organisms in experiments.

Survival tests have shown that larval fish that have experienced passage through a power plant cooling water system suffer increased levels of mortality. The increased mortality is evident over all time periods studied, and fish still show an excess mortality over controls, even many days after entrainment.

Mortality is calculated by studying larvae from before (control) and after entrainment (experimental). The two samples are observed at intervals, often immediately and at 24, 48, 72 and 96 hours, and the number remaining alive in each sample noted. The mortality that is attributed to the entrainment is the difference in the number alive in the experimental and control sample. Performing these experiments is difficult and has many problems, not least because larval fish are extremely delicate.

The collection and handling of these very young fish is a difficult task. The stress of handling the fish can often lead to significant mortality, even in the control populations. This can lead to a masking of any entrainment effects, when the survival rate is lower in the control population than in the entrained fish. In the most extreme example, 100% mortality of the control sample leaves no mortality that can be attributed to the entrainment; combined with 100% mortality of the experimental sample it could even be taken to imply 100% survival. Control samples with 100% mortality occur at several sites, for example from chapter 7 of the § 316(b) Existing Facilities Benefits Case Studies, Part A: Evaluation Methods:

"In many studies, the survival in the intake sample is extremely low, for example the intake survival for bay anchovy was zero percent in studies conducted at Bowline (Ecological Analysts Inc., 1978), Brayton Point (Lawler, Matusky & Skelly Engineers, 1999), and Indian Point (Ecological Analysts Inc., 1978 and 1989)."

However even a more modest mortality level in the control population will mask the true effect of entrainment. If, for example, 50% of the larvae in a control sample were so delicate that they died as a result of the handling procedure, they presumably would also be killed by entrainment. However there is no means of separating the two mortality effects and it can lead to an underestimation of entrainment mortality.

A further bias occurs with the instant mortality rate, as 29 of the 36 studies counted stunned fish as alive, the rest of the studies did not explain how they dealt with these animals. Longer-term studies revealed that the majority of the fish classed as stunned died.

The samples taken are often not representative of the community of organisms entrained. Some species will be under-represented, and others over-represented. This can be due to a variety of factors, including the behaviour of the animals and the pattern of flow through the plant. Some species are extremely fragile and will disintegrate during collection or preservation, and are thus not documented when samples are processed (Boreman and Goodyear 1981).

Boreman and Goodyear (1981) showed that delicate organisms could easily be damaged beyond identification. This leads to an over-estimation of survival as these fish are not counted. Problems with the selection of dead and dying animals also lead to over-estimations of survival. Marcy (1975) showed that healthy specimens are sampled in preference to dead organisms, particularly if the dead organisms tend to settle out of the water.

Mortality of both control and experimental samples increases over time. In other words, fish can take many days to die from the effects of entrainment. Most studies only present the immediate and 48 hour survival times, whereas the effect on larvae might be apparent over a much longer period than this. No experiment has ever shown exposed fish to recover to a mortality rate as low as the controls.

Paucity of the data

The EPA reviewed 36 studies of entrainment survival. Only 21 different facilities have been examined. Only 20 of the 36 studies relate to in-scope facilities, which in turn represents only 3.7% of all section 316(b) Phase II existing facilities. The data presented for the entrainment survival are limited in several ways.

- Limited range. Most of the studies (24) were in the north east of the country with 17, nearly half, of all the studies in the Hudson River. Many studies were old, with 25 being undertaken in the 1970s. Changes in water quality and other environmental factors, biocide usage and plant operations make it difficult to extrapolate from the old data.

- Restricted species list. Possibly due to the restricted geographical range, very few species are represented in the survival figures. Only 24 species or families have data and only a few species have significant number of studies performed on them.

- Short duration. Several studies were short-term, with 15 only sampling for about 2 months. These sampling periods did not always coincide with the period of highest entrainment.

- Low numbers. It is difficult and time-consuming to sample entrained animals. Several of the species in the samples were caught in too small a number to be meaningful. Twelve of the studies had less than 100 individuals of a species in the discharge samples - not enough to estimate the survival of the species.

- Biocide use. The studies were undertaken when biocides were not in use. Biocides will increase the proportion of the larvae which die. With the spread of zebra mussels across the US the strength of any biocides and duration of their use is likely to increase in facilities within affected waters.

The existing studies had many problems with their methodologies. These result in a low confidence in the resultant survivorship estimates. Problems include:

- Counting organisms that have disintegrated or are unidentifiable.

- Difficulty identifying whether fish are alive or dead before entrainment.

- The loss of dead or damaged fish as they settle out of the water column in the discharge canal.

- Including stunned larvae as alive.

- The length of the survival studies.

- Unnatural rearing conditions after entrainment.

- High death rate in the controls.

- Controls being within the power plants intakes, possibly after some mortality has occurred.

- Poor sampling methods, using damaging collection techniques.

- Too short a sampling period to obtain a range of fish sizes and a range of environmental conditions.

- Too few fish recovered in the discharge to make good estimates.

- A lack of information on the amount of water sampled to collect the fish.

- The assumption that sampling mortality and entrainment mortality are independent of each other.

Most of the studies have problems with one or more of the above issues. Some of the problems make the interpretation of the results very difficult.

Predation on entrained organisms

The predation pressure on young fish is very high. Fish returned to the water body after entrainment, even if they are alive, are likely to suffer much higher predation rates than individuals that have not been entrained. It is well-established that injured or disorientated larval and young fish are highly vulnerable to predators. It is therefore likely that many entrained organisms that have survived passage will be eaten. Because returning entrained organisms are easy to catch, there is often a concentration of predators at the outfall that will increase the mortality still further. Increased likelihood of predation can occur for a number of reasons, including:

- Position in the water column. Many species have developed vertical migration patterns within the water column to reduce the predation. On returning to the water body via the outfall of a facility they are unlikely to be in their favoured part of the water column and hence will be more vulnerable to predation.

- Behavioural disturbances. The ability of larval fish to behave normally after entrainment is under-studied. However those studies review by Schubel et al, (1978) found a range of behavioral differences. These included erratic swimming, convulsions, disorientation and jumping.

- Physical effects. It was noted that the response to a rapid cooling, as experienced by a fish returning to its water body after entrainment, is often more severe than the one caused by the initial temperature increase.

Longer term effects

It has been shown that thermal shock can disrupt development of eggs and larvae in fish even if they survive entrainment (Schubel et al, 1978). Long term sub-lethal damage is difficult to observe in larval fish.

There is good evidence that any growth check during the early stages of a young fish's life can results in subsequent poor growth and an inability to compete effectively. Many fish that suffer in early life do not survive their first winter, as they have been unable to grow and lay down sufficient fat reserves.

In the experiments reported, all the fish were reared under carefully-controlled laboratory conditions. In the real world the larval fish and eggs are released back into a natural water body. Natural waters generally have very high levels of bacteria and viruses present, and any slight damage to a larval fish will make it highly susceptible to disease. Eggs' main protection from disease is the integrity of the egg membrane, which is likely to be damaged during entrainment. Larval fish have almost no antibody defense against disease and any small breach of the skin is likely to become infected.

Applicability of data from one station to another.

The effects of entrainment will vary considerably between power plants, which makes it extremely difficult to extrapolate results from one facility to another. Factors such as the length of the culverts, depth and type of intake, the pressure change across the pumps, the rate of mixing at the outfall and the smoothness of the cooling water system would all need to be the same. The environment from which the facility withdraws its water would also need to be similar. Here, factors such as temperature, species composition, water chemistry, presence of diseases, and water movements would all need to be considered.

Conclusion

As has been shown above, quantifying the mortality of eggs and larval fish caused by entrainment is very difficult. Several studies have been undertaken but the totality of the knowledge gained from them does not allow generalisations to be made.

The fact that there is mortality caused by entrainment is certain. The long-term survivorship of eggs and larvae is not. Some fish are certainly alive after entrainment, but how many will survive the longer-term effects of increased predation, affected growth and disease, is still unknown. Given the amount of acute damage and the steady mortality subsequently observed, the increased likelihood of predation, and the long-term impacts of poor growth following trauma, everything points to a very poor likelihood of reaching adulthood. The entrained fish are effectively lost to the population even if they die well after the entrainment event. Combined with the difficulty of using existing survival data to predict the survival rates at another station on a different water body, it becomes clear that the only path the EPA can follow with any degree of certainty is to assume 100% mortality for any entrained fish.

EPA Response

EPA thanks this commenter for this submission. To calculate the environmental benefits associated with the reduction of entrainment due to the implementation of technology to comply with this rule, EPA used the assumption that all organisms passing through a facility's cooling water system would experience 100 percent mortality in the final rule. Please see the chapter, Entrainment Survival, in the Regional Studies for the Final Section 316(b) Phase II Existing Facilities Rule for the updated analysis of this topic.

RFC: Proposed use of restoration measures

Restoration Measures

EPA is proposing to allow facilities to use “restoration measures” in lieu of or in addition to technologies to reduce impingement and entrainment. In this section we consider the potential for success and the drawbacks of various forms of restoration measures.

Aims of restoration measures

At several power plants, restoration measures have been proposed as a means of mitigating impingement and entrainment (I&E) losses. The concept is that if the productivity of organisms can be increased or augmented, or the organisms’ habitat can be improved or supplemented in the vicinity of a power plant, the increased number of organisms produced by these measures can be discounted from those killed by the plant. For example if the plant were to kill 100 salmon, and 100 salmon were released from a hatchery, and survived to adulthood, the overall reduction in salmon numbers ascribable to the plant would be, arguably, 0.

Types of restoration and measurement of success

There is a very wide range of methods available to man for modifying, restoring or creating habitat; covering the full spectra of scale, target species, habitat type, antiquity and, ultimately, effectiveness. Below are listed some means of altering the physical and biological characteristics of an ecosystem; divided into habitat- (H) and species-related (S) measures. It is of course probable that a combination of measures would be used to address different aspects of an ecological problem.

Creation

- Saltmarsh and wetland creation: managed retreat from protected areas by breaching of existing sea defences or creation of new creek systems. Creation
of entirely new reclaimed land by dumping of spoil, or encouragement of silt deposition and stabilisation. (H)

- Artificial reefs: disposal of fly ash, tyres, etc, sinking of old ships, oil rigs. (H)

- Creation of new river channels; permanent or temporary diversion of flow. (H)

- Translocation of animal or plant species – to new non-threatened habitat or to replace organisms lost/damaged. (S)

- Flooding of low-lying farmland to create water meadows (H)

Restoration/modification

- Physical cleaning, removal of oil, debris, contaminated silt etc; biological or chemical cleaning methods. (H)

- Dredging to restore estuarine habitat lost to siltation (H)

- Removal or modification of large-scale river obstructions: weirs, dams etc. (H)

- Removal, addition or modification of small-scale features, such as litter banks or debris dams, bank profiling, meanders, riffles/pools, adding obstructions, pinch points, bed widening, reedbed and bankside planting, weed-cutting, removal of shading vegetation. Provision of shallows for breeding and juvenile fish. (H)

- Culling or discouragement of damaging species, such as geese or birds of prey: herbicides to remove alien plant species – water hyacinth, Crassula, etc, biological control species. (S)

- Stocking with increased numbers of existing species, or with new, higher value species. (S)

- Regulation of salinity, water depth, sedimentation, by sluice gates; augmentation of flow. (H)

- Closing (or opening) of channels; building of protective barriers, wave screens to protect fragile inshore habitats. Groynes & breakwaters to prevent erosion of beach substrate. (H)

- Changes in input to food chain; removal of organic input from sewage works, agricultural run-off etc. (H)

- Building of fish-passes and ladders. (S)

- Cleaning, de-silting or addition of fish spawning areas such as gravel beds. (S)

EPA Response

EPA believes that there are a large number of restoration methods available.

RFC: Performance/effectiveness of restoration

Defining and assessing ecological equivalence

Having identified habitat enhancements which may be employed, the key is to assess how much enhancement, and of what type, is necessary to offset a given scale of ecological harm caused by impingement and entrainment losses. It is clear that, in certain circumstances, like-for-like replacement can sometimes be achieved. For instance, if a power station is built on reclaimed saltmarsh, then a similar area of adjacent saltmarsh can be created or restored. Similarly, an area damaged by thermal discharges could be compensated for by restoration nearby. However, like-for-like restorations for impingement / entrainment are impossible on the community level, implying that a means of assigning equivalence to such losses is necessary.

The principle of Habitat Equivalency Assessment (HEA) demands that

- both a scale or multiplier, and a measure common to both damaged and replacement habitats, exist, and that

- the damage to the original habitat be measurable.

“For compensatory restoration actions, the scaling question is: what scale of compensatory restoration action will compensate for the interim loss of natural resources and services from the time of the incident until full recovery of the resources? The scale of compensatory restoration actions is conditional upon the choice of primary restoration actions. … Necessary conditions for the applicability of HEA include that (1) a common metric (or indicator) can be defined for natural resource services that captures the level of services provided by the habitats and captures any significant differences in the quantities and qualities of services provided by injury and replacement habitats, and (2) the changes in resources and services (due to the injury and the replacement project) are sufficiently small that the value per unit of service is independent of the changes in service levels”. - (NOAA, 1995).

According to this principle, therefore, it is possible to place a value on the resource that is damaged or lost, and create or improve habitat with an equivalent value. For example, if X thousand of a particular species die each year, then their loss can be offset by creating enough habitat to support X thousand more. In most cases, this implies the creation or restoration of estuarine and wetland habitat. It should be noted that almost all examples of habitat equivalency analysis are concerned with the replacement of past damage, such as compensation after oil spillage. It is also evident that a considerable time-lag is likely, between the original damage and the establishment of the new resource at its full potential.

Nona's Habitat Equivalency Analysis (HEA) states: “The principal concept underlying the method is that the public can be compensated for past losses of habitat resources through habitat replacement projects providing additional resources of the same type”. (NOAA, 1995). Thus the origin of the concept appears to be as compensation for finite, existing, discrete and quantifiable losses, rather than justification for continuing and unquantified future loss.

EPA Response

For a discussion of approaches used to determine equivalency in the restoration measure context, see EPA's response to comment 316bEFR.091.014.

For a discussion of EPA's authority to include restoration measures in the final rule, see the preamble to the final rule.

For a discussion of compensation for past damages through the use of restoration measures, see EPA's response to 316EFR.206.055.

RFC: Performance/effectiveness of restoration

Measuring the success of a restoration project.

Probably the most appropriate and complete list of principles for successful restoration is set out by the partnership of Restore America's Estuaries and the Estuarine Research Federation, (RAE-ERF 1999).

RAE-ERF guidelines for successful restoration of estuarine habitat include:

- Preservation of existing habitat is critical to the success of estuarine restoration

- Estuaries can be restored only by using a long-term stewardship approach and developing the constituencies, policies and funding needed to support this

- Restoration plans should be developed at the estuary and watershed levels to set a broad vision, articulate clear goals and integrate an ecosystem perspective

- Project goals should be clearly stated, site-specific, measurable and long-term – in many cases greater than 20 years

- Success criteria for projects need to include both functional and structural elements and be linked to suitable local reference habitats

- Site plans need to address off-site considerations, such as potential flooding and salt water intrusion into wells, to be sure projects do not have negative impacts on nearby people and property

- Scientifically-based monitoring is essential to the improvement of restoration techniques and all-over estuarine restoration

- Ecological engineering practices should be applied in implementing restoration projects, using all available ecological knowledge and maximizing the use of natural processes to achieve goals

- Long-term site protection is essential to effective estuarine habitat restoration

- Public access to restoration sites should be encouraged wherever appropriate, but designed to minimize impacts on the ecological functioning of the site.

EPA Response

Overview of I & E effects on organisms

Organisms affected by impingement and entrainment

Power plants are indiscriminate feeders, since they can use very large volumes of water in the cooling process. Most power plants take their water from natural water bodies such as lakes, rivers, estuaries or the ocean. The volumes of water abstracted and velocity at which it travels are such that few organisms within the water taken in by the plant can escape. The great majority of organisms within the water column are potentially threatened by I&E.

The organisms which are affected by I&E include many that are not traditionally considered as vulnerable. All planktonic organisms are entrained in approximately the proportion at which they occur in the water. This includes many species of microscopic organisms such as viruses, bacteria, cyanobacteria, fungi, yeasts, protozoa, dinoflagellates, diatoms, algae and many other groups of microscopic life found in water. Amongst the larger animal groups, nearly all those known to occur in the aquatic environment have been impinged or entrained at power plants. This includes crustaceans, insects, molluscs, medusae, fish, reptiles and mammals.

Many studies have been performed on entrained and impinged organisms. A review of entrainment studies was performed by (EPRI 2000), who listed 36 discrete entrainment studies from 21 power stations. Most studies were performed in the 1970s with a few in the 1980s and 90s. Most were performed in the northeast of the country, primarily the Hudson River. The majority of the impingement studies were on fish and the larger crustaceans. Of the entrainment studies most concentrated on young stages of fish and a few common invertebrates. No data were found on numbers of plants, bacteria or protozoans entrained by power plants.

Fish survival of both impingement and entrainment is very variable and changes with species, biocide levels, temperature, time of year, life stage and water type. It can range from 0% for some clupeids to near 100% survival for some gobies. Some groups of zooplankton appear to be quite hardy – many groups of crustaceans showing survivals of 70-90% (EPRI 2000), whereas the worms tested show survival rates as low as 10%. Little is known about the survival of bacteria, viruses or protozoans. Very little work has been done on phytoplankton. Studies by Braind (1975) (in (Beck 1978)) showed diatoms having survivals between 10 and 70%, and dinoflagellates between 50 and 90%. (Morgan and Stross 1969) found that phytoplankton photosynthesis was depressed by the passage through a power plant if the water was warmer than 20°C, showing no recovery after 4 hours.

The majority of the available data relate to fish and some macroinvertebrates from the north east of the USA. This makes predicting the effect on the entire community of animals affected by I&E across the whole of the USA very difficult.

EPA Response

Please see response to comment 316bEFR.206.001. EPA agrees with this commenter in that very few studies have been performed to determine the survival of microscopic organisms such as viruses, bacteria, cyanobacteria, fungi, yeasts, protozoa, dinoflagellates, diatoms, or algae. Nor have studies been performed on higher plants. This lack of data does increase the difficulty and uncertainty when attempting to predict the effect on the entire community of impingement and entrainment by cooling water intake structures.

Role of Restoration

Available compensation measures

Several measures have been suggested as possible methods for compensating for the loss of animals by impingement and entrainment. Below is a brief review of each of the major types.

Habitat replacement

The principle of habitat replacement as a mitigation for I&E is to modify existing habitat, or create new habitat, to increase production of the species killed. For example, one might modify an area adjacent to a power plant to create a salt marsh, creeks, or eelgrass beds.

What it can do

Habitat replacement is attractive as it can appear simple to cost and cheap to maintain. It can be used to produce large amounts of new habitat of use to both aquatic and non-aquatic organisms. For example eelgrass beds have been produced which benefit several species of fish and invertebrates. However, the drawback is that the community structure of the new habitat is unrelated to the community of the water that is being used for the power plant – the organisms actually lost to I&E. As an example, let us propose the creation of a new salt marsh. This will likely increase the habitat available for inter-tidal and salt marsh fauna, and in consequence increase food resources for predator species. The creeks and channels within the salt marsh will contain some young fish that utilise the shallows as a refuge, and some specialist inshore fish. However, it will do nothing to increase migratory and pelagic fish or invertebrates.

What it can not do

The species composition of a replacement habitat will not be the same as the composition of the animals killed by the power plant. The salt marsh cannot increase the abundance of pelagic fish such as herrings, nor will it help many of the planktonic organisms such as phytoplankton or medusae, or any animal that is only migrating through when it is impinged or entrained.

Drawbacks of habitat replacement

To create a new environment an existing one must be destroyed, or at the very least, altered considerably. If a mud flat is converted to an eelgrass bed the community associated with the mud flat is changed, or lost altogether. Hence, any gain must be measured against the loss of the original environment.

Habitats which are considered of low quality often have their own communities associated with them. Mud bottoms are not as obviously diverse as eelgrass beds or saltmarshes. They do, however, contain important and diverse communities.

Typical examples of abundant organisms on a mud bank include:

- on the surface, diatoms that are preyed on by small surface living snails - Hydrobia (mud snails).

- A large range of small crustaceans called Amphipods; a very common genus is Corophium.

- A wide variety of polychaete and oligochaete worms live in the mud.

Other abundant animals include many burrowing mollusks, particularly bivalves such as cockles and clams, and a range of small crabs. At high water fish will move over the mud to feed - particularly gobies and small flatfish. If the mud is uncovered at low tide, the mud flats are important feeding grounds for waders and ducks. These feed mainly on crustaceans, worms and molluscs.

The abundance of invertebrates on mud flats is often exceptionally high, which is why they are such important feeding grounds for birds. In the above list we have not included the very high number of microscopic forms, including vast numbers of bacteria, nematodes, protozoans and microcrustaceans such as ostracods.

In order for habitat modification to be effective it must be stable. If an eelgrass bed is created there can be no guarantee that it will still remain throughout the 20 to 40-year operating life of the power plant, without a very considerable commitment to protecting and maintaining it. Eelgrass beds can be disturbed by many factors, including hurricanes, pollution, salinity changes, erosion and competition (Thorhaug 1986). The power plant operators are unlikely to be able to guarantee that the bed will maintain its original size, or that a salt marsh will not be altered by sedimentation over the life of the station.

In short, intending to produce a habitat and successfully sustaining it in the long term are two different things. In a review of eelgrass beds (Thorhaug 1986) found that out of 165 attempts to transplant eelgrass, only 75 were successful.

Most species are dependent upon more than one type of habitat in their lives, and have their population size constrained by a variety of different factors. The use of habitat replacement as mitigation for I&E losses will only be effective for species whose primary limiting factors can be affected by the new habitat. One may envisage a power plant impinging considerable numbers of a fish species, with enhancement of neighbouring salt marshes proposed as a mitigating measure. If the size of that species' population is primarily dependent on conditions in the spawning grounds upriver or out at sea, or fishing and predation pressures during its migration, then enhancing the areas used by the fish during this different part of their life cycle can never be an effective mitigation for I&E.

Finally, significant habitat alterations can lead to unexpected results elsewhere. It is difficult, for instance, to model exactly what effect the construction of a large area of salt marsh may have on the deposition or erosion regime of the coast several miles away. This in turn may affect (negatively or positively) the productivity of species throughout the area. These changes, as well as the potential benefits in the immediate area of the habitat alterations, should be factored in when calculating the overall value of mitigation. However, given the unpredictability of such changes, it is likely that the full effects can only be calculated in hindsight.

Summary

In practice habitat replacement cannot replace I&E losses like for like, although it can help with a subset of the lost species favouring the habitat modification. However, habitat must be lost in order to create a new habitat type and unless the area to be reclaimed is abiotic then a judgment must be made whether the new habitat is preferable, in terms of population sizes and diversity, to the existing one.

Removal of fish migration barriers

Many fish face significant obstacles and hazards moving up- or downstream in rivers. Weirs, dams, hydroelectric plants and water works, reduced flows, underwater noise levels, temperature and oxygenation effects all can reduce the ability of a migratory fish to reach its breeding ground, or of its progeny to make the return journey. Removal or modification of these barriers has been suggested as a suitable mitigation for the organisms killed by I&E.

What it can do

Often simple modification of in-river structures can have a large effect on the ease with which fish can pass them. For example fish ladders can be added to weirs, to allow fish to jump from one pool to the next, or safe passages can be build into dams to allow the downstream migration of fish. However, it is plain that removing these obstacles will only help fish that are directly impacted by them.

What it can not do

Because the migration barrier only affects migratory fish, it is obvious that most of the organisms killed by I&E will not be helped by this type of restoration.

Drawbacks of removal of fish migration barriers

Only a few species can benefit from the removal of a migration barrier. What is more, if the migrating species are being heavily impinged or entrained as they pass the power plant, traveling both up- and downstream, then there will still be a large number killed. If the population increases because of the removal of a barrier to migration then it is possible that even more fish will be killed by impingement or entrainment as they pass the station.

Summary

The removal of barriers to migration can be very beneficial to migratory fish. However, it is not, on its own, a useful mitigation to impingement and entrainment of organisms by a power plant, since it does nothing to protect the wider assemblage of organisms killed by the station.

Water quality improvement

It has been suggested that by funding improvements to water quality, power plant operators can mitigate for the losses due to impingement and entrainment.

What it can do

If the water quality is very low, (and in consequence just a few species are present) then improvements to it can make a profound difference to the whole community, by increasing energy flux throughout the system. If the water quality is already reasonable, and many of the hardier species are present, then the improvement may be of greater significance for species that are sensitive to low water quality.

What it can not do

Again, the increased populations found in the improved water will not necessarily be the same as the organisms killed.

Drawbacks of water quality improvement

Improving water quality does not begin to mitigate for the loss of the organisms killed in I&E unless the water is of very poor quality. If the water quality is improved, and the populations recovers in the area, then it is possible that the plant will start to kill more organisms than before the improvements.

Summary

Again the improvement of water quality is a very important issue. On its own, it does not, however, mitigate against the loss of animals by I&E.

Hatchery programs

The concept of hatchery programs is to breed and release organisms (in practice, fish) to mitigate for the loss of organisms to the power plant.

What they can do

Breeding programs can produce large numbers of fish, which when released can augment, or even replace, wild populations. However, breeding animals is a complicated task, and to produce fish in the numbers required to make a noticeable difference can require considerable resources. This has meant that in practice breeding programs may concentrate on only one or two species.

The species chosen for breeding programs are often trophy fish such as salmon and bass. These species, although impacted by I&E, may not be affected as much as the forage fish. Moreover, augmenting numbers of predatory fish will quite possibly increase the predation pressure on already-depleted forage fish.

What they can not do

Being species-specific, breeding programs cannot mitigate at the community level. It is not feasible to produce anything like enough species to help repair the impingement and entrainment losses caused by the power plant.

Drawbacks of hatchery programs

Releasing hatchery-bred fish into the wild has several problems. Studies have found very high mortality rates amongst the released fish, probably due to the fish not having learned predator avoidance behaviour (e.g. (Brown and Laland 2001) For migratory species there are differences in timing of return and in faithfulness to their natal river.

There has also been concern about the presence of different genetic strains in the released stock where the breeding stock is not from the water body where the young will be released (Einum and Fleming 1997).

Environmental impact of large-scale breeding projects include lowered water quality downstream, escaped fish in areas they do not naturally occur in, and the build-up of disease and parasites present in the breeding stock.

Summary

As mitigation for a single-species impact, hatchery programs can help to mitigate losses. However, estimating numbers needed to balance the loss of natural populations is very difficult, complicated by differences in value, whereby a single wild fish is often 'worth' more than a single hatchery-bred fish.

General problems with restoration measures

The restoration measures outlined above can only partly mitigate for the losses caused by I&E. They produce an increase in a few target species and do nothing to mitigate for the loss of the other species impacted. In addition, they may have other ecological effects which tend not to be fully quantifiable until after the event.

EPA Response

For a discussion of EPA's authority to include restoration measures as a compliance option in the final rule, see EPA's response to comment 316bEFER.056.003 and the preamble to the final rule.

EPA believes that there are uncertainties associated with the design, implementation, performance, and assessment of restoration measures. For a discussion of these uncertainties, see EPA's responses to comments 316bEFR.206.055 and 316bEFR.077.013. The requirements in the final rule are intended to help reduce uncertainties associated with restoration measures and enhance their overall performance. EPA also believes restoration measures may not be feasible for all sites.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

For a discussion of the role of ancillary benefits in the final rule, see EPA's response to comment 316bEFR.032.011. EPA encourages permit applicants and permitting authorities to consider the net environmental benefits of a restoration measure.

All restoration measures used to comply with the performance requirements of the final rule must meet the requirements described in the final rule, including those in sections 125.94 and 125.95.

RFC: Proposed use of restoration measures

The complexity of ecosystem damage

The damage caused by I&E at the community level can be extremely complex, with different species, groups, and trophic levels being affected in widely differing ways. This can, for instance, have the effect of creating an imbalance between predators and prey in the populations in an area. As a simplified and hypothetical example, one may envisage 3 species, A, B and C. Species C forms the major food source for Species B, which is in turn preyed upon by Species A. If large numbers of C are killed by I&E, but few of A are affected, then population numbers of B will almost certainly decline, and in the long term the levels of all 3 species must be altered, with consequent effects on the rest of the ecosystem.

Figure 1 (below) shows a food web from the northwest Atlantic. This is a vastly simplified representation, with many of the boxes on the figure represents several tens, or even hundreds of species. Predicting the effect that adding one of two species by using a hatchery program, or increasing the amount of salt marsh present, will have on the dynamics of such a complicated system, in beyond the capability of ecology today.

Figure1. Species and links of the northwest Atlantic food web, This tangled “bird’s nest” represents interactions at the approximate trophic level of each species, with increasing trophic level towards the top of the web. The left side of the web generally typifies pelagic organisms, and the right to middle represents more benthic/demersally oriented organisms. (from Link, 1999)
[See hardcopy]

Restoration measures are often, in themselves, good environmental practice. Trying to use them as mitigation of I&E is, however, unjustified. The fact that they are all species-selective in their effects means they cannot in mitigate for the total loss of the community to I&E. In addition, the timescales over which restoration methods work are not the same as the continual killing of organisms by a power plant. For example a restored marsh may take several years to reach its full potential in terms of the mitigated species. During all this time the existing power plant will still be killing the organisms by I&E. The success or failure of a restoration method can take many years to see, whereas decreasing or stopping I&E mortality is measurable immediately.

Unintended effects of restoration measures

Some restoration measures can prove to have worse environmental impacts than the problem they were intended to solve. For instance, following the removal of dams or weirs, or changes in their regime of water flows, increased current velocity downstream can scour sand and silt, disrupt spawning areas, remove nutrients, and damage fragile banks and shallows. It can also release contaminants locked in the accumulated silt layer behind the obstruction, or lead to physical choking by silts.

Following severe erosion problems caused by flow fluctuations at the Glen Canyon dam on the Colorado River, efforts were made to restore beaches and other features of the river; firstly by limiting variations in flow, and secondly by more extreme measures:

“[After limiting flow variations] the center found that conditions on the river were deteriorating alarmingly. Whole beaches had disappeared. Four species of native fish had become extinct. An Asian tapeworm appeared; it now infects most native fish that survive. Rainbow trout, now spawning naturally in the wild, increased their numbers sixfold, so that some parts of the river contained 17,000 trout per mile. Steadier flows apparently increased their survival rates but reduced their food resources, so they became smaller and thinner.

In the spring of 1996 … researchers tried out their first big experiment using the Glen Canyon Dam. For one week, they released 45,000 cubic feet of water per second, using special spillways. They figured the high water would lift sand stored on the bottom of the river and deposit it onto beaches.

While the experiment looked like a huge success at first, it quickly went awry. A year later, most of the sand was gone. “We made a huge mistake,” said Dr. Theodore Melis, a sediment expert at the research center. The sand that built the beaches, it turned out, had come not from the river bottom but from existing beaches and eddies. Then fluctuating flows continued to erode sand as before. Two different experiments in 1997 and 2000 also failed to make beaches or retain sand.

Meanwhile, the rainbow trout continue to proliferate, said Dr. Lew Coggins, a fisheries biologist at the center. As many as a million rainbow trout are now in the river, eating midges, plants and possibly a native fish called the humpback chub. Ten years ago, some 8,300 adult chub lived in the river; today there are only 2,100 large enough to spawn. Biologists worry that this may not be enough to sustain the population”. - (Blakeslee, 2002)

Restoration measures: not a viable answer to I&E

Fundamentally, it is arguable whether designing and building a habitat to promote the few key species identified as being under threat is a suitable replacement for an entire mature ecosystem. It is also questionable whether replacement wetland and estuarine habitats can effectively mitigate for the extremely high numbers of fish and larvae impinged and entrained by CWIS. For example, PSEG planned and created considerable areas of wetland and estuary to offset I&E losses at their Salem plant on Delaware Bay. Their initial estimate that over 5000 hectares would be required to offset losses gives a reasonable indication of the scale of mitigation required. The assumption that the productivity of a relatively small area of habitat can truly replace potential losses of several billion eggs, larvae and adult fish every year must be questioned.

In addition, estuarine improvement may provide extra habitat for estuarine and brackish water spawning species, but it cannot mitigate for losses of deepwater spawners whose juveniles subsequently move into estuaries and are entrained (e.g. atlantic croaker, spot and menhaden), or those species which spawn upstream in freshwater (for instance salmonids and shad) and are entrained or impinged on their journey downstream. Further, it provides no recompense for losses of threatened and endangered species such as the shortnose sturgeon and various turtles.

Whether restoration measures should be offered as a viable alternative to effective measures against

I&E is open to question. The mitigation is never replacing like for like, the outcomes are uncertain and can take many years to see any benefit to the populations being mitigated for. This should be compared to a reduction in I&E, where the benefit is given far more equitably to all species concerned, is guaranteed and is immediate.

EPA Response

EPA believes that there are a number of uncertainties associated with the assessment, design, implementation, and performance of restoration measures. For a discussion of the uncertainties associated with restoration measures, see EPA's responses to comments 316bEFR.206.055 and 316bEFR.077.013.

For a discussion of EPA's authority to include restoration measures in the final rule, see EPA's response to comment 315bEFR.056.003 and the preamble to the final rule.

For a discussion of the use of out-of-kind restoration in the context of the final rule, see EPA's response to comment 316bEFR.206.055.

EPA believes permit applicants and permitting authorities should take the net environmental impacts into account when assessing an environmental measure. All restoration measures must meet the requirements of the final rule.

The Benefits of Cooling Water Intake Technologies

EPA is attempting to quantify in dollars (monetize) all of the environmental benefits of its regulation, i.e., the benefits of requiring all 550 existing US power plants with cooling intake flows above 50 MGD to install technologies in compliance with the regulation's standards. In this section we discuss some of the many problems in EPA's benefits methodology, including (1) weaknesses in EPA's impingement and entrainment and flow data, as well as in the life stage conversion factors EPA uses to extrapolate and standardize regional and ultimately national loss totals; (2) weakness in EPA's models for calculating the worth of commercial and forage species entrained and impinged; (3) the extent of threatened and endangered species affected by intakes; and (4) a discussion of some of the ecological benefits of intake technologies that are difficult or impossible to monetize.

EPA Response

This comment is simply an introduction to other comments, to which EPA responds elsewhere, and therefore provides no specific comment requiring a response from EPA.

Impingement And Entrainment Data, Flow Data, And Life Stage Conversions

EPA Entrainment Estimates

Description of method used for Total Number

To calculate the entrainment levels at the various stations, the EPA take the data from each station in turn. The data often have been collected for each life stage entrained (egg, larvae, post-larvae, juvenile etc.). The total numbers of all the life stages are combined to give a total number entrained by that intake for a particular year. Several years are then combined to give a mean level of entrainment. On a site-by-site basis, adjustments are made to the years used to obtain the mean. For example, 1996 data are not used at Salem as the power station was not running for much of that year. For some stations the reported number of entrained animals has been adjusted to allow for survival. The EPA re-adjust the figures to assume 100% mortality. These calculations of the raw numbers of entrained animals are well done.

The method for age 1 equivalence

To obtain a total number of age-1-equivalent fish for each site, the age-1-equivalents are calculated for each year and each life stage in turn. A mean value is then obtained. For entrained animals normally only a few days or weeks old this could be done by simply multiplying the life stage by the probability of survival to age 1. However, as the exact age of animals when they are entrained is not known, a modified survival rate is applied to the first age transition. For example if an egg is caught just before it would hatch the survivorship probability of that egg to a larva is obviously much higher than a newly laid egg. This has the effect of increasing the age 1 equivalent number of fish. Again site-by-site adjustments are made to years used. These calculations of the age 1 equivalents of entrained animals are well done.

Issues Identified with Entrainment Methods

Are the years left out reasonable?

For Salem the EPA omit 1996. The station was shut down for most of this year, and hence the numbers of impinged and entrained fish were very low. Removing 1996 increases the mean catch of the station. It is reasonable to leave the year out of the analysis.

At Brayton the EPA disregarded the last decade's fish numbers, as the populations were severely depressed. However there is a steady decline in numbers impinged throughout the study. The mean numbers for this station will therefore be underestimates.

For all other stations the EPA have used the available data reasonably. They have been fair in their selection of years to use in the case studies.

When the data is given with the assumed survived animals not counted - is the calculation of total mortality reasonable?

Where the survival factors for species entrained are not given in a report, an estimate of the effect is based on a probit method. This is used to back-calculate the effect of the survivorship factors applied to the data. The method does result in higher entrainment figures and is probably the best available.

EPA Response

The commenter approves of several aspects of EPA's assessment, with the exception of the years of I&E data evaluated for the Brayton Point Station. EPA selected these years because (1) the data included more species than recent I&E records, and (2) the data represent I&E rates prior to the significant decline in winter flounder that has occurred in recent years.

EPA methods: age 1 equiv, yield, prod foregone

EPA Impingement Estimates

Description of method used for total number

Data are taken from each station and the total number of animals killed in each of the life stages summed for each year.

Description of method used for age 1 equivalents

For life stages below age 1, the numbers of animals impinged are multiplied by the survival probability through each of the life stages that the animal has to pass to get to age 1. Animals impinged at age 1 or higher were assumed to be age 1.

“EPA used life stage-specific annual losses for assessment of entrainment losses and assumed that all fish killed by impingement were age 1 at the time of death.” (A5-2-1)

“The Equivalent Adult Model (EAM) is a method for expressing I&E losses as an equivalent number of individuals at some other life stage, referred to as the age of equivalency (Horst 1975a; C.P. Goodyear, 1978; Dixon, 1999), The age of equivalency can be any life stage of interest. The method provides a convenient means of converting losses of fish eggs and larvae into units of individual fish and provides a standard metric for comparing losses among species, years, and facilities. For the § 316(b) case studies, EPA expressed I&E losses as an equivalent number of age-1 individuals. This is the number of impinged and entrained individuals that would otherwise have survived to be age 1 plus the number of impinged individuals (which are assumed to be impinged at age 1).” (A5-3.1)

Having made this sweeping generalisation a rather curious adjustment is introduced to allow for the fact that fish may be caught over an entire year and thus are assumed to range from just age 1 to just below age 2. This adjustment has the effect of increasing the number of age-1-equivalents above the actual number impinged.

EPA Response

The majority of the comment is a restatement of EPA methods, which does not require a response. The commenter questions the method of using modified survival rates for application to the life stage in which I&E occurs. The commenter seems to have misinterpreted the motivation for the adjustment and the effect of the adjustment, and the definition of an age 1 equivalent. EPA believes the adjustment is warranted because it accounts for the fact that information about the precise age at impingement is not available. It is reasonable to expect that the estimated number of age 1 equivalents is larger than the number impinged because the definition of age 1 equivalents is the equivalent number of fish on the day they enter their second year. Impinged fish that are labeled "age 1" are actually between 1 and 2 years old, therefore one such fish represents more than one age 1 equivalent because it is older than a fish that is just entering the second year.

Overview of I & E effects on organisms

The effect of ignoring annual variation in flow.

The importance of flow

One of the key aspects that must be considered is the relationship between the number of organisms killed by impingement and entrainment and the location and size of the intake. It is apparent that within a single water body, the larger the volume pumped the larger the number of passively transported planktonic organisms that will be entrained. However, water bodies differ in their ecology and animal abundance and species differ in their preferred position within a water body, so it can be argued that the locality and position of the intake can have a large effect on the number of fish and other creatures captured. Living animals, particularly the larger fish and crustaceans that are powerful swimmers, do not behave like passive objects and thus their catch rate can vary in a non-proportional manner with the volume of water pumped. As will be shown below there is a clear tendency for catch rates to increase as a power function of the volume of water extracted, but there are some species that behave very differently. Wyman (1984) in a study of impingement at Lake Ontario power plants operating with different numbers of cooling water pumps found that species responded differently. Alosa pseudoharengus and Osmerus mordax were apparently attracted to the water currents entering the intake and were caught in greater numbers per unit volume as the volume pumped increased. This response has often been observed but is usually explained by increased intake velocities leading to more fish entering a zone where water speed exceeds their sustainable swimming speed. Morone americana, Morone chysops, Dorosoma cepedianium and Perca flavescens were caught at a constant rate per unit volume irrespective of flow and Micropterus dolomieui were caught in lower numbers per unit volume as flow increased. It was concluded that this latter species avoided faster flowing waters and was thus proportionately more vulnerable to intakes with a reduced pumping rate.

One of the most comprehensive studies of the relationship between the volume of water pumped and the number of freshwater fish impinged and entrained in power station cooling water systems was that undertaken by Kelso(1979) for direct-cooled power plants on the Great Lakes. They analysed entrainment and impingement rates separately. Using data collected from 37 power plants, the number of fish impingement per annum (I) was related to power plant generating output capacity in Megawatts (Mwe) by the regression equation:

$\log10(I) = 0.414 + 1.844 \log10(Mwe)$.

The number of fish entrained per annum (E) was similarly related by the equation:

$\log10(E) = 2.103 + 1.658 \log10(Mwe)$.

From this analysis they concluded that for entrainment: “The ‘harvest’ is apparently influenced more by plant size than location within the great lakes” and impingement: “ in general there is a significant influence exerted by power plant size”.

The output capacity and the rate of water extraction by direct cooled power stations is positively correlated, irrespective of plant design and Kelso(1979) gave the relationship between cooling water extraction rate (C) in m3s-1 and capacity in Megawatts (Mwe) as:

$C = -1.288 + 0.049$ Mwe.

This empirically derived equation obviously cannot be used to extrapolate water usage for plants much smaller than those included in the dataset, as it would predict negative water use. However, it is sufficiently reliable to be used to predict fish impingement and entrainment mortality at the working power stations that were studied.

Combining the above equations and converting water flow to gallons per second (G) the following equations relate impingement and entrainment rates to flow:

$\log10(I) = 0.414 + 1.844 \log10(G+340.25)/12.944)$

$\log10(E) = 2.103 + 1.658 \log10(G+340.25)/12.944)$.

Antilogging and simplifying the above equations gives the power curves:

$I = 0.023(G+340.25)1.844$ and

$E = 1.816(G+340.25)1.658$ respectively.

A clear example of the importance of the volume of water extracted on the number of fish impinged is given by Benda (1975) in a study of impingement at the Palisades Nuclear Power Plant, Lake Michigan, while operating with once-through and evaporative cooling tower closed cooling. The volume of water extracted in each mode was 8101 and 1226 gallons s-1 respectively. Annual estimates of fish impingement were approximately 452,577 and 7,488 for once through and closed cycle respectively. However, the number of crayfish, Orconectes propinquis, actually increased (see above Benda, John et al. 1975).

Flow calculations for Salem

At Salem, the EPA give the number of fish caught at the station each year for the conditions at the plant that year. They then average this amount to give an estimate of the number that will be caught in the future. They do not seem to take into account flow issues at all.

In table B3-15 the EPA give the operational flow as 1722 MGD. This is much lower than the use when it is running at normal output (see figures B2.1 and 2). The EPA state in B3-5 paragraph 5 that the catch was much larger in 1998 as the flow was higher, and that the flow was expected to be at this higher level from then on. The costs for this plant should be based on this higher figure. This would produce an increase in the value of the catch at the station (see section 3.4).

In this example we will examine the effect that not using the different annual flow of a station has on the predicted number of fish caught in the future. As an example the data from Salem is re-analysed to calculate the number of fish caught per MGD of water. This analysis predicts that the power station would kill on average 160% more age 1 equivalent fish by both impingement and entrainment that the EPA's estimate. The power station has pumped differing amounts of water each year. The catch in age 1 equivalents is divided by the annual flow in each year to give the number of fish caught per MGD (Table 4). This is then used to predict how many age 1 equivalents the power station would kill per year if it were to run at 2612 MGD, since the EPA state in B3-5 paragraph 5 that the catch was much larger in 1998 as the flow was higher, and that the flow was expected to be at this higher level from then on.

The flow to predict the catch of the station was 2612 MGD. The predicted number of fish entrained as age 1 equivalents at Salem increased from 336,020,975 to
553,211,986 and the number impinged from 4,801,447 to 7,894,006.

Table 4. Total Salem catches of all species, excluding the Non RIS species. Adjusted to 2612 MGD.
[See hardcopy]

EPA Response

Please see response to Comment 316bEFR.041.037 regarding the assumption used in EPA's benefits analysis that I&E are proportional to flow.

EPA methods: age 1 equiv, yield, prod foregone

Is Age 1 equivalent a fair method?

Assessing the value of fish of differing life stages and ages is difficult. How do you compare the value of an egg of a striped bass with an eight year-old fish? To overcome this problem the EPA have used the adult equivalent method. They have projected the number of eggs, larvae and juvenile eggs to the equivalent number of age 1 fish. They do not take into account that older fish impinged are worth more than age 1 fish.

Age 1 equivalent methods only work given good information to base the model on. This includes:

- Good estimates of entrainment and impingement numbers

- Data split into the correct life stages

- Accurate survivorship factors from stage to stage

Impingement and entrainment data quality

For the entrainment and impingement data, the data has been extensively corrected to account for problems found in the sampling methods, day/night and seasonality. The corrections have all been applied to the data to improve its quality, before the age 1 equivalent method is undertaken. There are still many issues with the quality of the data used (see later sections of this document)

Data split into correct life stages

Entrainment data is split into age classes at nearly all stations. There are problems with the identification of some species at the egg and larval stages. The impingement data are sometimes collected with all the age classes separated but the data are combined and treated as age 1 fish. This can have great effects on the estimates of the value of the fish impinged. (See section 3.5.1)

Accurate survivorship factors

Many of the survivorship factors used in the calculation of age 1 fish are based on back calculations assuming a stable population. This is a dubious assumption as there have been major environmental changes in the last 30 years. If, for example, the entrainment data is from the 1970s, before the Clean Water Act significantly improved water quality, the populations of fish could have been suppressed by the poor water quality. This would lead to a significant underestimation of the survival factors. The effect of errors in the estimate of these factors is discussed in section 3.6.

Underestimation of the effects of impingement caused by the assumption that all impinged fish are age 1.

All the calculations are made using as a measure of the total number of fish killed: the age one equivalent value. This is the case for both entrainment and impingement. The situation with respect to entrainment is easy to understand. If a plant sucks through the cooling water system say 10,000,000 larval animals then we cannot value these animals until they reach an age (size) at which they have passed through the period of high juvenile mortality and are at a size that fishermen can catch. The number of larvae is therefore adjusted by the mortality rate up to age 1. The survival rate could be 0.000001, in which case our 10,000,000 fish become 10 age one equivalent individuals. This is a useful way of dealing with the problem, as a larval fish has no market value whereas a one year old or older fish does, so by making the equivalency calculation we are allowing for mortality and getting to an age (size) where it is possible to give a value. Perhaps more importantly, it provides an estimate of the number of individuals that would be lost to the reproducing population, so it is a fair way to proceed.

As the EPA are using age one equivalent calculations for young fish, they should also use them for fish older than age one to take into account impingement losses. They do not, as is made clear in the documentation:

From A5-2-1

“EPA used life stage-specific annual losses for assessment of entrainment losses and assumed that all fish killed by impingement were age 1 at the time of death.”

From A5-3.1 Modeling Age-1 Equivalents

“The Equivalent Adult Model (EAM) is a method for expressing I&E losses as an equivalent number of individuals at some other life stage, referred to as the age of equivalency (Horst 1975a; C.P. Goodyear, 1978; Dixon, 1999), The age of equivalency can be any life stage of interest. The method provides a convenient means of converting losses of fish eggs and larvae into units of individual fish and provides a standard metric for comparing losses among species, years, and facilities. For the § 316(b) case studies, EPA expressed I&E losses as an equivalent number of age-1 individuals. This is the number of impinged and entrained individuals that would otherwise have survived to be age 1 plus the number of impinged individuals (which are assumed to be impinged at age 1).”

It has been demonstrated in numerous impingement studies that for many species of fish there are large numbers of individuals above age one that are impinged. Just as the larval number was adjusted downwards to make an age one equivalent the older fish need to be adjusted upwards to give an age one equivalent. The size of the error that is introduced by the assumption that all fish impinged are age 1 is illustrated below using data from Salem.

The EPA estimate the number of age 1 equivalent white perch impinged at Salem as 540,109; re-calculation indicates that the correct value is 37,880,764 fish. White perch shows a particularly clear example of an underestimate that occurs for all species that live for more that 1 year. This underestimate applies to many of the species caught at power stations. In the following calculations the figures for age 1 equivalent do not match the EPA figures exactly, as the monthly data used to adjust the totals by screen mortalities were not available. However, this is a small proportional difference and does not affect the outcome of the calculations.

The values of the survivorship for each life stage are given in Table 5. The final column shows the number of age 1 equivalents that a fish at a particular life stage represents. For example, it requires 13,500 white perch to enter the age 1 life stage for 1 eight year old fish to be produced.

Table 5. The survival factors (SJ) used to calculate the age 1 equivalents of white perch at Salem. SJ* takes into account the uncertainty of the age at which a individual is caught.
[See hardcopy]

Table 6 shows the unadjusted figures for white perch impinged at Salem as raw numbers and as age 1 equivalents using the assumption that all impinged adult fish are at age 1 (EPA method). The raw number is adjusted to take into account the unknown age at impingement.

Table 6. The raw numbers of white perch impinged at Salem and the age 1 equivalents.
[See hardcopy]

The white perch spends much of its life in inshore waters where it is vulnerable to impingement. In Table 11 the numbers caught in each year class are given. It is evident that there are large numbers of older fish killed by Salem. As a fish above age 1 is equivalent to many age 1 fish, this age distribution can have a significant effect on the total number of age 1 equivalent fish caught at a power station. Table 12 shows the number of age 1 equivalents that the impinged fish of each age represent.

Ignoring the age structure of the white perch impinged results in an underestimation of the number of age 1 equivalents killed by Salem power station by two orders of magnitude. This effect will be found for all species of fish that are impinged at ages above 1. The relative effect will differ depending on the number of year classes vulnerable to impingement and the relative proportions of the age classes caught.

Comments on the changes from phase II. The EPA has now revised its methodology and will be using a realistic age structure to calculate the age 1 equivalent for impinged fish. They are using a correction factor of between 3 and 10 times depending on the type of fish caught. The upper value of 10 may well be too low for some long-lived coastal species. However this modification will result in a more reasonable estimate of the importance of the impinged fish.

Age 1 Equivalent calculation for commonly impinged fish at Salem.

Table 7 shows the number of each age group of the commonly impinged fish caught at Salem. Table 8 expresses these number as a proportion of the total adult catch. It can be seen that for many species, the assumption that most individual caught are age 1 is false. For example, over 90% of the catch bay anchovy is age 2 or over, 30% of blue crab, 80% of non-RIS forage species, 25% of striped bass and 42% of white perch.

Table 7. Numbers of fish caught at each age at Salem.
[See hardcopy]

Table 8. Proportion of the fish caught at each age at Salem.
[See hardcopy]

Table 9. Age 1 equivalent values of species of fish impinged at Salem (total number over all years). These are adjusted for the age at capture.
[See hardcopy]

Table 10. Number of Age 1 equivalents total and mean caught in at Salem. Number of age 1 equivalents calculated totals from report and change expressed as a percentage.
[See hardcopy]

The number of age one equivalents of each of the age groups is given in Table 9. The total number of animals caught at Salem is used. No adjustments are made to account for the problem of 1996 flow rates. This has the effect of slightly lowering the mean number of age 1 equivalent fish killed by the power station. The survivorships used are based on figures given in the Salem input spreadsheet.

Table 10 shows the total and mean number per year of fish killed (age 1 equivalents) when the age of the fish is taken into account. The table also shows the values given in the case study (in table B3.3) for each of the species and the new higher value expressed as a percentage. The increases can be considerable. There are several ways that catching older fish can cause very high age 1 equivalent values.

- For long-lived species which spend a lot of their life in estuaries, such as the white perch, the increase is very significant as some relatively old fish can be caught.

- Some species are caught mainly as older fish, for example the bay anchovy and the non-RIS species. This can result in a much larger number of fish caught in terms age 1 equivalents than a simple total would suggest.

- Species that are impinged at age 2 or more which have a very low survivorship from year to year also give high age 1 equivalents; an example of this is the blue crab. Only about 10% of crabs make it through the first year and only 20% through the second. A two-year-old crab equates to many individuals at the beginning of their first year of life.

For the species that are only caught at age 1 or have very few age 2 or more individuals caught, this method of calculation makes very little difference to the overall total.

Morro Bay on the Californian coast: another example of a locality where age structure is important.

Here we present some examples of species that are caught at greater than age 1 from Morro Bay. Assuming that these are all age 1 would significantly underestimate the number of age 1 equivalent fish caught.

- Topsmelt, Atherinops affinis: the size frequency distribution suggests that almost all the fish impinged were 2 or 3 years old.

- Northern Anchovy, Engraulis mordax: about 50% of the catch were greater than 90 mm SL and presumably older than age 1.

- Plainfin midshipman, Porichthys notatus: the majority of the fish impinged were mature and thus two or more years old. This is to be expected as this species migrates into bays and estuaries to reproduce.

- Pacific sardine, Sardinops sagax: all the impinged fish were larger than the minimum size at maturity and were likely to be 2 or more years old.

EPA Response

The commenter enumerates many principles that guide model development and corresponding possible sources of uncertainty in EPA's analysis. EPA agrees that there can be significant regional and species variation in the age composition of impinged fishes. However, EPA's methods were selected to be widely applicable for the purposes of its national benefits analysis. EPA acknowledges that its analysis will not capture the exact conditions present at each CWIS, but this was not the goal of the analysis. Nonetheless, EPA has revised its assumptions about age distributions of impinged fish in a manner that acknowledges that YOY may be abundant among impinged fishes, as described in the EPA response to Comment 316bEFR.029.105.

Assumptions about I&E survival

The effect of changing the estimates of survivorship through life stages on the age 1 equivalent calculations.

In this example we will examine the effect of differing values for survivorship on the age 1 equivalent calculations. Data will be presented showing that the survivorship values used by the EPA are not the same as some published data. The two examples chosen show variations of up to 50%. Varying the survivorship values used in the age 1 equivalent model produces estimates of age 1 equivalents of up to 116 % higher. First, we examine the survivorship values used by the EPA. Here we will look at two species where we have found published data for survivorship of species entrained at case study power stations.

To match published data some life stages have to be combined. Table 13 shows the values obtained for the striped bass at Salem and by NOAA. The values at Salem are consistently lower that those found in the NOAA estimate. They are on average 48% of the value of NOAA estimates.

Table 13. The proportion of striped bass that survive from one life stage to the next. Data from Salem and the NOAA technical report NMFS circular 443, Synopsis of Biological data on striped bass, Morone saxatilis (Walbaum). E M Setzler et al.
[See hardcopy]

In Table 14 the survivorship estimates of Cunner (Tautogolabrus adspersus) calculated by the EPA and those quoted in Horst are presented. It can be seen that the Seabrook values are on average 72 % of the values quoted by Horst.

Table 14. The proportion of Cunner (Tautogolabrus adspersus) surviving from one age to the next. Data used by the EPA at Seabrook and estimations of the factors from Horst et al.-Effects of Power Station Mortality on Fish Population Stability in relationship to Life History Strategy.
[See hardcopy]

As can be seen from the two examples above, differences of 50% in survivorship estimates are possible. By re-running the entrainment to age 1 equivalent model and adjusting the survivorship values we could examine the effect on the number of age 1 equivalent fish estimated. We adjusted the survivorship by 25, 50,75 and 100%. This was done across all the survival factors.

Table 15. The effect of changing the estimates of survival on the number of entrained fish in various species found at Salem.
[See hardcopy]

Table 15 shows that a 50% increase in the estimates of survival can result in a 116% increase in the estimate of the age 1 equivalent number entrained.

The survivorship figures used in the EPA case studies are largely based on the assumption that the populations are in equilibrium. Because of this assumption, the data used to calculate these figures already have the effect of the power stations built into them. As conditional mortality rates from entrainment are often in the 10 - 25% range and the survivorship values can vary by significant amounts it would seem reasonable to err on the side of caution and increase all the estimates by 25%.

EPA Response

EPA agrees that age 1 equivalent estimates are sensitive to the survival rates assumed for the analysis. Please see Chapter A6 of the Regional Analysis Document (DCN # 6-0003) for further discussion of this topic. For information about EPA's assumptions regarding entrainment survival, please see Chapter A7.

Source data used by EPA

Dataset Weakness

Old data

How intensively were the stations studied?

Salem is a well-studied station, with 21 years of data available, although there have been some changes in the way the samples have been taken over that period. Pilgrim and Brayton are also well-studied with data from 1974. For Brayton, data are only used from 1974 to 1983 as the populations of fish declined after that time. They do not provide the data to show this effect. Seabrook has 8 years of data. The other sites are restricted to 1 or 2 years of data, often from the 1970s.

Impacts of CWIS on impaired waterbodies

Trends

Many fish communities have shown larges changes in recent years. In some habitats species are recovering after anthropomorphic impacts, others are still in serious decline. Here we present some data for the Hudson, New York, and Morro Bay, California, to demonstrate that significant changes have occurred over this period.

Hudson River, New York

Taking the Hudson River striped bass and Atlantic tomcod as examples (Henderson and Seaby 2000), it can be seen that data from the 1970s would give very misleading results if applied to the area today.

Figure 4 shows the number of various life stages of striped bass in the Hudson between 1975 and 2000. It can be seen that there has been a 15-fold increase in
numbers over this time. This is related to the reduction in fishing pressure and the cleaning of the estuary.

Figure 4. The abundance indices for the adult stock (CFM) and the larval (YSL) and post larval (PYSL) stages of striped bass. Note that all these indices show a similar trend and sequence of high and low abundance years.
[See hardcopy]

The Atlantic tomcod has been in steady decline over the last 25 years in the Hudson (Figure 5). Again using data from the mid 1970s would lead to a serious misinterpretation of the impact of a station in the Hudson on the tomcod population.

Figure 5. The change in estimated abundance of Atlantic tomcod at age 1. A linear regression has been fitted to the data to show the trend of declining number.
[See hardcopy]

Morro Bay, California.

A comparison of impingement levels observed during the periods 1977-79 and 1999-2000 at Morro Bay, California, illustrates the large changes in fish abundance and thus rate of impingement that have occurred in American waters.

In this example there has been a loss of fish such as shiner perch, Cymatogaster aggregata, and bocaccio, Sebastes paucispinis, which were much more abundant in the earlier study. For shiner perch the following account was given by Duke Energy (APPLICANT'S TESTIMONY ON GROUP IV ISSUES, Energy Resources Conservation and Development Commission Docket No. 00-AFC-12)

“During the 12-month sampling period of 1978, over 5,400 shiner perch were collected (Behrens and Sommerville 1982), while during this study (1999-2000) only 45 were collected. Over 75 percent of the shiner perch impinged during the previous study were newborns (Behrens and Sommerville 1982). Annual indices for young-of-the-year (YOY) shiner perch from the San Francisco Bay monitoring program show a decline from the early 1980s through the last data point in 1993 (CDFG http://www.delta.dfg.ca.gov/baydelta/monitoring/shper.html). This decline is attributed to loss of saltwater marsh areas that are recognized as important nursery areas for this species. Female shiner perch will enter coastal bays prior to giving birth to utilize saltwater marsh and eelgrass beds as nursery areas (Bane and Robinson 1970). The reduction in the area coverage of eelgrass beds in Morro Bay, especially in areas of the Bay that are closer to the intake structures (Tetra Tech 1999) may partially account for the reduced numbers of shiner perch in impingement collections.”

In the case of bocaccio the population along the Californian coast has declined significantly over the past decade, and management measures are in effect to regulate the take of this species. The reduction in impingement may therefore reflect a general decline in the abundance of the species.

Increased species richness and fish and crustacean abundance following plant closure – studies in the Bristol Channel, England

Regular long-term monitoring of fish and crustaceans impinged and entrained at Hinkley Point 'B' Power Station in the Bristol Channel, England has been undertaken for more than 21 years. Henderson & Seaby (2002) conclude “Fish abundance in the estuary is probably 3 times higher than that recorded in the early 1980s and there is also a clear trend for increased species richness” (Figure 6). They consider the reasons for this extraordinarily large increase and suggest that the reduction in power plant entrainment and impingement following the closure of a number of direct-cooled power plants from the late 1980s may be a contributory factor. The passages below are taken directly from their recent report, available from: http://www.irchouse.demon.co.uk/latestreports.html.

Figure 6. The change in the number of fish species impinged per month between 1981 and 2002. The black trend line was fitted by linear regression.
[See hardcopy]

Amongst a number of climatic and anthropogenic changes that may be contributing to the observed increase in species richness and abundance must be considered the recent closure of a number of direct-cooled power stations. Since sampling commenced in October 1980, Berkeley closed in 1989, Uskmouth in 1995, Pembroke in mid 1997 and Hinkley A in May 2000. All of these stations would have been killing fish and crustaceans that were members of the populations subject to capture at Hinkley B. It is highly unlikely that entrainment and impingement in power station cooling water systems would have changed species richness in the region because the estuary presents an open system that would receive a flow of recruits from other waters. However, if mortality rates are sufficiently high it is possible that direct cooled power stations could reduce abundance by a detectable amount. Table 16 gives estimates of the number of fish > 3 cm in length that are captured per year by power stations in the Bristol Channel. The four power stations that have closed since 1989 were estimated to kill 3.44 x 106 individuals per annum. The number of small individuals that would have passed through the filter screens and been killed following entrainment has not been estimated, but would have been at least an order of magnitude greater. “

“…there are indications that the increase in abundance of some species has occurred since power station closure as would be anticipated if power stations had been having an effect on population size. For example, Palaemon serratus (Figure 7) showed a reasonably stable mean population size until 1998 after which it has been increasing almost exponentially. There are also indications that the Common shrimp, Crangon crangon, may have recently increased in average abundance. Amongst fish, sprat, whiting, flounder and sand goby abundance have all increased since the initiation of power station closures.

Figure 7. The change in abundance of Atlantic prawn impinged at Hinkley Point in the River Severn between 1981 and 2002.
[See hardcopy]

Such coincidences cannot be considered proof of a causal relationship. However the Severn Estuary Data Set should allow a more rigorous statistical analysis to be undertaken within the next 18 months.”

Table 16. Estimated number of fish killed on the filter screens of marine and estuarine power stations situated in the Bristol Channel.
[See hardcopy]

EPA Response

EPA agrees that some fish populations have shown significant trends over time. EPA also notes that fish abundances may have increased, decreased, or stayed the same since the time that I&E data were collected, which was often as many as three decades ago. However, EPA asserts that it is extremely difficult to detect ecological effects at the population level (see the book by Schmitt and Osenberg, "Detecting Ecological Impacts", Docket # DCN 2-019A-R21). For this reason, EPA did not attempt to identify potential trends in fish populations for its benefits analysis.

Data Issues

Exclusion of species

How were species selected for analysis?

The EPA first pick rare and endangered species that have been affected by the station. They then move on to commercial or recreationally caught species. Finally they consider populations thought likely to be affected by the station. It is not obvious how a species is chosen to be ignored. From the numbers given EPA do, however, analyse all of the significant species present.

The Salem study is the only study where non-RIS species account for a high proportion of the total catch. Non-RIS species were between 30 and 60% of the total impingement and 10 to 40 % entrainment.

At Big Bend unidentified fish make up about a fifth of the total fish count while at San Francisco, Contra Costa and Pittsburg, about 15% of the entrained species are unidentified and about 2% of the impinged species.

Pilgrim gives full numbers of all species caught from 1990 onwards, while before that, from 1974, the non-RIS species are reported as one number. Brayton reports only 19 species caught, though there are unidentified species mentioned.

J.R. Whiting gives all the information for all species caught. Relatively few species are caught at this station. At Monroe unidentified species account for less than 1% of total numbers caught. In the Ohio study approximately 80 species are caught, but full data is given for a reduced set of species.

Did this affect the outcome?

Species that are not rare and have no commercial or recreational value are classed as forage fish. All forage fish appear to be treated the same in terms of value. They only come into play in the calculation of production foregone. Addressing each species individually is unlikely to make much difference at most stations. The exception is where the fish are rare or have a very local population. If the forage fish caught at stations can be shown to have a higher value then it might be worth treating them individually.

Comments on the changes from phase II. These species will need to be separated to allow age 1 equivalents to be calculated for impingement.

EPA Response

Extrapolation Methods

Extrapolation from the case studies to other stations

Here we are looking at whether it is reasonable to extrapolate the data from one or two case study power stations to many stations. In this example we examine the similarity of the types of species impinged and entrained in the Great Lakes and estuaries.

The Great Lakes

Impingement in the Great Lakes.

The two case study stations are dominated by clupeids (over 90%). Table 17 show the different types of fish impinged at two case studies and several other power stations in the Great Lakes (as raw numbers) (data from Sharma, R. K. and Freeman, R. F. 1997, Survey of fish impingement at power plants in the United States. Argonne National Laboratory). The stations are ordered in the table by the abundance of clupeids.

At most stations on the Great Lakes, clupeids are the major species caught (Figure 1), however, at Oak Creek the smelt species make up over 17% of the total catch. Similarly over 18% of impinged fish at JP Pulliam and DE Karn are Perch species. Palisades, a closed-cycle cooling station, mainly catches sculpins whereas at Big Rock and Kewaunee, both once-through systems, smelt species are impinged in large numbers.

Table 17. Proportion of the major species caught at power stations on the Great Lakes. All species with more than 100,000 individuals caught at the case study stations and any species with more that 10% of the other stations are included.
[See hardcopy]

Entrainment in the Great Lakes.

From data given in Kelso and Milburn (1979 no. 453) (Figure 2) it can be seen that entrainment at power plants in each of the Great Lakes is very different. In Ontario, Detroit River and Michigan, clupeids are the dominant group entrained. In Lake Erie it is smelt and in Superior it is the percids. In Huron, smelt and the clupeids are entrained in equal measure.

The two case study stations are on Lake Erie. Kelso and Milburn’s (1979) data would suggest that the species entrained would be predominantly smelts, however the case studies are dominated by clupeids, with more than 85% of the total catch. It can be seen from this that extrapolating from the case studies to other stations on Lake Erie would produce a very different result from that found in Kelso and Milburn (1979). Extrapolation to power plants situated on different lakes is even more liable to error. Extrapolation to all the Great Lakes stations from the case studies is therefore likely to produce an extremely poor match with reality.

Estuaries

The Salem case study is meant to be representative of other estuaries. To examine this we looked at the nearby Hudson estuary and compared the major groups of fish impinged and entrained at each station.

Impingement in Estuaries

Data was obtained for Salem (the case study), Danskammer, Roseton (State Pollution Discharge elimination system permits for Bowline Point Indian Point 2 & 3 Roseton Steam Electric Generating Stations 2000) and Albany (PSEG Power New York Inc's Bethlehem Energy Centre SPDES Modification 2002). The data was classed into five groups - others, bay anchovy, drums, Morone spp and clupeids (Figure 3).

The graph shows that Salem is a poor model station for the Hudson. All the Hudson stations impinge mainly clupeids and Morone spp. whereas Salem impingement is dominated by bay anchovy, drums and the group Others. The Others at Salem include the RIS and non-RIS forage fish plus others that did not fit the above classes.

Entrainment in Estuaries

Data was obtained for Salem (the case study), Bowline, Indian Point, Roseton (State Pollution Discharge elimination system permits for Bowline Point Indian Point 2 & 3 Roseton Steam Electric Generating Stations 2000) and Albany (PSEG Power New York Inc's Bethlehem Energy Centre SPDES Modification 2002). The data from each station was classed into four groups, others, bay anchovy, Morone spp. and clupeids and plotted (Figure 4).

The picture is more complicated for entrainment than it is for impingement. Salem primarily entrains bay anchovy (90%). This is similar to Bowline and Indian Point, but both these stations also entrain significant numbers of clupeids and Morone spp. The species composition of entrained fish at Salem is completely different from Roseton and Albany, which are dominated by clupeids and Morone spp.

The presence of eggs, larvae and young fish is very dependent in estuaries on the exact salinity conditions, flow rates and habitats present.

Implications of extrapolations from case studies to other stations

As can be seen from these examples, extrapolating the catch of fish from one station is prone to many errors. The result of this is that the costs calculated for a case study will not be directly comparable with any other site. For example, using Salem as a model for the catch at Roseton would result in a completely inaccurate estimation of the value of the lost fish. At Salem the majority of all the fish killed are bay anchovy, which has very little commercial value. The majority of the fish entrained and impinged at Roseton are the valuable Morone spp. and clupeid species. Using Salem as the model for the Hudson Estuary would significantly underestimate the values of the fish killed.

EPA Response

The commenter refers to analyses done for proposal. For EPA's final analysis, many additional facilities (a total of 46) were used as the basis for extrapolation, which was conducted on a regional basis. Estimates of I&E for the Great Lakes region were based on extrapolation from three facilities. Estimates of I&E in the mid-Atlantic region were based on six facilities, not just Salem. Please see response to Comment 316bEFR.041.041 concerning EPA's extrapolation approach.

Methods to Evaluate I&E

Calculating The Worth Of Commercial And Forage Species Entrained And Impinged

The worth of an individual lost to a population can be assessed in terms of the immediate loss to the other species, or man, which might have consumed the individual, or in terms of the future loss caused by the loss of reproductive potential.

In the EPA's calculations, the commercial species killed by entrainment and impingement are valued by calculating the age 1 equivalent number killed and multiplying it by the proportion of the population taken by commercial fishing and their market value. This only considers the immediate loss and places a value on only a proportion of the number killed. This is felt to be an extremely significant omission, liable to underestimate the value of fish killed severely.

Comments on the changes from phase II. This has been addressed by the EPA using a correction for the age structure of the impinged fish.

The fish killed also represent a loss in reproductive potential to the population and thus represent a future loss to the ecosystem and fishermen. The average contribution of an individual to future generations changes with age, so that the contribution of an egg is much less than that of a one year old fish. This is because fish at or close to reproductive age are no longer subject to high mortality rates and will soon produce eggs. Fisher defined a quantity, termed the reproductive value, V, to measure the extent by which an individual of age x contributes to the next generation.

To calculate the reproductive value of fish of age a, we need a table of age-specific survival and mortality rates. If we assume that the population size is stable then the reproductive value is given by:

[See hardcopy for equation]

where l(x) is the survival to age x and m(x) is the fecundity at age x.

If the population is growing or declining then the expression is a little more complex as it includes a term to describe the change in population number. In practice, the above description should give us an approximate measure of the worth of an individual in terms of future eggs contributed to the population that is accurate enough for the estimation of the value of the loss to the population. The reproductive value of a newly produced egg is assumed to be 1 and all later ages have a reproductive value expressed as the number of eggs that would be produced on average over the rest of their lives.

Having calculated the reproductive value for age 1 fish we can use the estimated number of age 1 equivalent fish killed by impingement and entrainment to calculate the lost egg production they represent. This total lost production of eggs can then be converted into age 1 equivalent reproductive value by multiplication with the survival rate to age 1. This age 1 equivalent reproductive value gives the true loss over time to the population of the age 1 equivalent animals killed. The economic loss can then be calculated by multiplying the age 1 equivalent loss by the unit monetary value. One important general observation is that reproductive value tends to increase until an age is reached that is close to when all the fish have reproduced once, and then tends to decline for older age groups.

Striped bass at Salem as a worked example

These calculations will be illustrated using the striped bass at Salem as an example. At Salem the average numbers of entrained and impinged fish (excluding 1996) were 419,505 and 7,200 respectively. When reduced by the 18% lost to commercial fishing, the values were 343,994 and 5,904. Thus the total number of individuals as age 1 equivalent that were not valued was 347,898. It is these fish for which we will calculate a reproductive value and thus estimate the value of their loss to the population.

Table 18 shows the age-specific fecundity and survival of striped bass and the calculated reproductive value at age(x). The change in reproductive value with age is plotted in Figure 12, which shows a typical maximum at an intermediate age in the life cycle.

The total lost production (expressed as numbers of eggs) was calculated by multiplying the reproductive value of age 1 fish (6,515 - see Table 18) by the number of age 1 equivalents caught at the station. This product was then adjusted to an age 1 equivalent number using the survival from age 0 to age 1. These calculations are shown in Table 19. This shows that the 347,898 fish not valued as age 1 equivalents have a future age 1 reproductive potential of 596,142 age 1 equivalent fish. Thus the value of the uncounted fish is the economic value of 596,142 age 1 equivalent fish.

In summary, the EPA calculations are based on the value of 18% of about 420,000 age 1 equivalent fish with a value of about $56,000. Using lost reproductive value we have a future loss of 596,142 individuals which has a value of about $79,000 plus the immediate loss of $56,000 giving a total annual loss of about $135,466 per year.

These calculations can be undertaken for all the commercial species plus many others and will allow a full valuation to be made of the loss

Pilgrim - a worked example of a site

To illustrate the method the most frequently-encountered species at Pilgrim were chosen. The reproductive values of the top 7 species impinged and the top 5 species entrained were calculated using the same method as the Salem above example. The results are given in Table 20 & Table 21.

Comments on the changes from phase II. It seems that the EPA is not fully valuing the non-landed proportion of commercial fish species. By converting young fish into older fish then using the older fish totals as the inputs for their harvest and forage models, they are not counting the fish lost at the younger life stages towards the total production. For example forage fish are translated from eggs/larvae into age 1 equivalents. This is then used to calculate the percentage of those age 1s that are converted to harvestable protein because they are consumed by harvested fish. If so the EPA are not counting the many eggs and larvae that did not reach age 1 and were also consumed by harvestable fish.

Table 18. The age-specific fecundity and survival of striped bass and the calculated reproductive value at age (x).
[See hardcopy]

Figure 12. The change in reproductive value with age for striped bass.
[See hardcopy]

Table 19. The age 1 equivalent values for striped Bass (+ 58% Morone spp.) from Salem (Tables B3-3 and B3-8), multiplied by the reproductive value to find the total number of eggs lost in the future, shown as age 1 equivalents. (From egg to age 1 factor=0.0002615).

Impacts to T&E species

Threatened And Endangered Species Affected By Intakes

Cooling water systems impact threatened and engendered species directly by entrainment and impingement and indirectly by habitat degradation. Fish, crustaceans and molluscs are often directly impacted because they have swimming stages that can enter the intakes. However, other animal groups such as turtles and even seals have been entrained and caught on screens or in screen wells. Aquatic birds and mammals tend to be indirectly affected via lost food supplies and habitat degradation.

How widespread are threatened and endangered species problems in water bodies affected by power plants?

It should be assumed that all power plants situated on estuarine and coastal sites will impact to some degree threatened or endangered (T & E) species. Major American river estuaries are all heavily utilised by man and because of overfishing and habitat damage they all hold fish populations that are considered endangered or threatened. In many cases these species are fish that were once quite abundant but have been much reduced by man, such as sturgeon and migratory salmonids. Where entrainment or impingement data for a power plant has been thoroughly collected for a number of years it is usually the case that T & E species have been recorded. Where insufficient data are available to make it likely that a rare fish would have been detected there is often information to suggest that T & E species occur in the area and would be vulnerable to harm by the cooling water system. For example, the San Francisco Bay / Delta estuary study includes the following in the list of species vulnerable to I&E:

- Central Valley ESU steelhead - Oncorhynchus mykiss

- Central Valley fall/late fall-run ESU Chinook salmon – Oncorhynchus tshwytscha

- Central Valley spring-run ESU Chinook salmon – Oncorhynchus tshwytscha

- Delta smelt – Hypomesus transpacificus

- Green sturgeon – Acipenser medirostris

- Longfin smelt – Spirinchus thaleichthys

- Sacramento River winter-run ESU Chinook salmon – Oncorhynchus tshwytscha

- Sacramento splittail – Pogonichthys macrolepidotus

Along the same coast at Morro Bay, the April 2002 staff report for the California Energy Commission notes that the estuary used for cooling water by Morro Bay GS is inhabited or potentially inhabited by the federally endangered tidewater goby (Eucycloglobius newberryi) and the steelhead trout (Oncorhyrnchus mykiss). Note that the tidewater goby is not listed as present in the San Francisco Bay area.

Similarly sized lists of T & E species could be complied for almost all ocean and estuarine sites. For example, in the Hudson Estuary both shortnosed (Acipenser brevirostrum) and Atlantic sturgeon (Acipenser oxyrinchus) have been impinged on cooling water intakes.

At many ocean and lower estuarine sites young turtles are potentially vulnerable to entrainment. For example, in the recent assessment of the impact of the Sunset Energy proposal for a power plant in New York harbour the following turtle species were listed as potentially present:

- Green sea turtle – Chelonia mydas

- Loggerhead sea turtle – Caretta caretta

- Leatherback - Dermochelys coriacea

- Kemp’s ridley turtle – Lepidochelys kempii

- Hawksbill – Eretmochelys imbricata

With the exception of a few leatherbacks, most of the turtles in nearshore waters in the New York coastal region are small juveniles. The loggerhead is the most abundant, followed by the Kemp's Ridley. These two species, along with a few green turtles, move into harbours and estuarine waters, while the leatherback turtles remain along the coast and are rarely seen in embayments. Kemp's Ridley inhabits the shallower areas of Chesapeake Bay in search of blue crab, their preferred prey. Their preference for shallow waters and blue crabs makes the Kemp's Ridley the most likely sea turtle species to venture into the New York & New Jersey Harbor area. Similar lists would be produced for many east coast marine or lower estuarine power plants situated to the south of New York.

A point to note is that if conservation measures for species such as sturgeons and turtles were successful then populations could greatly increase, resulting in extended ranges and the risk of higher impingement in future years.

It is not so easy to make generalisation about freshwater habitats. Plant situated on rivers, particularly smaller rivers, are almost certain to impact T & E species, as are those situated on the great lakes. Kelso and Kilburn (1979), in an examination of impingement and entrainment at Great Lakes power stations, report:

“There were seven species found among impinged fish that were rare or never before detected (Scott and Crossman 1973) in the Great Lakes including pirate perch (Aphredoderus sayanus), redfin pickerel (Esox americanus americanus), golden redhorse (Moxostoma erythrurum), orange spotted sunfish (Lepomis humilis), brindled madtom (Noturus miurus), warmouth bass (Chaenobryttus gulosus) and chestnut lamprey (Ichthyomyzon castaneus)”.

Plant using water from reservoirs or smaller lakes may not directly impact T & E fish, birds or reptiles. This is because these may be in areas of low aquatic biodiversity or even utilise water from man-made water bodies. However, the isolation inherent in freshwater water lakes and some river catchments results in the formation of distinctive biological races of many species of fish. The maintenance of this genetic biodiversity is recognised as important and loss of genetic diversity may be a more important impact on freshwater fish than is generally appreciated.

In addition to direct impacts indirect effects in terms of habitat degradation are likely to be affecting other T & E species. This is particularly the case when power plants are situated on smaller estuaries, inlets or close to less common types of habitat. For example, Morro Bay Power Plant is situated on a small estuary on the Californian coast and the region holds threatened sea otter (Enhydra lutris) and federally endangered California brown pelican (Pelicanus occidentalis). These species rely on the Bay for food that can be reduced by impingement and entrainment. In many localities the abundance of fish feeding birds is probably directly proportional to the level of food resources available for the birds. Thus any damage to the populations of often rather small, non-commercial fish species can have a direct impact on aquatic birds.

Valuing CWIS effects on other species

Ecological benefits of intake technologies that are difficult or impossible to monetize

Only a small fraction of the life forms present in a water body can be given a monetary value. Yet almost all the species present in the water column or living on the river or seabed in the vicinity of an outfall will be impacted by a direct cooled power plant. Most are not fished or sold in any form and are not of immediate value as tourist features as may be the case for an elephant seal colony or turtle breeding beach. In general somewhere in the region of about 20 of the about 2000 species of multi-cellular animals typically entrained by a power plant can be assigned a monetary value.

The question is how should we consider the worth of the other 99%, many of which are small or even microscopic? The interdependence of species and the fact that all species can be viewed as interconnected units within a food web immediately suggests that the economically important species are dependent upon the existence of many other species either directly because they are their food or indirectly because they help to create some aspect of the habitat that is essential for their existence.

Perhaps the most clear cut, but unusual, situation would be where total dependence can be shown between two species such that a dependent species that has an economic value cannot exist without another supporting species. With this type of situation the supporting species can be assigned a value as a resource base for the economically important species. Given sufficient ecological knowledge it would be possible to calculate how many of the economically important species would be lost if the resource base was diminished in size.

Because almost all the commercially important fish and crustaceans are predators that feed on a variety of prey and can often be quite flexible in their feeding behaviour such a simple relationship will not generally be the case. However, as the vast majority of species with no economic value are lower down the trophic chain than those with economic value, they can be viewed collectively as the resource base upon which the economically important species depend.

Such an approach suggests how we might give a value to the majority of species. Suppose that an estuary has 20 species that can be given a commercial value and these 20 have a production of say 50 kg per hectare per year and this is supported by an ecosystem that achieves a maximum annual standing crop of say 50,000 kg per hectare. Then we might roughly state that 1000 kg of standing crop of all species is needed to produce 1 kg of commercially important species.

Then if entrainment reduces the standing crop by say 10% we can conservatively assume that this will result in a proportionate reduction in the commercial species of 10%. It is conservative because in some cases the reduction could be far greater. Some top predators need a critical mass of food or food density to exist. If the available food drops below the critical amount then their population dies out. To give an unrealistic and extreme example which shows how this can be a grey whale eats about 2500 kg of crustaceans per day, in a habitat that can only supply 10,000 kg per day it is not possible to support a grey whale family group so they will move away or die out. The habitat has food just not enough for the minimum population size required.

Once such a rough relationship is established we can then give a monetary value to any loss to the ecosystem. Some measure of the likely loss of standing crop of plankton can be gained from simple modeling. We can model the plankton community using say a logistic equation such that in the absence of the power plant the population would be at carrying capacity. Then given a daily mortality rate determined by the proportion of the total volume of the habitat that is pumped via the plant the fractional reduction below carrying capacity that results can be estimated.

While the approach outlined above might be used to estimate the overall value of the resource in terms of its food value to economically important species this does not represent the full value of species lost by entrainment and impingement. Unquantifiable losses include the following.

- Loss of recycling efficiency and the loss of nutrients and materials to the local ecosystem. Damage to ecosystems typically results in a loss of ecological efficiency and the release of materials that would have been retained within the ecosystem. Thus a river or estuary may export to the ocean more resources than would have been the case if the ecosystem had been undamaged. In freshwater habitats on hard geology the amount of nutrients in the water can be limited and minerals such as calcium in short supply. Such ecosystems are highly conservative of these limiting minerals and very little is washed down the river to leave the immediate habitat. However, if the ecosystem is damaged or reduced then some of the nutrients that are normally retained locally may escape down stream. Such effects have been shown to occur. The loss in recycling efficiency may result in a gradual long-term degradation.

- Power plant mortality will tend to favour short-lived species at the expense of long-lived forms. This tends to produce a bias in favour of more ‘weed-like’ life forms. The naturally occurring species towards the top of the food chain such as striped bass are typically adapted to live in climax ecosystems in which short-lived species are less dominant. Further, the bias produced may result in a loss of biodiversity resulting in a less stable ecosystem

- Damage and alteration to the ecosystem may allow the invasion of unwelcome aliens. In particular, fasting growing invasive species that have adapted to manmade or disturbed habitats may reach pest levels. It is notable that most of the alien species that have become established in the Hudson estuary for example are invasive ‘weeds’ suggesting that human disturbance may be implicated in allowing them to become established. There are examples of exotic species particularly warm water loving forms becoming established in power plant systems and outfalls. Damage to ecosystems may increase the risk of the development of organisms dangerous to human health. Water bodies receiving heated effluent have been closed to water sports because of the risk of pathogens. Red tides may become more frequent and toxic in highly disturbed and unnatural waters. This can increase the costs associated with environmental monitoring and the processing costs of drinking water. Legionella has been found in power station cooling systems. A protozoan pathogenic to humans called Naegleria fowleri has been found in heated industrial effluents. In the US pathogenic Naegleria have been found in some freshwater lakes receiving effluents from power stations. Pathogenic Acanthamoeba and Nagleria were isolated from cooling water discharges at several coal-fired power stations in the USA (Shapiro et al 1980) and these authors concluded that cooling systems may be the source of some infections.

In addition to the costs that may accrue we can also view the ways in which the ecosystem as a whole can offer us services. Some of the most important are listed below.

- Recycling of human waste. This is probably the most important service that is offered by waters close to human habitation.

- Demobilisation and detoxification of chemical waste products. The living world is involved in both the breakdown and locking away within the sediments of dangerous metals, petroleum products and a vast range of chemical wastes and products.

- The stabilisation and accumulation of sediments. Without vegetation soft sediments would be far more mobile resulting in increased turbidity and sedimentation of channels.

- Support to the terrestrial ecosystem. In many localities there can be a major reexportation of biomass from water to the land via insects and other invertebrates but also via fishing birds and mammals. Thus the presence of a diverse and rich aquatic fauna can enhance the health of the associated terrestrial flora and fauna.

Many animals feed on fish. To illustrate this we show below a list of mammals that are known to feed on fish. The list of birds, reptiles and crustaceans would be very long indeed.

Fish-Eating Mammals Of North America
[See hardcopy for list]

EPA Response

EPA agrees that the majority (98%) of impinged and entrained fish are forage fish have no direct market value, but are nonetheless important for aquatic food webs. To capture the indirect use value of such species as food for recreationally and commercially important species, EPA used a simple trophic transfer model to estimate the contribution of forage species to foregone fishery yield (see Chapter A5 of the Regional Study Document, DCN #6-0003). However, nonuse values are not accounted for.

RFC: 5% threshold and supporting documents

5% flow threshold for rivers

This proposal is based on the concept that the proportion of eggs and larvae and juvenile fish entrained from a population is directly proportional to the volumetric proportion of the habitat that is pumped through the cooling system. This will rarely be the case because larvae and juvenile fish are not randomly distributed throughout the water. For example, the common eel Anguilla, which migrates up East coast rivers as elvers, often travels close to the bank, sometimes in ribbons of thousands of individuals. For such species the position of the intake is an important factor in determining the level of entrainment. It is therefore essential that the 5% threshold is never taken as a sufficiently protective measure to protect fish, hence allowing poor design and placement of intakes. Given good intake design, the proposed threshold has merit and, as will be discussed below, is probably superior to some of the alternative withdrawal thresholds.

There are concerns relating to the use of mean annual flow, as the level of protection given to the fauna would be far from certain. The use of mean flow could result in a far higher proportion than 5% of the flow being taken during seasonal or unusual periods of low flow. If an animal is to be afforded good protection, then all of its life stages must be protected. Using average flows as the basis for 5% threshold calculations may result in variable levels of protection through time and could produce high mortalities during low flow periods sufficient to negate any protection afforded at other periods. It is common for regions to suffer extended periods of drought lasting one or more years when river flows may be well below the long-term average. During such periods the plants would presumably still be able to extract at a rate determined by the mean annual flow prior to the drought; this could be particularly damaging.

5% of mean flow during the spawning season. This proposal would likely be less protective of juvenile fish and would offer no protection to small migratory fish such as eels and lamprey that can be subject to entrainment and might not be moving past the intakes during the spawning season. It would presumably allow a far larger proportion of the mean flow to be taken outside of the spawning season, resulting in far greater damage to populations than would be the case with the 5% flow threshold.

10% to 15% of mean annual or spawning season flow. These options are considerable less protective of the fauna than the 5% preferred option and should be avoided.

25% of the 7Q10. The flow of most US surface waters is highly seasonal and varies considerably between years so it is possible that the 7Q10 minimum constraint would give a lower constraint than the 5% of average flow threshold. In drought years this constraint would effectively allow a reduction in the level of environmental protection over that offered in more typical periods. Over the usual life of a power plant of 40 years or more it is likely that there will be periods when flow is lower than the 7Q10 and thus, for short periods, even more than 25% of the flow could be removed. The problem from the ecological viewpoint with this proposal is that during extreme droughts, when the aquatic

life is already stressed, the impact from water extraction (and discharge) would be particularly high. This could result in considerable ecological damage from which it might take the river fauna a number of years to recover. It is unclear if this option is
better or worse than the 5% annual average. It is certainly much more difficult to quantify.

Subject Matter Code 16.0

Capacity Utilization

15% Capacity utilisation cutoff

This proposal would remove plants that operate for less than 55 days per year from the need to reduce entrainment. Providing such plants are usually operated during mid summer and mid winter this is probably a reasonable concession. However, there are ways in which it could result in far higher entrainment levels than is implied in the proposed rule.

First, the 15% is “over the course of several years”. This would allow a plant that meets an average of 15% to be used for far more 55 days in some years. This in turn could result in large entrainment losses for some years.

Second, it is implied that the 15% of available operating time would be taken as one or two blocks: “the plants typically operate during two specific periods: extreme winter and extreme summer demand periods”. The implication is that this pattern reduces the need for entrainment protection as these periods correspond to periods of naturally low entrainment, which they often do. However, it is possible to envisage other patterns of operation that would result in 15% availability and which would result in far higher entrainment losses. For example, a plant could be used to meet peak morning and evening demand only.

Third, there is no assurance that the 55-day period of operation would not correspond to periods of high larval fish abundance. Indeed, in a worst possible scenario a plant with 15% utilisation could kill almost as many organisms by entrainment as a plant with a 60-80% utilisation. To illustrate the point the Table 22 shows the conditional mortality rates for abundant larval fish at the Indian Point Power station in the Hudson estuary, NY (reproduced from the Indian Point Draft DEIS).

Table 22. The conditional mortality rates for abundant larval fish at the Indian Point Power station in the Hudson estuary, NY. (Entrainment CMR x 1000). (Reproduced from the Indian Point Draft DEIS). [See hardcopy]

Note that almost all the larval entrainment occurs over two periods, 23-Feb to 28-Mar and 17-May to 25-July. If the plant were used in both these periods even a 55-day utilisation could produce high levels of entrainment. It should also be noted that February and July are often months when electricity demand is at a peak so such an outcome is quite possible.

The above considerations indicate that a simple 15% threshold would not necessarily give the level of entrainment protection that the modest level of utilisation might suggest. A low-utilisation plant kills a large number of organisms by entrainment then the fact that it is not used for the majority of the time should not exclude it from taking protective measures.

Alternative thresholds

All the alternative thresholds proposed are higher than 15%. Given the stated concerns about the 15% level there are even more grounds for concern that higher threshold levels could allow excess entrainment.

EPA Response

The Agency has analyzed the potential national effect of the capacity utilization rate threshold on entrainment. The capacity utilization rate threshold allows facilities with capacity rates of less than 15 percent to comply with impingement requirements, and removes entrainment requirements where they apply. In this analysis (see DCN 6-3586) the Agency determined that less than 1 percent of the actual annual intake flow of facilities projected to upgrade technologies as a result of the rule would fall under the capacity utilization rate threshold. Therefore, more than 99 percent of the actual annual intake flow of facilities that pose significant potential entrainment concerns would not be subject to reduced standards. This is a reasonable basis on the national level for a capacity utilization rate threshold (which, in its implementation will allow the rule to be more affordable to the complying industry without sacrificing the entrainment reduction performance retaining all of the impingement performance and of the rule), in the Agency's opinion.

The Agency has analyzed the potential for overlap of the facilities falling under the capacity utilization rate threshold and the periods of concern to the commenter (i.e., what the commenter terms periods of peak spawning). The Agency analyzed all facilities projected under the threshold and examined the likely operating periods for these facilities. Of the 42 facilities projected to fall under the threshold, 17 of these facilities would be subject only to impingement requirements regardless of the existence of the utilization threshold. Further, of the 25 facilities (5 percent of Phase II facilities) that would receive reduced entrainment requirements under the capacity threshold, the total median operation period per year would be 28 days. Considering that this operational period is broken about in two likely periods in winter and summer, the 2 week period in each season would likely overlap only a small portion of the periods of concern to the commenter. The operational flow of the facilities receiving reduced entrainment requirements over the typical 28 days per year would be 1 % of the total annual intake of facilities within the scope of the rule that are subject to entrainment reduction requirements. Therefore, the capacity utilization rate threshold will not appreciably decrease the entrainment efficacy of the final rule.

Additionally, should the local conditions of the plant warrant, special considerations can be made at the local level by the Director to allow for more stringent requirements than those in the final rule for certain circumstances. See the preamble to the final rule.

Spatial scale for entrainment trading

Trading Mechanisms

Spatial scale

The EPA would prefer that trades be conducted between water bodies that share similar ecological characteristics regardless of geographic proximity of the facilities to each other.

There are two problems with this preferred option. First, it is unclear what is meant by share similar ecological characteristics. All estuaries share the characteristic that they are nursery areas for marine fish, however the species occupying estuaries differ with geographical locality. This phrase would need to be carefully defined. In particular, the use of ecological characteristics is too vague to be useful.

The second problem relates to the sharing of populations within the region where trading would be allowed. The one key ecological characteristic that must be shared for trading to be ecologically protective would be the populations of the impinged or entrained species. Two rivers or lakes may have many species in common and a generally similar ecology, but their populations may be completely isolated. Therefore improvements in one system would be of no benefit to the populations in an unconnected system. Also, the characteristics and genetics of species change with geographical locality. Therefore geographic proximity and in particular some degree of connectivity are important so that waters can share populations or occasionally swap migrants. This is essential if they are to have ecological characteristics that can be considered shared.

If the primary aim is to protect the populations of fish and crustaceans, then the geographical scale and the nature of the ecological characteristics for consideration must be determined by the extent and isolation of the populations of target species. A necessary, but not sufficient, criterion must be that all waters over which trading is conducted must be connected so that they interchange their most abundant fish species. In situations, such as estuaries, where they are connected by the ocean it must also be proven that trading is occurring between localities between which the main species do actually move. While for some species, such as striped bass, the ocean may be no obstacle, for others it may be effectively insurmountable. A similar situation can occur in large rivers where different tributary catchments can be isolated islands for species unwilling to enter the main stem of the river. This brings into sharp focus the fact that the appropriate geographical scale changes with the species.

The above considerations suggest that trading should only be allowed over limited geographical zones and normally confined within a single estuary, river or lake. Further, in large water bodies, where clear environmental gradients are present, it would be inappropriate to allow trading between sites with very different lists of commonly entrained and impinged species. For example, in the River Hudson Estuary there are great differences in the larval fish entrained between low salinity waters towards the head of the estuary and higher salinity waters towards the mouth. In the case of ocean sites they would need to be within a zoogeographic zone that shared fish populations. For large rivers there would also need to be habitat subdivisions reflecting habitat features. This leads to the conclusion that the appropriate spatial scale is trading within specific water bodies with further subdivisions for large and very large water bodies.

The above arguments lead to the view that trading should only be permitted between sites situated on the same water body and ecological community and that impact the same populations of common species at similar life stages.

RFC: Potential trading units/ credits

The unit for trading

The EPA propose three possible units of exchange, species density, species counts and biomass. As will be discussed below there are considerable problems with all 3 possible units for trading and further clarification and definition is required.

Using species density; numbers of eggs, larvae, juvenile fish and shellfish species entrained per unit volume would be used. This could only be an appropriate measure for trading if trading were strictly limited between sites in the manner proposed above under spatial scale. The distribution of all species is far from uniform and is variable through time. Therefore this proposal will not offer equal protection to all species. In particular, the density of shellfish species needs to be considered in more detail as it may seriously distort the outcome. Crustaceans are normally much more abundant than fish in both entrainment and impingement samples. For example, in estuarine and marine sites very large numbers of shrimp (Crangon spp.), mysids and young crab are entrained. Is it proposed to give these organisms equal weighting to that of larval fish? The situation is even more difficult if molluscs are to be considered. In some estuarine and marine localities large numbers of small molluscs such as just ready to settle mussels (Mytilus spp.) may be entrained. Such ‘fouling’ organisms are frequently viewed as a pest and sometimes are actively killed using biocides or heat treatment. The implication would seem to be that these would be given equal weight to larval fish for trading purposes. The example of trading under the EPA’s preferred alternative (p17172) is based on only a few abundant fish species and gives no mention to shellfish. A final area that needs to be clarified is the base data that will give a measure of the entrainment at each plant between which trading is proposed. The recruitment of fish and the abundance of other entrainable organisms can vary dramatically from year to year and change greatly through time. A clear example of long-term change is the 15-fold increase of abundance in striped bass in the River Hudson estuary since the 1970s. If trading is to be fair and appropriate it is essential that each of the sites within the trading group must have contemporaneously collected entrainment data and that the time period for comparison between the sites must be of equal length.

Species counts would use data on the numbers of each species. Further, these numbers would be subdivided into age classes. A value would need to be given to each species at each life stage. It is far from clear how each species and stage will be given a monetary value, and the amount of work required to collect and organise the data would be considerable. In reality this method could only be used for selected species. How would these species be selected? There would be a great temptation to focus on important commercial species, as they would be easier to value in monetary terms. As for species density, if trading is to be fair and appropriate it is essential that each of the sites within the trading group must have contemporaneously collected entrainment data and that the time period for comparison between the sites must be of equal length.

Biomass; trading would be based simply on the weight of entrained organisms per unit volume. This would give equal weight to all living (or possibly recently killed) life. The effect would be to effectively have a trading system based on phytoplankton. For marine and estuarine systems these would be mostly diatoms, Phyocystis and other colonial forms and dinoflagellates. In some freshwaters diatoms and even blue-green algae could dominate. The most abundant animal groups are frequently ciliates and other protozoans and microcrustaceans such as copepods and cladocerans. At ocean sites it is often observed that the biomass of ctenophores entrained is considerable. The biomass of eggs and larvae of fish and macrocrustaceans such as crab and lobster would be negligible. A biomass trading system would be completely inappropriate, as it would focus protection towards the rapidly reproducing, short-lived lower-life forms that are best able to cope with the losses caused by entrainment.

Cooling system costs (e.g., dry, wet, recirculating)

The EPA has revised its estimate of the net downtime of retrofitting cooling towers at a nuclear power plant from 4 weeks to 7 months. This revision appears to be based solely on the experience when cooling towers were added to the Palisades nuclear power plant in 1973/1974. We do not believe that this change is justified for the following reasons.

First, the amount of time it took to retrofit cooling towers at the Palisades nuclear power plant 30 years ago is not persuasive evidence of how long it would take to complete similar work at nuclear power plants today. In particular, the durations of refueling/maintenance outages at nuclear power plants have been significantly reduced during the past decade. Outages which previously had required two or three months of plant downtime are now routinely completed in fewer than 30 to 40 days. Similar improvements can be expected in the amount of additional plant downtime that would be required for the installation of cooling towers and related plant modifications at nuclear power plants.

Second, Consumers Power Company, the owner of the Palisades plant, has told the EPA that:

Based upon a site review of engineering, accounting and purchasing documents, we can infer that the conversion process spanned over a period from mid-1971 to May of 1974 when the cooling towers became operational. It appears that the outage time for the conversion took about 10 months from August 1973 to May 1974.

Consumers Power also told the EPA the there were several maintenance-related tasks performed during Palisades' 1973/1974 extended outage. Nevertheless, Consumers Power claimed that "it appears that the outage was primarily for the purpose of installing the new circulating water system and the modifications necessary for its operation."

We have reviewed contemporaneous nuclear industry and regulatory documents from 1973 and 1974. Contrary to what Consumers Power has told the EPA, it appears that the extended outage of the Palisades nuclear plant was primarily due to factors other than the installation of the new circulating water system and related modifications.

For example, the NRC has reported the following concerning Palisades August 1973 to April 1975 outage:

An outage was initially estimated for 3 months to repair [the plant's steam generators]. Internal reactor problems and a waste gas release investigation prolonged the outage into 1974. The new cooling towers were completed and placed in operation and the turbine-generator was overhauled.... [Consumers Power] filed a suit against several vendors for startup problems with the condenser, [steam generators], and core internals. Turbine repairs and condenser-retubing extended the outage even further.

According to an article in the October 1974 issue of Nuclear News, Consumers Power had said that the outage was "due principally to steam generator corrosion and damage caused by vibration of the reactor core internals, as well as defective main condenser design and tubing." As a result, Consumers Power sued Bechtel Corporation and four other companies who helped to build the Palisades nuclear plant because "equipment supplied [in 1966 and 1967] was defective" and that defective equipment had not been promptly and adequately repaired.

This information suggests that the Palisades plant remained shutdown during the period August 1973 through May 1974 (and, in fact, into 1975) as a result of serious problems unrelated to the installation of the new circulating water system and related modifications. Unfortunately, the EPA does not appear to have verified or confirmed what it was told by Consumers Power. Instead, it has increased the additional plant downtime for a cooling tower retrofit by roughly 600 percent (from 4 weeks to 7 months).

Third, even if work on the installation of the new circulating water system and related modifications began in August 1973 and was completed in May 1974, it is possible that this work could have been completed in less time if it had been the most critical work during the outage. For example, our review of more than 100 power plant outages has revealed that critical path projects are frequently worked seven days a week and sometimes 24 hours a day. Unfortunately, Consumers Power has not provided any information to enable the EPA or anyone else to determine whether the installation of the new circulating water system and related modifications was worked on such a schedule. Indeed, other, more critical projects during the 1973/1974 Palisades outage might have diverted management, engineering and manpower resources from the cooling tower retrofit and/or might have made the retrofit more difficult and, therefore, longer.

In addition, there is no evidence that the installation of the new circulating water system was even worked every day during the period August 1973 through May 1974. There may have been significant periods when little or no work was being performed on this project.

For this reason, it is unreasonable to judge how long a cooling tower retrofit project might take at existing nuclear power plants based on at the start and finish dates at Palisades in 1973 and 1974.

Finally, the U.S. Department of Energy's National Energy Technology Center issued a study in October 2002 entitled "An Investigation of Site-Specific Factors for Retrofitting Recirculating Cooling Towers at Existing Power Plants." This study was prepared by the Parsons Infrastructure and Technology Group, Inc. ("Parsons"). In this study, Parsons examined the possible retrofitting of cooling towers to four different power plants, one of which, the Surry site, has two nuclear units.

Parsons concluded that the construction and startup of new cooling tower systems at the Surry nuclear site would not result in extended outages:

With proper planning and coordination with other planned outages, cutover from the older cooling systems to the new cooling towers could be accomplished without loss of generating time. This has been the experience with other plants. Therefore, the analysis shows no cost penalty for extended outages at this time.

In conclusion, we find no evidence supporting the EPA's revised seven month estimate of the additional downtime that would be required to retrofit cooling towers at nuclear power plants. There also is a complete lack of credible support for Consumers Power Company's claim that the retrofit of cooling towers at the Palisades nuclear plant back in 1973 and 1974 required an additional ten months of plant downtime.

EPA Response

First, EPA notes that an estimate of 7 months downtime for nuclear plants is not the full time (10 months) it took the Palisades plant to retrofit their cooling system.

Second, EPA notes that because the maintenance, refueling, and inspection outages for nuclear plants has decreased somewhat over the past 30 years means that construction schedules for connections of cooling systems would have even LESS offset time to coincide with during maintenance and refueling outages compared to 30 years prior. To illustrate the point, the Agency presents a simple example. If the total duration of a downtime takes 10 months in 1974 and the duration of the predictable refueling/inspection outage was two to three months, then the total NET duration of the downtime caused by the cooling tower connection would be from 7 to 8 months. Now, fast forwarding to the present where refueling/inspection outages last between 30 and 40 days on average (say 1.5 months for simplicity's sake) a 10 month total construction downtime due to cooling tower retrofits would only be offset by 1.5 months, thereby giving a NET duration of a modern downtime of approximately 8.5 months (i.e., 1.5 months LONGER than in the past).

The commenter's conclusion that Consumers Energy misrepresented the cause of the construction downtime is not persuasive. In the Agency's view, the contemporaneous reports summarized and referenced by the commenter support the conclusion that the cooling tower conversion could have played the critical role in the outage. The Agency notes that the condenser tube failures at the plant are predictable due to the conversion of the cooling system from once-through to recirculating. The Agency was aware of this possibility in its proposal and NODA analysis of cooling tower retrofits, as evidenced by the fact that the Agency included condenser upgrades for a significant portion of those facilities analyzed for cooling tower retrofits under the rejected regulatory alternatives. EPA notes that the commenter has omitted any discussion of the cause of the condenser failures. Because the main condenser design and tubing were mentioned directly as (at least partial) causes for the outage, and the degree of their contribution cannot be discerned further by the commenter's references, the Agency continues to consider the cooling tower retrofit as a direct contributor to the 10 month outage. In addition, the commenter's discussion of the lawsuit by Consumers Power because of defective equipment and failure to repair said equipment, could be interpreted to support the assertion that the condenser failure was not adequately predicted and that the cooling system change could still be responsible for the majority of the outage.

The rest of the commenter's discussion of the reasons for the Palisades outage are mere speculation without evidence. As such, the Agency maintains that the outage at Palisades could be truly as Consumers Energy reported to the Agency and primarily the result of the cooling tower conversion.

EPA notes that the commenter is either misinterpreting or omitting the findings of the DOE/NETL study (prepared by Parsons). The following quotation from the DOE summary of the study underlines the concerns of the Agency in mandating cooling tower retrofits to nuclear plants:

"Dominion expressed concern with respect to maintaining the integrity of operation of the Surry

Power Station’s Emergency Service Water pumps under the proposed wet cooling tower retrofit design. Preserving the integrity and operation of the Surry Power Station’s Emergency Service Water pumps is a significant safety issue. Dominion’s concern is valid and serves to underscore how the understanding of truly site-specific issues is critically important to the retrofit design process.”

In addition, the DOE study makes note of the fact that construction downtimes were potentially optimistic in the study.

EPA notes that the commenter failed to consider that major construction projects at nuclear plants in many cases cannot operate such as those at other fossil-fuel plants where blasting, major civil works, or intermittent interruptions to intake water can be carried out while operating the plant. Therefore, the commenter’s conclusion (without empirical evidence) that predicted generation loss are phantom is not realistic nor supported by their comment.

Streamlined Technology Option

Author Name Randy L. Kowalski
Organization North Dakota Department of Health

We encourage EPA to expand on the approach suggested in the NODA for a streamlined technology option proposed for CFR 125.94 that would consider the engineering features of a cooling water intake. Considering the rule is for existing facilities with a variety of configurations it seems that a suite of technology options should be available for consideration under a streamlined approach. We encourage EPA to expand on defining systems that would meet streamlined technology option. This would reduce the burden state NPDES regulators by reducing the number of individual site specific determinations requiring review and determinations regarding adequacy. The engineering aspects of a facility are readily measurable and verifiable. In our experience, studies of aquatic populations can be extremely hard to meaningfully to relate to a single operation particularly when other influences on the water body such as climate, flow management and land use can dramatically effect the populations. Given the extensive analysis conducted to extrapolate the cost of impingement and entrainment from a few study cases, it seems additional effort could be put into quantifying the performance of additional situations and technologies currently in use.

EPA Response

EPA believes that it has expanded and clarified the site conditions required to qualify for the Approved Design and Construction Technology Option. For extensive detail on this option, please see § 125.99 of today's final rule, as well as preamble section VII.C.3

Proposed standards for FW rivers and streams

The inland waters appear to be poorly represented in the data analysis used to determine adverse impacts and BTA for existing facilities. The limited number of facilities and data for inland waters was not expanded with the NODA. Of interest to us is the lack of consideration by EPA of the existing technology applications in moderately fast moving cold climate river systems where ice and debris would potentially limit the feasibility of some technologies. It does not seem equitable that facilities operating in streams with velocities in the 2 - 3 fps range and intakes with velocities from 0.5 to 1.0 fps should be considered to have the same effect as those operating in near reservoir conditions with their differing aquatic communities.

EPA Response

EPA disagrees. EPA acknowledges that detailed case studies or analyses have not been developed for every region in the United States, nor does it expect to do so. Today's rule establishes protective requirements for all waterbodies, regardless of geographic considerations, by establishing requirements that are not region-specific. For example, the proportion of the mean annual streamflow of a river by a facility or the design intake velocity of a technology are characteristics that are universally applicable to all facilities.

A goal of today's rule is to set national minimum performance standards that reflect the best technology available for minimizing adverse environmental impacts. EPA believes that these performance standards are appropriate for most facilities.

Additionally, EPA compiled a database of documents that analyzed the efficacy of specific control technologies (see DCN 5-4420 in the Phase II NODA docket, Section VII.A in the NODA [68 FR 13538]). This database was the result of an international literature search to develop the compliance ranges for the performance standards. As such, EPA believes these performance standards to be appropriate for most facilities.

EPA also notes that the rule does distinguish between freshwater rivers and reservoirs. Please refer to § 129.93 for definitions of a freshwater river and a reservoir for this rule.

Option 3--Site-specific determination

We anticipate that the affected facilities in our state will be opting for the site-specific options. If a streamlined technology option reasonably applicable to the region is not provided, the facilities will likely seek the site specific BTA determination option. The site specific options appear to be quite resource intensive for NPDES programs as well as the facility.

EPA Response

EPA disagrees that most facilities will seek a site-specific determination of best technology available. Please refer to the response to comment 316bEFR.202.002.

Streamlined Technology Option

Selecting one or two prescriptive technologies for a streamlined approach seems overly simplistic to characterize the performance of the variety of existing systems.

EPA Response

EPA disagrees that it has only selected one or two prescriptive technologies in the Approved Design and Construction Technology option. Rather, EPA has included a provision which allows any interested person to submit a request to the Director that a technology be approved in accordance with the compliance alternative, making the potential number of technologies limited only by the creativity of the interested parties or by the physical limitation of the technologies themselves. For extensive detail on this option, please see § 125.99 of today's final rule, as well as preamble section VII.C.3.

Comment ID 316bEFR.333.005

Author Name Randy L. Kowalski

Organization North Dakota Department of Health

Subject Matter Code 7.04

Streamlined Technology Option

The rule for existing facilities should provide a streamline option for cooling water intakes on reservoirs constructed solely for the purpose of supplying (recirculating) cooling water. We do not believe it is worth our resources to oversee and assure a site-specific study is completed in accordance with 40 CFR 125.94(a)(3) of the proposed rule when if it were not for the facility the fishery would not exist.

EPA Response

Please refer to § 125.93 for EPA's definition of closed cycle cooling, and to EPA's response to comment 316bEFR.032.015 for EPA's position on determining whether a facility meets the definition of closed cycle cooling.

RFC: Definition of "adverse environmental impact"

General Comments:

While the NODA does not specifically request additional discussion regarding the definition of Adverse Environmental Impact (AEI), Reliant would like to reiterate that the adoption of a practical definition is vital to implementation of the proposed rule. Sound fisheries management principals dictate that impacts or improvements to fisheries resources are best measured at the population and/or community level, not at the individual organism level. A clear definition of AEI based on sound fisheries management principals is required before any management strategies involving CWIS can be realistically contemplated.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule.

Comment ID 316bEFR.335.002

Organization Reliant Energy

Subject Matter Code 6.01

Overview of I & E effects on organisms

As stated in our previous comments, despite years of extensive study nationally, there are very few cases of demonstrative evidence that any fisheries species has been negatively impacted by once-through cooling operations. Where impacts have been identified, they appear to be very specific to certain facilities, further emphasizing the site-specific nature of the impacts. Consequently, it makes little sense to mandate expensive technology-based regulatory solutions to address previously unobserved adverse impacts on an across the board basis. We believe that local and state regulatory agencies, burdened with limited budgets, should have substantial latitude on how best to define, identify and address fisheries impacts under 316(b).

EPA Response

Please see response to comment 316bEFR.025.018 for the discussion regarding the environmental impacts associated with cooling water intake structures. EPA believes that today's final rule gives substantial flexibility to permitting authorities to determine the best technology available for each site. Please see § 125.94 which describes the five compliance alternatives. In addition, § 125.90 allows States to demonstrate that it has adopted alternative regulatory requirements in its NPDES programs that will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment that would otherwise be achieved under § 125.94.

Available I&E technologies

In regard to EPA's proposed technological solutions, Reliant again questions the efficacy of fine-mesh screens, cylindrical wedge-wire screens, and filter fabric barriers, especially when used in waterbodies subject to; 1) high suspended solids or biofouling loads, 2) frequent occurrence of tropical storms, hurricanes, or flood flows, or 3) limited hydraulic cross-flow to remove impinged debris or nekton. As such, there is considerable question as to whether the implementation of these technologies could achieve the proposed performance measures in various site circumstances.

Technology Efficacy Database

Performance Standards

EPA requested comments on the Technology Efficacy Database and its ability to support the performance standards. Reliant notes that the database, while fairly robust, demonstrates wide variability as to study approach and design, methodology, implementation and results. This variability underscores the need for site-specific evaluations to determine efficacy of any given design and construction technology for each type of waterbody where it would be employed. Of particular concern, the database contains limited information to support contentions that such technologies could be implemented, much less demonstrated to be effective, in the turbid, particulate-rich waters of many Gulf Coast estuaries.

EPA Response

Organization Reliant Energy

Subject Matter Code 11.01
RFC: Proposed use of restoration measures

Restoration Activities

EPA identified several sources of uncertainty regarding restoration activities such as marsh creation. Reliant recognizes there is a lag-time before full productivity in constructed wetlands, but suggests that the lost productivity during this lag-time is more than fully off-set by the continued productivity associated with a created wetland that will function long after a specific generation facility has reached the end of its service lifetime. Reliant suggests that voluntary restoration approaches, such as constructing functional wetlands, are an effective way to offset loses associated with impingement and entrainment of organisms at CWIS.

EPA Response

All restoration measures must meet the requirements described in the final rule.

Subject Matter Code 11.06
RFC: Performance/effectiveness of restoration

Reliant agrees that peer review conducted by local resource agencies familiar with such projects can be an effective means to achieve mitigation success as well as lowering overall mitigation costs, especially for companies with limited experience in such restoration activities.

EPA Response

EPA agrees with the commenter that peer review may be helpful for facilities with limited experience in restoration activities. For a discussion of the role of peer review in the final rule, see EPA's response to comment 316bEFR.312.006.

Comment ID 316bEFR.335.008

Author Name Kerry M. Whelan
Organization Reliant Energy

Subject Matter Code 21.04
Determination of compliance

Representative Indicator Species

EPA requested comments on use of the representative indicator species (RIS) approach to evaluate compliance. Reliant strongly favors this approach over the all species approach. It is simply not feasible to measure performance standards against every single species that may come into contact with a CWIS. For species that are encountered on an extremely rare basis, the impingement of a single organism could cause a facility to violate the performance standards. Instead, by using the RIS approach, facilities could focus their efforts on the few species that are considered ecologically pivotal for the given ecosystem. In Gulf Coast estuaries, the RIS approach may indicate that a relatively limited number of species need to be monitored to demonstrate compliance with performance standards.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Comment ID 316bEFR.335.009

Author Name Kerry M. Whelan

Organization Reliant Energy

Subject Matter Code 21.04

Determination of compliance

Moribund Fish

EPA requested comment on whether a facility should have the opportunity to remove the number of moribund organisms from calculations when conducting impingement studies. Reliant believes the ability to remove previously moribund organisms can be critical to obtaining representative data at a CWIS. All waterbodies can be subject to natural or manmade fish kills. For example, Gulf Coast estuaries encounter extremes in temperature and other weather conditions that often contribute to fish kills. High temperature and algal blooms can promote fish kills due to oxygen depletion in the shallow turbid estuaries. Freezing weather can likewise result in substantial fish kills when fish are trapped in shallow water bodies. Other fish kills may result from man-induced episodes such as oil or chemical spills. In such cases, large numbers of previously stressed fish can drift into CWIS where they are removed at the rotating screens. Reliant suggests that these fish logically should not be counted as impinged organisms and that the permittee should be able to discount those organisms if they so choose.

EPA Response

For EPA's position on the factoring of naturally dead or moribund organisms, please see EPA's response to comment 316bEFR.306.116.

Comment ID 316bEFR.335.010

Author Name Kerry M. Whelan
Organization Reliant Energy

Subject Matter Code 21.04
Determination of compliance

Compliance Determinations, Timelines, and Schedules

EPA requested comment regarding options for evaluating compliance with performance standards. Specifically, EPA requested comment on whether the Agency should allow the Director to determine how best to measure compliance, either programmatically or as part of individual permit decisions. Reliant stresses that a programmatic "one size fits all approach" while efficient from a regulatory point of view, would likely lead to over regulation of some facilities and under regulation of others. Reliant believes that compliance with performance standards can only be determined on a site-specific basis. We suggest that the implementing authority at the state level is best positioned to determine compliance.

EPA Response

EPA agrees that a one-size-fits-all approach is not appropriate for determining compliance. In today's final rule, therefore, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Organization Reliant Energy

Subject Matter Code 21.09

Permit applications/implementation schedule

EPA requested comment on whether the final rule should allow additional time to complete required studies when a facility's permit renewal date falls shortly after the regulation becomes final. Reliant favors this approach recognizing that the studies required under this regulation will likely require a number of years to complete due to the seasonal and annual variations in species abundance. Reliant suggests that local resource protection agencies are in a better position to determine timeframes appropriate to characterize aquatic species abundance in specific waterbodies

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

Comment ID 316bEFR.335.012

Subject Matter Code 21.04

Determination of compliance

Author Name Kerry M. Whelan

Organization Reliant Energy

Due to the variability in biological communities, EPA is considering implementing compliance schedules for facilities that have installed technologies to optimize their performance in order to meet the performance standards. Reliant strongly endorses this approach and recommends a minimum five-year timeline for such compliance schedules. This would allow for evaluation of impacts under a range of operating conditions through several seasons leading to optimization of control technologies. During this period of optimization, EPA should not hold a facility subject to enforcement for violating the Section 316(b) requirements. When performance standards have been met, EPA should allow facilities to use previous studies and data for future permit renewals as long as conditions at the facility and within the waterbody remain largely unchanged since the previous studies were conducted.

EPA Response

EPA has attempted to address these concerns through the use of a TIOP, when approved by the Director. See the preamble for more discussion of the TIOP. In today's final rule, a permit applicant may have reduced submittal requirements under certain circumstances following the initial permit cycle. Please see EPA's response to comment 316bEFR.034.005 for more details.

Comment ID 316bEFR.335.013

Author Name Kerry M. Whelan

Organization Reliant Energy

Subject Matter Code 7.04

Streamlined Technology Option

In addition to compliance schedules, EPA should expand the approach discussed under "Streamlined Technology Option for Certain Locations". EPA, in conjunction with state resource protection agencies, could identify prescriptive approaches deemed to meet performance criteria protective of aquatic species in specific habitats. Such approaches could include specific control technologies at the CWIS, operational measures, and/or mitigation and restoration activities. Once implemented and maintained, state resource protection agencies could certify that performance criteria have been met. This would greatly reduce the information collection burden imposed on permit applicants and resource agencies should a permittee choose to follow such a prescriptive approach.

EPA Response

EPA believes that it has provided industry and State resource protection agencies the opportunity to expand the Approved Design and Construction Technology Option. For details, please refer to EPA's response to comment 316bEFR.306.062.

Benefit Estimation Methodology

We are pleased to have the opportunity to submit comments on the above-captioned notice of data availability. As we discuss below, in our view cost-benefit analysis is an inappropriate tool for adjudicating the policy questions currently facing the Agency. However, even if one accepts cost-benefit analysis as an appropriate means to determine the appropriate level of regulation for power plant cooling water intake systems, the magnitude of the omissions in the NODA renders the exercise meaningless. The difficulties encountered in the attempt at monetization of benefits underscore the need for other approaches to evaluation of policy options.

As we discuss in detail below, despite the large amount of analysis that went into the NODA, the document includes only a fraction of the data that EPA itself considers to be relevant for the regulation. Having discarded the approach to nationwide calculations it used for the original proposed ruling, in the NODA the Agency presents benefit calculations for just two regions of the country. Calculation of both use and nonuse benefits is attempted for only one of the two regions; and even this calculation omits consideration of key biological facts.

The lack of key information in the NODA does not reflect lack of effort in gathering and analyzing data. Rather, the shortcomings of the NODA illustrate the flaws in the methodology that EPA is now pursuing. The task of quantifying benefits will require significant further analysis, and involves methodological quandaries that will not be resolved easily. In our opinion, by converting its regulatory mandate into a lengthy and methodologically questionable program of data collection and analysis, EPA has failed to meet its responsibilities under the Clean Water Act. The Agency has, however, developed a substantial body of data and background information. These data can be applied usefully to developing sound regulations, which should take account of benefits without holding them to the unrealistic standard of precise monetization, as the Agency has done thus far.

EPA Response

EPA's approach to economic analysis of the final Section 316(b) Phase II rule is consistent with principles outlined in the EPA's Guidelines for Preparing Economic Analyses, United States EPA (EPA 240-R-00-003).

Although EPA presents benefit calculations for just two regions of the country in the NODA, benefit estimates were developed for all study regions for the final 316b rule analysis. See the Regional Analysis Document for the Final Section 316(b) Phase II Existing Facilities Rule for detail (DCN #6-0003).

The Agency recognizes that quantification and monetization of ecological benefits involves unavoidable uncertainties and thus monetization of nonuse benefits was not included in the final benefit summation for the final Section 316(b) Phase II rule. For example, in addition to presenting monetized benefits EPA presents a qualitative assessment of ecological benefits. The Agency explains its approaches in the Regional Analysis Document for the Final Section 316 (b) Phase II Existing Facilities Rule (DCN #6-0003).

Finally, EPA points out that economic considerations should not strictly determine policy decisions, and that other factors should also be weighed.

Subject Matter Code 10.02.04

Valuing Forage Species (incl non-use and non-landed)

Background

EPA's original proposed rule calculated estimated costs and benefits for seven possible regulatory options: a waterbody/capacity-based option with two possible tracks; the proposed rule, with "alternative less stringent requirements based on both costs and benefits"; impingement mortality and entrainment controls everywhere; all cooling towers; a dry cooling option; and a waterbody-based option. According to EPA's analysis, net benefits were positive for four of the options examined; they were negative for the "all cooling towers" and "dry cooling" options, and were not costed for the "waterbody-based option." EPA's calculated net benefits were highest, by a small margin, for the "proposed option." For another option, which would have placed more stringent controls on cooling water intake systems, estimated net benefits were more than 99% of the estimated net benefits of the proposed option. <FN 2>

In our comments on EPA's original draft ruling, <FN 3> we presented a number of criticisms. We pointed out that EPA's estimation of net benefits was seriously flawed, and that even conservative adjustments to account for some of EPA's omissions would produce significantly higher benefit figures, and would imply that a different regulatory option had the highest net benefits. In particular, we noted that EPA's use of an outdated "rule of thumb" for calculating nonuse value was misleading, and lacking in theoretical or empirical justification.

We noted that EPA had effectively valued large portions of aquatic resources at zero. One striking omission was the failure to place any value on the unharvested fish that regenerate the population from year to year. We also expressed concern that EPA overlooked important sources of value, ranging from commercial value of shellfish through ecological, recreational, and nonuse value of aquatic flora, bird life, and other organisms.

Footnotes

2 See 316(b) Phase II EBA, Part D: National Benefit-Cost Analysis, Chapter D1: Comparison of National Costs and Benefits. Available at http://www.epa.gov/waterscience/316b/econbenefits/d1.pdf, visited May 2003. Estimated net benefits for the proposed rule were $452 million, while estimated net benefits for the "Impingement Mortality and Entrainment Controls Everywhere" option were $449 million.

3 Comments submitted by Frank Ackerman, August 1, 2002.

EPA Response

EPA acknowledges that its focus on direct use benefits for recreational and commercial fisheries may result in many other types of benefits being omitted from the empirical estimates.

In regard to the comment that commercial shellfish were excluded from the analysis - this is not accurate for the final rule. Commercial shellfish were included in all regions, for all species that the available data permitted.

In the cost-benefit analyses for the NODA and for the final Section 316(b) Phase II rule, EPA did not use the 50% rule-of-thumb to estimate non-use benefits. As stated in the NODA, EPA agrees with the commenters that the 50% rule relies on outdated studies. For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. See Chapters A12, Non-use Meta-analysis Methodology, and A9, Economic Benefit Categories and Valuation Methods of the final Phase II Regional Studies Document (DCN # XX). Please see Chapter D1 of the final Phase II EBA document regarding break-even analysis.

Impacts to T&E species

We found EPA's consideration of threatened and endangered species to be a worthwhile, but limited, first step toward an analysis of this topic.

EPA Response

It is unclear in what way the authors believe EPA's consideration of threatened and endangered species to be limited. Please see the response to comments 316bEFR.077.008, 316bEFR.077.053 and 316bEFR.206.064.

Use of Replacement Costs (HRC and hatchery-based)

We supported EPA's efforts to develop "habitat replacement cost" (HRC) as a methodology for developing more complete and accurate benefits estimates, but cautioned that this methodology requires a level of biological information that is often unavailable.

EPA Response

As in many environmental assessment methods, data limitations can be a significant hurdle to successful implementation. As the commenter duly notes, biological data may not be readily available for broad application of the HRC approach to the full range of biological outcomes associated with I&E. However, the Agency is no longer applying the HRC approach as part of the 316b benefits assessment.

Benefit Estimation Methodology

What Changed in the NODA?

The NODA includes a number of adjustments in EPA's methodology. Some of these adjustments respond directly to our criticisms of the original analysis. However, additional methodological problems introduced in the NODA make it difficult to draw clear conclusions about whether EPA's analysis has, on balance, improved.

Important new elements that appear in the NODA include abandoning the outdated "rule of thumb" according to which nonuse benefits were formerly calculated as 50% of recreational use benefits; acknowledging the nonzero value of unlanded fish; and grouping several previously distinct categories of value together in a new "nonuse" category. However, there are also methodological setbacks, where EPA retreats from desirable features of its earlier analysis. For instance, EPA abandons the "Habitat Replacement Cost" method of estimating total ecosystem value; gives little indication of how it expects to calculate use benefits in six of the eight regions or nonuse benefits in seven of the eight regions; and does not attempt any calculation of the value of threatened and endangered species lost to impingement and entrainment in the NODA.

Due to these and other limitations, it is difficult to evaluate the changes in EPA's methodology represented in the NODA. In the absence of a completed national benefits analysis, it is not clear how benefits will be calculated for each region and for the country as a whole. For example, is EPA planning to perform analyses for all eight regions, comparable to the NODA estimates for the North Atlantic? If not, what method of extrapolation will be used to scale regional estimates up to a national total? Within regions, what methods will be used to scale estimates for individual plants up to regional totals? The reclassification of power plants, from waterbody-based categories in the original analysis to regional groupings in the NODA, means that category totals from the two analyses cannot be directly compared.

EPA Response

The commenter notes EPA's revisions to benefits assessment methodologies presented in the NODA. The commenter, however, states that "additional methodological problems introduced in the NODA make it difficult to draw clear conclusions about whether EPA's analysis has, on balance, improved." Specifically, the commenter criticizes EPA for abandoning the HRC method, presenting result for only two of the eight study regions, and not presenting any calculations of the value of threatened and endangered species lost to impingement and entrainment in the NODA.

For EPA's response to comments on the HRC method, please see response to comment #316bEFR.005.035.

For the final 316b rule analysis, the Agency developed benefit estimates for all study regions and presented calculations of the value of threatened and endangered species lost to impingement and entrainment for the region where impingement and entrainment data on special status species were available. See the Regional Analysis Document for the Final Section 316(b) Phase II Existing Facilities Rule for details (DCN #6-0003).

National Benefits

Despite these difficulties, we have made an approximate comparison of the NODA to the Economic Benefits Analysis (EBA) performed by EPA last year, by looking at the three plants in the North Atlantic region, Brayton, Pilgrim, and Seabrook, that were included in EPA's case studies for the EBA. We have compared the case study benefits for these three plants to the NODA benefits for the North Atlantic region as a whole, as shown in Table 1 (next page), using the average of high and low case benefit estimates throughout.

When benefits are expressed as dollars per cubic foot/second (cfs) of water flow, the North Atlantic regional benefits are now estimated at roughly $9,000 per cfs of flow. Since most of the region's plants (all but Pilgrim and Seabrook, in fact) are located on estuaries, the closest comparison may be to Brayton, the one North Atlantic estuary plant analyzed in the case studies. The benefit estimate for Brayton amounts to $10,350 per cfs, which is broadly comparable to the NODA value for the region as a whole. Thus we would guess, from the limited information available, that the NODA calculations introduce little change in aggregate estimated benefits. If this is the case, then the effort required to develop and implement the NODA methodology has little impact on the bottom line evaluation of policy options. While some problems in the analysis have been fixed from last year, other problems have been introduced. We showed last year that reasonable adjustments to the EBA methodology would produce much larger benefit estimates; we will demonstrate below that reasonable adjustments to the NODA methodology would likewise produce much larger benefit estimates for the North Atlantic, and thus presumably for the nation as a whole.

Table 1. Benefits/flow, North Atlantic region

[Please See hardcopy for table]

EPA Response

EPA notes this comment and notes that the methods used in the cost-benefits analyses to estimate commercial, recreational, and non-use benefits have changed. This alters the benefits estimates. Because the benefits for the proposed rule were estimated by water body type and benefits for the NODA and the final rule are estimated by region, they are not directly comparable to the results from the proposal.

Please refer to Dr. Ackerman's comments #316bEFR.014.004 and #316bEFR.014.005 as well as EPA's responses to those comments.

Benefit Estimation Methodology

NODA Benefits Analysis: Methodological Problems

In the NODA, EPA significantly revises the methodology it uses to calculate the expected benefits of the proposed ruling. However, the NODA includes only a fraction of the information that EPA itself considers to be relevant for the regulation. In our view, EPA has failed to develop a credible estimate of the benefits of the proposed regulation.

Our discussion of the NODA benefits analysis begins with issues of regional disaggregation and the role of meta-analysis. We then turn to the North Atlantic benefits estimates, where we focus on the missing categories of use value, the limited number of species included in the nonuse value analysis, and the geographical coverage of the nonuse value. Finally, we review some of the important categories of ecosystem value that are excluded from the NODA.

Among other points, we note that EPA's nonuse valuation of fish affected in the Peconic Bay estuary is highly incomplete; EPA inappropriately limits the geographic scope of its nonuse benefits analysis; and the NODA fails to consider key biological facts, including interdependence among species and precarious stock status for many populations. Minimal requirements for completing the analysis EPA has begun should include developing a use value for unharvested fish and completing the meta-analysis of existing studies on nonuse value. In addition, EPA must avoid placing an effective value of zero on categories of value the Agency does not have time or resources to analyze in detail.

EPA Response

For EPA's response to the issues listed in this comment see responses to the following comments: comment # 316bEFR.336.001 regarding appropriateness and completeness of information presented in the NDOA; comments 316bEFR.206.047 and 316bEFR.336.013 regarding missing benefit categories in the benefit costs analysis of the Section 316(b) Phase II regulation; 316bEFR.336.008, 316bEFR.336.009 regarding valuation of non-landed fraction of recreational and commercial fish species; comments 316bEFR.336.010 and 316bEFR.336.011 regarding the North Atlantic Benefits Estimates.

EPA did not consider fish population or food web dynamics in its I&E analyses for reasons explained in EPA's response to Comment 316bEFR.005.009. EPA agrees that many fish stocks are in jeopardy, but it was not the intent of EPA's analysis to evaluate the stock status of any commercial or recreational fishery species. EPA notes that fishery species represent only about 2% of I&E losses.

For the final 316b rule analysis, EPA has changed its assessment of non-use values. As stated in the NODA, EPA agrees with the commenters that the 50% rule relies on outdated studies. In response to public comments, EPA agreed to undertake an improvement to the benefits transfer used in the analysis of non-use benefits of the 316b rule presented at proposal. Specifically, EPA developed a more rigorous regression-based meta-analysis that allows for estimation of the relative influence of various study, economic, and natural resource characteristics on willingness to pay (WTP) for non-use benefits. The results of such a regression-based meta-analysis make it possible to predict non-use WTP for aquatic resource changes as a function of site characteristics, the magnitude of environmental improvements, and study design attributes. Chapter A12, Non-Use Meta-Analysis Methodology, in the regional study document prepared for the analysis for the final Phase II rule provides detail on the meta-analysis approach to estimating non-use benefits of the 316b rule (see DCN # 6-0003).

Valuing Forage Species (incl non-use and non-landed)

Regional disaggregation and meta-analysis

In the NODA, EPA discards its previous system of categorizing power plants by water body type, and instead divides the country into eight regions. The level of detail provided for the North Atlantic region, and for the partial analysis of Northern California, together with the absence of any nationwide generalizations or extrapolations from this data, suggests that most data must be developed separately for each of the eight regions. However, EPA considers only two regions in the NODA: the North Atlantic region and the Northern California region. Furthermore, EPA attempts a full accounting of benefits for the North Atlantic region only; for the Northern California region, EPA has not yet looked at nonuse benefits.

One of the areas that required substantial, and creative, analytical effort in the NODA was the estimation of nonuse values for the North Atlantic region, a topic we discuss below. Unfortunately, the disaggregated NODA methodology suggests that a new analysis at this level of complexity needs to be done seven more times, once for each region. EPA's analysis suggests, though it never states explicitly, that nonuse values must be estimated on a locally specific basis. However, sufficient data may not be available for some regions; will nonuse values be declared to be zero for such regions? On a deeper level, the need for region-specific nonuse studies reflects the dubious assumption (discussed below) that nonuse values are only important in the immediate vicinity of the affected ecosystems. On the more reasonable assumption that nonuse values apply over much wider areas, it would be appropriate to develop a common national methodology to supplement the regional approach.

One way to develop such a methodology is to conduct a meta-analysis of the numerous existing studies of nonuse values. Meta-analysis is a well-established research technique, used in many scientific and economic analyses to evaluate and combine the body of data and results contained in a range of similar studies; the expanded database allows researchers to develop greater confidence and precision in their results. EPA began, but did not complete, a meta-analysis of nonuse values of water resources for use in this case. We recommend that EPA complete that meta-analysis, and use it to support and contextualize national projections of nonuse value. The raw data provided by EPA, from its initial work on the meta-analysis, makes it clear that substantial nonuse values for water resources have been estimated, in several regions of the country.<FN 4> In addition, studies in other contexts consistently support the view that Americans place a high nonuse value on natural resources. Annual willingness-to-pay values for highly visible animals such as bald eagles, humpback whales, and gray wolves add up into the tens of billions; the existence of a less famous endangered species, the striped shiner, is reportedly worth an average of $6 per household per year to the American public, or more than $600 million annually on a nationwide basis.<FN 5> The clear lesson of these studies is that nonuse values are substantial; thus, for a benefits analysis to be complete, nonuse values must be estimated for all the affected organisms.

EPA Response

The Agency agrees that estimating non-use values is critical to obtaining comprehensive estimates of total resource value such that the resulting total value estimates may be compared to total social cost. For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN #6-0002).

EPA has responded to concerns regarding the Agency’s non-use valuation methods in responses to a number of comments. For EPA’s benefit transfer approach, please see EPA’s response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA’s meta-analysis please see EPA’s responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA’s meta-analysis. For EPA’s response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Valuing Forage Species (incl non-use and non-landed)

North Atlantic benefits – use values

For more detailed comments on the NODA benefit estimates, we now turn to the North Atlantic regional benefits, the only complete benefits analysis offered in the NODA. The benefits, as estimated in the NODA, consist of commercial use values, recreational use values, and nonuse values. While commercial and recreational benefits are of great importance, they are not the only use values that could and should be estimated.

Another category was omitted in both the earlier analysis and the NODA, namely the use value of the "unlanded" fraction of I&E losses. Estimates of commercial and recreational values are based only on the fraction of fish lost to I&E that would have been caught ("landed") in the absence of cooling water withdrawals. Normally only a small fraction of fish, even of the most valuable species, are caught by commercial and recreational fishing each year. In other words, most of the fish lost to I&E would have survived – and therefore are not included in estimates of either commercial or recreational value. The unlanded fish not only survive, but also reproduce, creating the fish that will be caught in future years. In effect, they are the natural capital of the fishing industry, analogous to the capital goods that are used in manufacturing.

The NODA recognizes that unlanded fish have a nonzero value (NODA, p. 13567), but focuses on their nonuse value; EPA does not propose a methodology for adequately estimating the use value of the unlanded fish. In our comments last year, we demonstrated that even a conservative estimate of the value of the unlanded fraction of I&E mortality has a large impact on total benefits.

EPA Response

As noted by the commenter, EPA's analysis indicates that the direct use benefits estimated for recreational and commercial fishery impacts reflect only a very small portion of the physical losses associated with impingement and entrainment (i.e., EPA's direct use benefits analysis reflects landed age 1 equivalent fish, and the I&E assessments reveal that these account for less than 2% of the individual fish lost to I&E, and over 98% of the physical loss are for the age 1 equivalent fish that not landed by recreational or commercial anglers).

Accordingly, a comparison of the estimated direct use benefits alone to compliance costs probably would be very incomplete and potentially misleading. Taking account of the beneficial values (to reflect the value of protecting the predominant share of the I&E-impacted fish) thus becomes a critical component of the benefit-cost analysis for this rulemaking.

There are several challenges – both conceptual and empirical – associated with trying to estimate the benefits of avoiding losses of fish that are not projected to be landed by commercial or recreational anglers. These issues have been discussed elsewhere in these responses to comment, on topic areas including nonuse value estimation and valuing forage species. A critical concern is that EPA try to reflect the value of unlanded fish in a logical and sound manner without either double-counting or omitting potentially important motives and sources of value.

Forage species are valued in part in the existing analysis through EPA's production foregone or trophic transfer approach, in which the losses in forage fish are converted into changes in the mass of landed recreational and commercial fish. Thus, forage fish are valued in part – but only to the extent that some fraction of forage fish that are spared from I&E due to the rule would be eaten by the specific individual fish ultimately landed by commercial or recreational anglers. This partial accounting of forage species value may only reflect a small fraction of the value of unlanded forage and other fish that benefit from the rule. For example, the forage fish spared by the rule (other than those ultimately consumed by a fish that is later landed) are likely to provide ecological and other value as well, but not through the landed biomass reflected in direct use benefit categories per se. The same point may arise for the recreational and commercially targeted fish spared by the rule from I&E, but that are not part of the landed fraction.

The issue raised by the commenter here is that some value should be assigned to the unlanded fraction. While some portion of the unlanded fraction is valued through the production foregone method as noted above (i.e., the forage fish that add biomass to the landed fish), there remains a large proportion of the physical impact of the rule that does not appear to be accounted for in the benefits analysis of direct use values. In large measure, this fact has led to the considerable discussion about how the Agency might best estimate nonuse values, since nonuse motives may be the category under which such values might be ascertained.

While the issue of potentially omitted benefits is a key concern for this rulemaking, it also is important to recognize the potential for inadvertent double counting when issues of "stocks" and "flows" become intermingled. This may arise, for example, when trying to consider the value of unlanded fish from the recreationally or commercially targeted species. The question is if and how one should value an additional striped bass (for example) that survives to harvest age because of the rule, where this specific individual fish is never landed by an angler. This added individual becomes part of the enlarged fish stock that presumably supports a larger annual harvest. EPA's approach to estimating direct use benefits of the rule is to focus on the "flow" concept of increased annual landings. An added fish that eludes harvest is not directly reflected in the flow values, but instead becomes part of the stock that enables the benefits of higher flows.

Please also see EPA's response to comments #316bEFR.336.009, #316bEFR.306.105, and #316bEFR.005.004; as well as Chapters A12, Non-use Meta-analysis Methodology, and A9, Economic Benefit Categories and Valuation Methods of the final Phase II Regional Studies Document (DCN #6-0003) and Chapter D1 of the final Phase II EBA document regarding break-even analysis.

Valuing Forage Species (incl non-use and non-landed)

Other important categories of value were also omitted, both in the EBA last year and in the NODA, as discussed on pp.11-13 below.

North Atlantic benefits – species included in nonuse value. In the analysis for its Phase II proposal, EPA developed an estimate of nonuse value by using the outdated "50% rule." This rule arbitrarily sets nonuse value equal to half of the use value enjoyed by recreational users of a resource. As we have previously discussed, <FN 6> in many cases nonuse value is likely to be significantly higher than this figure. Furthermore, it is misleading to develop a nonuse value estimate that refers solely to the recreational users of a resource, since many of the people who place a nonuse value on natural resources are not, in fact, recreational users.

In the NODA, EPA develops an estimate of nonuse value for commercially and recreationally harvested fish, as well as for forage fish and the unharvested portion of the harvestable population. This estimate is based on a willingness-to-pay (WTP) study of values placed on submerged aquatic vegetation (SAV) and wetlands in the Peconic Estuary. EPA's attempt to develop nonuse value estimates on the basis of the Peconic Estuary WTP study is a significant improvement over the arbitrary application of the 50% rule, but still presents serious problems. In particular, SAV and wetlands can serve to regenerate some species of fish, but are inappropriate habitats for others. Thus, some species are not accounted for by a system in which SAV and wetlands are used as a proxy for fish abundance. Furthermore, data limitations forced EPA to base its analysis on a minority of the species that can regenerate in SAV or wetlands; other species might have greater requirements for SAV and wetlands.

EPA's analysis is based on I&E data collected at the Brayton Point and Pilgrim power plants. These data show levels of I&E losses for 37 fish species; apparently EPA did not consider non-fish aquatic organisms in this analysis. EPA attempted to estimate the amount of wetland and/or SAV habitat required to offset I&E losses of these fish species, "based on the amount of habitat necessary for a few species that could benefit from restoration of SAV and wetlands." Of the 37 fish species considered, "losses of seven species could be offset by tidal wetland restoration, and losses of six species could be offset by SAV restoration." EPA notes that these 13 species account for 45.7% of the total I&E losses in the North Atlantic Region.<FN 7> The Agency apparently makes no attempt to calculate nonuse values for the other 24 affected species, accounting for more than half of the region’s I&E losses.

Of the 13 fish species for which wetland and SAV restoration could be relevant, EPA was able to obtain sufficient information to proceed with the analysis for just six species: winter flounder, Atlantic silverside, and striped killifish as candidates for benefiting from wetland restoration, and threespine stickleback, northern pipefish, and scup for SAV restoration. EPA had no data on production rates in the relevant habitats even for these species, so the Agency estimated densities per acre based on abundance data. No abundance data were gathered for the remainder of the 13 species, which include some of the best-known and most valuable ones: American sand lance, grubby, striped bass, bluefish, Atlantic cod, weakfish, and pollock.<FN 8>

In summary, in the attempt to generate data on the nonuse value of the fish lost to I&E in the North Atlantic region – losses that include at least 37 species – EPA estimated the relationship between acreage of two habitat types and likely density of just six fish species. EPA conducted no analysis whatsoever for the other affected species, even though well-known species such as striped bass, bluefish, and Atlantic cod are likely to have substantial nonuse values.

Having estimated area requirements for three species per habitat type (three for wetlands and three for SAV), EPA bases its final analysis on the species that, of each set of three, have the highest area requirements for regeneration. EPA expresses concern that this overstates the acreage required for the other two species for which calculations (in the same habitat type) have been done. But the greater concern is the potential understatement of requirements: there is no way of knowing whether EPA's calculation accurately represents the requirements for regeneration of the seven other species for which wetlands and SAV are relevant; and it explicitly does not include the other 24 species identified in the region's I&E mortality data, ones that cannot be regenerated by these habitats. Nor, of course, does EPA's analysis attempt to measure the value of losses of nonfish species, such as shellfish or smaller, but nevertheless vital, components of the aquatic food web.

Given these large omissions, EPA should, at the very least, state what percentage of total nonuse value for the region it has analyzed and multiply its results by a corresponding factor. For example, does the nonuse value calculated for the Peconic Bay estuary represent an appropriate value for 6 out of 37 species, or about one-sixth of the species identified in I&E loss data? It may be difficult for the Agency to estimate what fraction of the affected fish it has accounted for in its analysis, but if the Agency fails to factor in those it has not accounted for, it has, once again, effectively placed a value of zero on many affected organisms.

Footnotes

6 See Ackerman comments on the proposed rule, August 1, 2002.

7 DCN 5-1010: Tudor, et al., "Estimating Total and Non-Use Values for Fish, Based on Habitat Values for Coastal Wetlands and Eelgrass (SAV)," memo to the 316(b) record, March 12, 2003, p. 3.

8 Ibid., p.4.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

EPA recognizes that not all species and organisms are included in the restoration-based non-use value analysis and that, therefore, the estimates presented may be understated. However, habitat restoration will benefit other species and organisms to some degree, although which species will be affected and by how much is not known. Thus, it would be difficult to multiply results by a particular factor in order to account for these species and organisms.

Valuing Forage Species (incl non-use and non-landed)

North Atlantic benefits – geographical scope of nonuse benefits

EPA then converted estimates of required habitat areas into dollar values on the basis of a survey in which people were asked how much they value wetlands and SAV. The researchers did not tell respondents which fish the wetlands and SAV were expected to regenerate, so responses presumably reflect respondents' general impressions about fish populations, rather than values placed on individual species.

EPA examines two overlapping populations that may place a nonuse value on the aquatic resources of the North Atlantic region -- the 3.65 million households located in the counties abutting affected water bodies, and the 4.2 million households living within a 32.4 mile radius of the affected water bodies. The Agency develops both total and per-household value estimates for each of these areas. Using the households in abutting counties, EPA calculates "a total WTP to reduce impingement and entrainment losses of $4.07 to $7.83 and non-use WTP of $3.44 to $6.52 per household residing in the counties abutting affected water bodies." Using the larger area, with the 32.4-mile radius, EPA finds that "implied WTP values to reduce all I&E losses range from $5.63 to $23.43 and non-use WTP range from $5.61 to $21.83 per household residing in the 32.4 mile-radius area." <FN 9>

It is well known that people living a significant distance from a resource can still value that resource. For example, people throughout the US placed a substantial nonuse value on the ecosystems damaged by the Exxon Valdez oil spill – even though Prince William Sound was hardly a household word before the spill occurred.<FN 10> The Grand Canyon has a powerful meaning to people who live outside Arizona; Yellowstone is important to people who live far from Wyoming. There is no reason to think that the aquatic resources of the North Atlantic region are an exception to this pattern. Indeed, both the Atlantic and the Pacific coasts of the US are generally considered to be a national resource and birthright. Schoolchildren across the country – not just in coastal communities – sing about “America the beautiful” stretching “from sea to shining sea.” All of this suggests that Americans across the country place a nonuse value on coastal ecosystems.

A model for the analysis of nationwide nonuse values for a local resource can be found in the early work of Robert Stavins. It provides an interesting contrast to his recent criticism of EPA’s treatment of nonuse value (and his criticism of our earlier comments on the subject). In 1984 Stavins was the principal author of a cost-benefit analysis of a proposed hydroelectric development on the Tuolumne River, in California.<FN 11> The analysis, which showed that the benefits of development were less than the costs, helped to defeat the proposed dam and to preserve the river in its natural state for recreation. The nonuse benefits of preserving the river were crucial to Stavins’ analysis; without those benefits, his calculations would have strongly favored development.

Stavins argued that it was not surprising that the nonuse value of the Tuolumne was large:

In the case of environmental resources, the so-called nonuser or intrinsic benefits may represent a substantial portion of the resources' total value. <FN 12>

He employed a ratio of nonuse to use value, derived from other published studies, to estimate the per-capita nonuser value. Stavins' next step was to multiply the per-capita nonuser value "by an estimate of the number of people in various regions of the country who are likely to" assign a nonuse value to the resource.<FN 13> His estimate of the number of "interested nonusers," as he called them, was the entire California membership of the Sierra Club (some of whom lived hundreds of miles away from the Tuolumne), plus half of the membership of the Sierra Club in the other 49 states. His calculations assigned a sizeable nonuse value to each of these individuals, even those who lived across the continent from the Tuolumne.

Alternatively, he discussed public opinion surveys suggesting that 40% of the US population feels strongly about the preservation of wilderness, and pointed out that his total nonuser benefit estimate could also be the result of 40% of the US population having a willingness to pay to preserve the Tuolumne of just $0.33 per person per year. After calling for more research to determine the nonuse value more directly, he concluded that

In the meanwhile, however, these estimates represent, at the very least, a reasonable first approximation… [nonuse value] is too important to be ignored. <FN 14>

Following the example of Stavins' early work, we recommend that EPA reconsider its restriction of nonuse value to the population living very close to the plants in question. Suppose, for instance, one accepted EPA's nonuse value for the population in bordering countries, and also assumed that the use value per household in the rest of the country is even 10% as high as in the bordering counties (or alternatively, one could assume that 10% of the households in the rest of the country have a non-use value as high as those in the bordering counties). <FN 15>

There were 106.3 million households in the United States in 2001.<FN 16> Of these, 3.7 million lived in the counties bordering the North Atlantic facilities in question, and 102.6 million lived elsewhere. According to the NODA, the nonuse WTP to eliminate all I&E losses was $20.73 to $33.97 per household in the bordering counties.<FN 17> Thus, our 10% assumption implies that the nonuse WTP for the 102.6 million households in the rest of the country was $2.07 to $3.40 per household; this implies a total nonuse WTP, beyond the bordering counties, of $212.4 to $348.8 million. As shown in Table 2, this adjustment more than triples the total value of baseline losses due to North Atlantic I&E.

Table 2. Value of North Atlantic Baseline Looses

[Please see hard copy for table]

As Stavins accurately observed in 1984, the effect of nationwide nonuse value is too important to be ignored.

EPA Response

EPA agrees that the extent of the market could be larger than that used in its analysis. See EPA's response to comment 316bEFR.311.017 regarding the effect of distance on WTP for non-use values.

The Agency, however, relied upon empirical evidence to determine what the Agency believes is a reasonable and conservative estimate of the affected population. EPA believes that it has conservatively estimated the extent of the affected population in the study area based on households in counties abutting the affected water body, and households within 32.4 miles of the affected water body. The 32.4 mile figure was chosen based on results from the Rhode Island wetlands study. This study showed that Rhode Island residents who live in the most western parts of Rhode Island and as far as 32.4 miles from Narragansett Bay value wetland restoration in the Bay (see Chapter C6 the final Phase II Regional Studies Document, DCN # 6-0003).

Regional Benefits Approach

Author Name Frank Ackerman & Rachel Massey

Organization Global Development and Environment Institute

Ecosystem values omitted from the NODA

As in EPA's earlier analysis, the NODA omits important categories of ecosystem value – many of them acknowledged and listed by EPA itself. Thus the calculation of benefits of reduced cooling water take is necessarily incomplete; even if EPA had completed a cost-benefit analysis along the lines of the NODA, a comparison of complete costs with such incomplete benefits would be of little value in evaluating public policy options.

EPA notes that it has no information on the stock status of many of the species affected by I&E. For the North Atlantic region, EPA reviews the information available on stock status of 25 stocks (15 species) of groundfish, noting whether a given stock is "subject to overfishing (the harvest rate exceeds threshold)" or "overfished (stock size is below threshold)." Of these 25 stocks, fully 15 are categorized as "currently subject to overfishing," "overfished," "approaching an overfished condition," and/or "in an unknown condition with regard to overfishing." <FN 18>

Thus, more than half of the groundfish stocks considered are in a condition such that, as far as EPA knows, further I&E losses could conceivably drive the population down to zero. While this will presumably not occur for all the listed stocks, a complete quantification of the baseline losses should include the possibility that a given stock of precarious (or unknown) status could be destroyed by continued I&E. Just as cost estimates include the possible shutdown of plants subject to regulation, benefit calculations should include some calculation of the probability that a population will collapse.

Footnotes

18 NODA, p. 13549.

EPA Response

Data are unavailable to estimate the probability of stock collapse for the commercial and recreational fishery species included in EPA's analysis. Such analysis is beyond the scope of this rulemaking.

EPA acknowledges that its estimates of monetized benefits is incomplete. For a discussion of omitted benefits categories, please see response to Comment 316bEFR.206.047. For a discussion of the benefit-cost test, please see response to Comment 316bEFR.005.020.

Benefit Estimation Methodology

To be complete, a benefits analysis should consider all the organisms harmed by I&E losses. Like the analysis conducted for the original ruling, however, the NODA includes no attempt to quantify the value of damage inflicted on birds, or on fish-eating mammals. The NODA also does not look at ecosystem services provided by other organisms likely to be affected by I&E, such as small invertebrates. According to the scientists at Pisces Conservation, important services provided by aquatic ecosystems as a whole include recycling of human waste in waters close to human habitation; demobilization and detoxification of chemical waste products; stabilization and accumulation of sediments, preventing soft sediments from producing turbidity and sedimentation of channels; and support to terrestrial ecosystems (including exportation of biomass from water to the land via invertebrates, birds, and mammals).<FN 19>

Footnotes

19 Pisces Conservation, Ltd., Technical Evaluation of US Environmental Protection Agency's Proposed Phase II Cooling Water Intake Regulation for Existing Facilities (including Comments on NODA), June 2003.

EPA Response

EPA agrees with the commenter that there are many potentially important indirect ecosystem effects resulting from the loss of impinged and entrained fishes. Unfortunately, data are generally not available for quantifying such potential impacts. Nonetheless, EPA has not ignored this issue. Chapter A4 of the Regional Analysis Document (DCN 6-0003) discusses potential direct and indirect I&E effects on birds, Chapter A3 discusses I&E of organisms other than fish, and Chapter A9 discusses the many ecosystem services provided by fish in addition to commercial and recreational fishing and other direct use benefits.

Regional Benefits Approach

Author Name Frank Ackerman & Rachel Massey

Organization Global Development and Environment Institute

EPA gives some attention in the NODA to non-fish species such as lobsters and shellfish, but does not explore fully the range of possibility for these species. For example, EPA discusses the high-value lobster fishery of the North Atlantic region and notes that this fishery is currently subject to severe overfishing. However, EPA does not appear to factor into its analysis the possibility that the lobster fishery could collapse due to continued combined pressure from harvesting and from I&E losses. EPA notes that "the Northeast lobster fishery is second in commercial value after the multispecies groundfish fishery," <FN 20> so the Agency's decisions about how to analyze this population's fate are significant.

Footnotes

20 NODA, p. 13550

EPA Response

EPA was able to identify data on I&E losses of lobster at the Millstone facility only, and the data were insufficient for developing estimates of age 1 equivalents, foregone yield, and production foregone, and therefore could not be included in EPA’s analysis. However, future, more detailed I&E monitoring for permitting purposes will help to fill such information gaps.

EPA methods: age 1 equiv, yield, prod foregone

By its own admission, EPA consistently underestimates the number of fish lost to I&E.<FN 21> Many of the data on which EPA bases its estimates are outdated, and were collected during a period when some fish stocks were severely depleted. Furthermore, even current data are misleading with regard to total baseline I&E losses, because many fish stocks have been depleted, for instance by years of continual I&E losses. If initial stocks were at natural levels unaffected by past and present I&E, estimated baseline losses would be higher.

In order to quantify the effects of I&E losses on aquatic ecosystems, an analysis must take into account the full range of trophic interactions. Boreman (2000) emphasizes that all fish in an ecosystem, including those considered "surplus," have ecological significance, noting that "use of 'surplus' production is essentially an allocation issue among competitors for that resource." Thus, 'surplus' can be used "for supporting fisheries, for allowing the population to hedge against bad times, for providing extra sustenance for natural predators, or for supporting other uses of the resource." <FN 22>

Link (1999) describes several trophic phenomena that should be taken into account in analyzing the likely effects of anthropogenic damage to fish populations. One of these is the phenomenon of cycles, in which species A feeds on species B at one life stage, while B feeds on A at another life stage. These cycles can lead to "stock bottlenecks" and can create a negative feedback loop as populations change. Likewise, cannibalism, in which fish consume younger members of the same species, can also interact with these cycles to create negative feedback loops. Link constructs a simplified model of the food web in the northwest Atlantic system in which humans are just one of 75 distinct nodes (some of which represent tens or hundreds of individual species, as Pisces explains in their NODA comments). Link emphasizes the "stochastic nature of this ecosystem" and the "consequent uncertainty in the predictions...." emerging from a system with complex dynamics.<FN 23> Strictly speaking, if we are to correctly carry out the goal of quantifying the benefits of saving an aquatic ecosystem, all the elements of Link's model should be examined and traced through to a service that can be quantified and valued. Examining all these elements may well be an impossibly or impractically large task; once again, this problem highlights the difficulty of using a flawed methodology to develop policy.

Footnotes

21 See 316(b) Phase II Economic Benefits Analysis, Part C: National Benefits, Chapter C1: Case Study Introduction, Section C1-5.1: Data Limitations. Available at http://www.epa.gov/waterscience/316b/econbenefits/c1.pdf. EPA notes: "EPA's analysis is based on facility-provided biological monitoring data. These facility-furnished data typically focus on a subset of the fish species impacted by I&E, resulting in an underestimate of the total magnitude of losses. ... The facility-derived biological monitoring data often pertain to conditions existing many years ago (e.g., the available biological monitoring often was conducted by the facilities 20 or more years ago, before activities under the Clean Water Act had improved aquatic conditions.) In those locations where water quality was relatively degraded at the time of monitoring relative to current conditions, the numbers and diversity of fish are likely to have been depressed during the monitoring period, resulting in low I&E. In most of the nation's waters, current water quality and fishery levels have improved, so that current I&E losses are likely to be greater than available estimates for depressed populations."

23 Link, J.S., 1999, (Re)Constructing Food Webs and Managing Fisheries, in Ecosystem Approaches for Fisheries Management, Alaska Sea Grant College Program, AK-SG-99-01, at p.10.

EPA Response

EPA notes that fish abundances and I&E rates at particular sites may have increased, decreased, or stayed the same as rates reported in older studies depending on the many factors that influence fish populations.

EPA agrees that food webs are complex and multiple trophic interactions must be considered in evaluating ecosystem-level dynamics. Since such information is generally lacking, EPA did not attempt to conduct such analyses for its 316b Phase II rulemaking.

Commercial Fishing Benefits

The NODA relies on other questionable methodologies as well. The grounds for discounting future environmental benefits are debatable; underwater ecosystems are not financial assets that can be consumed or saved, depending on an investor's rate of time preference.<FN 24> The calculation of producer surplus, an important part of the estimated use value of fish killed by I&E, is based on a "rule of thumb" derived from just a few published studies – and is now estimated to be significantly smaller than in the EBA.<FN 25> While these points do not have a large impact on the overall benefits estimate in the NODA, they are worth noting for future analyses.

Overview of I & E effects on organisms

Responses to Stavins Comments

In comments submitted in this docket, dated April 21, 2003, Dr. Stavins (who is now commenting on behalf of PG&E Energy Systems) responds in detail to our earlier comments on EPA's original cost-benefit analysis. Stavins repeatedly asserts, on the basis of his personal judgment, that we have confused positive and normative analysis or otherwise misunderstood basic principles of economics. Many, though not all, of the issues he raises remain relevant to the NODA. A point-by-point response is inappropriate here; suffice it to say that we continue to disagree on numerous aspects of the substance of the analysis, some of them discussed above.

Perhaps our most important disagreement concerns the magnitude of the environmental damages at stake. See, for instance, Stavins' statement that it was appropriate for him to estimate little or no nonuse value because only "incremental changes in the populations of various aquatic species" are involved in this case (April 21, 2003 letter, p.10, emphasis in original). Since EPA is valuing individuals, not populations, all the changes being analyzed are in a sense "incremental," though perhaps fairly big increments in some cases. Stavins' wording on this subject suggests a prior judgment that the increments at stake are, in fact, all so small that their nonuse value can be ignored.

EPA Response

As noted in responses to numerous other comments on issues related to this topic, EPA's analysis indicates that there are a large number of individual organisms that are impacted by I&E, and that only a small fraction (e.g., 2%) are directly captured in the benefits analysis that focuses on direct use values for recreational and commercial angling. EPA agrees with the comment made here that it is not possible to dismiss nonuse values as irrelevant. It also is not possible to state factually and definitively that the impacts are so small on a population basis (or even an individual basis) that this would make nonuse values trivial or irrelevant. This remains an open, empirical question.

Stated preference (Contingent Valuation)

Author Name Frank Ackerman & Rachel Massey

Organization Global Development and Environment Institute

We also want to respond briefly to Stavins' unfounded claims about the economics profession, and the extent of dissent within it. In effect, Stavins asserts that all reputable economists agree with him, and rejects our statements about the extent and influence of dissenting voices within the profession. To cite only the most important example, we mentioned that Amartya Sen, a recent Nobel laureate in economics (and the source of many provocative, innovative new approaches), rejected the idea of individual willingness to pay as a measure of the value of major environmental problems, because a rational individual's willingness to pay depends on what others are doing. Stavins suggests that we misinterpreted Sen, who, he says, was merely making a minor technical point about the free rider problem in the provision of public goods. Here is what Sen actually said on the subject:

The philosophy behind contingent valuation [CV] seems to lie in the idea that an environmental good can be seen in essentially the same way as a normal private commodity that we purchase and consume. The valuation that is thus expressed is that of achieving single-handedly – this is crucial – this environmental benefit. Consider, for example, a case in which it is inquired how much I would pay to save all the living creatures that perished as a result of the Exxon Valdez disaster, and I say $20. As interpreted in CV, it is now presumed that if $20 paid by me would wipe out altogether all these losses, then I am ready to make that payment. It is hard to imagine that this question and answer can be taken seriously by any practical person (with some idea of what the Exxon Valdez disaster produced), since the state of affairs I am asked to imagine could not possibly be true. <FN 26>

Footnotes

26 Amartya Sen, "The Discipline of Cost-Benefit Analysis," Journal of Legal Studies 29 (2) part 2, June 2000, 931-952, quote from 948.

EPA Response

EPA acknowledges that there are many debates within the economics and related professions regarding the best way to design and implement a stated preference (SP) survey instrument, and that writing an SP instrument to pose realistic questions is a challenge. There is some debate on how reliable the findings would be from such an effort. Overall, however, well conceived and designed SP research has provided useful and credible results in many areas. The SP approach is widely recognized and accepted, if the application is done well. Please see response to comment 316bEFR.306.105 for additional information and discussion.

Use cost-benefit tests

Conclusion: The Need For Alternative Approaches

Comparison of costs and benefits is not a necessary part of the decision about regulation of cooling water intake systems. The language of the Clean Water Act does not require cost-benefit analysis; rather, like many other environmental statutes, it sets forth technology and performance-based standards for protection of our natural environment. Retrospective analysis has shown that technology-based regulation is not always the economic disaster that regulatory critics sometimes suggest. For example, a massive, peer-reviewed study found that the first twenty years of the Clean Air Act had monetized benefits of more than $20 trillion, or more than 40 times its costs. <FN 27>

It is fortunate that good decisions can be made without cost-benefit analysis, because it is so often necessary. The problems we have cited in the analysis of the benefits of regulating cooling water intake systems are similar to problems that arise in many cost-benefit studies. Many costs are readily monetized, while many of the benefits of protecting life, health, nature, and future generations are, literally, priceless – not infinite in value, but rather, incapable of meaningful monetization.<FN 28> A broader, multi-dimensional approach to decision-making is required to reflect society's true preferences in such cases; technical economic analysis alone cannot reliably produce the right answers to questions of regulation and environmental protection.

Benefit Estimation Methodology

Here we restrict our attention to a narrower question of alternative methods: when a comparison of costs and benefits is desired, what methods should be used? In our previous comments, we recommended that EPA abandon the impossible effort to calculate monetary values for all relevant benefits and costs of regulatory options. Instead, we recommended that the Agency simply calculate the cost per household of implementing regulations to protect aquatic ecosystems. These cost calculations could then allow a comparison of aggregate (largely monetized) costs and aggregate (largely non-monetized) benefits. The aggregate comparison of dissimilar categories of value is more sensible than the attempt at disaggregation and monetization of every conceivable benefit. The aggregate comparison recognizes the broad political and social, as opposed to narrow, technical and economic, nature of decisions about protection of natural resources.

EPA Response

The comment recommends that EPA calculate cost per household of implementing regulations. The Agency did present the cost per household of implementing regulations to protect aquatic ecosystems and considered this information in evaluating alternative policy options. See Chapter B2, of the final Section 316(b) Phase II EBA document for detail (DCN #6-0003). In addition, the Agency used the breakeven analysis for the final Section 316(b) Phase II rule. The breakeven analysis calculates the annual value of non-use benefits that would need to be held on average by households in the defined benefit region in order for the final Section 316(b) Phase II rule's total benefits (annual use plus nonuse values) equal or exceed the estimated annual social costs of compliance. EPA then compared the calculated breakeven values to the per household non-use values that were found in the empirical literature. See Chapter D1 of the final Section 316(b) Phase II EBA document for detail (DCN #6-0002).

Organization Global Development and Environment Institute

Subject Matter Code 10.02.04

Valuing Forage Species (incl non-use and non-landed)

The "break-even" methodology that EPA proposes in the NODA is a promising start in this direction, but does not go far enough. Recognizing that it is far easier to estimate complete costs than complete benefits, the break-even calculation identifies the cost per household of regulations. However, this cost is presented in the NODA as a hurdle that has to be cleared by the data-intensive calculation of benefit values. We recommend that EPA go further, presenting costs per household of different regulatory options as key inputs into public decision-making. These costs could be accompanied by quantitative and qualitative descriptions, in natural units (e.g., numbers of various species of fish killed, not hypothesized monetary values of those fish), of the benefits of regulation – a vastly simpler task than the NODA agenda of monetization, or even last year's cost-benefit calculations. Under our method, there would undoubtedly still be controversy about the details of the cost calculations, and of the description of benefits - but these would be far simpler, more transparent and manageable disputes than the ones surrounding cost-benefit analysis.

EPA Response

EPA's approach to benefit cost analysis of the final Section 316(b) Phase II rule is consistent with principles outlined in the EPA's Guidelines for Preparing Economic Analyses, United States EPA (EPA 240-R-00-003). The Agency agrees with the commenters that looking at the costs of the regulation on a per household basis is a useful tool in the regulatory process.

The cost per household of implementing regulations to protect aquatic ecosystems can be found in Chapter B2 of the final Section 316(b) Phase II EBA (DCN #6-0002). In addition, the Agency presents a breakeven analysis for the final Section 316(b) Phase II rule. The breakeven analysis calculates the annual value of non-use benefits that would need to be held on average by households in the defined benefit region in order for the final Section 316(b) Phase II rule's total benefits (annual use plus nonuse values) equal or exceed the estimated annual social costs of compliance. EPA then compared the calculated breakeven values to the per household non-use values that were found in the empirical literature. See Chapter D1 of the final Section 316(b) Phase II EBA for detail.

For EPA's response to comments on breakeven analysis please see comment #316bEFR.306.106.

Organization Global Development and Environment Institute

Subject Matter Code 10.02

Benefit Estimation Methodology

The ultimate problem is that the conventional methodology of cost-benefit analysis, no matter how carefully performed, is still a conceptually flawed and inadequate method. As Robert Stavins eloquently expressed it in his Tuolumne analysis,

When particular categories of benefits and/or costs are systematically excluded from an economic assessment, benefit-cost analysis loses its value as an aid to societal decision-making… The B/C [benefit-cost] criterion is neither a necessary nor a sufficient condition for project investment… What is crucial to keep in mind is that the benefit-cost criterion should not be used as an absolute decision rule… Public-policy decisions regarding the use of the nation's scarce natural resources are ultimately political decisions, and should remain so. <FN 29>

In the words of Amartya Sen,

When all the requirements of ubiquitous market-centered evaluation have been incorporated into the procedures of cost-benefit analysis, it is not so much a discipline as a daydream. If, however, the results are tested only in terms of internal consistency, rather than by their plausibility beyond the limits of the narrowly chosen system, the glaring defects remain hidden and escape exposure.<FN 30>

Footnotes

29 "Tuolumne River," 16, 31, 32, 101.

30 Sen, "Discipline of Cost-Benefit Analysis," 952.

EPA Response

This comment is a philosophical one centered on the overall validity of benefit-cost analysis. For discussion of cost benefit as a decision-making rule, see response to comment 316bEFR.005.020.

EPA's approach to benefit cost analysis of the final Section 316(b) Phase II rule is consistent with principles outlined in the EPA's Guidelines for Preparing Economic Analyses, United States EPA (EPA 240-R-00-003).

Comment ID 316bEFR.336.023

Author Name Frank Ackerman & Rachel Massey

Organization Global Development and Environment Institute

Subject Matter Code 10.02

Benefit Estimation Methodology

In conclusion, we regret that the limited scope of the NODA prevents us from commenting fully in advance of the final rule. The lack of information in the NODA creates a serious lack of transparency in EPA's decision-making process; we have no way to examine or evaluate the calculations that will, presumably, form the basis for EPA's final ruling. We recommend first, recognition that comparison of costs and benefits is not the only way to make good decisions, nor is it the method of decision-making set forth in the Clean Water Act. Second, when comparisons of costs and benefits are desired, we recommend that an alternative method of comparison be adopted, building on the foundation of EPA's break-even calculation and comparing monetary costs to environmental benefits. In our view, this will highlight the vast ecological benefits available from strict regulation of cooling water intake systems, at a very modest nationwide average cost – a bargain we believe the American people should, and would, accept.

EPA Response

Although EPA presents benefit calculations for just two regions of the country in the NODA, benefit estimates were developed for all study regions for the final 316b rule analysis. See the Regional Analysis Document for the Proposed Section 316(b) Phase II Existing Facilities Rule for detail (DCN #6-0003).

Economic considerations should be considered with other factors in making decisions. EPA has significant discretion in weighing overall costs and benefits in evaluating various policy options. For detail on application of the cost-benefit test to assessing the value of alternative CWIS technologies, please see EPA's response to comment #316bEFR.005.020.

For EPA's response to comments on breakeven analysis, please see response to comment #316bEFR.306.106.

The Agency agrees with the commenter that the expected ecological benefits of the final Section 316(b) Phase II regulation are likely to outweigh its costs.

Response to Public Comment

---National Pollutant Discharge Elimination System---
Regulations Addressing Cooling Water Intake Structures for Phase II Existing Facilities

(40 CFR Parts 9, 122, 123, 124, and 125)

Response to Comments Submitted by:

Elsie N. Zoli

On Behalf Of:

Goodwin Procter obo Entergy

Comment ID 316bEFR.337.001

Author Name Elsie N. Zoli

Organization Goodwin Procter obo Entergy

Subject Matter Code 2.01

Authority to modify 40 CFR

THE NODA, WHICH WOULD APPLY 316(B) TO EXISTING ELECTRIC-GENERATING STATIONS, IS ULTRA VIRES.

As Entergy discussed in its initial comments, the single-sentence mandate of 316(b) provides in its entirety:

Any standard established pursuant to section [301] or section [306] and applicable to a point source shall require that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact.

CWA, 316(b), 33 U.S.C. 326(b).

In the NODA, EPA does not respond to Entergy's initial comments questioning EPA's purported "legal authority" for the Rule. See 67 Fed. Reg. at 17124-27; 68 Fed. Reg., passim. Rather, EPA merely asserts without support that it intends to implement the Rule through N/SPDES permits.<FN 2>

Section 316(b) Does Not Apply to Existing Facilities, Absent Significant Modification of Such Facilities' CWISs.

Section 316(b), by its express terms, is not applicable to existing facilities with CWISs.<FN 3> Rather, 316(b) mandates a one-time, pre-construction review of the "location, design, construction, and capacity" of a CWIS. See CWA 316(b), 33 U.S.C. 1326(b) (emphasis supplied). All of these terms - whether the "location," "design," "construction" or "capacity" -correlate to initial construction of CWIS, but are not reasonably applicable once construction has been completed. As such, they cannot reasonably be construed as parameters subject to ongoing post-construction review. Further, they must be considered together, as the conjunction "and" requires, undermining EPA's selective reliance on ''capacity" to support the Rule and the NODA.

The structure of the Act, particularly the absence of ongoing enforcement mechanisms for 316(b), confirms that 316(b) is a one-time, pre-construction provision. EPA has no right to enforce 316(b) after a pre-construction determination is made (as already has occurred for every existing facility). See CWA 309(a), 33 U.S.C. 0 1319(a) (indicating that EPA may enforce in a state-issued permit only 33 U.S.C. 1311, 1312, 1316, 1317, 1318, 1328 or 1345, not 1326); CWA 309(b), 33 U.S.C. 1319(b) (federal enforcement coincident with 1319(a)). Likewise, the citizen-suit provisions of the Act contemplate enforcement of ongoing discharge limitations, but not the pre-construction concerns of 316(b). See CWA 505(a, f), 33 U.S.C. 1365(a, f) (allowing citizens enforcement only of effluent limitations, or EPA or state orders relating to effluent limitations, and specifically defining effluent limitation without reference to 33 U.S.C. 1326(b)). This absence of enforcement mechanisms for 316(b) is irreconcilable with a continuing N/SPDES requirement or effluent limitation, for which EPA and citizens retain considerable enforcement rights.

Rather, the structure and language of 316(b) mirrors the pre-construction mandates of the National Environmental Policy Act, 42 U.S.C. 4331, et seq. ("NEPA"), and any number of state analogues. See, e.g., 42 U.S.C. 4332 (requiring, for "major Federal actions" significantly affecting the quality of human environment, an assessment of "environmental impacts" and "adverse environmental effects," among other factors); 40 C.F.R. 1508.18 (defining "major Federal action" to include "approval of specific projects, such as construction or management activities . . . ."); State Environmental Quality Review Act ("SEQRA"), N.Y. Envtl. Conserv. Law 8-0109(2) (requiring an assessment for any action that may have significant adverse effect on environment); 6 N.Y.C.R.R. 617.2(b)(l) (defining action to include "projects or physical activities, such as construction or other activities, that may affect the environment by changing the use, appearance, or condition of a natural resource or structure . . . ."). The gravamen of these laws - each similar to 316(b) - is that they apply to proposed projects or certain qualifying expansions, not to existing facilities.

The clarity of the Act avoids any need to consult the legislative history. Nonetheless, it is clear from that history that Congress never contemplated that the "location, design, construction, and capacity" of CWISs for electric-generating stations - infrastructure that may cost tens to hundreds of millions of dollars to locate, design and construct - would be subject to relocation, redesign, reconstruction and reconfiguration at every five-year N/SPDES-permit-renewal cycle. See CWA 316(b), 33 U.S.C. 1326(b) (emphasis supplied). More particularly, in 1971, then-Senator Charles Mathias asked then-Senator Edmund Muskie, a 316(b) proponent, whether, in light of the EPA's attempts to require "new steam electric power plants" to build cooling towers, every power facility "to be built anywhere in the United States in the future would have a cooling tower." 117 Cong. Rec. 38855 (1971) (statement of Senator Mathias) (emphasis supplied). Senator Mathias's question demonstrates that Congress understood that, at the time of 316(b)'s enactment, 316(b) was limited to new facilities, i.e., those "new" facilities "to be built" sometime "in the future." Id. (emphasis supplied). Senator Muskie did not disagree, undoubtedly because he also believed that 316(b) did not apply to existing facilities.

Footnotes

2 EPA implicitly has recognized that 316(b) does not fall within the legal limits of EPA's (or states') authorization to issue N/SPDES permits under 402 of the CWA. See, e.g., 67 Fed Reg. at 17125 ("N/SPDES permits restrict the types and amounts of pollutants, including heat, that may be discharged from various industrial, commercial, and other sources of wastewater.") (emphasis supplied). Likewise, EPA implicitly has recognized that 316(b) does not fall within the legal limits of 301 or 306, both of which solely govern discharges. See, e.g., 67 Fed. Reg. at 17125 ("Section 306 of the CWA requires that EPA establish discharge standards for new sources.") (emphasis supplied); id. ("Sections 301,304, and 306 of the CWA require that EPA develop technology-based effluent limitations guidelines and new source performance standards that are used as the basis for technology-based minimum discharge requirements in wastewater discharge permits.") (emphasis supplied). Rather, EPA maintains that 316(b) is "closely linked" to "several of the core elements" ofthe N/SPDES permit program to support EPA's otherwise groundless contention that every existing electric-generating station, at each five-year permit-renewal, is subject to 316(b). See 67 Fed. Reg. at 17125.

3 Substantial reconstruction or expansion of a CWIS, including at an existing facility, may trigger reconsideration under 316(b), consistent with the EPA's 316(b) regulations for new facilities.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII. In addition, EPA disagrees that there is an absence of enforcement mechanisms applicable to section 316(b) requirements. As discussed in the preamble, this rule properly requires implementation of CWA section 316(b) standards through CWA section 402 permits. As such, all CWA enforcement authority applicable to NPDES permit requirements, including the authority to enforce the requirements of the CWA are available to enforce section 316(b) requirements. EPA further maintains the plain language of 316(b) distinguishes it from NEPA.

Applicability to facilities subject to NPDES permit

Section 316(b) Cannot Be Implemented in N/SPDES Permits.

Likewise, nothing in the Act allows 316(b) determinations to be made in the context of N/SPDES permits, as EPA indicates it will do. See proposed 40 C.F.R. 125.90(a) and 125.92. N/SPDES permits address surfacewater discharges through 301 effluent limitations. See CWA, 53402 (a, b) and 301, 33 U.S.C. 1342 (a, b) and 1311.<FN 4> Effluent limitations solely regulate surfacewater discharges from point sources. See CWA 502(11), 33 U.S.C. 1362(11); see also CWA 301, 33 U.S.C. 1311 ("Except in compliance with this section and sections 1312, 1316 1317 1328, 1342 and 1344 of this title, the discharge of any pollutant by any person shall be unlawful."). Section 316(b) is not an effluent limitation, because it does not govern surfacewater discharges. See, e.g., Virginia Elec. & Power Co. v. Costle, 566 F.2d 446,449 (4th Cir. 1977) (it is "obvious" that regulations implementing 316(b) are not effluent limitations); see also CWA 301(a), 33 U.S.C. 1311(a) (omitting reference to 316(b), but not various other standards regulating "discharges," as providing effluent limitations); CWA 505(f), 33 U.S.C. 1365(f) (deeming certain standards "effluent limitations" for citizen-suit purposes, but not 316(b)).

EPA's many approvals of state-delegated SPDES-permit programs confirms that EPA has never considered 316(b) essential to or even part of the N/SPDES program. To our knowledge, EPA never has required, as a condition to approval of a SPDES-permit program, the State to include a requirement relating to 316(b). Indeed, few of the many states with approved SPDES programs have promulgated any requirements designed to implement 316(b). Were 316(b) an essential element of the N/SPDES requirements, SPDES programs would provide for 316(b)-type determinations, or EPA's approval of them would contravene the Act. See CWA 402(b), 33 U.S. 1342(b) (setting forth the requirements); see also proposed 40 C.F.R. 125.90(d) (proposing to allow states to incorporate alternative 316(b) requirements in SPDES programs by the Rule). Since EPA has taken no steps in over three decades to incorporate 316(b) into delegated SPDES programs, it cannot now reasonably contend that 316(b) is appropriately implemented in N/SPDES permits.

Footnotes

4 N/SPDES permits also implement 306 "standards of performance," but again only as effluent limitations. See CWA 402 and 306, 33 U.S.C. 1342 and 1316. Even if one were to assume, as EPA does, see 67 Fed. Reg. at 17125, that 316(b) is functionally analogous to 306 "standards of performance," EPA's efforts to implement 316(b) at existing facilities through N/SPDES permits must again fail. As EPA acknowledges in the Rule, see 67 Fed. Reg. at 17142,g 306 "standards of performance" apply solely to new, not to existing, facilities. See CWA, 306, 33 U.S.C. 1316; see also S. Conf. Rep. No. 91-1236, reprinted in 1972 U.S.C.C.A.N. 3776,3804-05 (rejecting House bill proposal that 306(a) should apply to modified existing facilities, with the goal that 306(a) applies "solely to new construction").

EPA Response

EPA disagrees with the comment that the Agency lacks authority to include Section 316(b) requirements in NPDES permits. Section 316(b) requirements apply to "any standard" established under sections 301 or 306 of the CWA, and section 402(a)(1) of the CWA authorizes the issuance of discharge permits provided they comply with, in relevant part, CWA sections 301 and 306. Thus, these provisions provide authority for EPA to implement section 316(b) requirements through NPDES permit conditions.

EPA also disagrees that EPA approval of State NPDES programs is relevant to or inconsistent with Agency authority to implement section 316(b) requirements in NPDES permits. The NPDES State program approval regulations implement CWA section 402(b). Generally, these provisions identify NPDES program regulatory requirements that States seeking authorization to implement the NPDES program must have or be consistent with (States requirements need not be identical to, but must be as stringent as, the specified federal requirements). See, 123.25. Until the final Phase I rule, there have been no federal regulations that do more than repeat section 316(b); therefore, 316(b) requirements were (and for facilities not subject to Phase I or Phase II still are) established on a BPJ basis. With promulgation of the Phase I rule, EPA has explicitly added the Phase I regulations to the State program requirements. Nevertheless, among the long-established permit requirements applicable to state programs are requirements that permit conditions require compliance with CWA sections 301 and 306 (as noted above, section 316(b) requirements apply to “any standard” established under sections 301 or 306 of the CWA), as well as with all CWA requirements, which includes requirements in section 316(b). Finally, section 316(b) requirements have historically been implemented in NPDES permits by both EPA and states authorized to implement the NPDES program.

RFC: Definition of "adverse environmental impact"

EPA MUST DEFINE THE STATUTORY TERM ADVERSE ENVIRONMENTAL IMPACT.

EPA's fundamental justification for the Rule, including as articulated in the NODA, is that the technology changes that the Rule requires - at a considerable disruption and cost to the nation's electricity providers - nonetheless are "worth it," because such technology will offset significant demonstrable damage reasonably attributable to CWISs - that is that an AEI actually exists. However, despite the many comments from regulators and regulated entities requesting a definition of AEI, EPA continually has declined to undertake the necessary analysis to establish whether AEIs will exist and, therefore, to what extent national environmental policy will affect the U.S. power supply and numerous American resource waters. See 68 Fed. Reg. 13522; see also 67 Fed. Reg. at 17136-40; proposed 40 C.F.R.125 and 85 (omitting any definition of AEI) and 93 (same); Comments of the Utility Water Act Group on EPA's Proposed 316(b) Rule for Phase II Existing Facilities and ICR No. 2060.01, at 21-23; U.S. Department of Energy, Detailed Comments on the EPA's April 9, 2002 Proposed Regulations to Establish the Requirements for Cooling Water Intake Structures at Phase II Facilities, Comment No. 16.

Rather, EPA continues to dodge this threshold issue, instead presuming an AEI necessarily results from the entrainment and impingement of early life stages of fish and other aquatic organisms. See, e.g., 68 Fed. Reg. at 13524 ("EPA expects that the proposed regulation would minimize adverse environmental impact, including substantially reducing impingement.. .and entrainment.. .at existing facilities over the next 20 years) (emphasis supplied); 67 Fed. Reg. at 17137 ("EPA believes that many cooling water intake structures clearly have a significant negative impact on aquatic organisms at the individual level.") (emphasis supplied).

As discussed herein, EPA's presumption, hedged as an "expect[ation]" or "belie[f]," remains untenable. Id. First, EPA must define AEI to properly carry out its functions under the Act. Indeed, by avoiding notice and comment on a definition for AEI, EPA sidesteps a critical debate about the heart of 316(b). Second, EPA's presumption that harm to individual fish from impingement and entrainment invariably constitutes an AEI contravenes the plain language of 316(b) and sound science. Both inadequacies are detailed below.

As EPA has acknowledged, the plain language of 316(b) expressly provides that AEI is a threshold issue - one which must be definitively established prior to the application of any analysis of the "best technology available" ("BTA'). See CWA 316(b), 33 U.S.C. 1326(b); see also In the Matter of Pub. Sew. Co. of N.H., Case No. 76-7, Decision of the EPA Administrator (June 10, 1977), 1977 WL 22370 (E.P.A.),*6 (noting that, consistent with the preamble to the then-existing EPA regulations governing CWISs, at 40 C.F.R. Part 204, "the Agency must identify or predict adverse environmental impacts and then select the most effective means of 'minimizing' . . . the adverse effects"); 41 Fed. Reg. at 17387, 17388 (Apr. 26, 1976) (same). Thus, establishing an AEI is an essential condition of any 316(b) determination.

Certainly, by authorizing the EPA Administrator to "prescribe such regulations as are necessary to carry out his functions under this chapter," see 33 U.S.C. 1361, Congress contemplated, and the federal courts expect, that EPA would appropriately define all operative 316(b) terms, including AEI. Michigan v. EPA, 268 F.3d 1075, 1082 (D.C. Cir. 2001) ("When Congress has explicitly or impliedly left a gap for an agency to fill, there is a delegation of authority to the agency to, give meaning to the specific provision of the statute by regulation . . . ."); United States v. Markgraf, 736 F.2d 1179, 11 85 (7th Cir. 1984) (noting that it is the agency's responsibility to fill in "essential details" of a statute that only provides "generalized guidance" to an administrative agency, owing to the "danger of arbitrary action in the absence of articulated standards"); Stephenson v. Davenport Cmty. Sch. Dist., 110 F.3d 1303,1310 (8th Cir. 1997) ("[F]ailure to define the pivotal term of a regulation can render it fatally vague."); Georgia Pacific Corp. v. Occupational Safety and Health Review Comm'n, 25 F.3d 999, 1005 (11th Cir. 1994) ("Where the Secretary is unable to settle on a single definition of a critical term or phrase in its own regulation, . . . the regulation is unconstitutionally vague . . . .").<FN 5>

Worse yet, while it has declined to define AEI, EPA has not declined to presume AEIs exist - an abdication of EPA's policymaking function, because the Act contemplates that a selected technology will be used to resolve an identified AEI. Thus, EPA's presumption circumvents the essential balancing test that 316(b) requires, particularly in the context of the site-specific analysis EPA has established as a "safety valve" for the regulated community.

EPA's presumption of AEI also impermissibly contradicts the scientific evidence that has been submitted for the record. See, e.g., Motor Vehicle Mfis. Assn. v. State Farm Mut. Ins. Co., 463 U.S. 29,43 (1983) ("[A]n agency rule would be arbitrary and capricious if the agency . . . offered an explanation for its decision that ran counter to the evidence before the agency."). The record is replete with the evidence of leading fisheries experts who have concluded that it is inappropriate to invariably equate individual entrainment and impingement losses with an AEI. See, e.g., Status and Trends of Hudson River Fish Populations and Communities Since the 1970s: Evaluation of Evidence Concerning Potential Impacts of Cooling Water Withdrawals (Jan. 2002) (Appendix 3 to Comments of Entergy Corp., Its Subsidiaries and Affiliates on EPA's Proposed 316(b) Rule for Phase II Existing Facilities). EPA has not responded to, let alone addressed this evidence in the administrative record. These infirmities, unless resolved by the EPA's appropriate definition of AEI, compromise the Rule, inviting time-consuming and protracted litigation.

Footnotes

5 Where Congress has intended that EPA focus on individuals, it has clearly directed as much. Thus, the Endangered Species Act ("ESA") protects individual members of certain species. EPA's presumption also contradicts twenty-five years of interpretation of 316(b) by the Agency and other regulators. See, e.g., Seacoast Anti-Pollution Leanue v. Costle, 597 F.2d 306 (1st Cir. 1979) (upholding EPA's acceptance of once-through cooling, despite entrainment); New Jersey Dep't of End. Prot., NJPDES Permit No. NJ 0005622, Salem Generating Station (June 29, 2001) (SPDES-permit renewal with once-through cooling); Maryland Dep't of Env't, NPDES No. MD0002658B, Chalk Point, Potomac Electric Power Co. (Apr. 29,2001) (SPDES-permit renewal with once- through cooling). Implicit in each of these permitting decisions is a rejection of an overly narrow focus on only entrainment and impingement losses.

EPA Response

Please see the response to comment 316bEFR.011.004 for the discussion regarding EPA's decision not to define "adverse environmental impact" in today's final rule. See also preamble to the final rule.

Comment ID 316bEFR.337.004

Author Name Elsie N. Zoli

Organization Goodwin Procter obo Entergy

Subject Matter Code 2.01

Authority to modify 40 CFR

THE NODA IS PROCEDURALLY FLAWED.

As discussed below, EPA has failed to include in the NODA several documents, studies and analyses that EPA will rely on or consult in promulgating a final rule, precluding meaningful public comment.

The Administrative Procedure Act ("APA"), particularly the APA's public-comment period for proposed rulemaking, is designed to provide sufficient information and opportunity for meaningful comment by affected entities. 5 U.S.C. 553(b)(3); see, e.g., Connecticut Light & Power Co. v. NRC, 673 F.2d 525,530 (D.C. Cir.), cert. denied 439 U.S. 835 (1982) ("The purpose of the comment period is to allow interested members of the public to communicate information, concerns, and criticisms to the agency during the rulemaking process."). Because technical interpretations and decisions by an agency often, as is the case here, drive the rulemaking process, it is fundamental that an agency must "identify and make available technical studies and data that it has employed in reaching the decisions to propose particular rules." Id.

Failure to reveal even portions of the technical basis for a proposed rule in time to allow for meaningful comment is procedural error sufficient to invalidate the resulting rule. See, e.g., Sierra Club v. Costle, 657 F.2d 298,397 n.484 (D.C.Cir.1981); National Crushed Stone Association v. EPA, 601 F.2d 11 1, 117 (4th Cir. 1979), reversed on other grounds, 449 US. 64, 101 S.Ct. 295,66 L.Ed.2d 268 (1980); United States v. Nova Scotia Food Products Corn., 568 F.2d 240 (2d Cir. 1977); Home Box Office. Inc. v. FCC, 567 F.2d 9, 55 (D.C.Ck.), cert. denied, 434 U.S. 829, 98 S.Ct. 111,54 L.Ed.2d 89 (1977); Portland Cement Association v. Ruckelshaus, 486 F.2d 375,392 (D.C.Cir.1973), cert. denied, 417 U.S. 921 (1974). As evidenced by the NODA, the EPA has yet to complete studies, calculations and a peer review of central importance to the Rule; has correspondingly failed to publish the results and findings; and, therefore, has denied Entergy and other interested members of the public the opportunity to critique and comment upon those matters.

Specific incomplete and/or undisclosed technical information on which EPA suggests it will rely in promulgating the proposed Rule are numerous, and include the following:

- EPA acknowledges that it has not completed its analysis of the potential economic and operational impacts of the various regulatory options considered in the NODA, including the preferred option. See 68 Fed. Reg. at 13530 n.8 ("EPA is currently completing additional IMP runs and will develop analyses of both options using both base cases.").

- EPA has not undertaken planned peer review of Chapter A7: Entrainment Survival Analysis of the Section 316(b) Phase II Existing Facilities Rule ("Entrainment Survival Analysis") - the document in which EPA rejects the entrainment survival data established by multiple facilities. Instead, EPA concludes that a zero percent entrainment survival default assumption is proper. See 68 Fed. Reg. at 13541.

- EPA has not yet examined other new information suggesting site-specific factors may affect other costs of retrofitting wet towers at existing power plants. See 68 Fed. Reg. at 13527.

- EPA intends to expand the Tampa Bay case study used in the Rule, but has not completed or made available the results of the revised study. See 68 Fed. Reg. at 13543.

- EPA has yet to complete its review of 18 surfacewater-valuation studies that will impact the Agency's treatment of non-use and use values in the Rule. See 68 Fed. Reg. At 13575.

- EPA admits that it has not analyzed all options, but seeks to reserve the right to promulgate said options without publicizing the results of such an analysis. See 68 Fed. Reg. at 13528 ('EPA would use the same methodology as described in Chapter B3 of the EBA [as amended in this NODA] to analyze other options not explicitly analyzed in this NODA if they were chosen for promulgation.").

The individual and cumulative effects of EPA's failure to undertake, complete and publish the studies and analyses listed above prevents interested parties, such as Entergy, from critiquing and commenting upon technical determinations that EPA admits will influence the final Rule. 5 U.S.C. 553(b)(3); see, e.g., Portland Cement Association v. Ruckelshaus, 486 F.2d 375,392 (D.C.Cir.1973) (finding "critical defect in the decisionmaking process" in the inability of petitioners to obtain in timely fashion the test results and procedures which "formed a partial basis" for the rule under challenge).

In particular, EPA's failure to timely conduct and publish the results of its anticipated peer review of its Entrainment Survival Analysis, see 68 Fed. Reg. at 13541, the outcome of which EPA presumes will support its decision to reject the findings of site-specific entrainment studies in favor of a default assumption of zero percent survival, illustrates the degree to which EPA's failures to complete and disclose in the NODA the technical analysis and review on which the Rule will be grounded impermissibly denies Entergy and other interested parties the opportunity to critique and comment on technical issues of central importance to the proposed Rule.

As discussed herein, Entergy firmly supports the use of site-specific entrainment survival data in individual 316(b) determinations and believes that there is simply no justifiable reason for EPA's wholesale rejection of the accumulated entrainment data that the Entergy facilities and others would intend to use for the purpose of establishing compliance with performance standards. Entergy also believes that, having rejected the numerous individual studies establishing entrainment survival rates of up to 100%, there is similarly no justifiable basis for the EPA to adopt a zero percent survival assumption. EPA's decisions have the effect of profoundly distorting the national benefits analysis <FN 6> To justify its decision, EPA invokes an anticipated "external peer review" (the results of which EPA presumes) that it ''plans to conduct" of the document by which it has rejected all 36 studies in favor of the zero percent survival assumption. However, such review has not been undertaken. The results of such review have not been noticed. No opportunity has been given for comment and critique of this "planned external peer review," as a foundation for an EPA decision that unquestionably impacts the national benefits analysis of the Rule.

Footnotes

6 Where the benefits of the Rule with respect to commercial fishing are defined as "the increase in gross revenue that would be expected if all impingement and entrainment impacts were eliminated," see 68 Fed. Reg. At 13547, use of a default zero-percent entrainment survival rate causes any entrainment survival (which multiple studies have calculated as high as 70%) to be improperly counted as a "benefit" of the Rule.

EPA Response

EPA provided adequate notice of the final rule and its bases and therefore, EPA has complied with the Administrative Procedure Act's requirements and due process requirements.

EPA published the proposed rule on April 9, 2002, and made the supporting records and technical development documents available to the public. EPA published the NODA on March 19, 2003, along with support documents to update the data, information, and rulemaking process for the public consideration. In addition, as described in detail in section III of the preamble to the final rule, EPA has conducted extensive public outreach throughout this rulemaking and the Phase I rulemaking that preceded it, including holding or participating in stakeholder meetings, forums, workshops, and technical symposiums. Further, in a concerted effort to respond to a questions concerning the data and analyses that EPA developed as part of the Phase II proposal, EPA held a number of conference calls with multiple stakeholders to clarify issues and generally provide additional information. To supplement these verbal discussions, EPA drafted three supporting documents: one that explained the methodology EPA used to calculate entrainment rates; and two others that provided specific examples of how EPA applied this methodology to calculate benefits for the proposed rule. In addition, EPA prepared written responses to all questions submitted by the stakeholders involved in the initial conference calls. Thus, EPA has made substantial efforts to make information available, be responsive to inquiries, and to generally provide reasonable notice regarding this rulemaking. EPA notes that given the complex technical issues addressed in this rule, and the variety of comments and information developed and received, final rule development has been very dynamic. For example, much of the information presented in the NODA was generated based on comments on the proposal. Throughout this process and to the extent consistent with the defined schedule under the consent decree, EPA has provided reasonable notice of, and access to, available information and how the Agency anticipated using such information, particularly with respect to the core aspects of the rule, including the scope of the rule, the basic options proposed and considered, and the performance standards. EPA notes that the Agency received a significant number of substantive comments (i.e., estimated in excess of 3000 distinct comments) in response to the public notice provided in the proposal and NODA.

With regard to EPA's peer review of its assessment of entrainment survival data, EPA notes that EPA initial findings were fully described and discussed in the proposal and NODA. The peer review process was sought to gain an additional level of review of these data. EPA also notes that the final rule allows for consideration of an entrainment survival rate other than zero based on a study approved by the Director where a facility is seeking a site-specific determination of BTA.

EPA provided adequate notice of the methodologies it used to assess cost and benefits in the proposal, the NODA, and supporting documents.

Discussion of Site-Specific Approaches

EPA'S JUSTIFICATION FOR THE RULE REMAINS INFIRM, AND MAY COMPROMISE INDIVIDUAL 316(B) DECISIONMAKING.

In the Rule and NODA, EPA presents the basis for its national policymaking, and also provides direction regarding future individual 316(b) decisionmaking. As discussed below, EPA's estimates of both benefits and costs are flawed, undermining the basis for its decisionmaking. Further, EPA's poor justification for its national policymaking infects future individual 316(b) decisions.

The comments below address EPA's justification for the Rule. Discussion of the inadequacy of EPA's direction to regulators regarding individual 316(b) decisionmaking follows in Section V of these comments.

EPA 's National Benefits Assessment is Overstated.

Entergy appreciates EPA's clarification that its national benefits assessment, as described in the Rule and NODA, is not intended for use in individual 316(b) determinations. In particular, Entergy strongly agrees with EPA that:

[a]t the individual permit level it should be generally necessary to conduct a more detailed, site-specific analysis of the environmental ramifications of the cooling water intake structures . . . than is necessary or feasible for this national-level rulemaking analysis.

68 Fed. Reg. at 13543. Moreover, this comports with the most rational approach to individual 316(b) determinations - that is, using site-specific information over inaccurate extrapolations from information related to noncomparable facilities. To that end, an appropriate methodology for site-specific cost-benefit analyses is set forth and well-documented in National Economic Research Associates' ("NEIU") White Paper on the Use of Benefit-Cost Analysis in Site-Specific 316(b) Determinations Under the Clean Water Act (attached hereto, and incorporated herein, as Exhibit A), the use of which Entergy supports. In particular, NERA establishes an approach consistent with settled EPA guidelines and three decades of EPA and state permitting practice.

With this background, Entergy approaches EPA's lengthy discussion of its estimated national benefits solely as EPA's means of legitimizing what EPA perceives to be the national costs of compliance. See 68 Fed. Reg. at 13543-80. Conceptually, EPA's movement to a regional benefits assessment represents a step in the right direction, as it may reduce the errors inherent in extrapolating data from coast to coast, as EPA initially proposed. Unfortunately, EPA's regional approach to benefits estimates in the NODA suffers from many of the flaws of EPA's initial approach in the Rule.<FN 7> In particular, as discussed below, EPA's approach to commercial, recreational and non-use benefits fails to consider fundamental biological and economic principles and, in so doing, substantially and needlessly overestimates the benefits of the Rule.

As tellingly, the NODA confirms that fish populations - measured by EPA as stock available for commercial and recreational fishermen - remain far more robust than EPA's approach in the Rule and NODA suggests.

Footnotes

7 Indeed, by largely targeting the Northern California and North Atlantic "regions," see 68 Fed. Reg. At 13544, it is far from clear in the NODA whether EPA actually has produced a genuinely regional assessment.

EPA Response

EPA disagrees that the framework of the final rule is inappropriate. Please refer to section VII of the preamble to the final rule for more information.

While EPA rejected a purely site-specific approach, EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

For detailed responses to the NERA report, please refer to the responses to comments 136bEFR.338.501 to 521.

EPA Overstates Commercial Fishing: Benefits

The first flaw in EPA's approach is the assumption that the relationship between stock and harvest is linear, "such that if, for example, 10% of the current commercially targeted stock is harvested, then 10% of any increase in stock due to the rule would be harvested." 68 Fed. Reg. at 13547. This linearity assumes a demand for the theoretical increase in stock size due to a reduction in impingement and entrainment. Of course, if only 10% of an available stock is harvested, it suggests that demand is limited and, in fact, is the dominant factor in the market for that particular species. Without evaluating the strength or weakness of demand in the market for a given species, EPA assumes additional demand exists and, therefore, substantially overstates the commercial fisheries benefits of the Rule.

EPA Response

Levels of harvest (e.g., 10%) are a function of supply, in addition to demand, making it difficult to conclude that demand is a dominant factor in the market for a particular species. EPA only included in the commercial analysis species for which there was a significant annual catch from 1993-2001. Several species with low demand were excluded from the model or classified as a forage species only.

For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits, please see the response to comment 316bEFR.005.029.

Commercial Fishing Benefits

Second, EPA calculates benefits as “the increase in gross revenue that would be expected if all impingement and entrainment impacts were eliminated.” See id. (emphasis supplied). Of course, EPA’s proposed performance standards do not purport to eliminate all impingement and entrainment. The proposed standards are 60-90% for impingement and 80-95% for entrainment and, therefore, benefits are needlessly overstated by as much as 40% for impingement and 20% for entrainment.

EPA Response

In the cost-benefit analysis EPA estimated benefits to commercial fisheries in three steps (see Section XII.D of the preamble). First, EPA estimated total current losses to commercial fisheries in each region. These losses can correctly be interpreted as “the increase in gross revenue that would be expected if all impingement and entrainment impacts were eliminated.”

Second, EPA estimated the percentage reduction in impingement and entrainment at each in-scope facility and calculated an expected percentage reduction for the region.

Third, for each region EPA multiplied the estimated total losses by the estimated percentage reduction to calculate estimated benefits.

Thus, benefits are not over-stated as suggested by this comment, because EPA did account for the fact that the 316b would not totally eliminate all I&E at in-scope facilities.

Further information on the methods EPA used to estimate commercial fishing benefits is provided in the regional study document prepared for the analysis for the final Phase II rule. See Chapter A10: Methods for Estimating Commercial Fishing Benefits.

Organization Goodwin Procter obo Entergy

Subject Matter Code 10.02.02

Commercial Fishing Benefits

Third, EPA neglects the simple fact that any impacts to commercial fisheries from impingement and entrainment necessarily already is on the margin, representing an imperceptible fraction of existing losses that EPA recognizes are solely attributable to commercial fishing. See, e.g., 68 Fed. Reg. at 13558 (estimating a loss of 46,355 pounds of winter flounder lost due to entrainment, or a mere .4 % of NMFS commercial catch data indicating annual regional landings exceeding 11 million pounds). Thus, the proper measure of impact to the commercial fishery is the increase, if any, in marginal cost of capturing the fish necessary to satisfy demand, not the theoretical increase in gross revenues. This is particularly appropriate, given that the marginal theoretical impacts to the commercial fishery price will remain essentially unchanged, and fishermen may not experience any increase in revenues. Consequently, any increase in marginal costs to the fishermen would be the extent of the impacts to the commercial fishery. If the market is supply driven, and price increases with a reduction in supply, the fishermen is left with the choice of catching the same number of fish at marginally higher costs and selling them at a marginally higher price (thus recovering those costs). In the supply-driven market, the extent of impact is the marginal increase in price to the consumer, which would essentially be the same as the increase in marginal costs to the fishermen to satisfy demand. Entergy submits that EPA must consider these and other market fundamentals in assessing impacts to the commercial fishery.

EPA Response

EPA's analysis assumes that a reduction in impingement and entrainment will result in a small increase in the quantity of fish caught while fishing effort remains the same. Thus, overall costs will not increase significantly and the marginal cost will decrease slightly. In an unregulated market, fishing effort will increase until marginal costs return to their original level. In a regulated market, fishing effort will remain unchanged and there will be a small perpetual benefit to fishermen. The magnitude of the changes in quantity is not expected to be large enough to affect prices.

For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits please see the response to comment 316bEFR.005.029.

Subject Matter Code 10.02.02

Commercial Fishing Benefits

Fourth, EPA's assumptions compound errors when the change in consumer and producer surplus are considered. While Entergy applauds EPA's reduction in the range of effects on producer surplus (from 40-70% to 0-40%) where no change in price is expected for individual species, the fact that the surplus is calculated as a percentage of the gross revenues exacerbates the error inherent in the gross revenues calculation (discussed above).

For additional comments on the calculation of commercial fisheries benefits, including a discussion of the economic incentives inherent in an open access fishery, which lead to zero profit for each fisherman, please refer to NERA's White Paper on the Use of Benefit-Cost Analysis in Site-Specific 316(b) Determinations Under the Clean Water Act (Exhibit A).

EPA Response

For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits, please see the response to comment 316bEFR.005.029.

Recreational Fishing Benefits

EPA Exaggerates Recreational Fishing Benefits

The NODA does not provide substantially greater detail on the analysis of recreational benefits. However, EPA persists in its assumption that recreational anglers "will get greater satisfaction, and thus greater economic value, from sites where the catch rate is higher due to reduced impingement and entrainment." 68 Fed. Reg. at 13546. Whatever the truth may be, EPA's approach fails to consider several essential threshold questions: What is the increase in catch rates, if any, due to reduced impingement and entrainment? What level of increase in catch rates is necessary to generate the "greater satisfaction" EPA presumes for recreational anglers? On what basis does EPA assume that any increase in catch rates, even an increase that is not perceptible by the individual angler, represents a recreational benefit?

A more sound and defensible approach is that EPA first should determine the likely actual increase in catch rates associated with the Rule, which in all likelihood is quite small given the size of the populations of interest. Then, recreational anglers should be surveyed to determine what they would be willing to pay for the projected incremental increase in catch rates. This information would form a reasonable basis for developing estimates like these that EPA relies on in the Rule and NODA.

For additional comments on EPA's approach to recreational benefits, please refer to NERA's White Paper on the Use of Benefit-Cost Analysis in Site-Specific 316(b) Determinations Under the Clean Water Act (Exhibit A).

EPA Response

The commenter states that EPA’s approach to analyzing recreation fishing benefits for the final 316(b) rule fails to consider several important questions. The commenter questions the validity of this method and further suggests that EPA should use a stated preference approach (i.e., “survey”) to evaluate recreation fishing benefits of the 316 (b) rule. Each of the specific issues raised by the commenter is addressed below.

Question 1 – What is the increase in catch rates: EPA does in fact determine the likely increase in catch rates associated with the Rule. The comment does not offer a specific critique of EPA's method for doing so, or offer an alternative, so EPA cannot provide a more thorough reply to this point.

Question 2 – What level of catch rates provides "greater satisfaction" to anglers: EPA's RUM models show that any increase in catch rates would provide greater utility to anglers, based on the fact that the coefficients on catch rates in the models are positive and significantly different from zero. EPA uses these coefficients to determine the value of specific increases in catch rates, estimated using the anticipated changes in I&E resulting from the Rule. EPA estimated the RUM model using the square root of catch rates, to allow for diminishing marginal utility with larger increases in catch rates. Therefore, estimated values change with the change in catch rates, in a non-linear fashion. This is in accordance with standard economic utility theory.

Question 3 – What is EPA's basis for assuming increases in catch rates provide benefits: First, there is no evidence that the anticipated increases in catch rates would be imperceptible to anglers. Numerous recreational fishing studies have shown empirically that anglers respond to, and receive positive benefits from, a wide range of changes in catch rates. Second, EPA assumes that anglers receive benefits from increases in catch rates based on the empirical evidence provided by the statistical results of the RUM model, as described above.

Finally, the comment suggests that EPA should have used a CV survey of recreational anglers' willingness to pay for increased catch rates. EPA does not believe that a CV survey is the best option for valuing recreational angling benefits. There is general consensus in the economics profession that revealed preference methods are preferred to stated preference methods for measuring use values, as revealed preference methods rely on observation of actual behavior, rather than questions about hypothetical behavior. There is a long history of revealed preference modeling of recreational angling benefits, and the methods have been well-researched, extensively developed, and demonstrated to be valid. In fact, most of the comments received by EPA agree that RUM models are the best means of estimating recreational fishing values. EPA has thus used the best available method for valuing increases in recreational fishing catch rates – the RUM method - and has applied that method according to generally accepted standards. The results show that anglers do, indeed, value increases in catch rates of recreationally important species.

See response to comment 316bEFR.041.452 for additional details.

Valuing Forage Species (incl non-use and non-landed)

EPA Improperly Relies on Non-Use Benefits in its Assessment

EPA necessarily concedes that "estimating non-use values is an extremely challenging and uncertain exercise, particularly when primary research using state preference methods is not a feasible option (as is the case for this rulemaking)." See 68 Fed. Reg. at 13579. Moreover, "EPA recognizes that benefits transfer of state preference-based [willingness to pay] estimates to a policy context that differs from the study context can be problematic, given the significant influence of context on stated-preference values." See 68 Fed. Reg. at 13568. Nonetheless, EPA appears ready to forge ahead with valuing non-use benefits, using what is essentially its concededly debunked HRC methodology to do so. See id. ("First, the Agency developed a benefit transfer approach that combines an estimate of the amount of habitat required to offset impingement and entrainment losses . . ."). The HRC methodology is roundly criticized in both NEWS Economic Evaluation of the Habitat Replacement Cost Methodology in the U.S. Environmental Protection Agency's 316(b) Benefits Case Study for Pilgrim Station, and ENSRs Comments on Proposed EPA 316(b) Regulations for Existing Facilities, both submitted in conjunction with Entergy's initial comments on the Rule.

Perhaps even more fundamental to the non-use benefits analysis is the threshold question whether such benefits are likely to be relevant or significant under the Rule. As more fully described in NERA's White Paper on the Use of Benefit-Cost Analysis in Site-Specific 316(b) Determinations Under the Clean Water Act (Exhibit A), non-use benefits are not expected to be relevant or significant in the context of 316(b) determinations. As NERA's assessment confirms, EPA's use of the methodology contradicts settled scientific practice.

EPA Response

EPA disagrees that use of HRC methodology contradicts settled scientific practice. EPA used the best scientific practices available and, in some cases, chose to use less sophisticated models because of the greater scientific uncertainties associated with more sophisticated models. In this rule, however, EPA chose not to use the HRC methodology.

EPA disagrees that it is evident that "non-use benefits are not expected to be relevant or significant" for the 316b rulemaking. This is a matter that can only be resolved through additional, credible empirical research. As discussed in the Regional Study Document for the final rule, EPA believes that non-use benefits are significant (please see Chapters A12, Non-use Meta-analysis Methodology, and A9, Economic Benefit Categories and Valuation Methods).

EPA notes that "NEWS Economic Evaluation of the Habitat Replacement Cost Methodology in the U.S. Environmental Protection Agency's 316(b) Benefits Case Study for Pilgrim Station" is a document prepared by industry consultants, and is not a peer reviewed article or paper.

Please also see EPA's response to comments on the habitat replacement cost (HRC) methods

(#316bEFR.005.035), the societal revealed preference (SRP) methods (#316bEFR.005.006), and the feasibility of doing original stated preference research ((#316bEFR.306.105). Please also see the following documents for EPA's discussion of non-use valuation: Chapters A12, Non-use Meta-analysis Methodology, and A9, Economic Benefit Categories and Valuation Methods of the final Phase II Regional Studies Document (DCN # XX); and Chapter D1 of the final Phase II EBA document regarding break-even analysis.

Cooling system costs (e.g., dry, wet, recirculating)

EPA 's National Costs Assessment Is Likewise Flawed

The many flaws that characterize EPA's national benefits assessment also infect the Agency's national cost calculations. Several of these flaws are discussed below.

EPA's Capital Operation and Maintenance Cost Estimates Remain Error-Ridden.

EPA's revisions to its cost calculations in the NODA, while appreciated, illustrate the fallibility of EPA's approach and the lack of reliability of its data. In the NODA, EPA indicates that "[f]or the preferred option" capital costs increased by 66% and operation and maintenance costs increased by 48%. See 68 Fed. Reg. at 13524. No discount factor is applied, with the result that EPA substantially has understated the effect of its correction. See id. Not surprisingly, therefore, the U.S. Department of Energy, among others, continues to maintain that EPA's cost assessment is unsupported. See, e.g., 68 Fed. Reg. at 13527. In short, EPA's efforts to establish the national costs of the Rule remain speculative. Absent a reliable assessment, the Rule continues to be impermissibly flawed.

EPA Response

The commenter is incorrect in asserting that the U.S. Department of Energy stated that EPA's cost assessment for the preferred option were unsupported. To the contrary, the Agency worked closely with the U.S. Department of Energy in evaluation of the costs of the final rule (based upon the preferred rule option from the proposal and NODA) and have jointly determined that the costs of the final rule are accurate.

The commenter asserts that the Agency's cost estimates remain "error-ridden," and yet their only example pertains to the Agency's generic and narrative comparison of the general change in costs of the preferred rule option from proposal to NODA. Despite its best efforts, the Agency fails to understand how a generic comparison of total technology capital costs or total O&M costs should be discounted for the purposes of comparison, as the commenter strangely believes. The commenter does not declare what type of discount factor he believes should be utilized, nor the methodology for his recommendation to utilize discounting. The Agency notes, for the record that the cost basis for the preferred option at proposal and NODA inherently incorporated an annual construction cost index, and in the chance that the commenter was mistaken that the dollar years had not been "discounted" to compare on a equal basis between NODA and proposal, that this was not the case. Regardless, incorporation of a discount factor of any other type for this basic and broad-brush comparison (which the Agency reiterates was provided in the NODA as a narrative comparison of costs) is a concept that in no way supports the commenter's assertion that cost estimates are "error-ridden."

Mkt-level impacts/Reliability/EO 13211: Energy Effects

EPA's Assessment of Energy Costs Is Misleading

It is axiomatic that energy costs - the effect on the various independent systems that compromise the national electric system - must be accounted for with utmost accuracy and credibility. The reason is simple: Electricity remains the nation's economic engine, as well as an essential service for Americans. Significant adverse impacts to system reliability or increases in electricity prices have the ability to derail that engine and to compromise the services on which Americans depend.

Despite the importance of system impacts, EPA's assessment in the NODA remains glib. For instance, as the Agency concedes, EPA's Integrated Planning Model ("IPM') runs are incomplete, internally inconsistent and have not been made available to the public. See, e.g., 68 Fed. Reg. at 13528 (conceding that EPA had failed to analyze its preferred option in the Rule "because of time constraints"); 68 Fed. Reg. at 13530, n.8 ("'EPA is currently completing additional IPM runs . . . EPA intends to place these additional analyses in the docket during the comment period on this Notice. EPA expects to use . . . these additional analyses to support decisionmaking for the final [R]ule."); 68 Fed. Reg. at 13534 ("EPA intends to place additional IPM runs in the record during the NODA comment period to allow direct comparisons of both policy alternatives under both cases.").

Further, in the NODA, EPA aggregates the information for all 551 affected facilities into ten (10) North American Electric Reliability Council ("NERC") regions, distorting the significant likely effects of EPA's decisionmaking at the relevant level, namely on independent system operators or even more localized units (depending on system constraints). See 68 Fed. Reg. at 13527. In fact, EPA provides no reasoned explanation for its NERC-wide view and does not identify the obvious weaknesses of this unusual selection process; e.g., that a NERC-level analyses focuses on interconnected bulk power, not relevant system function.

By way of example of the risk of power reductions on electric systems, the New York Independent System Operator's ("NYISO) annual assessment conveys a dire assessment of current power production in New York State:

[T]he State's short-term needs continue to be met only by a combination of emergency actions . . . the prospect for a steady addition of plants to meet long-term needs has gotten significantly worse

The future outlook for adequate, efficient and environmentally friendly generation is bleak.

NYISO, Power Alert III (May 2003), pp. 9-10 (attached hereto, and incorporated herein, as Exhibit B). The EPA's assessment of the relevant NERC region, i.e., that power losses will have no significant effect, cannot be reconciled with the conclusions of NYISO regarding its own system. Certainly, however, additional power losses in New York attributable to the Rule would produce an even more grim prognosis by NYISO, one that EPA's analysis has entirety failed to capture or account for.

Further, EPA is nonchalant about its conclusions, despite the fact that even its skewed analyses reveal baseline closures (e.g., of nuclear assets), increases in energy prices and decreases in generation, among other significant consequences. See 68 Fed. Reg. at 13530-32. In short, EPA has failed to adequately assess and account for electric-system impacts.

EPA Response

EPA disagrees with this comment. EPA notes that complete and internally consistent IPM runs were provided for the NODA. The additional runs referred to by the commenter were placed into the docket on June 19, 2003.

EPA further notes that analysis at the NERC region level is entirely consistent with regulatory analyses such as the one in support of the section 316(b) regulation.

Finally, the commenter provides no support for the claim that the final Phase II rule might cause additional power losses in New York. EPA's analysis shows minimal impacts as a result of the final rule on the Northeast Power Coordinating Council: cost increases are estimated to be 0.2 percent and no additional capacity is projected to close as a result of the final rule. EPA notes that baseline closures are not an impact attributable to 316(b) regulation and that estimated increases in energy prices (-0.1%) and decreases in generation (0.4%) are small.

Comment ID 316bEFR.337.014

Organization Goodwin Procter obo Entergy

Subject Matter Code 16.01

RFC: Regulating limited capacity facilities

EPA's Capacity Utilization Rates Are Improper and Poor Policy

The Rule and NODA exempt certain so-called "peaking" facilities from the performance standards applicable to all other electric-generating facilities, including those that are indistinguishable from exempt facilities except in their operating behavior. See 68 Fed. Reg. At 13528 ("facilities with a capacity utilization rate of less than 15 percent may be subject to less stringent compliance requirements than facilities with a utilization rate of 15 percent or more,,); see also 68 Fed. Reg. at 13525, 13529 (indicating that the capacity factor is based on 2008 or forward-looking data, not historic operations). As a result, EPA encourages "peaking" power- production behavior, by rewarding such facilities with significantly reduced costs of compliance. As discussed below, whatever EPA intends to achieve with this approach, the Agency's short- sighted scheme creates perverse incentives that are likely to be damaging to existing power production, electricity pricing and the environment.

In particular, the Rule and NODA provide that any facility that operates less than 15% of the available operating time, i.e. , a peaking facility, is exempt from installing entrainment-compliance technology. See 67 Fed. Reg. at 17153-54; 68 Fed. Reg. at 13586 (perpetuating in the NODA the exemption for these facilities in the Rule).<FN 8> In doing so, EPA ignores the consequences of its policy decision, assuming economically rational behavior by existing facilities to operate as peaking facilities. Certain existing fossil-fuel facilities undoubtedly will undertake cost-benefit analyses and conclude that reducing operating times to avoid 316(b) compliance makes economic sense. This is because peaking facilities may be able to operate when market prices are highest and, therefore, may be able to reduce operations without significant decreases in total annual revenue.<FN 9> If output of otherwise "base load" facilities is limited to avoid 316(b) compliance, the electric system experiences a net loss in available capacity and likely a corresponding increase in market price. Further, more plants are necessary to generate the same needed power, with attendant environmental impacts; e.g., additional use of land resources, additional interconnections and related aesthetic considerations. Indeed, EPA's stated 316(b) goals may not be realized: The operation of multiple peaking facilities, all operating at just less than 15% without 316(b) controls, if EPA's presumed AEI assessment is to be believed, not only avoids decreases in entrainment but could result in greater cumulative entrainment.

Certainly, EPA has not in the Rule or NODA taken into account the results of the peaking facility exemption on its decisionmaking, national energy supplies or the environment. In particular, we have identified no modeling by EPA of the likelihood that facilities would change their operating behavior to avoid 316(b) compliance costs, the number of such facilities, the resulting reduction in energy production, the impacts on electrical-system reliability and market pricing, or the impacts on the environment. Without this analysis, EPA has failed to address fully the costs and benefits of the Rule.

Footnotes

8 Significantly, the NODA does not identify how such facilities would be "capped" to operate less than 15% of the year, particularly relative to the effect of IS0 or regulatory mandates, exacerbating the concern identified in these comments. See

68 Fed. Reg. at 13529.

9 By contrast, certain facilities, such as nuclear facilities, cannot feasibly function as peaking units. Accordingly, EPA's policy decision also favors fossil-fuel facilities and correspondingly may result in a net increase in air emissions.

EPA Response

The Agency analyzed the energy generation implications from the capacity utilization flow cutoff. The Agency determined that less than 1/2 of 1 percent of the annual electricity generation from the facilities within the scope of the rule would be from those facilities receiving regulatory relief from the entrainment reduction requirements due to the capacity utilization threshold. Additionally, the Agency examined those facilities within reasonable range of the 15 % capacity threshold (i.e., those at or below 20 percent capacity utilization threshold), whom according to the commenter "might" seek to reduce their generation in order to receive reduced requirements and, in turn, marginally reduced costs. The percentage of total annual generation associated with those facilities with entrainment requirements at or below 20 % capacity utilization is approximately 1 percent of that within scope of the final rule. Hence, the hypothetical, and undocumented theoretical concept that the commenter has outlined might have the not-so-dramatic effect of reducing the annual electricity generation of the Phase II in-scope facilities by approximately 1/2 of 1 percent.

These facts contradict the commenter's assertions that there exists the potential for even a minor disruption to electricity generation due to the capacity utilization rate threshold. Never mind the fact that the commenter has dramatically overstated the difference in costs between impingement only requirements and those of entrainment requirements, let alone when they are considered in light of the revenues for even the smallest of facilities within the scope of the rule. The median annual cost difference between entrainment and impingement requirements is roughly a factor of 2. This means that should a small generator experience annual costs on the order of $150,000 for entrainment requirements, that it would (if not already only subject to impingement only requirements) potentially save on the order of $75,000 annually by seeking to limit its generation by a marginal percentage. If the combined set of facilities between 15 % and 20 % capacity utilization rate that are subject to entrainment requirements decide that they wish to consider lowering their generation to comply with lesser requirements of impingement only, the total savings for these facilities would be on the order of $775,000 annually. Meanwhile, these facilities would be sacrificing approximately $500 million dollars in net generation revenue in order to save these meager compliance costs for the 316(b) rule. The comparison is elementary and does not require further analysis. Nonetheless, the Agency examined the break-even point for facilities examining the prospect of small amounts of money to comply with lesser 316(b) requirements versus generating electricity. This break-even point will fall around the capacity utilization threshold rate of 15.1 %. The Agency estimates that one facility out of the entire phase II in-scope list will be close to this break-even threshold.

Option: Site-specific determination of BTA

Author Name Elsie N. Zoli

Organization Goodwin Procter obo Entergy

EPA'S DIRECTION TO REGULATORS REGARDING INDIVIDUAL 316(B) DECISIONS IS INADEQUATE.

EPA's direction to regulators wrestling with 316(b) implementation, particularly its direction in individual 316(b) decisionmaking efforts involving the "significantly greater" tests, is woefully inadequate.

EPA Should Clearly Affirm its Commitment to Site-Specificity in Individual 316(b) Decisionmaking.

As discussed above, Entergy firmly supports EPA's clear distinction between its rulemaking function, in which extrapolation of appropriate facility-specific data may allow assessment of national benefits, and its decisionmaking function, in which site-specific information must be the basis for individual 316(b) determinations. See, e.g., 68 Fed. Reg. At 13543.<FN 10> EPA's approach makes common sense, as the relevant factors that may vary from site to site are innumerable, but likely include the biology of representative important species, hydrology, impacts of bio-fouling, geotechnical constraints on the implementation of specific technologies, navigation considerations, space limitations, a facility's generation profile (e.g., base load facility), and climatic conditions. EPA's approach also fosters consistent regulatory policy, since for three decades EPA and other regulators have sought and performed site-specific 316(b) determinations. As such, Entergy supports EPA's efforts to resist a "one-size fits all" approach to implementation of the Rule.

Moreover, EPA should not limit the use of site-specific data to the "significantly greater" context. See 68 Fed. Reg. at 13524. Rather, site-specific data is essential to determining whether a facility already meets the proposed performance standards by virtue of previously-installed technologies and site-specific ecological data. Thus, for instance, the first of EPA's three options for compliance, i. e., demonstrating that the facility's existing design and construction technology, operational measures and/or restoration currently meets specified performance standards, see 68 Fed. Reg. at 13524, also must rely on site-specific information. Accordingly, EPA should expand its commitment to the use of site-specific data in the final Rule to any circumstance where its use is appropriate.

Footnotes

10 Each presentation at the EPA-sponsored Symposium on Cooling Water Intake Technologies, held on May 6-7, 2003 in Arlington, Virginia, emphasized the need to use and importance of site-specific information in individual 316(b) determinations.

EPA Response

While EPA rejected a purely site-specific approach, EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b) determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact associated with cooling water intake structures.

For more information on the use of the term "significantly greater," please refer to the response to comment 316bEFR.006.003.

RFC: Appropriateness of "significantly greater"

The "Significantly Greater" Test Remains Needlessly Vague

The Rule and NODA fail to provide adequate or appropriate guidance on the application of the "significantly greater" tests that are, as the "safety valve" for the regulated community, a critical component of the Rule. See 67 Fed. Reg. at 17221 (to be codified at 40 C.F.R. 125.94(c)) (the facility's costs are to be compared to "the costs considered by the Administrator when establishing such performance standards" or to the "benefits of complying with such performance standards at your facility"); 68 Fed. Reg. at 13541 (not altering Rule).<FN 11>

Absent a standard for comparing the site-specific costs against EPA's estimates, the basic structure of the Rule remains unclear. See, e.g., Georgia Pacific Corp. v. Occupational Safety & Health Review Comm'n, 25 F.3d 999, 1005-06 (11 th Cir. 1994) (where a regulation "forbids or requires the doing of an act in terms so vague that [people] of common intelligence must necessarily guess at its meaning and differ as to its application" it is impermissibly vague). First, the "significantly greater" standard for the cost-cost and cost-benefit tests should be clarified to aid regulators in determining what qualifies as "significant" and to appropriately limit discretion. As a corollary, where a facility does not meet the standards, EPA must clarify how compliance will be determined. Second, in relation to the cost-benefit test, EPA must allow facilities to identify, as EPA's chosen technology, the least-cost solution that will meet EPA's performance standards; instead, EPA appears to have effectively inflated costs and benefits by requiring something more, namely the best-performing solution. Third, EPA must establish what the essential comparison is. This requires clarification of what factors EPA proposes as relevant for the test, including how energy costs and impacts are evaluated in the site-specific analysis. Each of these flaws is discussed below.

Footnotes

11 This "alternatives" approach to the otherwise applicable numerical performance standards provides flexibility in application of the Rule, by responding in those important circumstances where the costs of meeting the performance standards are "significantly greater" than either the benefits or costs that EPA has developed. See 67 Fed. Reg. at 17143-44.

EPA Response

See responses to 316bEFR.006.003, 018.009 and 337.021. EPA also notes that the rule and preamble address how costs are assessed and how the site-specific portions of the rule are to be implemented.

RFC: Appropriateness of "significantly greater"

EPA Must Provide A Clear Standard for the "Significantly Greater" Test

EPA has not provided a clear standard for implementing the "significantly greater" analysis for the cost-cost or the cost-benefit tests. First, EPA has failed to account for economic practicability on a facility-level. Second, EPA has provided insufficient guidance for implementing the "significantly greater" standard. Each is discussed below.

Anything that compels a standard in excess of economic "practicability" contravenes the express language and legislative history of 316(b) and, therefore, must be rejected. See CWA 316(b), 33 U.S.C. 1326(b) (establishing a correlation between impacts and technology); Conf. Rep. No. 92-1236 (1972), reprinted in 1972 U.S.C.C.A.N. 3776,3814-15; In the Matter of Pub. Serv. Co. of N.H., Case No. 76-7, Decision of the EPA Administrator (June 10, 1977), 1977 WL 22370 (E.P.A.) (determining that it would not be reasonable to interpret Section 316(b) as requiring use of technology "whose cost is wholly disproportionate to the environmental benefit to be gained"). EPA makes no allowance for economic impracticability in the NODA. Instead, EPA determines, on a national level, that its estimated compliance costs are practical, by comparing the estimated costs to revenues, either as determined by EPA's modeling or based on each facility's "domestic parent's sales revenue," where publicly available. See 68 Fed. Reg. At 13535-36. EPA's comparison is false. Among other errors, a cost-to-revenue comparison is not an accurate measure of economic practicability, because it fails to take into account the cost of achieving that revenue. Likewise, a parent company's financial status is not relevant, as such revenue may not be a measure of the subsidiary's revenues. Thus, EPA's national assessment is not appropriate guidance for individual 316(b) decisionmaking.

EPA Response

See responses to 316bEFR.006.003 and 018.009. EPA agrees that economic practicability is an appropriate test for determining section 316(b) requirements. EPA is authorized to exercise its discretion in how it determines such practicability in this rule. See the preamble to the final rule and the record for discussion of EPA's basis for the site-specific provisions in the final rule and the Agency's determinations regarding economics and costs for this rule.

RFC: Appropriateness of “significantly greater”

Further, the “significantly greater” test fails to identify what difference in cost is “significantly greater” than EPA’s estimate of costs or benefits. EPA’s failure to clarify this vague standard leaves regulator with no guidance for applying this critical component of the Rule, and likely will result in arbitrary determinations.

EPA Response

See responses to 316bEFR.006.003 and 018.009.

RFC: Test: benefits should justify the costs

Further, in relation to the cost-benefit test, the "significantly greater" standard is ill-advised. Requiring costs that exceed benefits by any amount is irrational, and cannot be based on sound economic principles.<FN 12>

Footnotes

12 Further, a "significantly greater" standard is a departure from EPA's mandate to maximize net benefits. See Executive Order 12866(1)(b)(6) (requiring that agencies "propose or adopt a regulation only upon a reasoned determination that the benefits of the intended regulation justify its costsyy). As such, "significantly in this context must be low hurdle; i.e., where the facility-level costs of complying exceed the benefits of compliance by the facility, the test is met.

EPA Response

For EPA's response to comments on application of the cost-benefit test to assessing the value of alternative CWIS technologies, please see comment #316bEFR.005.020. See also response to comment #316bEFR.060.002.

Process for determining site-specific BTA

Author Name Elsie N. Zoli

Organization Goodwin Procter obo Entergy

As a corollary to this discussion, and as EPA has requested, see 68 Fed. Reg. at 13527, Entergy submits that EPA must clarify the process for applying the cost-cost or cost-benefits tests as follows: Each facility will propose compliance technology at its facility that meets the Rule's performance standards at the least cost to that facility. The facility may then undertake site - and facility - specific costing of the selected least-cost compliance technology, with the goal of determining if its costs are "significantly greater" than EPA's cost estimate for the least-cost option selected for comparable model facilities. Thus, for example, a facility that determines that fine-mesh screens are its selected technology and will achieve compliance with a selected performance standard (e.g., 60% reduction in entrainment) will perform a site-specific assessment of the costs of that equipment at that facility. If costs are significantly greater than EPA's least-cost model costs for a comparable facility, then that technology is too costly and need not be implemented.

Once the site-specific cost tests have resulted in a determination that the selected compliance technology is too costly, the facility may propose less costly technology, operational measures and/or restoration measures "to the extent justified by the significantly greater cost." See 67 Fed. Reg. at 17,144. EPA concedes that this analysis may result in a determination that no additional technology is required. See 67 Fed. Reg. at 17,146. No further clarification of this approach is provided. Entergy submits that this process is iterative. The facility would then compare site-specific costs of its proposed alternative technology (that may not meet EPA's performance standards) to EPA's least-cost model costs (or, if not available, a cost estimate prepared using EPA's methodology) of similarly effective technology or to EPA's estimated benefits of that technology to determine if these costs are "significantly greater." At this point, however, the facility should have the option of proposing alternative operational measures and/or restoration measures that would meet the anticipated performance standard for the alternative technology. EPA should clarify this process in the Rule.

EPA Response

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Please refer to the responses to comments 316bEFR.005.020 and 316bEFR.410.001 for a discussion of the application of the cost-benefit and cost-cost tests.

For information on the role of restoration, please refer to sections VII and VIII in the preamble to the final rule.

RFC: "Significantly greater" for eval. alt. req.

EPA Must Clarify Its Intention to Require More Costly Technology than Necessary to Meet Performance Standards, To Avoid Biasing the "Significantly Greater'' Tests

EPA appears to have "tipped the scales" to increase costs and benefits by modifying, in the NODA, the technology on which the test is based. In particular, "EPA revised its traditional least cost approach," see 68 Fed. Reg. at 13526, and "selected the best performing technology . . . that was suitable for each site, in order to ensure that the technology on which costs were based would in fact achieve compliance." See id. As such, EPA has selected technologies that cost more, and may exceed performance standards.

As EPA concedes, see 68 Fed. Reg. at 13527, this approach likely will adversely affect any facility conducting the cost-cost test, which must compare its chosen least-cost technology with a technology chosen by EPA that likely exceeds standards, presumptively at greater societal costs for which neither EPA, nor the regulator, has accounted. Likewise, a facility conducting the cost-benefit test is faced with comparing its chosen least-cost technology to benefits from a superfluous technology. In both cases, EPA has biased these tests to favor technology that exceeds EPA's statutory mandate. As such, they may bring about unforeseen and potentially damaging results to an already radical proposal.

EPA Response

EPA disagrees. In the NODA EPA attempted to refine costs primarily in response to comments that the proposed cost estimates may not have fully reflected actual facility costs. The revised approach and results were explained in detail in the NODA and background documents, and comments were requested. EPA notes that the comment is incorrect in its characterization that EPA selected compliance alternatives that exceed what was estimated to be necessary for a facility to meet the rule requirements. As described in the NODA, under the revised approach, EPA focused on compliance alternatives that were expected to achieve compliance with the rule, but did not assume the use of compliance alternatives that were expected to exceed rule requirements. Contrary to the implication in the comment, the cost estimate revisions were not based on any aspect of any compliance option. Nor does the comment identify any technical aspects of the revised cost estimates that are incorrect. The revised costs estimates are as accurate as possible within the constraints of this rulemaking.

RFC: Appropriateness of "significantly greater"

EPA Must Clarify Site- and Facility-Specific Costs Relevant to the "Significantly Greater'' Tests.

Nowhere does EPA specify what costs may be relied on by a facility in preparing its site-and facility-specific cost estimate.<FN 13> Presumptively, the range of costs EPA has evaluated and relied upon in its national assessment for the Rule and NODA are appropriately considered and employed in individual 316(b) decisions.

However, that baseline - mere inclusion in EPA's national or model assessment - is not enough. Rather, to foster appropriate decisionmaking, the costs of compliance relevant in any individual decision must incorporate any appropriate costs of the facility in question. See EPA's Guidelines for Preparing Economic Analyses at 119-22 (September 2000). Any contrary determination would be based on potentially misleading information. See, e.g., Alvarado Community Hosp. v. Shalala, 155 F.3d 1115, 1122-24 (9th Cir. 1998), op. amended, 166 F.3d 950 (1999) (determining that agency acted arbitrarily and capriciously in setting regulatory threshold based on older data without adequately explaining use of that data); Hughes River Watershed Conservancy v. Glickman, 81 F.3d 437 (4th Cir. 1996) (remanding where improper economic assumptions "impair[ed] fair consideration of the project's adverse environmental effects") (quotation marks and citations omitted). As such, it may result in a net detriment to society, an obviously improper result.

While the range of relevant costs will be necessarily site-specific, certain obvious omissions in EPA's national assessment exist and, therefore, require that EPA clearly affirm their use in individual circumstances. In particular, EPA fails to fully address costs attributable to the purchase of land, labor and non-NPDES approvals associated with complying with 316(b). Further, EPA's analyses of energy costs and the resulting electrical-system impacts are flawed, and should be abandoned in individual circumstances in favor of a cogent site-specific approach. Each is discussed below.

The Cost of Labor.

EPA acknowledges that labor costs will be incurred, but does not describe what constitutes "labor costs." See EPA's Technical Development Document for the Proposed Section 316(b) Phase II Existing Facilities Rule, April 9,2002 ('Phase II TDD") at 2.8. Labor costs should include salary, benefits and overtime costs for facility personnel to the extent they are working extended hours, and contractor and subcontractor labor costs (at union or prevailing wages), including overtime, contractor markup, supervision, administration and home-office support. See, e.g., An Investigation of Site-Specific Factors for Retrofitting Recirculating Cooling Water Systems at Existing Power Plants, prepared by Parsons Infrastructure and Technology Group, Inc., for the United States Department of Energy (October 8, 2002) ("Parsons Retrofitting Report") at 3-8. Labor costs will increase if expedited construction schedules are utilized, which is likely when a facility is down for interconnection or if EPA retains its current proposed compliance schedule, factors which should be account for. See EPA's Economic and Benefits Analysis for the Proposed Section 316(b) Phase II Existing Facilities Rule (February 28, 2002) ("Phase II EBA") at B1-3 to B1-6. These are essential costs, and, for the reasons discussed above, should be included.

Site Preparation and Acquisition Costs.

EPA acknowledges that some site-preparation costs are appropriate. See Phase II TDD at 2.7. Where necessary based on site-specific factors, more than clearing trees may be required. In particular, blasting may be required, at a significant expense, at many sites. Further, demolition or re-location of existing structures, including utilities, may be required. Where these site-preparation techniques are not feasible or would not provide sufficient land for siting cooling towers, purchase of additional land may be necessary, if available. Each of these and other analogous costs are essential costs of compliance, and, for the reasons discussed above, should be included.

Costs to Obtain Non-NPDE Approvals

As EPA acknowledges, governmental approvals may be required. See 316(b) Phase II Cost Module 2.2, at 5. These may include CWA 404 approvals, air permits, zoning approvals and environmental-impact reviews. Further, private authorizations or negotiations may be required, such as where existing easements or contractual obligations would interfere with retrofitting activities. Such approvals and authorizations, where obtainable, may lead to extended delays, and costs may be affected significantly. Where such approvals or authorizations cannot be obtained, the retrofit will be infeasible. In this latter circumstance, the proposed technology should not be deemed "available" technology, and also should be deemed "significantly greater" than estimated costs. Entergy further submits that where the facility determines appeal of such denials is appropriate, any requirement to complete the retrofit should be delayed, but that the facility should not be required to pursue such an appeal.

Energy Costs and Reliability Impacts

Because EPA's national analysis of energy costs and the resulting electrical-system impacts is flawed, regulators may fail to properly allow facilities to account for significant costs and impacts that may result in relation to individual technology retrofits. As EPA concedes, any cooling-tower retrofit, if feasible and within the range of acceptable costs, will result in a long-term reduction in available capacity due to the ongoing operation of the required technology, <FN 14> and a temporary outage for installation of the required technology.<FN 15> See Phase II EBA at B1-6. As discussed below, EPA's national analysis of energy costs and impacts improperly aggregated national and temporal effects, "averaging away" significant impacts, with the result that assumptions as to system reliability and energy prices are inaccurate. Further, EPA utilizes certain assumptions that, even if appropriate for a national analysis (which seems doubtful), are clearly inappropriate in individual 316(b) decisions. These errors and improper assumptions not only undermine the national analysis on which the Rule is based, but may mislead and confuse regulators, with the result that significant local effects may be ignored in the site-specific cost tests. Further, to avoid any confusion in implementation of the Rule by regulators with no expertise in energy policy, we recommend that EPA include quantitative impact-thresholds and require sign-off of the agency with authority over energy policy.

First, in individual 316(b) analyses, it is inappropriate to obfuscate critical power-supply impacts by national and temporal aggregation, as EPA has done. As EPA is aware, power does not flow freely within any NERC region.<FN 16> More particularly, use of the ten NERC regions fails to account for local distribution and transmission limitations (with the result that potentially severe local impacts may be averaged away). By way of example, a report recently issued by NYISO identifies significant transmission limitations within New York State which EPA's analysis overlooks. See NYISO, Power Alert III (May 2003), pp. 11-14, 22 & 39-40 (Exhibit B).

Second, in EPA's national assessment, the Agency arbitrarily determines that only a few facilities will be installing cooling towers each year, see Phase II EBA at B 1-20 to B 1-21, effectively masking the otherwise severe energy-supply impacts of simultaneous outages. The Rule and NODA, in conjunction with EPA's own assessment of the status of current permits, indicates otherwise. See EPA's Memorandum Regarding Implementation of Section 316b) in NPDES Permits (February 27, 2003) (identifying N/SPDES permits at existing sources with majority having expired and awaiting renewal as a "priority" upon promulgation of the Rule). EPA further limits impacts by modeling each facility as having one-fifth of its downtime in each modeled year during its five-year compliance period, although this is inconsistent ,with EPA's compliance schedule in the NODA. See 68 Fed. Reg. at 13529. Where these assumptions are inaccurate, as is the case absent a change in EPA's compliance deadlines, a site- and facility- specific cost analysis should have the opportunity to employ more appropriate assumptions for its analysis and to utilize cumulative impacts. Finally, in EPA's national assessment, the Agency assumes that the only increase in energy prices will be to recover the costs of the compliance technology. See Supporting EPA's Documentation of Changes to Economic Impacts (March 12, 2003) (Docket 5-3004). In reality, in non-regulated markets, prices may increase in periods of reduced supply. The social cost of this decreased electrical supply may be valued by analyzing the reduction in the capacity of the electrical system and the value of the lost power. See NERA'S White Paper on the Use of Benefit-Cost Analysis in Site-Specific 316(b) Permitting Decisions under the Clean Water Act, at 35-39 (taking into account any resulting increase in the price of power) (Exhibit A). These costs may be significant, especially in areas where distribution and transmission are constrained and new-capacity siting efforts may stall.

Indeed, removal of two baseline facilities serving metropolitan New York results in severe reliability impacts and an increase in the aggregate price paid by consumers over this period. See NEW'S Electricity System Impacts of Nuclear Shutdown Alternatives, March 2002, submitted in conjunction with Entergy's initial comments on the Rule. As this analysis shows, impacts may be substantial. As EPA is not in the business of electrical-system analysis or setting national energy policy, we recommend that EPA either incorporate into the Rule specific thresholds, which, if met, result in a retrofit being deemed too costly or require appropriate regulatory sign-off from the agency with authority over energy policy on any 316(b) decision where the electric-system impacts analysis submitted by the facility shows potential impacts on system reliability or the cost of power.

Footnotes

13 This confusion may be caused by EPA’s approach in the Rule and the NODA, which conflates national and individual analyses. See 68 Fed. Reg. at 13534; 67 Fed. Reg. at 17181 (in each case, discussing the annualized private compliance costs of all facilities before analyzing national impacts due to energy capacity decreases). As a result, regulators may incorrectly presume that national assumptions are appropriate in individual 316(b) determinations. The potential errors are substantial.

14 The long-term reduction in capacity may be due to reduced unit efficiency (which may be caused by increased turbine back-pressure) and/or increased auxiliary power requirements to operate the required technology. See Phase II EBA at B1-6 to B1-7. In addition, the long-term reduction in capacity may be due to shifts in planned outages and seasonal reductions in unit efficiency where seasonal flow reductions are implemented.

15 As EPA appropriately has acknowledged, especially at nuclear-power facilities, the temporary outage will significantly exceed EPA’s original estimate in the Rule of one (1) month, and may exceed EPA’s revised estimate of seven (7) months. See 68 Fed. Reg. at 13525. However, at all facilities, site- or facility-specific factors may further extend this period,

including where the facility must be taken off-line for construction of an additional intake or for blasting, where construction delays are encountered, and where downtime may be scheduled during an otherwise necessary outage.

16 By way of example, the NERC region includes the Canadian Maritime Provinces, Quebec, Ontario, Maine, Vermont, New Hampshire, Massachusetts, Connecticut, Rhode Island, and New York. Yet power does not flow freely within NERC regions. In particular, transmission constraints within the state of New York have required the NYISO to require certain generating capacity be located within New York City and Long Island. Further, transmission between independent system operators is limited. New York, for example, is able to receive only about 2,400 of its needed MWs from the neighboring Pennsylvania, New Jersey and Maryland interconnection. See NYISO, Power Alert III (May 2003), pp. 34,36-37 (Exhibit B).

EPA Response

See the preamble to the final rule and the record for discussion of EPA's basis for the site-specific provisions in the final rule, implementation of these provisions, and the Agency's determinations regarding economics and costs for this rule. Also see 40 CFR 125.94(a)(5)(i).

EPA notes that the final Phase II rule does not require installation of cooling towers. See the cost modules in the Technical Development Documents for a discussion on the costs considered for each technology.

RFC: EPA rationale to not require closed-cycle

OUTSTANDING ISSUES

EPA 's Lack of Clarity Regarding Cooling-Tower Technology Is Damaging.

We understand that EPA has not concluded that the Rule mandates cooling-tower technology. While the Rule and NODA support this conclusion, that support is not definitive. See, e.g., 68 Fed. Reg. at 13526 (estimating number of facilities that "would upgrade their cooling system from once-through to closed-cycle . . . ."). Clarification is appropriate.

EPA Response

Cooling towers do not form the basis for any requirements of the final rule. See the preamble to the final rule.

Determination of compliance

EPA Should Affirm its Use of Representative Important Species in the Rule.

EPA has used representative important species (‘RIS’’) in 316(b) decisionmaking for three decades. To abandon this approach now would constitute an unexplainable departure from historical practice and precedent, undermine the value of data collected at the direction of EPA, run contrary to the biological value concept and present a needlessly impracticable data, collection mandate.

Since 1977, beginning with its Draft Guidance for Evaluating the Adverse Impact of Cooling Water Intake Structures on the Aquatic Environment: Section 316(b), P.L. 92-500 (May 1, 1977) (the “Draft Guidance”), the EPA has directed the use of RIS for individual 316(b) determinations. In electing to employ RIS in the 1977 Draft Guidance, EPA expressly recognized that “[i]t is not practicable to study all species that may be directly or indirectly harmed by intake structure operations,” see Draft Guidance, p. 15, and the stated goal of conducting intake studies was to “obtain sufficient information to aid in determining whether the technology selected by the company is the best available to minimize adverse environmental impact.” See Draft Guidance, p. 4. Further, almost a year after publication of the Rule, EPA expressly affirmed the use of RIS in 316(b) determinations. See Memorandum to Water Division Directors Regarding Implementation of Section 316(b) in NPDES Permits (February 23,2003).

Today, study of all species is no more practicable, nor is it any more necessary to implement § 316(b), than it was in 1977. First, the various methodologies for assessing potential impacts of CWIS on aquatic species are informed by study of those populations over time. By introducing “all species” into the calculus now, the NODA drastically dilutes the value of existing data sets. Second, adoption of an “all species” approach necessarily requires facilities to undertake studies that EPA has recognized as impracticable, if not infeasible, at substantial costs. Third, an “all species” approach also contradicts the Act. Congress would have required an automatic AEI assessment if it believed every CWIS necessarily created an AEI. Likewise, EPA would not have authorized the construction of hundreds of once-through CWISs if it had concluded that such systems necessarily create AEIs. The RIS approach, as compared to an “all species” analysis, recognizes as much by providing a workable framework for a regulated entity’s and a regulator’s analysis.

EPA Response

In today’s final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA’s response to comment 316bEFR.017.003. For EPA’s explanation of EPA’s monitoring requirements, please refer to EPA’s response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Subject Matter Code 21.04
Determination of compliance

Utilization of a No-Controls Baseline is the Appropriate Measure for Achievement of Performance Standards

EPA has requested additional comment on the inclusion or exclusion of certain design specifications in the definition of the calculation baseline for evaluating compliance with the performance standards of the Rule. See 68 Fed. Reg. at 13581. Entergy suggests that a calculation baseline should reflect facility operation at full capacity and with no impingement or entrainment controls, presuming -to the extent that EPA rejects survival data in its national benefits assessment - 100% for impingement and entrainment mortality rates. This approach corresponds to what EPA proposed in the Rule, i.e., that the “calculation baseline was an estimate of impingement mortality and entrainment that would occur at your site assuming you had a shoreline cooling water intake structure with an intake capacity commensurate with a once-through cooling water system and with no impingement and/or entrainment reduction controls.” See 67 Fed. Reg. at 17221.

It also provides the platform for an equitable measure of compliance among facilities, by eliminating the influence of innumerable factors that may have depressed historic operations below 100% of permitted capacity. Use of a full operation/full capacity/l00% mortality baseline in the final Rule further accords the baselines adopted by EPA in analogous programs intended to allow measurement of decreases from existing operational facilities. See, e.g., 51 Fed. Reg. At 27977 (controls “not included in a federally enforceable requirement” not considered for purpose of estimating baseline emissions in establishing NESHAP for arsenic); 58 Fed. Reg. at 28843 (“no-controls” baseline proper for establishing NO, reductions).

In the NODA, EPA proposes changes that would focus in part on “baseline practices and procedures . . . that the facility would maintain in the absence of any operational controls . . . implemented in whole or in part for the purpose of reducing impingement mortality and entrainment,” see 68 Fed. Reg. at 13581 (emphasis supplied), and needlessly complicate the analysis by calling into question the purpose for which operational controls were implemented. This approach needlessly risks divergent calculation baselines and inequitable evaluations of compliance among various facilities.

EPA Response

As discussed in the NODA, EPA considered many suggestions for the approach to determining the calculation baseline, and has clarified its definition of calculation baseline in today’s final rule (see §125.93). For additional explanation of EPA’s definition of calculation baseline, please refer to EPA’s response to comment 316bEFR.034.013.

Response to Public Comment

---National Pollutant Discharge Elimination System---
Regulations Addressing Cooling Water Intake Structures
for Phase II Existing Facilities

Organization PSEG Services Corp obo PSEG Power, LLC

Subject Matter Code 7.01.03

Option 3--Site-specific determination

Site-Specific Determinations

PSEG remains convinced that the statutory mandate of selecting the best technology available ("BTA") for minimizing adverse environmental impact ("AEI") due to a CWIS is best addressed through site-specific decision-making. This is especially the case for existing steam electric generating stations that are the subject of Phase II Rulemaking. Scientific studies at such facilities have demonstrated the absence of AEI at the population and community levels of aquatic species, even after years of CWIS operations and numerically large losses of aquatic organisms due to entrainment and impingement.

PSEG believes that EPA's Preferred Approach can provide a workable and acceptable means of implementing § 316(b) if, and only if, the site-specific option can be reasonably utilized by facilities subject to this rulemaking. In other words, if EPA sets the bar so high for the threshold cost-cost or cost-benefit tests, then this option can be rendered illusory.

The site-specific option provides permitting authorities with an appropriate level of flexibility to allow them to consider the objective of § 316(b), the best available scientific data, and the unique circumstances found in the highly variable natural environment. States could consider developments in fisheries science, actual impacts on fisheries populations, the status of those fisheries, specific concerns about endangered species and other issues important and discernable on a case-by-case basis. States such Maryland, which endorse the site-specific option, could continue to implement their permitting programs in a manner that utilizes the States' knowledge and experience concerning their particular environmental needs and conditions, to achieve the goals of the CWA.

EPA Response

EPA recognizes the site-specific nature of impacts at some facilities and has established a flexible rule to accommodate site-specific conditions. However, EPA did not adopt an exclusively site-specific regulatory options for several reasons. Please refer to section VII.E for a discussion of why EPA opted not to promulgate a purely site-specific rule. Please also see the preamble for a discussion of the final rule.

EPA adopted this regulatory scheme because it provides a high degree of flexibility for existing facilities to select the most effective and efficient approach and technologies for minimizing adverse environmental impact associated with their cooling water intake structures. This approach also reflects EPA's judgment that, given the various factors that affect the environmental impact posed by the range of Phase II existing facilities, different technologies or different combinations of technologies can be used and optimized to achieve the best results. Finally, this approach provides clear standards of performance based on the criteria in Section 316(b).

RFC: Proposed use of restoration measures

Author Name Mark F. Strickland

Organization PSEG Services Corp obo PSEG Power, LLC

Restoration

Healthy tidal wetlands that are linked to estuarine and coastal waters provide critical ecosystem support through direct contribution to food webs and by serving as highly favorable habitat for aquatic organisms. EPA's inclusion of provisions for restoration measures in the Proposed Phase II Rule directly supports important Congressional and government-wide goals to promote the restoration of estuarine habitat and to create and maintain effective estuarine habitat restoration partnerships.

Wetlands restoration is a valuable and effective tool for coastal environmental management. With the experience developed by PSEG and others throughout the country in a variety of voluntary and compensatory wetlands mitigation projects, wetlands restoration can achieve reliable and predictable results. PSEG documents its successes in estuarine restoration in Chapter III, and addresses factors that could help ensure successful restoration projects, such as adaptive management plans, uncertainty analyses and margins of safety. PSEG notes, however, that such factors should be tailored to the individual restoration projects. Accordingly, the permitting authority should be allowed to apply them as appropriate to ensure a successful project.

EPA Response

For a discussion of EPA's authority to include restoration measures in the final rule, see the preamble to the final rule.

For a discussion of the three factors the commenter mentions, see EPA's responses to comments 316bEFR.311.022 and 316bEFR.307.047.

Determination of compliance

Metrics and Compliance with Performance Standards

Four different performance standards are defined in the Preferred Approach, and each facility that selects BTA demonstration alternative (1) or (2) would be required to comply with one of the four performance standards. The metrics and the tests of compliance are key to the reasonableness and technical validity of the performance standards.

In the NODA, EPA requested comments on alternative metrics that might be used in tests of compliance with performance standards. EPA indicated it was considering numbers of organisms, biomass of organisms, all species of fish and shellfish, and a subset of species of fish and shellfish. PSEG believes that the final rule should provide for flexibility in the choice of appropriate metrics that takes into account site-specific considerations. Flexibility is particularly important if a facility has implemented or plans to implement restoration measures. In some cases, the number of organisms from a subset of species (expressed in terms of numbers at a particular age) might be the most appropriate metric. In other cases, the biomass of all fish and shellfish by trophic level might be the most appropriate metric, particularly in cases where wetland restoration measures are used to satisfy performance standards.

While neither the Proposed Rule nor the NODA provide a clear or definitive statement of EPA's proposed approach for testing compliance with performance standards, PSEG makes several assumptions and provides comments concerning how compliance might best be measured and comments on compliance tests that it believes would be consistent with EPA's intent. Specifically, PSEG discusses approaches to address potential problems due to naturally-occurring inter-annual variability and technologies that increase impingement while reducing entrainment.

EPA Response

In today’s final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA’s response to comment 316bEFR.017.003. For EPA’s explanation of EPA’s monitoring requirements, please refer to EPA’s response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Benefit Estimation Methodology

Author Name Mark F. Strickland
Organization PSEG Services Corp obo PSEG Power, LLC

Economic Considerations

The methodologies that EPA applied to estimate national recreational and commercial benefits in the NODA are substantially improved over those applied in developing the Proposed Rule;

EPA Response

EPA agrees with the commenter.

the nonuser benefit methods discussed in the NODA, however, are not sound and cannot reasonably be applied to site-specific benefit assessments.

EPA's Guidelines for Preparing Economic Analyses 2002 ("Guidelines") provide a comprehensive set of recommendations for developing benefit-cost analysis studies for environmental regulations, including explicit discussions of the methods that should be followed to develop valid benefit transfer studies. Relying on these Guidelines, PSEG documents why the methodological approaches (benefit transfer methodologies) for estimating nonuse benefits described in the NODA are inconsistent with the Guidelines ,and with accepted economic analyses. Specifically, EPA's Single Study Approach is not an appropriate application of a benefit transfer methodology, the rule-of-thumb approach described by EPA has no valid conceptual basis, and the studies used in a meta-analysis are not relevant to this case.

The potential implications of incorrect methodologies are significant. Invalid benefits estimates would set incorrect precedents for EPA, result in inaccurate site-specific benefit-cost analyses, and lead to a § 316(b) rule that is not in society's best interests. EPA's acknowledgment that the nonuse benefits approaches in the NODA represent new studies that may be "problematic" greatly understates the issue, and the results of these analyses should not form the basis for the final rule. EPA, furthermore, should clarify that these methodologies are not valid for use in individual § 316(b) proceedings.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

As stated in the Notice of Data Availability (68 FR 13580), EPA is not using the rule-of-thumb approach in the cost benefit analysis for the final Section 316(b) Phase II rule.

Organization PSEG Services Corp obo PSEG Power, LLC

Subject Matter Code 7.01

RFC: Three-option framework for determining BTA

As PSEG has stated in its previous submissions to the Agency, PSEG believes that § 316(b) requires first a determination of whether an adverse environmental impact ('AEI") is occurring or will occur at a biologically relevant endpoint and, then next, the identification of measures to minimize that site-specific AEI. PSEG believes that such determinations would provide the best means of ensuring that aquatic ecosystems are protected. PSEG further believes that such site-specific determinations provide the requisite flexibility to allow states to address CWIS-related effects in a holistic manner that reflects the state's knowledge and understanding of the ecosystems within their jurisdictions and what is needed to best ensure their protection. Finally, this interpretation is clearly consistent with the language of § 316(b) and with EPA's initial and long-standing interpretation of its requirements.

EPA Response

EPA disagrees that a determination of whether an adverse environmental impact is occurring is a preliminary step in implementing 316(b). Please refer to the response to comment 316BEFR.313.001 for more information on EPA's position on minimum impacts at existing facilities.

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative. Please refer to the preamble for more information.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b)determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact associated with cooling water intake structures.

Option 3--Site-specific determination

USEPA's Proposed Phase II Rule includes a preferred regulatory option ("Preferred Approach") based on performance standards and proposes three alternative means of demonstrating best technology available ("BTA"):

- Cooling water intake flow commensurate with operating with a closed recirculating cooling system;

- Compliance with the performance standards applicable to the water body type and facility capacity factor of a given facility through the implementation of technological, operational and/or restoration measures; or

- A case-by-case determination of BTA, if the permittee can meet one of two proposed cost tests.

While EPA's Preferred Approach does not entirely endorse the site-specific approach PSEG believes to be the best means of implementing § 316(b), the Agency does propose to allow applicants to propose a technology most appropriate for achieving compliance with numeric performance standards as well as the option to petition for a site-specific determination of compliance with § 316(b) based on whether the applicant can meet either a cost-cost or a cost-benefit test. PSEG wholeheartedly endorses the Agency's recognition in its Proposed Phase II Rule that the regulation of a CWIS at an existing facility requires a substantially different approach than the establishment of uniform national technological requirements, which the Agency adopted in its final new facilities rule.<FN 4>

Organization PSEG Services Corp obo PSEG Power, LLC

Subject Matter Code 7.01.03

Option 3--Site-specific determination

EPA'S DECISION TO INCORPORATE A SITE-SPECIFIC OPTIOM REFLECTS SOUND PUBLIC POLICY, CAN BE IMPLEMENTED WITHOUT UNDUE BURDEN ON PERMITTING AUTHORITIES AND IS SUPPORTED BY THE ADMINISTRATIVE RECORD

As PSEG indicated in its Comments on the Phase II Rule,<FN 9> PSEG continues to believe that EPA's Preferred Approach can provide a workable means of implementing § 316(b). This, however, is the case if, and only if, Compliance Option III, the site-specific option, is included as a truly available means of determining compliance with § 316(b). In other words, if EPA sets the bar so high for the threshold cost-cost or cost-benefit tests, then this option can be rendered illusory. Given the language of the statute, the strong public policy reasons that support site-specific rulemaking and the flexibility such an option provides to states and EPA regional offices in terms of how to ensure protection of aquatic resources, the Agency has more than ample justification for allowing site-specific decision-making in the final Phase II Rule.

Option 3--Site-specific determination

The Goal Of § 316(b) - Minimization Of Adverse Environmental Impact- Can Be Fully Achieved Through A Site-Specific Approach

PSEG remains convinced that the statutory mandate of selecting the BTA for minimizing adverse environmental impact due to a CWIS is best addressed through site-specific decision-making. This is especially the case for existing steam electric generating stations that are the subject of the Phase II Rulemaking. To do anything other at existing facilities ignores the essential fact that the power plant and the CWIS have already been sited; further and more importantly, in many instances, it ignores the wealth of information that has been collected to assess the effects of the CWIS on the environment.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Impacts of CWIS at ecosystem level (popn. vs. indiv.)

As discussed below, there are studies that demonstrate the absence of AEI, based on data indicating the absence of adverse effects at the population and community levels, even after years of operation of intake structures, which causes numerically very large entrainment and impingement losses.

Certain of the most controversial of § 316(b) decisions related to power plants located on estuaries, including estuaries for which long-term data are available from monitoring programs <FN 10> to assess the effects of these facilities. These monitoring programs have demonstrated that the fish populations in the water bodies have continued to improve over the years of the facility's/ facilities' operations. As noted by Charles C. Coutant, Ph.D., Senior Scientist at Oak Ridge National Laboratory during the closing session of EPA's May 2003 Symposium on CWIS Technologies, the concerns about the effects of entrainment and impingement on fish populations based upon earlier, predictive studies of impact have been disproved by the long-term data on the status of the populations. Dr. Coutant referred specifically to the Hudson River and Salem power plant studies. The papers presented at an EPRI-sponsored symposium on Connecticut Yankee and the status of the fish populations in the Connecticut River reached similar conclusions. Likewise, scientists working for the State of Maryland's Power Plant Research Program ("MdPPRP") have published an article indicating similar results from their studies of fish populations in Maryland waters. <FN 11> The MdPPRP representative at the recent CWIS technologies symposium repeated these conclusions.

The studies conducted in the Connecticut River associated with the Connecticut Yankee Generating Station (''CY'') encompassed the period 1965-1987; the Station began commercial operations in 1968. On November 15-1 6,2001, EPRI sponsored a conference entitled, "Connecticut River Ecological Study Workshop: Revisiting the Impact of a Power Plant" ("Connecticut River Workshop"). The conference afforded scientists specializing in aquatic ecosystems and fisheries & opportunity to re-examine the original Connecticut River Study in relation to the long-term operation of CY and in relation to the current ecological condition of the Lower River. The published Summary from the Connecticut River Workshop include an assessment of the status of the river and its biota. Steve Gephard of the Connecticut Department of Environmental Protection ("CDEP") stated in his presentation entitled, "Status of Diadromous Fish Populations in the Connecticut River, Thirty Years Later" that "In general, the [Connecticut] [R]iver is in much better condition than it was during the ecological study. The ecological study and time have proven that the effects of the CY plant on the [Connecticut] [R]iver were relatively benign. "' <FN 12>

Likewise, the Delaware River studies associated with the Salem Generating Station have been on-going for better than 30 years. In 1999, an assessment of the potential for adverse environmental impact was conducted. This assessment concluded that Salem's operation had not resulted in a change in species composition, abnormal fluctuations in species abundance, or increase in nuisance species. It also concluded that Representative Important Species ("RIS") populations were stable or increasing except for two species, blueback herring and spot. Blueback herring have been subject to long term, coast-wide declines, which began prior to the initiation of the operation of Salem's cooling water system. Spot is subject to interannual variability in the Delaware Bay, which is the northern edge of this species, geographical distribution.

Footnotes

10 In some instances, the monitoring programs have been funded solely by the utilities in response to NPDES requirements. In other instances, such as the Delaware and Hudson Rivers, the data include the results of long-term studies conducted by the Delaware Department of Natural Resources and Environmental Control (“DNREC”) and the NJDEP on the Delaware and the New York State Department of Environmental Conservation (“NYSDEC”) for the Hudson.

12 EPRI. Workshop Summary. Connecticut River Ecological Study Workshop: Revisiting the Impact of a Power Plant, November 15 & 16,2001.

EPA Response

The information presented by this author highlight the fact that many factors concurrently affect fish populations. It is extremely difficult to separate the effect of any one factor. Today's final rule seeks to reduce the stress on fish populations due to impingement and entrainment by cooling water intake structures. Fishery management plans, water quality improvements and habitat restoration will also improve fish populations. Please see the response to comment 316bEFR.025.018 and 316bEFR.207.015.

Fish Population Modeling

Developments In Fisheries Science Support Inclusion Of A Site-Specific Option, Which Would Foster Appropriate Allocation Of Limited Societal Resources

To require facilities to install and operate technologies at considerable costs when no biologically meaningful AEI has been occurring and will unlikely occur in the future flies in the face of reason.<FN 13> Absent the inclusion of a truly workable site-specific option, this would be the outcome of this rule. Much more is known about fish populations and how they sustain themselves in 2003 than was known more than thirty years ago when Congress was debating the effects of steam electric facilities on fish population. <FN 14> In particular, the science of population dynamics and the understanding of how compensatory mechanisms operate have developed considerably over the last thirty years.

Any biological population that persists despite natural fluctuations in the environment must express some degree of compensatory process Le., an increase in the survival, growth, and/or fecundity with reductions in population size. The concept of compensation is known as "density-dependence" by ecologists, and is fundamental to the understanding and management of all biological populations. Different mechanisms of compensation have been well-studied in both terrestrial and aquatic systems (Krebs 1985; Hassell et al. 1989) for most animal groups (Hassell 1978) and for plants (Harper 1977). This compensatory response is the key factor that allows fish populations to maintain themselves when subjected to fishing mortality, and is a guiding principle of fishery management. If compensation did not exist, species could not sustain themselves in highly variable natural environments and in the face of long-term anthropogenic-stresses, such as mortality from fishing or power plant operations.

Identifying the operation of compensation in aquatic populations has been the focus of fisheries management over the past several decades. The prominence of the principle of compensation in the management of major fisheries by resource agencies is amply reflected in the many examples cited in Hilbom and Walters (1992). Quantitative estimates of compensation are now employed in fishery management to protect stocks from over exploitation, to define alternative criteria for optimal utilization, and to guide the course of rehabilitation of depressed stocks. Fisheries managers routinely use quantitative models to perform fish stock assessments, and these stock assessments are the foundation for the setting of fishery limits and quotas.

An example of this is evident in studies done on the Hudson estuary. Striped bass and white perch have been extensively surveyed at the egg, larval, and juvenile stages in the Hudson estuary since the 1970s. These research surveys show no decline in juvenile abundance (at about six months old) over a wide range of egg and larval abundance (Pace et al. 1993). The data on the Hudson estuary suggest strong density-dependent mortality between egg production and the winter of the first year of life.

Fisheries managers now employ biological reference points to evaluate the status of a fish stock and to guide them in setting allowable fishing rates. The role of compensation in present practices of fisheries management and regulation has recently been characterized by the following quote from the a 1998 study by the National Research Council ("NRC) Committee on Fish Stock Assessment:

Many species appear to have strongly compensatory [spawner-recruit] relationships; that is, per capita recruitment increases significantly as stock size decreases. Reference levels are now more commonly based on a % spawning stock biomass per recruit, but the percentage is often specified by analogy with other stocks or by using the results [of comparisons among other biological reference points]. A knowledge of the compensatory capacity of the stock is necessary to define the most appropriate biological reference points for a stock. Even without such knowledge, however, a conservative % spawning stock biomass per recruit still can be selected (Sissenwine and Shepherd, 1987). (NRC 1998).

As the above-referenced discussion clearly demonstrates, the level of understanding of the biological processes underlying density-dependent population regulation has increased dramatically in recent years, and databases and analytical techniques for quantifying density-dependence have become more reliable. The concept of compensation is now firmly entrenched in fisheries management practice.

The administrative record for the Proposed Phase II Rule pays lip service to these developments in fisheries science. The Proposed Rule discusses compensatory mechanisms and population dynamics as well as the models used by the National Marine Fisheries Service ("NMFS"). However EPA dismisses them from further consideration, citing too much uncertainty in these "scientific theories." There are uncertainties; EPA is correct. However, real world, long-term studies that demonstrate stable or increasing populations are more than adequate proof that the "scientific theories" do work and work, in fact, to sustain fish population.<FN 15>

USEPA must base its rulemaking on the best available information. The Agency should not ignore the body of scientific literature and the wealth of actual data that support the position that site-specific determinations of BTA have protected the resource.<FN 16> Deciding on the outcome of this rule without considering the developments in fisheries biology would be akin to seeking treatment for an illness such as cancer without considering the advances that have occurred over the past thirty years in understanding the causes of the disease and the treatments to cure it. At best, it would be highly irrational; at worst, it would not be in the patient's best interest. In this instance, relying on thirty year old data would mean that EPA is ignoring the administrative record and promulgating a rule that would result in the misallocation of limited societal resources to the ultimate detriment of the environment.

Footnotes

13 As PSEG's and WAG'S prior comments clearly set forth, the plain meaning of the statute requires no more.

14 It is worth noting that most of this debate focused on the effect of them1 discharges on fisheries and Congress's response to the debate was to craft 316(a), which established a variance provision. See Anderson & Gotbng's article, which provides a comprehensive summary of the legislative history of 316 of the Clean Water Act. William A. Anderson, II and Eric P. Gotting. Taken in Over Intake Structures? § 316(b) of the Clean Water Act 26 Col. Jour. Envtl L. - (2001). As demonstrated there, 316(b) was added without considerable debate during the House/Senate Conference. Congress was not focusing on entrainment and impingement losses and it is highly unlikely that Congress would have intended to undo what had been the subject of such intense debate, the need for site-specific regulation of power plant cooling systems, by mandating uniform technology requirements through 316(b).

15 National Marine Fisheries Service (NMFS). 30& Northeast Regional Stock Assessment Workshop (30th SAW), Public Review Workshop, April 2000. Northeast Fisheries Science Center Reference Document 00-04 and see electronic file Rider

insert for FN 5 in Chapter II.

16 While PSEG is not specifically addressing in this Response to the need for a biologically relevant definition of AEI, this body of scientific literature and the data referred to herein also providemore than ample basis for a population-based definition of AEI.

EPA Response

Option 3--Site-specific determination

Author Name Mark F. Strickland

Organization PSEG Services Corp obo PSEG Power, LLC

A Site-Specific Option Provides States Flexibility To Address Local Concerns While Ensuring That Federal Standards Are Met

When § 316(b) is implemented on a site-specific basis, regulatory agencies can assure that AEI is minimized through measures commensurate with the magnitude of the adverse effect, if any, as well as the nature and status of resource to be protected. NPDES permitting agencies have been making § 316(b) determinations now for almost thirty years on a case-by-case basis. These permits have required a variety of measures to address the effects of cooling water intakes, based upon the particular circumstances involved. Some of these § 316(b) determinations required a single measure such as making improvements to existing CWIS screen system;<FN 17> others required use of behavioral deterrents or other intake-related modifications."<FN 18> Other permit decisions have I required multiple measures to address the CWIS effect.<FN 19> These decisions were based upon considerations of the aquatic populations affected by the CWIS and the engineering and other site-specific factors that relate to the types of measures applicable for minimizing AEI. Time has proven the wisdom of these decisions.

Any number of §316(b) determinations from a variety of jurisdictions support these contentions. USEPA Region IV issued numerous permitting decisions based on EPA's 1977 Draft Guidance:<FN 20> including determinations for TVA's John Sevier Power Plant, Cape Canaveral, and Indian River Power Plants and TECO's Big Bend Power Plant. The New York State Department of Environmental Conservation ("NYSDEC") has likewise made decisions for numerous power plants throughout the state over the last 30 years. In the case of the Florida Power Plants, these case-by-case, site-specific determinations recognized the need to consider overall protection of the environment and not merely the reduction of entrainment and impingement numbers. In the case of the John Sevier facility, the Agency was able to offset the effects of the cooling system while enhancing the local sport fishery. In the New York power plant determinations, NYSDEC drew from a suite of measures ranging from behavioral deterrents to enhanced screen maintenance and operator training programs, based on the nature of impingement and entrainment effects occurring.

development of fishing access at another site).

20 U.S. Environmental Protection Agency, “Draft Guidance for Evaluating the Adverse Impact of Cooling Water Intake Structures on the Aquatic Environment: Section 316(b) P.L. 92-500” at 15 (“1977 Draft 316(b) Guidance”), May 1, 1977.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b) determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact at cooling water intake structures.

Organization PSEG Services Corp obo PSEG Power, LLC

Permitting Agencies Have Made And Can Continue To Make Site-Specific § 316(b) Determinations That Are Protective Of The Environment Without Undue Administrative Burden Or Cost

Since the initial enactment of the Clean Water Act in 1972, regional EPA and state NPDES permitting agencies have implemented 316(b) on a case-by-case basis, as shown above. Section 316(b) determinations have made for a wide range of existing power plants across the country. The vast majority of these decisions have been made in the normal courses of issuing NPDES permits<FN 21> other more controversial decisions were resolved via more extensive and, in some instances, even protracted proceedings.<FN 22> It is only natural that the protracted proceedings have captured the attention of the opponents of site-specific 316(b) determinations. These are the famous (or perhaps infamous is the better descriptor) matters that generated years of administrative proceedings and the attendant decisional documents that are more readily accessible than "Fact Sheets" or "Response to Comments" documents in non-adversarial permit proceedings.

In the instant rulemaking, EPA has sought the involvement of regional offices and state agencies not only through working groups, conferences and symposia, but also through the general request for comments in connection with the Proposed Phase II Rule and the NODA. While EPA continues to express concern about continuing its long-standing practice of implementing 316(b) on a case-by-case basis due to the burden on state agencies, the vast majority of states have not been participating actively in the rulemaking. Of the states that have submitted comments, many have endorsed providing flexibility to the states in making permit decisions and/or continuing to implement 316(b) through site-specific decision-making. These include the states of Maryland, Pennsylvania, Michigan, Florida, Arkansas, Alabama, and Indiana.<FN 23>

Footnotes

21 As discussed above in Section II.C., there have been numerous site-specific determinations that have not been burdensome. This is true even in New York State outside the Hudson River, where absent public interest group intervention, the regional fisheries offices in conjunction with the central NYSDEC office (for consistency) routinely assess power plant effects and make 316(b) determinations that have been fully protective of the environment in general and aquatic resources in particular.

22 These permit proceedings include the Hudson River Power Plant Matter, In re Seabrook Power Plant, and Salem's NJPDES Permit.

23 Letter from Richard J. McLean, Energy Resource Administrator; Maryland Department of Natural Resources - Power Plant Research Program and J. James Dieter, Wastewater Permits Program Administrator - Maryland Department of the Environment - Water Management Administration to
USEPA dated August 5, 2002; letter from Christine Martin, Deputy Secretary for Water Management, Pennsylvania Department of Environmental Protection to USEPA dated August 5, 2002; letter from Russel J. harding, Director, Michigan Department of Environmental Quality ("MDEQ") on behalf of the MDEQ and the Michigan Department of Natural Resources to USEPA dated August 6,2002; letter from Allen Hubbard, P.E., Supervisor - Steam Electric Power Plant NPDES Permitting, Florida Department of Industrial Wastewater to USEPA dated August 7, 2002; letter from Mo Shafii, Acting Engineering Supervisor - NPDES Permits, Water Division, Arkansas Department of Environmental Quality to USEPA dated July 16, 2002; letter from John A. Poole, Jr., Chief - Water Division, Alabama Department of Environmental Management to USEPA dated August 6, 2002; and letter from Timothy J. Method, Deputy Commissioner for Environmental

Results, Indiana Department of Environmental Management to USEPA dated August 9,2002.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b) determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact at cooling water intake structures.

EPA has made extensive efforts to solicit input from the states, as well as other stakeholders. Please refer to section III of the preamble to the final rule.

Option 3--Site-specific determination

Maryland’s PPRP provides a model for successful implementation of a site-specific 316(b) program.

In both its written comments on the Proposed Phase II Rule and at EPA’s CWIS Technology Symposium, the State of Maryland has fully endorsed the continued implementation of 316(b) on a site-specific basis. This endorsement does not arise out of naivete or ignorance of what is involved with making 316(b) determinations. To the contrary, Maryland has perhaps the most structured program for implementing 316(b) in the country. To its credit, Maryland has developed regulations that govern the implementation of 316(b) and has established a multi-disciplinary team that includes scientists, engineers and economists to review demonstrations. Maryland has also developed a reasonable structure to fund this process.<FN 24> With these components in place, 316(b) determinations can be made without triggering the specter that USEPA and certain states conjure up when developing the case for why 316(b) must be implemented via uniform national standards.

Maryland's program should serve as a national example not only because it is comprehensive yet efficient but also because of its success in not only minimizing AEI as required by 316(b) but also because it has resulted in the enhancement of the aquatic ecosystems in many instances. For example, the resolution of the Chalk Point NPDES permit resulted in the establishment of a hatchery. Striped bass was the initial species reared in the hatchery; with the complete recovery of the Chesapeake Bay striped bass stock, white perch and American shad have been reared and released. Mirant is also doing research at the request of MDNR on rearing sturgeon.

Footnotes

24 Maryland imposes a small annual tariff on the sale of electncity, which defrays the cost of the MDPPR.

EPA Response

The final rule provides for EPA approval of alternative State program requirements where such State NPDES requirements will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment that would otherwise be achieved under § 125.94.

Option 3--Site-specific determination

Other states recognize that 316 (b) requires a site-specific approach

Although their programs are not as sophisticated as the Maryland program, other states such as Florida, have supported EPA's inclusion of a site-specific option for complying with 316(b). The FDEP advocates a site-specific option so that it can continue to have the latitude to consider the totality of cooling system effects on the environment, both positive and negative, and the right to weigh them with the goal of maximizing environmental benefits. FDEP wants the flexibility to continue balancing the effects of impingement and entrainment losses with the need to provide an over-wintering area for manatees, a protected species. In other words, FDEP does not want to be forced to impose measures that would limit entertainment and impingement in 'the absence of evidence indicating harm due to these early life stage losses, if those same measures would eliminate key habitat for the manatee.

EPA Response

The final rule provides for EPA approval of alternative State program requirements where such State NPDES requirements will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment that would otherwise be achieved under § 125.94.

RFC: Use of previous demonstration studies

The Record For The Proposed Phase II Rule Includes Suggestions On How To Streamline Site-Specific Decision-Making

In its preamble to the Proposed Rule, USEPA sought comment on a number of proposals that would streamline the implementation of site-specific 316(b) determinations. Several states have supported these options. USEPA sought comment on whether states should be allowed to reaffirm prior 316(b) determinations and if so under what circumstance. A number of states, including Florida and Michigan, urged EPA to give full faith and credit to these prior decisions. For example, Michigan's Department of Environmental Quality (MDEQ) stated:

Michigan has implemented a 316(b) program for a number of years. Design, construction, and operation of intake structures have been evaluated on a case-by-case basis to minimize adverse environmental impacts for a majority of the intake structures for existing regulated facilities in Michigan.. .may not be necessary to require new studies or demonstrations for all those facilities with site-specific approvals.. .the regulations [should] provide flexibility for the states to exempt facilities with previously approved 316(b) demonstrations from further study, rather than require every facility to conduct new studies and demonstrations. The states should have the option to require the additional studies or demonstrations if conditions have significantly changed or if special concerns warrant a reevaluation of impacts.. .this approach will streamline the NPDES permit process and allow us to devote limited resources to facilities that need the attention. This approach will benefit permitting authorities faced with permit backlogs.

The Massachusetts Office of Coastal Zone Management offers qualified support for allowing continuations of prior decisions.<FN 25> They recommend this so long as the permittee can demonstrate no changes to the water body or the aquatic biota, since the last demonstration that formed the basis of the decision. Likewise, NJDEP supports allowing applicants to rely on information from prior determinations.

Footnotes

25 Letter from Thomas W. Skinner, Director - Massachusetts Office of Coastal Zone Management to USEPA dated June 14,2002.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule; however, existing data that is reflective of current conditions may be used to support the required studies. Please see response to comment 316bEFR.040.001 for details. EPA has also provided numerous efficiencies in today's final rule to streamline permitting. Please see response to comment 316bEFR.034.005 for a discussion

Option 3--Site-specific determination

The Arguments Against A Site-Specific Option Fall Short

The arguments against including a site-specific option in EPA's Preferred Approach fall short; in fact, PSEG believes that the totality of the record would support a determination by USEPA to implement 316(b) for existing power plants solely through case-by-case decision-making. This is the case for a number of reasons. First, the plain words of 316(b) in the context of the Clean Water Act support such a determination despite the opposition's invocation of the inclusion of references to 301 and 306 in 316(b) as clearly requiring national technology or performance standards for CWISs. Second, under EPA's Preferred Approach, only a subset of existing facilities will seek to make a site-specific demonstration. Third, even states that have raised concerns about site-specific implementation of 316(b) in their comments to USEPA on the Proposed Rule recognize the inherently site-specific nature of CWIS regulation at existing power plants and have implemented the statute accordingly. Finally and most importantly, there is no data or evidence that would support a conclusion that entrainment and or impingement losses have caused any appreciable impact to populations or ecosystems at the vast majority of power plants where site-specific 316(b) determinations have been the sole means of regulating CWISs over the past thirty years.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

While EPA has rejected a purely site-specific approach, EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information. Also refer to section VII of the preamble to the final rule for information on why EPA rejected a purely site-specific approach.

Implement a site-specific alternative

The Better Reading of the Statute Supports Site-Specific Implementation

Riverkeepers' and others take the opposition that 316(b) requires development of uniform technological standards for regulating CWISs. They invoke the reference to 301 and 306 in 316(b). Likewise, they argue that Congress' use of the phrase "best technology available", which is closely akin to "best available technology", must mean that this is a technology driven provision. Such a reading of the statute is clearly wrong; it ignores the critical linkage of the term BTA with the phrase "minimize AEI" in 316(b), the differences between this construction and 301 and 306, and 316(b)'s placement in the statute. When these are considered in toto, it is clear the 316(b) requires site-specific decision making or, at a minimum, the right to petition for such a determination, as in USEPA's Preferred Approach.

First and foremost, 316(b) requires the identification of BTA for "minimizing AEI." The marriage of a technology-based standard with an ecological endpoint is unique to 316(b). Sections 301 and 306, in comparison, are purely technology-driven sections. They require establishment of national uniform standards based on the technologies' capabilities to reduce pollutant loadings without any consideration of the effects of the reductions on the surface waters. The combining of the CWA's technology-forcing concepts as used in 301 and 306 together with the term "AEI" must, of necessity, be accomplished in the context of the environment within which a given CWIS operates. Hence, 316(b) requires site-specific decision-making.

Finally, as noted above, 316(b) arose out of the debate in Congress on the need for site-specific regulation of thermal discharges at power plants. This debate was resolved through the establishment of a site-specific variance proceeding based on protection of biota. Given the similar joining of technological and ecological goals in 316(b), it is logical to assume that Congress intended 316(b) to be implemented in a similar manner. USEPA's initial interpretation of the statute, as upheld by the Court of Appeals, supports this conclusion.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Option 3--Site-specific determination

Only A Limited Number Of Facilities Are Likely To Seek To Use A Site-Specific Demonstration

If the USEPA were to adopt as its Final Rule its Preferred Approach, it is likely that the number of power plants seeking a site-specific determination under Compliance Option III would be much smaller than EPA appears to anticipate. Using the ten power plants PSEG owns and operates that are subject to the Phase II Rule as an example, only four of the ten Phase II power plants would likely petition for site-specific determinations under 316(b). Two of the plants would be deemed to be in compliance by virtue of their operating with closed cycle cooling systems and cooling towers; the other four would likely seek to demonstrate compliance with the performance standards, including PSEG's Salem facility that has been held up as one of the prime examples of all that is wrong with site-specific decision-making.

If EPA is concerned with the precedent that including a site-specific option may create for its Phase III rule, all of PSEG's ten power plants that would likely be subject to the Phase III rule operate with closed cycle cooling and PSEG presumes these would likely be deemed to be in compliance based on the Agency's positions to date in the Phase I and Phase II rulemakings. As UWAG and PSEG have indicated in prior comments, applicants would, if possible, avail themselves of Compliance Option E, conformance with the Performance Standards, to minimize regulatory burden and increase regulatory certainly.

EPA Response

EPA agrees that it is unlikely that a large percentage of facilities would seek a site-specific determination of best technology. Please refer to the response to comment 316bEFR.202.002 for more information.

The proposed Phase III regulations are due to be published on November 1, 2004. At this time, EPA cannot comment on the approach those regulations may take. EPA welcomes comment during the comment period for those regulations.

Subject Matter Code 7.01.03

Option 3--Site-specific determination

Even States Such as New York and New Jersey Recognize that 316(b) Determinations are Inherently Site-Specific

Although the comments submitted by the NYSDEC and the NJDEP both indicate that they are opposed to site-specific implementation of 316(b), arguing that such determinations create a tremendous administrative burden although in both instances, these states have focused solely on the highly controversial and protracted proceeding and not on the burdens associated with their overall implementation of 316(b). Both, moreover, have indicated either in comments or at EPA-sponsored public meetings on the issue that the regulation of an existing CWIS requires consideration of site-specific factors.

As indicated above in section II.C, NYSDEC has applied a range of measures to address 316(b) in clear recognition of the diversity of effects at power plants located within New York. Even as recently as USEPA'S CWIS Technologies Symposium, a former NYSDEC staff person in charge of 316(b) assessments highlighted the range of measures employed and the need to balance the intricacy and cost of the technology to be employed with the type and magnitude of the harm to the aquatic ecosystem. Regardless of its definition of AEI that NYSDEC has put forward, it has not uniformly required closed cycle cooling or any other technology. This certainly appears to be an endorsement of site-specific 316(b) decision-making.

In its written comments to the USEPA on the Proposed Rule in August 2002, the NJDEP, like the NYSDEC, included a strong endorsement for application of a uniform technological approach. However, NJDEP also opposed USEPA’s suggestion of developing-a general permit for implementing 316(b), because:

By definition, a general permit prescribes a set of conditions for a number of facilities deemed eligible under those conditions. Establishment of appropriate cooling water intake technologies is dependent on numerous site-specific factors, where the regulatory authority should have oversight over any such choice.. .It could also cause a problem in prescribing a “one size fits all” mentality for intake protection technology which is simply not appropriate.<FN 26>

It is hard to reconcile the two positions the NJDEP has put forward in its comments. The position it espouses with respect to the general permits is consistent with its long-standing practices for implementing 316(b). One only has to look at the different CWIS requirements that have been required at facilities in New Jersey to see this.

Footnotes

26 See page 18 of NJDEP’s comments submitted under letter from Bradley M. Campbell, Commissioner of the NJDEP dated August 7,2002.

EPA Response

EPA is not in a position to respond to this comment. The prior implementation of 316(b) in these states and their present position on implementation are state-specific issues.

RFC: Proposed use of restoration measures

EPA'S DECISION TO INCORPORATE RESTORATION MEASURES IS SUPPORTED BY SOUND SCIENCE, AS THE ADMINISTRATIVE RECORD FOR THIS RULEMAKING DEMONSTRATES

EPA has very wisely determined to continue its long-standing practice of allowing permittees to propose restoration measures in lieu of or in combination with technological measures to address CWIS-related effects. (67 Fed. Reg. 17221). There is a wealth of scientific data and information that demonstrate the value of habitat restoration programs (e.g., wetlands and eelgrass restoration or installation of fish ladders) and other such measures (e.g., stocking programs). Moreover, EPA itself, its sister agencies charged with protecting the Nation's natural resources, including NMFS and the United States Fish and Wildlife Service ("USFWS"), and the Congress of the United States recognize the essential link between habitat and fisheries. Finally, the administrative record contains a substantial body of documents including scientific literature and government reports supporting restoration in general together with reports and information describing the restoration measures successfully implemented by power plants subject to the Phase II Proposed Rule.

In the NODA, EPA has sought comments on both the entire administrative record for the Phase II Rulemaking, which includes comments challenging the Agency's proposed determination to include restoration measures, and some specific proposals aimed at enhancing the likelihood that restoration projects implemented to address 316(b) would be successful (68 Fed. Reg. 13541). In this section, PSEG provides additional information demonstrating the value of restoration measures for aquatic resources to supplement the record and responds to the EPA’s request for comments on additional measures to enhance the success of wetlands.

EPA Response

In the final rule, EPA allows use of restoration measures to minimize or to help to minimize the adverse environmental impacts that derive from impingement and entrainment of aquatic organisms. For discussion of EPA's authority to include restoration measures in the final rule, see the preamble to the final rule.

RFC: Proposed use of restoration measures

Independent Scientists, EPA's Office of Wetlands and Resource Protection Agencies Recognize the Importance of Habitat Restoration to Maintenance of Fish Populations

While critics of restoration measures continue to question the merit of such programs and/or allege their experimental nature, there is an ever-growing body of peer-reviewed scientific literature authored by well-respected scientists at major universities that demonstrate the critical link between habitat and fisheries and report on the successes in developing and implementing habitat restoration programs. Recent government publications further highlight the critical importance of habitat and stress the importance of habitat restoration.

The Link between Coastal Wetlands and Estuarine and Marine fisheries is Well-Established

Healthy tidal wetlands that are linked to estuarine and coastal waters provide critical ecosystem support through direct contribution to food webs and by serving as highly favorable habitat for aquatic organisms: In particular:

- Marsh creeks are used for feeding, breeding, and shelter by a variety of fish and invertebrates, and marshes are important habitat for both estuarine resident and continental shelf species (Talbot and Able 1984; Rountree and Able 1992; Shenker and Dean 1979; Weinstein 1979; Rozas and Hackney 1984).

- Consumer fish in marshes feed on abundant bottom-dwelling invertebrates (Boesch and Turner 1984; Smith et al. 1984).

- The movement of fish in and out of wetland areas is an important energy transfer linkage between marshes and estuarine and coastal waters (Weinstein and Walters 1981; Conover and Ross 1982; Currin et al. 1984; Cadigan and Fell 1985; van Montfkans et al. 1991).

- Large carnivorous fish (including such commercially and recreationally valuable species as weakfish (Cynoscion regalis), summer flounder (Paralichthys dentatus), striped bass (Morone saltatrix), and bluefish (Pornatornus saltatrix) use the estuary on a seasonal basis and derive substantial food resources from forage fish and shellfish associated with marshes (Pennock 1988).

These findings have been confirmed, extended, and supported by recent studies and reviews. Large, carnivorous estuarine fish species have been documented to use shallow nearshore waters to a greater degree than was previously realized (Rountree and Able 1997; Salem's 1999 Application, Appendix G, Exhibits G-3-1, G-3-3, and G-3-5). Growth and survival of many species is promoted by tidal wetland habitats (Kneib 1997), and marshes are important contributors to growth of early life history stages (Ayvazian et al. 1992; Baltz et al. 1993; Kneib 1997; Salem's 1999 Application, Appendix G, Exhibits G-3-4, G-3-6, G-3-7 and G-3- 9). In addition to food, marshes provide fish and shellfish with other important habitat support (Salem's 1999 Application, Appendix G, Attachment G-3 and Exhibits

G-3-4, G-3-5, G-3-9 and G-3-10). Water on the marsh surface may shelter fish from cold winter temperatures (Smith and Able 1994) and provide optimal temperatures for growth during the active season (Brett et al. 1969; Pietrafesa et al. 1986). Marshes may shelter some fish from predation (Nixon and Oviatt 1973; Joseph 1973), but also serve as a focus for feeding by trophic generalists (Moyle and Cech 1996). Tidal wetlands provide important spawning habitat, for both marsh resident species and other estuarine species.

The United States Congress and federal regulatory agencies continue to recognize the importance of coastal wetlands and estuarine habitat to fish and wildlife. As mandated by Congress, there are a number of federal initiatives designed to promote estuary habitat restoration. USEPA should be commended for including provisions in the Proposed Phase II Rule that promote the implementation of restoration measures and support these national objectives.

As recognized by Congress in the 1996 amendments to the Magnuson-Stevens Fishery Conservation and Management Act (the “Sustainable Fisheries Act
amendments”) See Pub. L. 104-297 (1996):

one of the greatest long-term threats to the viability of commercial and recreational fisheries is the continuing loss of marine, estuarine, and other aquatic habitats. Habitat considerations should receive increased attention for the conservation and management of fishery resources of the United States.

The U.S. Environmental Protection Agency (USEPA 1998) concurs, stating that coastal wetlands:

are extraordinarily productive habitats that offer protective shelter and abundant food to juvenile fish, shellfish, migrating waterfowl, and thousands of other species.. ..Coastal wetlands also buffer the coastline from severe storms and intercept nutrients and sediments.. ..Ecologists estimate that more than half of the [Mid- Atlantic, including Delaware Bay,] region’s wetlands have been lost because of human activities dating from pre-colonial times.

USEPA also recognizes that the value of the system depends on the multi-habitat nature of the coastal complex (USEPA 1998):

Presently, about two thirds of the coastal wetlands are salt marshes colonized by salt-tolerant grasses and bushes. Much of the balance [is] tidal mud flats, areas that are exposed at low tide and are densely packed with shellfish, invertebrates, crabs and other organisms. The remainder [is] freshwater marshes, forests, and shrublands.

Recently, fisheries biologists with the NMFS published a review article titled

Catching the Link Between Wetlands and Fisheries Management. (Stedman and Brown 2000.) The authors point out that:

Fish use wetlands as nursery areas, spawning grounds, feeding areas, and refuge from predators. The wetland vegetation, the rich detritus, and the shallow water provide unique functions that benefit many fish. Approximately three-quarters of the commercial fish landings in the United States consists of species that depend on estuaries and their wetlands.

The NMFS further emphasized the critical link between wetlands and survival of fish populations in the recent publication, “Wetlands and Fish: Catch the Link: (NMI;S 2003). As stated by these fisheries biologists:

Wetlands are vital to fish populations because fish depend on certain wetland functions. Wetlands serve as a food base, shelter, spawning and nursery areas, and for water filtration.. . . Thus, a network of abundant and healthy wetlands is vital to the survival of most fish species.

To promote the restoration of estuary habitat and develop a national strategy for creating and maintaining effective estuary habitat restoration partnerships among public agencies at all levels of government, Congress enacted the “Estuary Restoration Act of 2000” . See Pub. L. 106-457 (Nov. 7,2000). This Act created the “Estuary Habitat Restoration Council” of which USEPA is a member, in conjunction with representatives from the United States Army Corps of Engineers, the National Oceanic and Atmospheric Administration (“NOM’), the USFWS and United States Department of Agriculture.

A stated purpose of the Estuary Habitat Restoration Strategy being developed by the USEPA and other “Council” members is to:

provide incentives for the creation of new partnerships between public and private sectors, and foster coordination of Federal and non-Federal activities related to restoration of estuary habitat.

Inclusion of provisions for restoration measures in the Proposed Rule directly supports these goals and is exactly the type of initiative intended by Congress when the “Act” was enacted.

The USEPA, in partnership with other federal agencies, is responsible for restoring and maintaining the chemical, physical and biological integrity of the nation’s waters and has recognized. the important of wetlands for fish and wildlife. USEPA uses a number of non-regulatory programs to supplement efforts under Section 404 of the Clean Water Act. As stated in the USEPA publication “America’s wetlands: Our vital link between land and water:,”

Most commercial and game fish breed and raise their young in coastal marshes and estuaries. Menhaden, flounder, sea trout, spot, croaker, and striped bass are among the more familiar fish that depend on coastal wetlands. (USEPA 1995)

USEPA promotes the restoration, creation and enhancement of wetlands and aquatic resources by providing technical guidance (USEPA 2000, Interagency Workgroup on Wetland Restoration 2003). Guidance provided by the USEPA Office of Wetlands, Oceans and Watersheds (USEPA 2000) supports current Federal initiatives, such as inclusion of restoration measures in the Proposed Rule, and can facilitate implementation of restoration measures by cooling water users choosing this option for compliance with the performance standards specified in 125.94 of the Preferred Approach.

EPA Response

In the final rule, EPA allows use of restoration measures to minimize or to help to minimize adverse environmental impacts that derive from impingement and entrainment of aquatic organisms. For a discussion of EPA's authority to include restoration measures in the final rule, see the preamble to the final rule.

EPA believes that restoration science continues to progress.

RFC: Proposed use of restoration measures

The Use of Fish Ladders and Other Similar Devices is a Well-Established Means to Enhance Production of Anadromous Fish

As recognized by fishery resource management agencies throughout the northeastern United States (Atlantic States Marine Fisheries Commission ["ASMFC"] 1998), the installation of fish ladders can result in increased commercial and recreational fisheries. Since colonial times, many tributary streams and rivers utilized by river herring, as well as other species, have been dammed or otherwise blocked for industrial, irrigation, recreational, and flood control purposes, leading to a decline in anadromous fish stocks (PSEG 1993; ASMFC 1985). Additionally, estuarine water quality contributed to declines in anadromous fish stocks (ASMFC 1998). River herring have suffered from a loss of spawning habitat in tributary streams and rivers along the Atlantic coast. Blockages of the tributaries have contributed to reduced anadromous species populations including river herring. Since the 1960s, efforts have been underway to provide passages
around dams for anadromous fish and to restore these depleted fish stocks. Fish ladders are a proven technology for enabling fish to pass upstream over natural and manmade barriers in rivers and streams.

Fish restoration plans are proceeding along the entire East Coast. Connecticut has an extensive program for enhancing and restoring river herring populations; it includes activities associated with upstream and downstream fish passage, juvenile monitoring, and adult stocking (Gephard et al. 1998). There are at least 25 fishways installed on Connecticut rivers and streams for the purpose of passing anadromous fish upstream. The State of Connecticut owns and operates five of these facilities; the remaining fishways are town-or privately-owned. The CDEP considers fish ladders to be a proven technique for restoring river herring runs and supports their continued installation at dams where no upstream passages are present (Gephard et al. 1998).

In Rhode Island, steeppass ladders have been used to restore runs of river herring. In some cases, these ladders have performed so well that they had to be replaced by larger Denil ladders in order to pass the increased number of fish arriving at the ladder sites (Gibson 1993).

Alaska steeppass ladders have been installed at several locations in Maine. Information that was obtained on four steeppass ladders indicates that they are effective. (Flagg 1998). Thousands of adult alewife (more than 10,000 at one ladder) use the ladders each year.

Alaska steeppass ladders also have been constructed for passing river herring at several locations in New Jersey (Byme 1993,1999). A ladder at Shenandoah Lake (south branch of the Metedeconk River) has passed alewives into the lake since 1973. PSEG has installed a total of eight fish ladders in Delaware and New Jersey on tributaries of the Delaware Estuary in order to restore spawning runs and provide habitat for river herring. Stuhes to date show that the ladders are properly located and designed, that fish are able to pass upstream through them, that spawning is successful, and that juvenile growth is occurring. Benefits of the ladders in enhancing fish production are only beginning to be realized because the ladders have only been operational for a few years and river herring spawning does not begin until three to six years from birth.

A total of 733 acres of additional habitat have been made available by the installed ladders. In addition to producing substantial numbers of additional adult river herring that will return to the Estuary, the newly accessible impoundments will also produce substantial additional forage for the predator species in the Estuary. The estimated range of potential juvenile production is 736,665 to 4,194,959 fish; it is likely that actual juvenile production will be near the higher end of the estimated range. Bioenergetics studies using the delayed consumption estimate method found that between 5,882 and 33,498 kg of striped bass and weakfish would be produced as a result of these predators' consumption of this increase in juvenile herring production (Salem's 1999 Application, Appendix G, Attachment G-5).

EPA Response

In the final rule, EPA allows use of restoration measures to minimize or to help to minimize adverse environmental impacts that derive from impingement and entrainment of aquatic organisms. For a discussion of EPA's authority to include restoration measures in the final rule, see the preamble to the final rule.

EPA believes restoration science continues to progress.

RFC: Proposed use of restoration measures

Restoring Wetlands is not an Experiment; The Science is Sufficiently Well-Developed

There is overwhelming support form the scientific community and regulatory agencies for habitat restoration programs. PSEG is supplementing its prior submission <FN 27> in this section to include additional peer-reviewed literature demonstrating the value of wetlands to fisheries.

PSEG's Wetlands Restoration Program was Based on Recognized Scientific Principles

Degraded wetlands can be successfully restored where conditions favoring restoration exist, an appropriate design properly addressing ecological considerations is implemented, and the program is monitored and managed to ensure the restoration becomes self-sustaining (Weinstein et al. 1997, Weinstein et al. 2000). PSEG has previously summarized the literature on wetlands restoration, described marsh restoration projects that offered methodological precedents, and demonstrated the effectiveness of restoration techniques (Salem's 1999 Application, Appendix G).

Recent projects that incorporate one or more of the wetland restoration principles in their design and Implementation include:

- Drakes Island Marsh (Maine) and Mill Brook Marsh (New Hampshire). These sites are formerly diked marshes with tidal flow recently restored. At Mill Brook, where full tidal exchange was effectively restored, healthy marsh structure and processes returned rapidly. At Drake's Island, tidal flow was not fully restored, and the vegetation recovery has lagged (Burdick et al. 1977).

- Tidal Wetlands, Vero Beach, FL. An impounded wetland was reconnected to the estuary. The system has matured and the restoration is considered a success, with tidal exchange supporting use of the restored area by fish, crustaceans, reptiles, and mammals, including the endangered manatee (Beeman 1992 and 1999, personal communication).

- Barn Island, Stonington, CT. Tidal flow was restored to a series of impoundments where salt marsh vegetation had been replaced by Phragmites and non-salt tolerant plants. Following restoration of full tidal exchange, establishment of desirable salt marsh grasses, and recolonization and use of the area by fish, birds, and invertebrates typical of healthy tidal marshes was rapid (Rozsa 1998; Brawley et al. 1998).

- Long Island Sound Marshes, Southern Connecticut. Restoration of tidal exchange to flow-restricted marshes resulted in a pattern of vegetation dieback (as salinity levels increased and accreted marsh plain re-established equilibrium with tide levels) and ongoing recovery of typical salt marsh mix of plants, tidal flats and open water (Rozsa 1998).

- Hammock River Marshes, Clinton, CT. Drained and dried marshes were restored to tidal flow by water management techniques,' resulting in rapid and cost-effective recovery of a typical mix of salt marsh vegetation and mud flats, including a healthy and stable upland edge of appropriately diverse shrubs and grasses (Rozsa 1997).

It is clear from the high level of activity in the wetlands restoration field and the increasing body of knowledge regarding techniques and monitoring data that wetlands restoration is a valuable and effective tool for coastal environmental management.

PSEG is successfully restoring five sites in New Jersey and two sites in Delaware using these demonstrated wetland restoration principles. These sites include three previously diked salt hay farms, located in Commercial, Dennis, and Maurice River Townships in New Jersey. The remainder of the sites are those that, prior to restoration, were dominated by the common reed, Phragmites australis ("Phragmites").

At the salt hay farms, normal daily tidal flow has been restored through a program of channel enhancement and excavation and dike breaching. Restoration construction was completed in accordance with the schedules approved in the Management Plans in October 1996 at the Dennis Township site, March 1998 at the Maurice River Township ("MRT") site, and November 1997 at the Commercial Township site. Two of the five sites have been deemed completely restored, based on their having met the NJDEP's success criteria. In 2001, the Dennis Salt Hay Farm site met both the vegetative and hydrologic criteria. In 2002, the Maurice River Township site met these success criteria. Section VI.B.4 below provides additional information on the status of PSEG's wetlands restoration sites.

The Phragmites-dominated sites are being restored by reducing monocultural stands of Phragmites, thereby minimizing the undesirable ecological conditions associated with Phragmites and fostering the growth of Spartina spp. and other desirable marsh species. In particular, the program employs a multi-phased approach that included baseline field data collection, initial Phragmites control through application of an herbicide (Rodeo (c) with a surfactant), additional field data collection, and supplemental Phragmites control using additional herbicide application and/or alternate technologies investigated as part of PSEG's test area program. Restoration activities were completed in accordance with the schedules in the approved Management Plans in September 1999 at the New Jersey Phragmites-dominated wetland restoration sites and in June 2000 at the Delaware sites.

RFC: Proposed use of restoration measures

PSEG's Wetlands Program Has Achieved its Predicted Results and the Benefits are Accruing to the Estuary

PSEG has performed the most comprehensive analysis of the faunal response to salt marsh restoration ever conducted (Salem's 1999 Application, Appendix G, Attachment G-3). The analysis includes extensive information on many aspects of the fauna (fishes, crabs, and invertebrates). For the fishes, it includes a variety of life history stages and incorporates information on habitat use, food, growth, and movements of fishes at several trophic levels. As summarized in PSEG's Biological Monitoring Program 2001 Annual Report (PSEG 2002), PSEG continues to collect and analyze data on fish utilization of the restored wetland restoration sites. Focusing on the restoration sites where restoration activities were first completed, data from the three restored salt hay farms demonstrates that:

- species richness, species composition, and abundance of marsh fauna at restored salt hay farms are equivalent to that of reference marsh or on a trajectory approaching them;

- habitat for reproduction, feeding and growth are equivalent for restored salt hay farm and reference marsh; and

- movements, feeding that occurs in marsh habitats and subsequent seasonal movements provide mechanisms for transferring energy ingested from restored marshes to the bay and ocean.

In the space of only a few years, the former diked salt hay farm sites are producing benefits for fish production that are equal to or even greater than those provided by nearby natural Spartina wetlands used as reference sites (Able et al. 2000, Able et al. 2001, Able et al. In review, Smith et al. 2000). The studies show that the restored marshes are being used by the same fish, and in the same numbers, as the reference marshes, and are providing food to RIS species, including weakfish caught in the open Estuary (Able et al. 2000). Comprehensive monitoring data document extensive use of the marsh plain and rivulets by small fishes and use of larger tributaries by predator fish. The evidence dramatically refutes the claims of the critics and skeptics of the restoration program, who chimed that it was unproven and experimental and could never succeed. The evidence fully vindicates the expectations of PSEG in proposing and the NJDEP in adopting the wetlands restoration program.

At the Phragmites sites, the larger tidal creeks supported functioning fish assemblages prior to restoration and, because of the early stage of restoration, would not be expected to show a dramatic response to restoration in the near term. Notwithstanding, data indicate that the abundance of fish in small marsh creeks generally remained steady or increased as the restoration of these sites progressed. Data regarding abundance of resident fish species, which use the marsh plain indicate increased abundance of mummichog in Spartina habitats (Able and Hagan 2000, Able and Hagan 2003, Able et al. In press). As further discussed below, as restoration of the Phragmites-dominated sites progresses, Phragmites is replaced by Spartina and other desirable species, and the habitat reverts to more natural conditions, fishes will be able to use the sites more effectively for feeding, reproduction and nursery

(Grothues and Able In press, Weinstein and Balletto 1999).

PSE&G undertook several comprehensive studies to determine whether, in fact, restored marsh successfully augments the aquatic food web, and provides habitat for reproduction, feeding, growth and refuge for numerous species of fish and other estuarine fauna (Salem's 1999 Application, Appendix G-3). These studies were focused on the restored salt hay farms because they are further along in the restoration process. PSEG's studies showed that by 1998, the seasonal occurrence, abundance, and size of blue crabs in the restored marshes were similar to or greater than that of the reference marsh (Able l et al. 2000, Able et al. 2001, Jivoff and Able In review, Miller and Able 2002, Tupper and Able 2000). Studies at the Dennis and Commercial Township sites found that the abundance of several fish species, including Atlantic croaker, bay anchovy, spot, striped bass, weakfish, and white perch in large marsh creeks was greater than or equivalent to abundance at the reference site (Able et al. 2000, Able et al. 2001, Miller and Able 2002, Tupper and Able 2000). Detailed analysis of the food habits of young mummichog, bay anchovy, spot, weakfish and white perch, and of adult striped bass and white perch, indicate that individuals in the restored and reference marshes eat equivalent food in equivalent amounts (Nemerson and Able In press, Teo and Able 2003). These studies found that fish were using the restored marshes for habitat for reproduction, feeding and growth on the same basis as the reference marshes. Indices of fish survival showed similar function between restored and reference marshes.

RFC: Performance/effectiveness of restoration

EPA Is Wisely Considering Incorporating Certain Requirements That Would Ensure The Success Of Restoration Programs To Be Implemented Under 316(b)

USEPA is considering requiring the following practices during the development of restoration, projects (68 Fed. Reg. 13542, col. 1):

- documentation of sources and magnitude of uncertainty in expected restoration project performance;

- creation and implementation of an adaptive management plan; and

- use of an independent peer review to evaluate restoration proposals.

PSEG supports the UWAG comments on incorporation of these practices and agrees that all three factors (uncertainty analysis, adaptive management, and peer review) may be useful for designing, assessing and managing restoration projects. PSEG also recommends that the USEPA issuance guidance for Directors and permit writers to use during their review of proposals by cooling water users to implement restoration measures. Attachment B to these comments includes some suggestions for the type of guidance recommended by PSEG.

Uncertainty in expected restoration performance can be addressed by requiring the inclusion of safety margins within the restoration plans submitted by operators of cooling water intakes. The appropriate margin of safety for particular conservation measures should be determined by the Director on a site-specific basis. The margin of safety appropriate for a particular restoration measure should depend on the circumstances under which they are proposed. Factors such as those listed below should be considered in determining the appropriate margin of safety to be applied: the degree of uncertainty concerning the adverse impact of CWIS operations (e.g., whether or not the aquatic populations demonstrate long-term trends of increasing abundance); the scientific understanding of the ecological benefits of the proposed conservation measures; the ability to monitor and quantify the ecological benefits of the proposed conservation measures; and the intended lifetime duration of CWIS. The required consultation with appropriate Federal, State and Tribal fish and wildlife management agencies proposed to be required under 125.94(d) of USEPA's Preferred Approach would afford regulatory agencies sufficient input to ensure that an appropriate margin of safety is defined.

As indicated in PSEG's prior submission to the Agency, adaptive management provisions also help to ,reduce the uncertainty of restoration activities. PSEG concurs with USEPA's recommendation that restoration planners further reduce uncertainty by creating habitat that replicates as closely as possible the natural habitats in which the aquatic organisms of interest naturally occur (67 Fed. Reg. 17148, col.2,§ VI). Given the level of complexity in the ecology of tidal wetlands and other types of potential restoration projects, and the inability to completely understand the details of the functioning of these systems; adaptive management is an appropriate framework under which a successful large-scale environmental restoration can be conducted. This is exactly what PSEG did in designing and implementing its Estuary Enhancement Program (Weinstein, et al. 2000). The "adaptive management" process has been followed to monitor, guide, and respond to the temporal process of restoration for habitat restoration sites (Salem's 1999 Application, Attachment G-2).

While PSEG agrees that these practices should be incorporated during the development of restoration proposals, it is important that each be tailored to the individual project. Therefore, the Final Rule should not require that these factors be applied whenever a restoration project is proposed, but should allow the Director to apply them as necessary to ensure a successful project.

EPA Response

EPA believes there are uncertainties associated with the design, implementation, performance and assessment of restoration measures. For a discussion of these uncertainties, see EPA's response to comment 316bEFR.206.055. The use of adaptive management, peer review, and uncertainty analysis is intended to help reduce uncertainties associated with restoration measures and enhance their overall productivity (see EPA's responses to comments 316bEFR.307.047 and 316bEFR.311.022).

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

EPA believes the requirements for restoration measures provide permitting authorities and permit applicants with flexibility. However, any restoration measure must meet all of the requirements described in the final rule.

Determination of compliance

EPA'S PREFERRED APPROACH FOR DETERMINING COMPLIANCE WITH 316(b) AT EACH FACILITY IS REASONABLE IF CERTAIN KEY COMPONENTS ARE APPROPRIATELY RESOLVED IN THE FINAL RULE

Although the Proposed Rule and NODA provide considerable information regarding EPA's Preferred Approach, key details on how compliance with all requirements of 316(b) would be determined are absent from the Proposed Rule and NODA. PSEG believes that the reasonableness and workability of EPA's Preferred Approach depends on how questions regarding these details are resolved in the Final Rule. This section of PSEG's comments identifies and provides suggestions on several key details that must be addressed in the Final Rule. Specifically, this section addresses details of the metrics that would be used to measure reductions in entrainment and impingement mortality, and details of the tests of compliance with performance options.

Background

In the Proposed Rule, EPA put forward a number of regulatory approaches it had considered for implementing 316(b). The Agency's Preferred Approach is described below.

Alternatives for Establishing BTA

The Preferred Approach provides three demonstration alternatives for establishing BTA at each facility (125.94(a)):

- Demonstration that the existing design and construction technologies, operational measures, and/or restoration measures meet performance standards;

- Demonstration that selected design and construction technologies, operational measures, and/or restoration measures will, in combination with existing design and construction technologies, operational measures, and/or restoration measures, meet performance standards;

- Demonstration that a site-specific determination of BTA is appropriate.

Performance Standards

The following are central to demonstrations of BTA alternatives (1) and (2): the definitions of the performance standards, the metrics that would be used to measure compliance with performance standards, and the tests of compliance with performance standards. These topics are discussed in the following sections.

Performance Standard Definitions

Four different performance standards are defined in the Preferred Approach (5 125.94(b)), and each facility that selects BTA demonstration alternative (1) or (2) would be required to comply with one of the four performance standards. The determination of which of the four performance standards would depend on the facility's cooling system characteristics and on the source water body. The four performance standards are:

- intake capacity commensurate with the use of a closed-cycle, recirculating cooling system; or

- reduction of impingement mortality of all life stages of fish and shellfish by 80 to 95 percent from the calculation baseline if the facility.

-- has a capacity utilization rate less than 15 percent, or

-- has a design intake flow 5 percent or less of the mean annual flow from a freshwater river or stream; or

- reduction of impingement mortality of all life stages of fish and shellfish by 80 to 95 percent from the calculation baseline, and reduction of entrainment of all life stages of fish and shellfish by 60 to 90 percent from the calculation baseline if the facility

-- has a capacity utilization rate of 15 percent or greater, and withdraws cooling water from a tidal river or estuary, from an ocean, from one of the Great Lakes, or

-- has a design intake flow greater than 5 percent of the mean annual flow of a freshwater river or stream; or

- reduction of impingement mortality of all life stages of fish and shellfish by 80 to 95 percent from the calculation baseline if the facility withdraws cooling water from a lake (other than a Great Lake) or reservoir <FN 28>

The calculation baseline in performance standards (2), (3) and (4) is defined in the Preferred Approach (125.93) as:

an estimate of impingement mortality and entrainment that would occur at your site assuming you had a shoreline cooling water intake structure with an intake capacity commensurate with a once-through cooling water system and with no impingement and/or entrainment reduction controls."

In the NODA, EPA proposed a modification to this definition that provided additional detail (68 Fed. Reg. 13581):

an estimate of impingement mortality and entrainment that would occur at your site assuming (1) the cooling water system has been designed as a once-through system; (2) the opening of the cooling water intake structure is located at, and the face of the standard 3/8 inch mesh traveling screen is oriented parallel to, the shoreline near the surface of the source water body; and (3) the baseline practices and procedures are those that the facility would maintain in the absence of any operational controls, including flow or velocity reductions, implemented in whole or in part for the purposes of reducing impingement mortality and entrainment."

Metrics for Measuring Reductions in Impingement Mortality and Entrainment

In the NODA, EPA indicated that it was evaluating several methods for determining percent reduction in impingement mortality and entrainment (68 Fed. Reg. 13582):

- consideration of all fish and shellfish species that have the potential to be impinged or entrained; or

- consideration of fish and shellfish from only a subset of species determined to be representative of all the species that have the potential to be impinged or entrained, and

-- applying the percent reduction requirements to all the representative species as a group, or

-- applying the percent reduction requirements to each and every species on the representative species list.

For each of the methods for determining percent reduction, EPA is considering two methods for measuring the species impinged or entrained (68 Fed. Reg. 13582):

- by counting the total number of individual organisms, or

- by weighing the total wet or dry biomass of organisms.

Footnotes

28 This performance standard also includes the requirement that if the facility proposes to increase its design intake flow, the increased flow must not disrupt the natural thermal stratification or turnover pattern (where present) of the source water, except in cases where the disruption is determined by any Federal, State or Tribal fish or wildlife management agency(ies) to be beneficial to the management of fisheries.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Subject Matter Code 21.04

Determination of compliance

Tests for Compliance with Performance Standards

The Proposed Rule and the NODA do not provide definitive statements of EPA's proposed approach for testing compliance with performance standards. Based on PSEG's review of the Proposed Rule and NODA, it appears that the best indication of EPA's proposed approach for compliance testing is provided in EPA's discussion of the Comprehensive Demonstration Study that must be submitted by all facilities (except those deemed to have met performance standard (l), above). The Comprehensive Demonstration Study would include information:

"to confirm that the technology(ies), operational measures, and/or restoration measures you have selected and/or implemented at your cooling water intake structure meet the applicable requirements of 125.94."

For facilities that select BTA demonstration alternative (1) (i. e., a demonstration that the existing design and construction technologies, operational measures, and/or restoration measures meet performance standards), the test of compliance apparently would be based on a comparison of current impingement mortality and entrainment to the Calculation Baseline impingement mortality and entrainment. The Comprehensive Demonstration Study would include an Impingement Mortality and Entrainment Characterization Study, the purpose of which would be (§125.95(b) (3)):

“to provide information to support the development of a calculation baseline for evaluating ,impingement mortality and entrainment and to characterize current impingement mortality and entrainment.”

The Impingement Mortality and Entrainment Characterization Study would include (125.95 (3) (iii)) :

“Documentation of the current impingement mortality and entrainment of all life stages of fish and shellfish at your facility and an estimate of impingement mortality and entrainment under the calculation baseline.”

For facilities that select BTA demonstration alternative (2) (I.e., a demonstration that the selected design and construction technologies, operational measures, and/or restoration measures will, in combination with existing design and construction technologies, operational measures, and/or restoration measures, meet performance standards), the test of compliance apparently would be based on a comparison of the Calculation Baseline impingement mortality and entrainment to impingement mortality and entrainment that would occur after the selected technologies and/or measures are implemented. The Comprehensive Demonstration Study would include a Design and Construction Technology Plan, which would provide (125.95(b) (4) (iii)):

“Calculations of the reduction in impingement mortality and entrainment of all life stages of fish and shellfish that would be achieved by the technologies and operational measures you have selected based on the Impingement Mortality and Entrainment Characterization Study.. .”

The Comprehensive Demonstration Study would also include a Verification Monitoring -Plan, which would be (125.95(b) (7)):

“a plan to conduct, at a minimum, two years of monitoring to verify he full-scale performance of the proposed or implemented technologies, operational measures, or restoration measures. The verification study must begin once the technologies, operational measures, and restoration measures are implemented and continue for a period of time that is sufficient to demonstrate that the facility is reducing the level of impingement and entrainment to the levels documented pursuant to paragraphs (b)(4)(iii), (b)(5)(ii), and/or (b)(6)(iii)(B) of this section.”

Some additional detail regarding EPA’s approach for testing compliance with performance standards was provided in the NODA. In its discussion of metrics of reductions in impingement mortality and entrainment (68 Fed. Reg. 13582), EPA provided the following suggested language that it might add at 0 125.95(b)(5):

“Compliance with impingement mortality and entrainment performance standards in paragraphs (b)(1) through (4) above must be determined based on a comparison of the enumeration of all fish and shellfish impinged and killed and entrained with those estimated to be impinged and killed and entrained at the calculation baseline.”

This suggested language provided the needed clarification that EPA intended “impingement mortality” to mean “the number of organisms impinged and killed”, rather than “the proportion of impinged organisms that are killed by impingement.” PSEG interprets EPA’s use of the phase “enumeration of all fish and shellfish” to indicate that the metric of interest is numbers of organisms, and assumes that EPA did not use the phase “enumeration of all fish and shellfish” to imply that a census (Le., a counting of each and every individual organism) of all organisms was needed. Clearly, estimates of impingement mortality and entrainment should be based on samples, not on a census which would be wholly unworkable.

EPA Response

In today’s final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA’s response to comment 316bEFR.017.003. For EPA’s explanation of EPA’s monitoring requirements, please refer to EPA’s response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Subject Matter Code 7.02
Performance standards

Facilities With a Low Capacity Utilization Should be Allowed to Meet the 15 Percent Criteria Through Administrative Controls

As described above, EPA proposes various performance standards against which compliance would be determined. Proposed performance standard 2 would provide that facilities having a capacity utilization rate of less than 15% would only be required to meet the entrainment reduction standards. EPA stated that the determination of whether or not a facility is meeting the 15% capacity utilization rate would be based on the facilities performance over the previous five years.

PSEG fully supports the concept of establishing an “impingement only” performance standard for facilities with a capacity utilization rate of less than 15%. PSEG, however, believes that the ability to demonstrate compliance using this performance standard should not be limited to facilities, which qualify based on historic capacity levels. PSEG proposes that EPA also allow facilities to commit to maintaining a capacity utilization rate of less than 15% in the future. This could be accomplished through administrative controls in the Special Conditions in the NPDES permit. This would achieve the same goal EPA intended to accomplish with the second performance standard while allowing facilities that have a low potential for adversely impacting the environment to avoid the additional costs of unnecessary compliance, reduce the potential for their shutdown and avoid unnecessary risks to electric supply.

EPA Response

Today's rule adopts less stringent criteria (impingement mortality only) for facilities having a capacity utilization rate of less that 15% (see § 125.94(a)(1)).

EPA believes the definition of a peaking facility as presented in the final Phase II rule is sufficient to identify those facilities that operate at an overall reduced capacity, thereby making them subject to less stringent compliance requirements as a typical base load facility (see § 125.93). To address commenter concerns, EPA has modified the capacity utilization definition to include the following language: “For the purposes of this regulation, the capacity utilization rate applies only to that portion of the facility which generates electricity for distribution and sale using a thermal cycle employing the steam water system as the thermodynamic medium.”

Peaking facilities are typically older, less efficient generating units. Because the cost of operation is higher, peaking facilities are generally employed when generating demand is greatest and economic conditions justify their use. Such usage is typically a fraction of the unit’s overall generating capacity and represents a significant reduction in the percentage of cooling water used when compared to the design intake capacity. This dramatically reduced flow would appear to obviate the need for entrainment controls for the facility.

Most peaking facilities are employed during the highest electrical demand period, typically mid-winter or mid-summer. It is generally accepted that while these seasons can sometimes be associated with a higher abundance of aquatic organisms or spawning events, mid-winter and mid-summer are not typically considered to be critical periods for aquatic communities. Given these operating conditions, entrainment controls would appear to be an unnecessary cost for these facilities.

Determination of compliance

Comments on Metrics for Measuring Reductions in Impingement Mortality and Entrainment

In the NODA, EPA requested comments on alternative metrics that might be used in tests of compliance with performance standards. As noted above, EPA indicated it was considering numbers of organisms, biomass of organisms, all species of fish and shellfish, and a subset of species of fish and shellfish. PSEG believes that the Final Rule should provide for flexibility in the choice of metrics that takes into account site-specific considerations. Flexibility would be particularly important if a facility has implemented or plans to implement restoration measures.

In some cases, the number of organisms from a subset of species (expressed in terms of numbers at a particular age) might be the most appropriate metric. For example, if a facility has implemented, or plans to implement, the rearing of fish to be released when they reach one year of age, the number of equivalent age-1 fish would be an appropriate metric. This metric would allow for direct comparisons of entrainment and impingement losses to fish production from the restoration measure. A similar situation might arise if fish ladders were installed (as a restoration measure) with the intention of producing annual out-migrations of age-1 fish.

In other cases, the biomass of all fish and shellfish by trophic level might be the most appropriate metric. For example, if a facility has implemented, or plans to implement, restoration of wetlands, the biomass of all species of fish and shellfish, by trophic level would be an appropriate metric. This metric would facilitate comparisons of entrainment and impingement losses at the facility to production of fish and shellfish by the restoration measures. This metric would take into account the benefits of restoration measures to the fish and shellfish communities of a source water body, even if the restoration measures were not intended to offset losses numerically nor to offset losses on a species-by-species basis. This community-level approach is consistent with sections of the Preferred Approach that address the use of restoration measures (125.94(d)):

“You must demonstrate to the Director that you are maintaining the fish and shellfish within the water body, including community structure and function, to a level comparable to those that would result if you were to employ design and construction technologies of operational measures to meet that portion of the requirements of paragraphs (b) or (c) of this section that you are meeting through restoration.”

For the reasons discussed above, PSEG recommends that EPA allow site-specific choices of metrics to be used in tests of compliance with performance standards. In particular, EPA should ensure that biomass of all species of fish and shellfish be allowed as the metric in cases where wetland restoration measures are used to satisfy performance standards.

EPA Response

In today’s final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Determination of compliance

Comments on Tests for Compliance with Performance Standards

As noted above, EPA has not provided documentation, in the Proposed Rule or the NODA, of its proposed approach for testing a facility's compliance with applicable performance standards. The discussion EPA has provided in the Proposed Rule and NODA suggest that its compliance tests, in general, will calculate reductions using impingement mortality and entrainment estimates for the Calculation Baseline as the starting point. However, the following critical aspects of compliance testing have not been adequately addressed in the Proposed Rule or NODA:

- What types of estimates are to be compared to the Calculation Baseline estimates (e.g., empirical loss estimates or model-based predictions)?

- How are the Calculation Baseline estimates to be computed (e.g., empirical loss estimates from a period when the facility operated under Calculation Baseline conditions or model-based predictions)?

- How will the comparison to Calculation Baseline estimates be performed (e.g., will different test procedures be used for each BTA alternative, and if so, what will they be)?

In the following section, PSEG summarizes compliance tests that it believes would be consistent with EPA's intent, based on the limited documentation provided in the Proposed Rule and NODA, and therefore appear to be EPA's proposed approach. In the Final Rule, EPA should provide descriptions (that are at least as detailed as the summaries listed below) of the types of compliance tests that permitting agencies can consider for use with each BTA demonstration alternative.

EPA's Apparent Approach to Compliance Testing

For the purpose of providing comments in response to the NODA, PSEG assumes (based on language, as noted above, in the Proposed Rule and NODA) that EPA envisions the compliance tests described below.

For facilities that select BTA demonstration alternative (1) (i. e., a demonstration that the existing design and construction technologies, operational measures, and/or restoration measures meet performance standards), the test would consist of:

1 A comparison of:

- an empirical estimate of the average annual number (or weight) of all species of fish and shellfish (or a subset of species) killed by impingement under current conditions, to

- an estimate of the average annual number (or weight) of all species (or a subset of species) killed by impingement under the Calculation Baseline condition -- this estimate would be based on the empirical estimate of impingement mortality for current conditions and estimates of the effectiveness for reducing or offsetting numbers killed by impingement of the implemented technologies and/or measures; and (if required by the applicable performance standard for the facility)

2 A comparison of:

- an empirical estimate of the average annual number (or weight) of all species of fish and shellfish (or a subset of species) entrained under current conditions, to

- an estimate of the average annual number (or weight) of all species (or a subset of species) entrained under the Calculation Baseline condition -- this estimate would be based on the empirical estimate of entrainment for current conditions and estimates of the effectiveness, for reducing or offsetting numbers entrained, of the implemented technologies and/or measures.

Although it might be desirable to compare the empirical estimates of impingement and entrainment losses under current conditions to empirical estimates of losses under the Calculation Baseline condition, data collected under the Calculation Baseline condition may not exist. Furthermore, it would be completely unreasonable to require a facility to implement Calculation Baseline technologies and/or measures for the purpose of compliance testing. Therefore, it seems the compliance test in this case would have to be based on estimates of effectiveness of the implemented technologies and/or measures, rather than empirical estimates of losses with and without the implemented technologies and/or measures.

For facilities that select BTA demonstration alternative (2) (i. e. , a demonstration that the selected design and construction technologies, operational measures, and/or restoration measures will, in combination with existing design and construction technologies, operational measures, and/or restoration measures, meet performance standards), the test would be conducted in two steps. The first step would document the basis for the planned technologies and/or measures and consist of:

1 A comparison of:

- an estimate of the average annual number (or weight) of all species of fish and shellfish (or a subset of species) killed by impingement under the Calculation Baseline condition -- this estimate would be based on an empirical estimate of impingement mortality for current conditions and estimates of the effectiveness, for reducing or offsetting numbers killed by impingement, of any already implemented technologies and/or measures, to

- an estimate of the average annual number (or weight) of all species (or a subset of species) that would be killed by impingement after implementation of the selected technologies and/or measures -- this estimate would be based on an empirical estimate of impingement mortality for current conditions and estimates of the effectiveness, for reducing numbers killed by impingement, of the selected technologies and/or measures; and (if required by the applicable performance standard for the facility)

2 A comparison of:

- an estimate of the average annual number (or weight) of all species of fish and shellfish (or a subset of species) entrained under the Calculation Baseline condition -- this estimate would be based on an empirical estimate of entrainment for current conditions and estimates of the effectiveness, for reducing or offsetting numbers entrained, of any already implemented technologies and/or measures, to

- an estimate of the average annual number (or weight) of all species (or a subset of species) that would be entrained after implementation of the selected technologies and/or measures -- this estimate would be based on an empirical estimate of impingement mortality for current conditions and estimates of the effectiveness for reducing numbers killed by impingement of the selected technologies and/or measures.

The second step would be an empirical verification that the expected effectiveness of the implemented technologies and/or measures was realized, and would consist of

1 A comparison of:

- an estimate of the average annual number (or weight) of all species of fish and shellfish (or a subset of species) killed by impingement under the Calculation Baseline condition -- this estimate would be based on an empirical estimate of impingement mortality for current conditions and estimates of the effectiveness, for reducing or offsetting numbers killed by impingement, of any already implemented technologies and/or measures, to

- an empirical estimate of the average annual number (or weight) of all species (or a subset of species) that would be, killed by impingement after implementation of the selected technologies and/or measures -- this estimate would be based on monitoring of impingement mortality after the selected technologies and/or measures were implemented; and (if required by the applicable performance standard for the facility)

2 A comparison of:

- an estimate of the average annual number (or weight) of all species of fish and shellfish (or a subset of species) entrained under the Calculation Baseline condition -- this estimate would be based on an empirical estimate of entrainment for current conditions and estimates of the effectiveness, for reducing or offsetting numbers entrained, of any already implemented technologies and/or measures, to

- an empirical estimate of the average annual number (or weight) of all species (or a subset of species) that would be entrained after implementation of the selected technologies and/or measures -- this estimate would be based on monitoring of entrainment after the selected technologies and/or measures were implemented.

Like the compliance test for BTA demonstration alternative (l), the first step of the compliance test for BTA demonstration alternative (2) would be based on empirical estimates of impingement mortality and entrainment under current conditions and on estimates of the effectiveness for reducing impingement mortality and entrainment of already implemented technologies and/or measures. In addition, the first step of this compliance test would require estimates of the expected effectiveness of the technologies and/or .measures selected for implementation.

The second step of the compliance test for BTA demonstration alternative (2) would be based on two sets of empirical estimates of impingement mortality and entrainment. The first set of empirical loss estimates would be based on data collected under current conditions (the same data that would be used to compute the Calculation Baseline estimates). The second set of empirical loss estimates would be based on data collected after the selected technologies and/or measures are implemented.

The use of empirical loss estimates based on data collected during two different time periods (i. e . , before and after implementation of the selected technologies and or measures), rather than empirical loss estimates from a single time period (ie., current conditions) combined with independent estimates of effectiveness of technologies and/or measures, can lead to invalid test results. Potential problems with the second step of the apparent compliance test for BTA demonstration alternative (2) are discussed in the following section.

Potential Problems Due to Naturally-Occurring Inter-Annual Variability

Naturally-occurring inter-annual variability in the abundance of organisms vulnerable to impingement and entrainment at a facility can be great enough to mask the effects of technologies and/or measures that reduce impingement and entrainment. Naturally-occurring inter-annual variability can be due to changes in population abundance of vulnerable fish and shellfish, or due to changes in spatial distribution patterns.

PSEG conducted analyses of its entrainment and impingement loss data from Salem to examine the effects of naturally-occurring inter-annual variability in entrainment and impingement with respect to BTA demonstration alternative (2). The results of this analysis indicate that the second step of the compliance test for BTA alternative (2) is scientifically invalid. The data that were analyzed and the results of the analysis are summarized below. In addition, an algebraic description/derivation of the potential problem is presented in Attachment C. Section IV.D.4 below presents scientifically valid proposals for addressing these concerns.

Data and Analysis Methods

Entrainment and impingement loss data from 1978 through 1998 for the nine finfish RIS (i.e., alewife, American shad, Atlantic croaker, bay anchovy, blueback herring, spot, striped bass, weakfish, and white perch) <FN 29> were examined for this analysis. All entrainment and impingement loss estimates were normalized to represent losses that would have occurred if the intake flow in each yeas- had been a constant amount (referred to in Salem's 1999 Application as the Basecase Scenario). Data on the forage species (i. e., alewife, bay anchovy, and blueback herring) were analyzed separately from data on the predator species (i.e., American shad, Atlantic croaker, spot, striped bass, weakfish, and white perch). Estimates of the annual entrainment losses (i.e., number entrained and killed, summed over all life stages) are summarized in Figures IV-1 and IV-2. [see hard copy for figures] Estimates of annual impingement losses (i.e., number impinged and killed, summed over all life stages) are summarized in Figures IV-3 and IV-4. [see hard copy for figures] As indicated by these figures, substantial inter-annual variability was present in entrainment and impingement losses. In addition, the data show a general trend of increasing entrainment losses for the predator species, and general trend of decreasing entrainment losses for the forage species.<FN 30>

The data were used in a simulation to determine the probability of passing the compliance test given a known percentage reduction in impingement or entrainment losses. The test was to determine whether the observed average annual losses from the , monitoring period after implementation of (hypothetical) control technologies and or measures was at least 80% lower than the observed average annual losses from the monitoring period before implementation. Five durations for the before and after monitoring periods were simulated:

- 1 year of monitoring before and 1 year of monitoring after implementation

- 2 years of monitoring before and 2 years of monitoring after implementation

- 3 years of monitoring before and 3 years of monitoring after implementation

- 4 years of monitoring before and 4 years of monitoring after implementation

- 5 years of monitoring before and 5 years of monitoring after implementation.

For the simulation, the loss estimates for the “after” implementation period were computed as the Basecase scenario loss estimates (described above) reduced by a known percentage, and the loss estimates for the “before” implementation period were the Basecase scenario loss estimates left unchanged. Three levels of percentage reduction were simulated: 80% reduction, 40% reduction, and no reduction.

Given the five different durations of monitoring periods, and the three different levels of known reductions in entrainment and impingement losses, the analysis included fifteen different scenarios. For each of the fifteen scenarios, ten separate simulations were run, with a different year (1985 through 1994) of the (hypothetical) implementation selected for each simulation. After running all ten simulations, the number of simulations in which the test criterion (Le., at least an 80% reduction in observed losses) was satisfied was recorded. The probability of passing the compliance test was computed as the number of simulations in which the test criterion was satisfied divided by the total number of simulations (Le. , ten).

Results and Conclusions

Results of the analysis indicate that for impingement losses of predator species, even with ten years of monitoring data (five before and five after), there would only be a 60% chance of passing the compliance test (for 80% reduction in impingement losses) when in fact an 80% reduction had been achieved (Figure IV-5). [see hard copy for figure] For forage species, and with ten years of monitoring data (five before and five after), there would be a 60% chance of passing the compliance test (for 80% reduction in impingement losses) when only a 40% reduction had been achieved (Figure IV-6). [see hard copy for figure]

For entrainment, the analysis results indicate severe problems as well. For forage species, and with ten years of monitoring (five before and five after), .there would be a 10% chance of passing the compliance test (for 80% reduction in entrainment losses) when no reduction had been achieved (Figure IV-7). [see hard copy for figure] For predator species, with 10 years of monitoring data (five before and five after), there would only be a 20% chance of passing the compliance test (for 80%

reduction in entrainment losses) when in fact an 80% reduction had been achieved (Figure IV-8). [see hard copy for figure]

In general, the presence of inter-annual variability in the abundance of organisms vulnerable to entrainment and impingement caused the compliance tests to perform very badly -- failing to pass reductions that actually satisfied the performance standard, and erroneously passing reductions that did not satisfy the performance standard. In addition, trends in abundance apparently introduced biases. Forage species (which exhibited a general downward trend) tended to pass the compliance test even when the actual reductions in losses were below the performance standard. Predator species (which exhibited a general upward trend) tended to fail the compliance test even when the actual reductions in losses satisfied the performance standard.

The results from this analysis, based on entrainment and impingement loss data from Salem provide a vivid, albeit limited, illustration of the types and magnitude of problems that likely will occur if EPA relies on a compliance test for BTA demonstration alternative (2) that is based on empirical impingement mortality and entrainment data from two separate time periods (i.e., before and after implementation of control technologies and/or measures). Attachment C contains an algebraic derivation that describes the problem in general. The following section contains recommendations for alternative compliance tests that are not affected by inter-annual variability in abundance.

Footnotes

29 The RIS for the Salem were identified and agreed upon by the Technical Advisory Group ("TAG) USEPA Region I1 established in the late 1970's to oversee the development and implementation of the biological monitoring and data analyses for Salem's initial ' 316(b) Demonstration. The RIS included forage, migratory and commercially and recreationally important species, consistent with USEPA's 1977 draft 316(b) Guidance.

30 Appendix J and Appendix H of the 1999 Salem Permit Renewal Application documented significant increases in abundance of age-0 weakfish, striped bass, Atlantic croaker, ,+merican shad, alewife, white perch; decreases in abundance of spot and blueback herring, and no consistent trend in abundance of bay anchovy in Delaware estuary from the 1980s through the 1990s.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

As discussed in the NODA, EPA considered many suggestions for the approach to determining the calculation baseline, and has clarified its definition of calculation baseline in today's final rule (see §125.93). For additional explanation of EPA's definition of calculation baseline, please refer to EPA's response to comment 316bEFR.034.013.

For EPA's position on accounting for the natural variability of fish populations, please see EPA's response to comment 316bEFR.034.017.

Determination of compliance

Approaches to Address Potential Problems Due to Naturally-Occurring Inter-Annual Variability

PSEG has performed preliminary evaluations of three alternative approaches (which are not intended to be an exhaustive set of alternatives) for testing compliance with performance standards:

- Ratio of Ratios,

- Ratio of Mortality Rates, and

- Weighted Average Flow Reductions.

Each of the approaches could be appropriate for determining compliance, depending on the technologies and/or measures used to satisfy the performance standards. A summary of the compliance test approaches that would be appropriate for several types of technologies and operational measures is presented in Tables IV-1 and IV-2. [see hard copy for tables] An algebraic description/derivation of each approach is provided in Attachment C.

Ratio of Ratios

The Ratio of Ratios approach uses a covariate (ie., an observable quantity that is proportional to the abundance of organisms in the withdrawal zone of the facility) to account for inter-annual variability in abundance of organisms vulnerable to impingement and entrainment at a facility. Rather than simply comparing an estimate of average annual losses before implementation to an estimate of average annual losses after implementation of the technologies and/or measures, this approach is based on the comparison (before vs. after) of standardized estimates of losses.

This standardization is accomplished by dividing each year-specific estimate of annual losses by a corresponding year-specific estimate of relative abundance in the water withdrawal zone of the facility. This approach could be used to estimate reductions in entrainment due to technologies such as physical barriers, behavioral deterrents, and collection/return systems (e.g., fine mesh on traveling screens). This approach could also be used to estimate reductions in impingement mortality due to those technologies.

Ratio of Mortality Rates

The Ratio of Mortality Rates approach would be appropriate for estimating reductions in impingement mortality (i. e., impinged and killed) due to collection/return systems. In this approach, it is assumed that the reduction in impingement mortality is due entirely to a reduction in the proportion of impinged organisms that die from impingement. Therefore, the estimate of reduction in impingement mortality is based on the ratio of impingement mortality rates (rather than the ratio of numbers or weight of organisms impinged and killed). Application of this approach would require data from special studies of impingement mortality rates performed after the technologies were implemented.

Since the comparison would be to Calculation Baseline conditions, which assume 100% impingement mortality rates, data collection prior to implementation of the technologies would not be needed if the technology used 3/8" mesh screen (i. e., the same screen as the Calculation Baseline). However, if the screen of the control technology was finer than the Calculation Baseline screen, then sampling of screens with both mesh sizes would be needed to determine whether small fish not impinged on the 3/8" mesh would be impinged on the finer mesh. This situation is addressed in the Section IV.D.4, below.

Weighted Average Flow Reduction

The Weighted Average Flow Reduction approach would be appropriate for estimating reductions in entrainment due to operational measures like seasonal flow reductions. This approach is based on EPA's assumption that entrainment (all other things being equal) is proportional to intake flow (67 Fed. Reg. 17141):

"EPA believes that, absent entrainment control technologies, entrainment at a particular site is proportional to intake flow at that site."

The Weighted Average Flow Reduction approach would begin with a delineation of the percentage reduction in flow that occurred in each week of a calendar year. Next, the proportion of the average annual entrainment losses that occurred in each week would be estimated. Then a weighted average of the percentage flow reductions would be computed using the proportion of the average annual entrainment loss in each week as the weighting factors. The resulting value is an estimate of the annual percentage reduction in entrainment due to the flow reductions.

Applicability of Alternate Approaches

The Ratio of Ratios approach (which requires before and after data) would be appropriate in the second step of a compliance test, for BTA demonstration alternative (2). The Ratio of Mortality Rates approach and the Weighted Average Flow Reduction approach would be appropriate for compliance tests for BTA demonstration alternative (1) or BTA demonstration alternative (2). None of the three alternative approaches has the severe problem of potential biases present in the approach based solely on comparing losses from before and after implementation of technology and/or measures.

EPA Response

In today’s final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA’s response to comment 316bEFR.017.003. For EPA’s explanation of EPA’s monitoring requirements, please refer to EPA’s response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

For EPA's position on accounting for the natural variability of fish populations, please see EPA's responses to comments 316bEFR.034.017 and 316bEFR.335.012.

Determination of compliance

Approaches to Address Technologies That Substitute Impingement for Entrainment

As noted in the previous section, some control technologies under consideration by EPA (e.g. , fine mesh screen) could have the effect of reducing entrainment while increasing impingement. In situations like this, a separate approach for determining compliance with performance standards may be needed. EPA anticipated this issue (i.e., the application of fine mesh screens could increase overall impingement mortality by increasing the number of small, delicate organisms impinged) in its preamble to the Proposed Rule (67 Fed. Reg. 17142):

“EPA notes that screening to prevent organism entrainment may cause impingement of those organisms instead. Questions regarding impingement survival of relatively delicate fish, larvae, and eggs would need to be considered by the Director and the facility in evaluating the efficacy of the technology.”

PSEG offers the following approach for determining compliance with performance standards when technologies that would substitute impingement for entrainment (or visa versa) are being evaluated.

The first step of the approach would be to determine which length classes and taxonomic groups would be entrained under the Calculation Baseline scenario, but would be impinged if the control technology were implemented.

The second step of the approach would be to estimate both the impingement survival rate (i. e., the proportion of impinged organisms that survive being impinged) and the entrainment survival rate (i. e., the proportion of entrained organisms that survive being entrained) of organisms that would be entrained under the Calculation Baseline scenario, but would be impinged if the control technology were implemented. This assessment of survival rates would be conducted by length class and taxonomic group.

PSEG notes (but does not agree with) EPA’s position on the validity of estimates of entrainment survival rates. However, the extent of entrainment survival, in comparison to the extent of impingement survival, is the critical factor that must be addressed in any scientifically valid and ecologically relevant assessment of the efficacy of a technology that substitutes impingement for entrainment. Furthermore, estimating impingement survival rates of organisms small enough to be entrained under the Calculation Baseline scenario poses many of the same difficulties as estimating entrainment survival rates of those organisms. Therefore, any approach for addressing the substitution of impingement for entrainment that relies solely on estimates of impingement survival rates (for organisms that would be entrained under the Calculation Baseline scenario) would be faced with the same types of difficulties (with estimating survival rates) as this suggested approach. Historically, larval impingement survival studies have been conducted in laboratories. Additional impingement survival studies of early life stages could reasonably address impingement survival of organisms that were entrained prior to implementation of control technologies.

The third step would be to estimate the annual number (or weight) of organism in each length class and taxonomic group that would be entrained under the Calculation Baseline scenario, but would be impinged if the control technology were implemented.

The fourth step would be to estimate the total (summed over all length classes and taxonomic groups that would be entrained under the Calculation Baseline scenario, but impinged if the control technology were implemented) annual number (or weight) of organisms that would be killed under the following four conditions:

- by entrainment under the Calculation Baseline scenario,

- by impingement under the Calculation Baseline scenario,

- by entrainment if the control technology were implemented, and

- by impingement if the control technology were implemented.

The fifth step would be to compare the combined total (summed over all length classes and taxonomic groups that would be entrained under the Calculation Baseline scenario, but impinged if the control technology were implemented) number (or weight) killed by entrainment and impingement under the Calculation Baseline scenario to the combined total (summed over all length classes and taxonomic groups that would be entrained under the Calculation Baseline scenario, but impinged if the control technology were implemented) number (or weight) killed by entrainment and impingement if the control technology were implemented.

For the purposes of testing compliance with the entrainment performance standard, the difference between:

- the combined -- entrainment and impingement -- total (summed over all length classes and taxonomic groups that would be entrained under the Calculation Baseline scenario, but impinged if the control technology were implemented) number (or weight) killed under the Calculation Baseline, and

- the combined -- entrainment and impingement -- total (summed over all length classes and taxonomic groups that would be entrained under the Calculation Baseline scenario, but impinged if the control technology were implemented) number (or weight) killed if the control technology were implemented

would be used as the estimate of the reduction in entrainment due to the control technology. If the combined -- entrainment and impingement -- total number killed under the Calculation Baseline is less than the combined -- entrainment and impingement -- total number killed if the control technology were implemented, then the control technology should be dropped from consideration as a means for reducing adverse effects of entrainment.

Any changes in entrainment survival of length classes and taxonomic groups that would be entrained under the Calculation Baseline scenario, and would also be entrained if the control technology were implemented, would also be considered when addressing the entrainment performance standards. Any improvements (due to implementation of the control technology) in impingement survival rates of length classes and taxonomic groups that would be impinged under the Calculation Baseline scenario, and would also be impinged if the control technology were implemented, would be used towards satisfying the impingement performance standards.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Benefit Estimation Methodology

The Methodologies That EPA Applied To Estimate National Benefits In This Noda Are Substantially Improved Over Those Applied In Developing The Draft Regulation; However, The Nonuse Benefit Methods Discussed In The Noda Cannot Reasonably Be Applied To Site-Specific Benefit Assessments

EPA in the NODA provides updated methodologies for estimating the national benefits of the Proposed Rule in response to comments received on its initial April 2002 proposal (67 Fed. Reg. 17121). In particular, EPA made the following changes:

- developed various region-specific models to estimate recreational fishing benefits;

- refined the commercial fishery analysis; and

- developed a revised benefit transfer approach to estimate nonuse benefits and also indicated additional benefit transfer approaches it might undertake in the future, including a meta-analysis.

As EPA notes, these revisions are in response to numerous discussions with industry and environmental groups to respond to questions on the cost-benefit analysis contained in the proposal as well as the written comments EPA received on the valuation approaches (68 Fed. Reg. 13523). The first two changes-those for recreational and commercial fishing benefits-represent modifications of the basic approaches outlined in the Proposed Rule and reflect comments received from economists and others. In contrast, the nonuse benefits approaches in the NODA represent new studies that EPA acknowledges may be "problematic." (68 Fed. Reg. 13568).

Evaluating the soundness of the methodologies for estimating benefits in the NODA is important for several reasons. For one thing, the methods selected by EPA for this analysis will affect the shape of the requirements promulgated in the Final Rule. In addition, although the methods used in the rulemaking do not constitute formal guidance to permitting agencies, the methods used by EPA to evaluate the benefits and costs of the Final Rule are bound to be given considerable deference by state authorities in evaluating cost-benefit studies relating to individual CWIS sites. This will be the case especially if the Agency does not issue guidance on how states and EPA regional offices should implement the Final Rule in a timely manner. Thus, the economic methodologies that EPA selects for inclusion in its Final Rule analysis have the potential to shape major expenditures at electricity generating facilities across the United States.

EPA's changes for recreational and commercial benefit methodologies are substantial improvements over the methods in the Proposed Rule, but the methodologies discussed for nonuse benefits are not sound. Thus, EPA's skepticism over the validity of the nonuser methodologies it has presented in the NODA is well-founded, at least as currently developed. A meta-analysis could be appropriate to estimate nonuser benefits if the appropriate underlying studies were available. PSEG is relying on and incorporates by references comments on the changes in recreational and commercial benefit methodologies prepared on behalf of UWAG and EPRI (See Desvouges et al. 2003 and Strand 2003), PSEG's comments focus on the methodologies described in the NODA for estimating nonuse benefits.

In summary, with respect to the implementation of benefit-cost analysis in individual 316(b) proceedings, although specific values for recreational and commercial benefits will, of course, need to be developed, the general approaches outlined in the NODA could reasonably be applied to site-specific assessments. However, in the case of nonuse benefits, the NODA does not provide methods that can reasonably be applied to site-specific benefit-cost-analyses.

EPA Response

The comment states that: “EPA's changes for recreational and commercial benefit methodologies are substantial improvements over the methods in the Proposed Rule, but the methodologies discussed for nonuse benefits are not sound.”

The commenter correctly states that benefits analysis for the final rule is not formal guidance for site-specific decisions under this rule. It is important to note that benefits analysis at the national scale versus site-specific scale will differ as a consequence of the degree of environmental and social variability; variability and uncertainty has a significant effect on feasible methodological decisions for benefits analysis. As stated in the proposed rule analysis and in the NODA the Agency explored various alternatives to quantifying and monetizing non-use benefits. However, given the unavoidable uncertainties in estimating non-use benefits for this rule, the Agency presented a qualitative assessment of the non-use benefits of the environmental protections at issue in the final 316(b) benefit cost analysis. The Agency has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN #6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN #6-0002).

EPA has responded to concerns regarding the Agency’s non-use valuation methods in responses to a number of comments. For EPA’s benefit transfer approach, please see EPA’s response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA’s meta-analysis please see EPA’s responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA’s meta-analysis. For EPA’s response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

EPA in the NODA Presents a Specific Benefit Transfer Approach for Nonuse Benefits and Also Indicates Other Benefit-Transfer Methods That Might be Developed, Including a Meta-Analysis

For the Proposed Rule, EPA used a “50 percent rule-of-thumb” to estimate nonuse benefits; this approach estimates nonuse benefits to be 50 percent of use benefits. In response to comments critical of this approach, EPA discusses two alternative methods for estimating nonuse benefits in the NODA. The first method is a benefit transfer approach that relies primarily on a single study concerning valuation of wetlands and eelgrass to develop values for fish and shellfish populations (hereafter, the “Single Study Approach”). The second method would rely on the available evidence concerning nonuse benefits from various studies to infer nonuse values for fish and shellfish populations in 316(b) case studies; this method might include the use of a meta-analysis, another benefit transfer approach (hereafter, the “Meta Analysis Approach”). In the NODA, specific values are developed only for the first method, the Single Study Approach.

In the NODA, EPA does not define a specific approach for estimating nonuse benefits, but rather presents the Single Study Approach and the Meta Analysis Approach-as well as a more general approach that would use existing studies in some other way-and asks for comments. Indeed, as noted, EPA expresses skepticism about both the Single Study Approach and the Meta Analysis Approach. With regard to the Single Study Approach, the NODA states:

“EPA recognizes that benefits transfer of stated preference-based WTP [willingness-to-pay] estimates to a policy context that differs from the study context can be problematic, given the significant influence of context of stated-preference values. EPA is still considering whether the underlying studies in the current analysis are close enough to the policy context to warrant benefits transfer and requests comment on this issue.” (68 Fed. Reg. 13568)

With regard to the Meta Analysis Approach (as well as other uses of multiple studies), EPA notes:

“One key challenge of both of the approaches discussed in this section [general use of studies and meta-analysis] is to determine the applicability of study results to the policy case of interest (i.e., fish impacts due to impingement and entrainment in this rule) because of significant variations in study objectives and methodologies ... EPA seeks comments on appropriateness of the meta-analysis approach for calculating nonuse values for aquatic habitat improvements associated with reduced impingement and entrainment in this rule.” (68 Fed. Reg. 13576)

This section evaluates the economic methodologies for valuing nonuse benefits that are discussed by EPA in the NODA, focusing on whether EPA’s skepticisms about the validity of the Single Study Approach and the Meta Analysis Approach are justified. , The criteria for these judgments are based primarily upon recent guidelines for regulatory analyses developed by USEPA (2000), the Office of Management and Budget’s (“OMB”) current regulatory guidelines (OMB 2000), and proposed revisions to the OMB guidelines (OMB 2003).

As noted, EPA develops estimates using the Single Study Approach. These nonuse benefit estimates are very large in relation to both the nonuse estimates developed by EPA in the Proposed Rule and to the use values associated with reductions in impingement and entrainment. If application of the same methodology in individual 316(b) proceedings were to produce proportionally large benefits estimates, the results of the benefit-cost analysis would likely be very different and conclusions about the appropriate degree of investment in modifications to CWIS would change. Consequently, these new methodologies merit close scrutiny as to whether they comport with accepted and established economic practices as well as EPA and OMB guidance.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

As stated in the Notice of Data Availability (68 FR 13580), EPA is not using the rule-of-thumb approach in the cost benefit analysis for the final Section 316(b) Phase II rule.

Valuing Forage Species (incl non-use and non-landed)

EPA’s Guidelines Outline a Clear Methodology for Performing a Valid Benefit Transfer Study

EPA’s Guidelines (USEPA 2000, or “Guidelines”) provide a comprehensive set of recommendations for developing benefit-cost analysis studies for environmental regulations, including explicit discussions of the methods that should be followed to develop valid benefit transfer studies. EPA notes in the Guidelines that benefit transfer is an appropriate valuation methodology.

“The advantages to benefit transfer are clear. Original studies are time consuming and expensive; benefit transfer can reduce both the time and financial resources needed to develop benefit estimates” (EPA 2000, p. 86).

EPA (2000), however, provides guidelines for implementing the benefit transfer methodology.<FN 31> This section describes the steps called for in EPA’s Guidelines.

Describing the Policy Case and Affected Population

EPA’s Guidelines indicate that the benefit transfer approach should begin with an identification and description of the policy case and the affected population <FN 32>:

The first step in a benefit transfer is to describe the policy case so that its characteristics and consequences are understood. It is equally important to describe the population impacted by the proposed policy. As part of this step, it is important to determine whether effects of the policy will be felt by the general population or by specific subsets of individuals (e.g., users of a particular recreation site or children) (EPA 2000, p. 86). This initial step is critical in defining the nature of the benefits involved in the policy, and thus the types of studies that would be relevant for potential transfer.

Selecting studies

The next step involves selecting studies to form the basis of the benefit transfer exercise. This process involves two subparts.

- Identify existing, relevant studies. Existing, relevant studies are identified by conducting a literature search. This literature search should, ideally, include searches of published literature, reviews of survey articles, examination of databases, and consultation with researchers to identify government publications, unpublished research, works in progress, and other “gray” literature.

- Review available studies for quality and applicability. The analyst should review and assess the studies identified in the literature review for their quality and applicability to the policy case. The quality of the study case estimates will, in part, determine the quality of the benefit transfer.

Indicators of quality will generally depend on the method used. (EPA 2000, p. 86)

The EPA Guidelines further note that, "assessing studies for applicability involves determining whether available studies are comparable to the policy case." USEPA, pp. 86-87). They offer three criteria to be used in assessing which studies are applicable for use in the benefit transfer:

- the basic commodities must be essentially equivalent;

- the baseline and extent of the change should be similar; and

- the affected populations should be similar (EPA 2000, p. 86-87).

This step is critical to ensure that the results from the studies used in the transfer are relevant to the policy being considered. As noted above, EPA expresses skepticism regarding the applicability of the studies it uses in the NODA.

Transferring the benefit estimates

After the analyst has identified .appropriate studies, the values from those studies must be transferred to the policy case. The EPA Guidelines discuss four approaches that can be used for doing this (EPA 2000, p. 87):

- Point estimate. This approach involves taking the mean value (or range of values) from the study case and applying it directly to the policy case. As it is rare that a policy case and study case will be identical, this approach is not generally recommended. Rather than directly using existing values, analysts will often adjust point estimates based on judged differences between the study and policy cases.

- Benefit function. This approach is more refined but also more complex. If the study case provides a willingness-to-pay ("WTP") function, valuation estimates can be updated by substituting applicable values of key variables, such as value estimates across studies. As with the benefit function transfer approach, key variables from the policy case are inserted into the resulting benefit function.

- Meta-analytic approach. Meta-analysis is a statistical method of combining a number of valuation estimates that allows the analyst to explore systematically variations in value estimates across studies.

- Bayesian approach. This is an alternative to the meta-analytic approach. The Bayesian approach provides a systematic way of incorporating case study information with policy case information.

It is important to note that all benefit transfer approaches are not equally valid. In particular, the EPA Guidelines indicate that using results from a single study is not "generally recommended" because it is rare that a single study would provide results relevant for the wide range of policy cases.

Addressing uncertainty

Finally, the analyst should address the sources of uncertainty involved in application of the selected studies and the chosen transfer methodology.

"Benefit transfer involves judgments and assumptions. Throughout the analysis, the researcher should clearly describe all judgments and assumptions and their potential impact on final estimates, as well as any other sources of uncertainty inherent in the analysis" (EPA 200, p. 87).

This step is important in order to provide a sense of perspective about the likely accuracy of the result of the benefit transfer.

Footnotes

31 OMB (2003) provides similar guidance with respect to steps to be followed in implementing the benefits transfer method.

32 “Policy case” refers to the specific policy being evaluated-in this case, the 3 3 16(b) Proposed Rule or a specific 316(b) case study. The “affected population” is defined as the portion of the population that would be affected by the proposed policy.

EPA Response

The commenter summarizes methodology for performing a benefits transfer study based on EPA’s Guidelines for Preparing Economic Analyses, United States EPA (EPA 240-R-00-003) (September 2000). No specific comment on EPA’s 316(b) cost benefit analysis is offered. Thus, no response is necessary.

Peconic-based approach

The Single Study Benefit Transfer Approach for Valuing Nonuse Benefits Discussed in the NODA Is Not an Appropriate Application of the Benefit Transfer Approach

This subsection evaluates the Single Study Approach, the approach that relies primarily upon a single study that estimates the value that nonuse places on changes in wetlands and eelgrass. This subsection first provides an overview of the specific calculations involved in the Single Study Approach. As noted above, EPA does not recommend this approach in the NODA and, indeed, mentions that there are reasons to doubt its applicability to 316(b) fish protection situations. As discussed below, EPA's skepticism about the validity of this study is valid. -It is not an appropriate benefit-transfer technique for valuing 316(b) benefits; this conclusion does not depend upon the validity of the underlying study, e.g., Opaluch et a1.1998.

The Single Study Approach Includes A Detailed Set Of Calculations Based Upon A Single Study Of Nonuse Benefits For Wetlands/Eelgrass Preservation To Infer Nonuse Benefits For Fish Protection

The NODA describes a revised technique that EPA has developed for valuing the nonuse benefits of fish lost due to impingement and entrainment. As EPA notes, its ,analysis conducted in support of the Proposed Rule (67 Fed. Reg. 17121) relied on a "50 percent rule of thumb" to estimate nonuse benefits. However, that methodology was considered "outdated," and the NODA provides a revised analysis that relies on a different benefits transfer technique (68 Fed. Reg. 13568).

EPA instead now relies on a stated preference study of households' WTP for preservation/restoration of eelgrass and wetlands, which provide habitat for fish and shellfish species. EPA's justification for using WTP for eelgrass/wetlands is the following:

"Because one of the results of aquatic habitat preservation/restoration is increased production of fish and shellfish, it may be appropriate to use valuation of habitat restoration as a proxy for the value of the fish and shellfish lost due to impingement and entrainment" (68 Fed. Reg. 13568). [emphasis supplied]

EPA's benefits transfer methodology follows a four-step approach in estimating the nonuse benefits provided by fish lost due to impingement and entrainment:

-estimate number of acres of habitat needed to produce fish and shellfish equivalent to those lost due to impingement and entrainment;

-develop nonuse WTP values for the "fish production services" provided per acre of habitat;

-determine the relevant geographic area over which individuals will have a nonuse value, and estimate the affected population's total WTP per acre of
habitat; and

- multiply the number of acres of habitat needed to offset impingement and entrainment losses (from step 1) by the total WTP values per acre of habitat (from steps 2 and 3).

EPA then provides an illustrative calculation for two power plants in the North Atlantic, region, the Brayton Point and Pilgrim Stations. Each of these steps is described in detail below.

Estimate habitat needed to replace fish losses due to impingement and entrainment

EPA's first step in developing estimates of nonuse benefits was to determine the amount of eelgrass and wetlands needed to replace the fish and shellfish lost due to impingement and entrainment at each of these stations. These estimates are based on abundance data for eelgrass and wetlands habitats, which were estimated by counting species in sub-sampling areas of each habitat (1 00 square meters) and scaling the values to generate a per acre estimate of abundance.

To develop the estimates, EPA determined the species that would require the maximum amount of acreage to replace impingement and entrainment losses. EPA bases its "lower bound" estimate for wetlands on the estimated wetlands acreage it estimated was necessary to replace winter flounder lost due to impingement and entrainment at Brayton Point and its equivalent "upper bound" estimate on winter flounder at Pilgrim.<FN 33> The lower bound estimate for eelgrass restoration is based on the acreage needed for northern pipefish at Pilgrim and the upper bound estimate is based on the acreage EPA estimated was necessary to replace the amount of scup lost due to impingement and entrainment at Brayton Point (68 Fed. Reg. 13568). The values are reported in Table V-1.

EPA notes that the estimates presented in Table V-1 [see hard copy for table] for winter flounder may be problematic as they "significantly overstate" the acreage needed for other species. That is, using other species to develop estimates of necessary acreage would have generated significantly lower estimates. EPA requests comment on this point and all aspects of these calculations.

Develop WTP values for habitat

To estimate WTP values for fish and shellfish habitat in the North Atlantic region, EPA relied on a 1995 study conducted for the Peconic Estuary on the eastern end of Long Island that examined stated preference for eelgrass and wetlands (Opaluch et al. 1998). At the time the survey was conducted, the Peconic Estuary was experiencing high levels of "brown tide" (ie., brown algae) that reduced the area's annual scallop harvest from 500,000 pounds a year to just over 50 pounds a year between 1982 and 1996 (Environmental News Network 2001). This heightened attention concerning the marine resources in the Peconic Estuary led to the study used by EPA (Opaluch, et al. 1998). The implications of this context are discussed later in this section.

EPA justifies its use of the study by noting that the eelgrass and wetlands in the Peconic Estuary support species found throughout the North Atlantic that are likely to be affected by impingement and entrainment: "The Peconic Estuary study thus provides values for eelgrass and wetlands that may be representative of habitat needed to produce many of the species affected by impingement and entrainment at power plants" (68 Fed. Reg. 13569). As a result, EPA assumes that individuals' valuations of eelgrass and wetlands habitat are transferable to valuations of fish and shellfish species.

The Peconic study relied on a contingent choice survey technique to provide individuals' WTP values for of wetlands and eelgrass (Opaluch et al. 1998).<FN 34> In order to develop specific estimates of the nonuse value of the habitat, EPA re-estimated the values in the Peconic study, separating out the values for users and nonusers. For the re-estimation procedure, EPA defined users as only those individuals who harvest fish or shellfish, treating the remainder of the population as nonusers. Table V-2 [see hard copy for table] provides the WTP values for users and nonusers that EPA estimated from the Peconic study.

EPA interprets the results to suggest that for wetlands, 94.4 percent of the total value for users is due to nonuse value, while 77.7 percent of user value is due to nonuse value for eelgrass. As the table shows, EPA reports that nonuser households have a WTP value of $0.054 per acre per year for wetlands and value of $0.052 per acre per year for eelgrass. EPA notes that the similarity of these values is surprising, considering that the survey specifically identified eelgrass as fish and shellfish habitat:

"It is difficult to determine ex post why the values for eelgrass and wetlands are similar for nonusers. However, the fact that nonusers assigned similar values to both types of habitat may indicate that they did not significantly differentiate the two habitat types on dimensions affecting valuation or, alternatively, they differentiated among habitat types, but assigned similar values. Since [eelgrass] was explicitly identified as fish and shellfish habitat and wetlands was not, this may mean that fish and shellfish services were not a significant attribute affecting respondents' valuation, or, alternatively that they were aware that wetlands also provide habitat for fish and shellfish based on knowledge external to the survey" (68 Fed. Reg. 13569).

Despite this skepticism, EPA fails to consider the implications of this finding any further in the NODA. EPA's omission is discussed further below.

As EPA notes, wetlands provide direct uses (e.g., birdwatching) other than fishing and shellfishing. In order to separate out nonuse values related to fish and shellfish, EPA relies on a different study from Narragansett Bay, Rhode Island that uses a survey technique to estimate the percentage of the value due to various wetland services (Johnston et al. 2002). Johnston et al. estimated that fish and shellfish habitat each account for approximately one-fourth (25.64 percent and 27.78 percent, respectively) of the total value individuals placed on wetland habitats in the Narragansett Bay study. EPA applied these values to the WTP estimates for wetlands provided in Table V-2 to separate out the nonuse (i.e., serving as shellfish and fish habitat) value. Table V-3 presents the results of these EPA calculations. [see hard copy for table]

In the NODA, EPA indicates that it is not aware of use benefits from eelgrass other than fishing and shellfishing. In addition, EPA notes that the survey in the Peconic study specifically identified the eelgrass as fish and shellfish habitat. Thus, EPA assumes that all of the value that respondents placed on eelgrass (shown in Table V-2) is due to nonuse value.

Determine appropriate geographic area and affected population's total WTP per acre of habitat

Tables V-2 and V-3 in the section above give estimates of the households' WTP per acre of eelgrass and wetland restoration/preservation in the Peconic Estuary. In order to develop estimates of the total benefits of eelgrass or submerged aquatic vegetation ("SAV") restoration/preservation, it is necessary to determine which households are willing to pay to restore or preserve these habitats (Le., which households have positive WTP values). These households are generally called the “affected population.” The Peconic Estuary study surveyed households in towns bordering the Estuary. This, EPA states, is consistent with EPA’s general approach to defining the affected population, which EPA defines as households in the counties that abut the relevant water body.

EPA also uses the Narragansett Bay study (Johnston et al. 2002) study to develop information about the size of the affected population. EPA determined that the surveys from Johnston et al. (2002) showed that respondents from throughout Rhode Island placed at least some value on salt marsh restoration. EPA took this result-which applied to salt marsh restoration at a specific site in Rhode Island-and assumed that it was applicable to nonuse value for eelgrass and wetlands throughout the North Atlantic. Based on this assumption, EPA calculated the average distance from Narragansett Bay (the site of the restoration) to the edge of Rhode Island (32.43 miles), and assumed that households within this radius should be included as part of the affected population.

EPA cites another study (Pate and Loomis 1997) that seeks to estimate the relationship between distance and WTP for preservation of natural resources. The study estimated individuals’ WTP values for natural resources in the San Joaquin Valley, comparing values of Valley residents to those of non-Valley California residents and residents of Washington State, Oregon, and Nevada. The Pate and Loomis (1997) study found that California residents had WTP values that were 97.7 percent of Valley residents’ values, while Oregon residents had WTP values that were 27 percent of Valley residents’ values.

EPA assumes that this study is applicable to nonuse values for fish protection in the North Atlantic and combines the findings from the Johnston et al. (2002) study with the findings from the Pate and Loomis (1997) study and the WTP values presented above in Tables V-2 and V-3 to estimate the affected population’s total WTP per acre of restore habitat. EPA calculates the total WTP using three separate metrics:

- including only the households in the abutting counties (210,357) with full WTP values;

- including all households within a 32.4 mile radius (737,711) with full WTP values for those in abutting counties and 97.7 percent of WTP-values for the remainder; and

- including all households within a 32.4 mile radius (737,711) with full WTP values for those in abutting counties and 27 percent of WTP values for the remainder.<FN 35>

The results of these calculations for wetlands and eelgrass are presented in Tables V-4 and V-5. [see hard copy for tables]

As the tables show, EPA estimates of total WTP per acre of eelgrass habitat range from $10,993 when metric (1) is used to $37,863 when metric (2) is used. The values EPA estimated for wetlands are substantially lower-approximately $3,000 under metric (1) and approximately $10,000 under metric (2). (In the wetlands case, the values vary for fish and shellfish for reasons described in section two above.

Step 4: Multiply the estimate of habitat needed to replace fish losses by the WTP values per acre of habitat

Based on the calculations explained above, EPA develops estimates of the total nonuse values of restoring the required amount of SAV and wetlands. EPA multiplied the estimates of the necessary acreage (developed in section one above) by the affected population's total nonuse value per acre (developed in section three above) to estimate the total nonuse value. These estimates are presented in Tables V-6 and V-7. [see hard copy for tables]

As these tables show, EPA's estimates for total fish restoration from eelgrass range from just under $1.7 million to over $22 million. EPA's estimates for fish restoration from wetlands range from slightly under $74 million to over $212 million.

Footnotes

33 These estimates are based on EPA's estimates of impingement and entrainment losses at these facilities, divided by the number of species produced per acre of habitat.

34 The contingent choice methodology gives survey respondents various policy/cost combinations from which to choose, including, in this case, a "no action" option.

35 Number of households is based on average number of households within the noted distance of "affected water bodies" (68 Fed. Reg. 13572).

EPA Response

The comment states that the single study approach is not an appropriate benefit transfer technique for 316(b) analysis. For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Peconic-based approach

The Single Study Used In The Single Study Approach Does Not Meet EPA's Criteria For Benefit Transfer

As noted above, the EPA 'Guidelines set out three essential criteria that must be met before studies can be determined to be applicable for use in the benefit transfer:

- the basic commodities must be essentially equivalent;

- the baseline and extent of the change should be similar; and

- the affected populations should be similar.

The study EPA used in its Single Study Approach for the NODA does not meet any of the three basic criteria laid out in the Guidelines.

The basic commodity in the single study is not "essentially equivalent" to the commodity in 316(b) cases

The first criterion set out in the Guidelines for appropriate benefits transfer indicates that the commodity in the policy case (i.e., the fish lost due to impingement and entrainment) must be "essentially equivalent" to the commodity in the study case (ie., the eelgrass and wetlands). As noted, the NODA recognizes the importance of this basic requirement:

"EPA recognizes that benefits transfer of stated preference-based WTP estimates to a policy context that differs from the study context can be problematic, given the significant influence of context on stated-value preferences. EPA is still considering whether the underlying studies in the current analysis are close enough to the policy case to warrant benefits transfer and requests comment on this issue" (68 Fed. Reg. 13568).

OMB's recently released draft guidelines (2003) provide further support for this criterion:

The good, and the magnitude of change in that good, should be similar in the study and policy contexts.

Notwithstanding EPA's recognition of this criteria, the NODA's study case fails to meet this criterion for at least two reasons:

- neither wetlands nor eelgrass habitat are "essentially equivalent" or "similar" to fish and shellfish; and

- the fish and shellfish populations in the Peconic Estuary at the time of the Opaluch (1998) study were a challenged resource, unlike most, if not all, of the fish populations affected by impingement and entrainment.

Each of these points is discussed in detail below.

Neither wetlands nor eelgrass habitat are “essentially equivalent” to fish and shellfish

As discussed above, the Opaluch et al. (1998) study estimates households’ willingness to pay for habitat restoration, including the willingness to pay of nonusers. EPA uses the nonuse results from the habitat restoration study to estimate willingness to pay for fish or shellfish preservation. EPA provides a brief justification for this application:

“Because one of the results of aquatic habitat preservation/restoration is increased production of fish and shellfish, it may be appropriate to use valuation of habitat restoration as a proxy for the value of the fish and shellfish lost due to impingement and entrainment.” (68 Fed. Reg. 13568) [emphasis added]

EPA provides no evidence or further discussion of this point, but goes on to solicit comment about the appropriateness of this transfer, noting a reason why it may not be valid:

“EPA requests comment on using estimates of fish production per acre as the basis for benefits transfer, given that respondents were likely not aware of the quantitative relationship between habitat and fish production when they provided valuation information.” (68 Fed. Reg. 13569)

Indeed, EPA goes on to note that the results of the study suggest that respondents may not have been aware of this relationship:

“The fact that nonusers assigned similar values to both types of habitat . . . may mean that fish and shellfish services were not a significant attribute affecting respondents’ valuation” (68 Fed. Reg. 13569).

Although EPA’s approach is admittedly resourceful, it is clear on its face that the study case does not meet the “essentially equivalent” requirement put forth in the Guidelines or the “similarity” criterion set out in OMB (2003). Although it is plausible that respondents to the Peconic Estuary survey may have been aware that eelgrass and wetlands support fish and shellfish populations, the survey clearly was not designed to measure this relationship.<FN 36>

Absent a specific model known to the survey respondents relating fish and shellfish population to eelgrass and wetlands habitat, there is no reason to believe that the values developed by the Opaluch et al. (1998) survey and EPA’s subsequent re-estimates convey any specific quantitative information about nonuse values associated with changes in fish and shellfish populations in the Peconic Estuary. All that one can infer from these results is the general speculation that some of the nonuse value attributed to preservation of eelgrass and wetlands habitat may be related to their role in supporting fish and shellfish populations.

Fish and shellfish in the Peconic Estuary at the time of the Opaluch et al. (1998) study were a much more challenged resource than most species affected impingement and entrainment

Another reason to question the similarity of the policy and study cases is the health or status of the resource in the Peconic Estuary at the time of the Opaluch et al. study, compared to policy cases in the North Atlantic region and elsewhere in the United States. At the time of the Peconic Estuary study, the Estuary's ecosystem had suffered significant damage, from years of "brown tide" (brown algae). As the Peconic Estuary study itself points out, "much of the Estuary's eelgrass was destroyed by the brown tide [prior to the survey]'' (Opaluch et al. 1998, p. 100). Peconic Estuary fish and shellfish populations were also declining significantly in the 1980s and 1990s. For example, at the time the survey was conducted, the Peconic Estuary was experiencing levels of brown tide so high that the area's annual scallop harvest had been reduced from 500,000 pounds a year to just over 50 pounds a year between 1982 and 1996 (Environmental News Network 2001). Fish, shellfish, and their habitats in the Peconic Estuary were clearly in substantial danger in the years leading up to the survey. This is a materially different scenario than the scenario at issue in the 316(b) rulemaking. Fisheries resources at the age classes likely to be the best indicators of CWIS effects (ie., age-one recruits to the Fishery) in many affected water bodies in the North Atlantic region are, on the whole, relatively stable populations. <FN 37>

This information provides further reason to question the "essential equivalency" of the policy and study cases. This is of particular concern given the significant effect of a resource's stability on its nonuse value. Indeed, nonuse values are only likely to be significant when the resource in question is unique and/or the loss or injury is irreversible: <FN 38>

"Another important question is, when are nonuse values likely to be important? The long literature on nonuse values emphasizes the uniqueness or specialness of the resource in question and the irreversibility of the loss or injury. For example, economists have suggested that there are important nonuse values in preserving the Grand Canyon in its natural state and in preventing the global or local extinction of species and the destruction of unique ecological communities. In contrast, resources such as ordinary streams and lakes or a subpopulation of a widely dispersed wildlife species are not likely to generate significant nonuse values because of the availability of close substitutes. Moreover, the literature does not suggest that nonuse values are likely to be important where recovery from an injury is quick and complete, either through natural processes or restoration" (Freeman 1993, p. 162).

Given that the resources (i. e. wetlands and eelgrass)-and commercially important species that were known to be dependent on the resource-were in substantial danger at the time of the Peconic study (Opaluch et al. 1998), these nonuse values are likely to exceed the WTP values in cases where the resource is not danger (as in the relevant policy cases for many 316(b) determinations).

Footnotes

36 Indeed, the Opaluch et al survey itself appears designed not to measure the absolute value of WTP for habitat changes but rather the relative values of various policy changes. The authors note: "The survey may be more effective at capturing the relative importance of various policy options than placing specific values on the natural resources in question" (Opaluch et al. 1998).

37See, e.g., Barnthouse et al. (2002).

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services.

Peconic-based approach

The baseline and the extent of the change are not similar

The second criterion in the Guidelines is that the scope of the change in the study case must be similar to the scope of change in the policy case. As discussed below, this can be particularly important when using contingent valuation ("CV") methods such as contingent choice, which was used in the Peconic study.<FN 39>

CV is widely accepted to be the only valid method of measuring nonuse benefits. As EPA notes, "Currently, contingent valuation is the only established method capable of estimating nonuse values" (EPA 2000, p. 83). However, the Guidelines indicate that there has been substantial debate surrounding the use of CV, and that is important to be particularly careful in its implementation. The Guidelines cite the NOAA (1993) study as providing "best practices" recommendations for the use of CV. The NOAA report (993, p. 4604) cites numerous concerns about the CV methodology that should be carefully avoided.

Ignoring, for the moment, the conclusion that the use of a nonuse value derived for wetlands or eelgrass is not relevant and applicable to the policy question at hand-as described above-the methodology described in the NODA fails to meet the second criterion articulated in EPA's Guidelines for use of a benefits transfer approach in at least two ways:

- EPA assumes that benefits estimates can be applied linearly, regardless of the magnitude of the change; and

- EPA ignores a commonly acknowledged problem with CV, known as "embedding."

Each of these points is discussed in detail below.

EPA applies the Peconic estimate to contexts with unknown baselines and different changes

The Peconic Estuary study asked survey respondents to choose among various policies. In the survey, the policies were explained in terms of the baseline acres of habitat and the number of acres that would be preserved/restored for various costs. The Peconic Estuary study then translated these responses into a WTP per acre per household, using a nested logic model. The value per acre per household is assumed to be linear, i.e. the same regardless of the baseline or change.

In the NODA, EPA extrapolates the results from the Peconic Estuary study to two specific example cases, related to fish losses at Pilgrim and Brayton Point.<FN 40> Table V-8 [see hard copy for table] shows the baselines and changes in the Peconic Estuary study and compares them to EPA's two example cases. As the table shows, the changes in the two EPA cases differ significantly from the changes in the Peconic Estuary study. With the exception of the Brayton Point example for eelgrass replacement, the changes in the Peconic Estuary study are not comparable to EPA's example cases.

Moreover, it would be pure chance if the Peconic Estuary study changes matched changes for other policy cases.

Contingent valuation studies must avoid common pitfalls such as embedding

One of the most significant concerns about the CV approach is the tendency for respondents to “embed” their valuations, which results in similar WTP estimates regardless of the quantity of the resource. The NOAA report cites two studies that have particularly striking results on this point:

- Kahneman (1986) found that WTP for the cleanup of all the lakes in Ontario was only slightly higher than the WTP for cleaning up just one lake.

- Desvousges (1992) found that people expressed the same WTP for measures that would prevent 2,000 migratory birds from dying in oil-filled ponds as measures that would prevent 20,000 or 200,000 birds from dying in the same way.

Results such as these are markedly inconsistent with standard assumptions about rational choice. For example, the Desvouges (1992) results suggest that individuals place a positive value on the lives of the first 2,000 migratory birds, but no value on the lives of any birds thereafter. As Desvousges (1 992) points out, this result is clearly not reasonable.

To deal with this concern, OMB’s guidelines (2000) indicate that studies should ‘‘Satisfy checks on their internal consistency”-that is, they should conform to standard assumptions about rational choice. In particular, the OMB guidelines recommend that users of such studies “apply a ‘scope’ test to show that individuals are willing to pay more for incrementally greater amounts of goods.” There is no evidence that EPA or the authors of the Peconic study have addressed this concern.

Footnotes

39 The Peconic study (Opaluch et al. 1998) that EPA relies on in its NODA analysis us a ‘‘contingent choice” method, which is a type of stated preference or contingent valuation approach to determine households’ WTP for various natural resources. Contingent choice allows respondents to make choices between actions that are explained in terms of the natural resources that would be restored or protected and the associated cost.

40 As explained above, EPA calculates acres of habitat it estimates would be required to compensate for estimated impingement and entrainment losses at Pilgrim and Brayton Point based upon calculations for various species.

EPA Response

The commenter argues that changes in Peconic Estuary case are not comparable to EPA’s case studies “with the exception of the Brayton Point example for eelgrass replacement.” The Agency agrees that changes in the attributes of resource improvements or policy will directly influence willingness-to-pay values. The Peconic study estimates marginal WTP for wetland and eelgrass restoration. Hence, as the extent of environmental improvements changes, total WTP values will change.

The commenter further argues that EPA ignores the “embedding” problem, that studies should satisfy tests of internal consistency. The Peconic study did apply a scope test. Although the scope test had mixed results, overall, based on most criteria applied, the study provided logically consistent results. Please see EPA’s reply to comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer.

Peconic-based approach

The affected populations are not similar

The third criterion that the EPA Guidelines identify for benefits transfer specifies that the affected population in the study case should be similar to the policy case. In this case, the “affected population” should include all those individuals who have a positive nonuse value for the resource in question. In Opaluch et al. (1998), the affected population includes individuals in towns bordering the Peconic Estuary. As noted above, EPA has two definitions of the affected population-all people residing in counties abutting the affected water body and all people residing within 32.43 miles of the affected water body.

There are at least two ways in which the population in the study case differs from the policy case:

- habitat restoration was an extremely salient issue in the Peconic population at the time the study was completed; and

- local residents were in a position to suffer economically from damage to the Estuary.

Each of these points is discussed in detail below.

The population in the study case was particularly concerned about environmental issues at the time of the study

As we have discussed, when the 1995 study was performed, the Peconic Estuary was experiencing a dramatic decline in fish population and habitats as a result of “brown tide.” Residents of the Peconic area were highly sensitive to this issue, as the Opaluch et al. (1998) study notes. Indeed, the study found that 90 percent of respondents had heard of brown tide, and 97 percent of those who had heard of it were “concerned” or “very concerned” about the phenomenon. It is unlikely that minimization of impingement and entrainment losses will be as salient an issue in the other cases to which the NODA proposes to apply these values. Unlike the fish populations of the Peconic, relevant life stages of fish populations in relevant 316(b) situations are relatively sound.<FN 41>

The Local Economy in the Peconic Estuary Region is Dependent on the Environmental Health of the Estuary

In addition to general heightened concern about the environmental health of the Estuary among residents of the Peconic Estuary region, local residents also had more to ‘lose from environmental problems at the Estuary than the typical affected population. Peconic Estuary area residents expressed particular concern about the potential impact of environmental problems on the local economy. Indeed, this is one of the findings of the Peconic study itself: “Most people interviewed were very concerned about water quality, declines in fish populations over the years, and the impacts on business if water quality continues to decline” (Opaluch et al. 1998, p. 93). The Opaluch et al. study also notes the “historical significance of shellfishing to the local economy.” (p. 100)

This information suggests that fishermen were not the only residents who had something to lose from damage to local fish and shellfish habitat. Thus, a web of economic considerations probably influenced many residents as they valued their WTP for habitat restoration. There is no reason to believe that populations throughout the North Atlantic region are as economically dependent on the resource as they clearly were in the study case relied upon the NODA.

Footnotes

41 See, e.g, Barnthouse et al. (2002).

EPA Response

EPA agrees that the affected population should be similar for the study case and policy case. Please see the response to comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region.

The comment states that habitat restoration was extremely salient issue for the Peconic population at the time the survey was conducted, and that local residents were in a position to suffer economically from damage to the estuary. From these points, the comment concludes that the study population and policy population differ. However, empirical evidence suggests that habitat restoration is salient for the population residing in the vicinity of water resources affected by power plants, and that residents of the area stand to suffer economically from damage to the affected water resources. For example, the Rhode Island/Massachusetts population in the region at issue is quite similar to that of the Peconic Estuary region in terms of their reliance on and values for the estuarine resources. Numerous articles in local newspapers about the sharp declines of flounder and other fish populations in the area; the fact that a local environmental organization, Save the Bay, spends significant resources to address issues related to fish habitat restoration in the area; and the results of the Johnston, et al. study used in EPA’s analysis are just a few of the indicators of the salience and value of estuarine resources to the local population. In terms of economic dependence on the estuary, Pacheco and Tyrell (2003, The Economic Value of Narragansett Bay, Department of Environmental and Natural Resource Economics, University of Rhode Island) found that the total value added to the Rhode Island economy from resources of Narragansett Bay is $2.3 billion per year, and that consumer surplus from recreational activities is $6.7 billion per year.

The comment states that the Peconic study found that people were very concerned about water quality, declines in fish populations and impacts on business. It concludes that “there is no reason to believe that populations throughout the North Atlantic region are as economically dependent on the resource” as those in the Peconic region. As noted above, these are important issues in the Rhode Island/Massachusetts areas as well, and these populations have significant economic dependence on their marine and estuarine resources.

EPA notes that the habitat-based approach is not used in the cost-benefit analysis for the final section 316(b) rule.

With Regard to the Future Steps Outlined by EPA for Nonuse Analysis, a Rule-of-Thumb Approach Has No Conceptual Basis, While Meta-Analysis Has the Potential to Be a Useful Technique If Appropriate Studies Are Used

This section discusses the two additional methodological approaches that are described in the NODA, which EPA states it is also considering as a means of estimating nonuse benefits for the Final Rule (68 Fed. Reg. 13575). Both involve using multiple studies, in contrast to the Single Study Approach. The first methodology involves conducting a literature review to develop a "rule-of-thumb" relationship between use and nonuse values. The second methodology-meta-analysis-is one of the four benefit transfer methods described above. The following provides a brief outline of these two possible future steps.

Overview Of EPA's Proposed Future Steps To Evaluate Nonuse Benefits

Both of EPA's proposed future steps would rely on a review of the existing literature. EPA describes a literature review it has undertaken, in which it has identified eighteen "surface water valuation studies that meet a set of criteria for suitability and reliability" These criteria include that:

- the resource amenities valued in the study must be water bodies that provide recreational fishing;

- United States populations are surveyed in the study; and

- research methods in the study are supported by literature.

These studies are described further in Tudor et al. (2003)

Developing a "Rule of Thumb"

One approach that EPA is considering is using the available literature to estimate a general relationship between use and nonuse benefits. EPA does not provide much detail on the specific methodology it would employ, but the methodology would presumably be similar to the rule-of-thumb analysis that EPA used in the original analyses used to support the 316(b) Phase II Proposed Rule.<FN 42> EPA recognizes that the application of a rule-of-thumb methodology "requires careful accounting of factors that are likely to affect nonuse values of aquatic resources" (68 Fed. Reg. 13576). In particular, EPA notes that special attention must be paid to the following factors:

- the geographic scale of environmental improvements;

- regional or national importance of the affected resources; and

- the magnitude of environmental quality changes.

EPA notes two potential approaches within this framework on which it is seeking comment:

- a percent or fraction of use values per household; and

- specific user and nonuser populations.

Performing a meta-analysis

In the NODA, EPA states that it is also considering "regression-based meta-analysis of nonuse WTP for water resources" (68 Fed. Reg. 13576). EPA notes that:

"Economic literature characterize[s] meta analysis as a rigorous alternative to the more casual, narrative discussion of research studies which typify many attempts to summarize available information about environmental values. The primary advantage of a regression-based approach is that it may account for differences among study sites that may contribute to changes in nonuse values, to the extent permitted by available data." (68 Fed. Reg. 13576)

EPA describes an approach in which either the total value or the nonuse value of "aquatic habitat improvements" could be modeled as a function of explanatory variables that include "core economic variables" (such as the type of resource, scope of resource improvement, estimated use values, quantitative or categorical measures of environmental quality improvements, and survey respondent characteristics such as income) and "study design effects variables" (such as the year, elicitation format, and elicitation method of the survey).

EPA goes on to note that:

"One key challenge of both of the approaches discussed in this section is to determine the applicability of study results to the policy case of interest (i.e., fish impacts due to impingement and entrainment in this rule) because of significant variations in study objectives and methodologies. The use (and interpretation) of the value estimates to predict WTP in specific cases will follow the methodologies from the benefits transfer literature (e.g., Vandenberg et al. 2001; Desvousges et al., 1998)."

"EPA seeks comments on appropriateness of the meta-analysis approach for calculating nonuse values for aquatic habitat improvements associated with reduced impingement and entrainment in this rule." (68 Fed. Reg. 13 576)

The next two sub-sections discuss conceptual considerations associated with use of a meta-analytic approach, and identify specific issues with respect to the methodology EPA describes.

Footnotes

42 For a discussion of this approach, see Harrison et al.(2002).

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment 316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment 316bEFR303.020 regarding the definition of users vs. nonusers; and comment 316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

The Agency did not include "the rule of thumb" approach to estimating non-use benefits in the final 316(b) analysis.

EPA Guidelines Provide Clear Criteria For Selecting Literature For Benefit Transfer And Meta-Analysis In General

The EPA Guidelines (2000) provide specific guidance on the correct procedures for performing an appropriate meta-analysis. Prior to evaluating the potential methodologies EPA has described in the NODA, it is important to review the conceptual foundation provided in the Guidelines.

Meta-analysis is a form of benefit transfer and as such, should adhere to the same guidelines

EPA's Guidelines identify meta-analysis as one of four types of methods for transferring the benefits estimates obtained from earlier studies:

"Meta-analysis is a statistical method of combining a number of valuation estimates that allows the analyst to systematically explore variation in existing value estimates across studies. As with the benefit function transfer approach, key variables from the policy case are inserted into the resulting benefit function." (EPA 2000, p. 87)

Of course, as a benefit transfer method, the meta-analytic approach should adhere to the guidelines identified for such studies.

The criteria for conducting an appropriate meta-analysis are clear

As described above, EPA's Guidelines (2000) provide clear guidance for how to conduct an appropriate benefit transfer study. The critical steps are selecting appropriate studies in order to obtain the values to be used in the meta-analysis and specifying the estimated relationship appropriately.

Selecting studies

As described above, the economic analyst must first identify and describe the policy case and the affected population. Once this is complete, the next two steps involve selecting studies to form the basis of the benefit transfer exercise:

- identify existing, relevant studies, (all potentially relevant studies should be identified by a means of a literature search); and

- review available studies for quality and applicability. (The quality of the study case estimates will, in part, determine the quality of the benefit transfer. Assessing studies for applicability involves determining whether available studies are comparable to the policy case.) (EPA 2000, p. 86)

As noted above, the EPA Guidelines offer three criteria to be used in assessing which studies are applicable for use in the benefit transfer:

- the basic commodities must be essentially equivalent;

- the baseline and extent of the change should be similar; and

- the affected populations should be similar (EPA 2000, p. 86-87).

As discussed above, the selection of appropriate studies is critical to the development of any correct benefit transfer.

When performed correctly, meta-analysis can be a more accurate method of benefits transfer than the single study approach

Because it does not rely on a simple point estimate, meta-analysis can be a more reliable method of benefit transfer than other methods. EPA's Guidelines note this explicitly: "The most rigorous benefit transfer exercise uses meta-analysis" (EPA 2000, p. 87). Thus, this method has been used successfully to value benefits in other related contexts where appropriate and applicable studies are available.<FN 43>

Footnotes

43 See, e.g., Salem's 1999 Application, Appendix F and relevant attachments, which used a statistical metalanalysis of marginal value of increased catch.

EPA Response

EPA agrees that meta-analysis has considerable promise in benefits transfer and that meta-analysis can produce more reliable results than other benefit transfer methods. Meta-analysis has a long history in fields such as epidemiology and education, with typical applications to sets of studies conducted under controlled conditions with standardized experimental designs. Recently economists have increasingly explored meta-analysis techniques as a potential basis of policy analysis conducted by various government agencies charged with the stewardship of natural resources. For the final 316b rule analysis, the Agency, has explored several measures that indicate the potential magnitude of non-use values, including peer-reviewed meta-analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN #6-0003). However, EPA has not included quantitative measures of nonuse values in the final 316b rule benefit cost analysis due to unavoidable uncertainty in monetizing non-use values for this rule.

EPA has responded to concerns regarding the appropriateness of the selected studies in Agency's response to comment #316bEFR.338.046.

Valuing Forage Species (incl non-use and non-landed)

A Rule-Of-Thumb Approach Has No Conceptual Basis, While Meta-Analysis Has The Potential To Be A Useful Technique

This section evaluates the two proposals that EPA outlines in the NODA for potential future steps in estimating nonuse benefits. While there is no conceptual basis for using a rule-of-thumb approach, a meta-analysis can be a useful methodology when certain guidelines are followed.

A rule-of-thumb approach has no conceptual basis

EPA's proposed use of a nonuse rule-of-thumb is questionable for at least two reasons. First, it does not appear in EPA's Guidelines. Second, as a benefit transfer approach, it fails to meet the criteria outlined in EPA's own guidance document.

There is no basis for a rule of thumb approach in EPA's guidelines

EPA's Guidelines (2000) provide a thorough discussion of appropriate methods for valuing the effects of environmental policies. They make no mention of the rule-of- thumb for estimating nonuse values.

The rule-of-thumb approach does not conform to 'EPA guidelines for benefit transfer

This approach to estimating nonuse values would rely on a crude form of benefits transfer, in which use values would be multiplied by a rule-of-thumb to estimate nonuse values. As discussed above, EPA's Guidelines lay out specific criteria for selecting studies to be used to perform benefit transfer analysis.

The NODA lists eighteen studies that EPA is considering in using to develop a rule-of-thumb or in a meta-analysis. The appropriateness of these studies is discussed below in the context of evaluating the potential meta-analysis. As noted below, these studies do not conform to the basic criteria for benefits transfer.

EPA Response

In the cost-benefit analyses for the NODA and for the final Section 316(b) Phase II rule, EPA did not use the 50% rule-of-thumb to estimate non-use benefits.

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values due to unavoidable uncertainty in monetizing non-use values for this rule. The Agency, however, has provided several measures that indicate the potential magnitude of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Comment ID 316bEFR.338.046

Organization PSEG Services Corp obo PSEG Power, LLC

Subject Matter Code 10.02.04

Valuing Forage Species (incl non-use and non-landed)

Meta-analysis has the potential to be a useful technique but the studies used must be relevant to the policy case

As indicated by EPA's Guidelines, a meta-analytic approach to benefits transfer clearly has the potential to be a useful technique for assessing benefits. However, the studies on which it relies must be relevant to the policy case, in this case the impingement and entrainment of aquatic organisms in affected waterbodies.

The criteria identified above can be used as the basis for an evaluation and identification of potential issues with the approach EPA discusses.

Will the "commodities" be equivalent?

One issue that is apparent from EPA's description of the eighteen studies it has preliminarily selected for review is that the "commodities" valued in the selected studies are not the same as the "commodity" at stake in the policy context.<FN 44> A review of the descriptions of the studies <FN 45> in Appendices A and B of Tudor et al. (2003) reveals that many of the studies described measure general changes in water quality rather than specific reductions in the mortality of individual fish and shellfish species-which is the policy context for the 316(b) rulemaking. Indeed, EPA itself characterizes the eighteen studies identified by its literature review in the NODA as eliciting values associated with "aquatic habitat improvements.

The amenities valued in many, if not all, of the studies that EPA has selected appear to be much broader in scope and more general than the relatively specific type of environmental effects that are relevant in the context of 316(b), namely decreased mortality of specific aquatic organisms as a consequence of complying with 316(b). Table V-9 [see hard copy for table] lists the eighteen studies identified by EPA in the NODA and in Tudor et al. (2003). Of these, only three identify specific changes in the fish or shellfish population as the amenity (or part of the amenity) that the respondents are asked to value. A fourth study, Kaoru (1993) identifies increased seasonal availability of shellfish beds as a benefit to be valued. The other fourteen studies attempt to measure respondents' values for generic improvements in water quality, generic values such as "protecting fish and wildlife habitat," or preservation of specific local resources (e.g., Mud Lake in Minnesota and South Dakota). These studies do not measure specific changes in fish populations.

Will the baseline and extent of change be similar?

Another important question is whether the baseline and extent of change are similar. Of course, this question will only be relevant for those studies that are valuing the same amenity or resource-namely changes in local fish populations. Table V-10 [see hard copy for table] shows the three studies identified in Table V-9 as valuing specific changes in fish or shellfish populations. As the table shows, these studies value large changes in population rather than the incremental changes at issue in the 316(b) rule and in individual 316(b) decisions.

Will the affected population be similar?

EPA notes correctly that income and other variables describing the affected population will be relevant to its selection of the studies (68 Fed. Reg. 13576). A review of the mean household income of each of the studies presented in Appendix A of Tudor et al. (2003) suggests that at least one study (Kaoru 1993) may not be appropriate for inclusion on this basis, as the respondents' mean household annual income of more than $137,000 makes them unlike the affected population in almost any area that would be relevant to the policy case.

Footnotes

44 Note that the use of the word "commodity" in the context of non-use valuation is somewhat problematic, since by definition the good is not marketed. Nevertheless, the basic principle--that what is valued in the study context and the policy context should be fundamentally the same-is what is important here, and so we use the term "commodity" somewhat loosely.

45 NERA and PSEG are relying on these descriptions since the Agency has not made the hll studies available as part of the Record and PSEG; despite its and NERA's best efforts, could not obtain copies of all of the studies.

EPA Response

The commenter states that meta-analysis has the potential to be " a useful technique", if the underlying studies are relevant to the policy case. The commenter then identifies three major issues with the 18 studies preliminary selected for meta-analysis and discussed in the NODA. First, the commenter states that the resources examined in the 18 studies included in the NODA are not similar enough to reductions in I&E to serve as a sound basis for such a transfer. Second, the commenter argues that specific environmental quality changes valued in the studies preliminary selected for the meta-analysis are much larger than those expected from the 316b regulation. Finally, the commenter questions similarity between the affected population considered in the 18 studies and the population affected by the 316 rule. Responses to these three issues are provided below.

1. Appropriateness of the selected studies

EPA agrees that the available primary studies included in the NODA do not (in general) value fish directly. The selected studies estimate willingness-to-pay for improvements to aquatic habitat that directly benefit fish populations. The policy context, however, calls for willingness-to-pay to prevent the loss of fish directly. The two are strongly correlated, but not identical. This divergence is imposed by the available meta-data: the original studies do not (in general) value fish directly. EPA, however, disagrees that the resources examined in these studies are not similar enough to reductions in impingement and entrainment to serve as a sound basis for a benefits transfer analysis.

In selecting studies to be used for the 316(b) rule meta-analysis EPA followed criteria outlined in EPA's Guidelines for Preparing Economic Analyses (U.S. EPA, 2000). Specific criteria used in study selection are also outlined in Chapter A12 of the Regional Case Study report (see DCN #6-0003). Only surface water quality studies that mentioned habitat improvements for fish were selected. Although meta-data include studies that estimated the willingness to pay for water quality improvements, these studies indicated that these improvements would lead to an increase in the commercial and recreational fishery and other aquatic species. It is not unusual in meta-analysis that some of these studies are a better match for the policy setting than others.

Benefit transfers are by definition characterized by a difference between the context in which resource values are estimated and that in which benefit estimates are desired. The ability of meta-analysis to adjust for the influence of study, economic, and resource characteristics on willingness-to-pay can reduce or minimize potential biases stemming from divergence of the original study and policy contexts. The meta-data compiled by EPA for the 316b rule meta-analysis provides a close but not perfect match to the context in which values are desired.

Finally, commenters should note that impingement and entrainment affects a large number of aquatic organisms directly and indirectly through the food chain and thus is likely to affect a wide range of ecosystem services in the affected waterbodies. See also EPA's response to comment # 316bEFR.206.047 regarding ecosystem services affected by impingement and entrainment.

The Agency conducted an external peer review of its meta-analysis developed for the final 316 (b) rule. Four peer-reviewers (Dr. John Loomis, Dr. John Whitehead, Dr. Katherine Kling, and Dr. Frank Lupi) were asked to assess appropriateness of the selected studies used in the 316(b) rule meta analysis. The peer reviewers concluded that the meta-data was compiled using accepted practices and that EPA's thorough consideration of studies resulted in a solid foundation of meta-analysis. For detail on results of EPA's external peer review of its meta-analysis, see DCN # 6-2500.

2. Will the baseline and extent of change be similar?

The key purpose of meta-analysis is to establish an adjustable link between willingness to pay values for habitat improvements and the attributes of resource improvements, including the extent of environmental quality change. Changes in the attributes of resource improvements or policy will directly influence willingness-to-pay values. EPA's model used the extent of environmental improvements as a systematic indicator of WTP values. Hence, as the extent of environmental improvements changes, WTP values will change. The model also allows for additional effects related to such factors as region and the type of water body in question. Therefore, the model will predict changes in WTP values for different types of policies, based on the predicted link between the extent of environmental change and WTP values and the characteristics of the water body in question.

3. Will the affected population be similar?

EPA notes that the variables that account for differences in population characteristics (e.g., income) between the policy sites and the sites considered in the other studies are included in the meta-analysis. Therefore, EPA's meta-model adjustment of adjust WTP values to account for characteristics (including income) of the population affected by the 316b rule.

4. Concluding Remarks

EPA considered the results of several different approaches to quantifying non-use values for the final Phase II rule due to unavoidable uncertainties in monetizing non-use values for the ecological resources that would be protected by the final 316(b) rule. EPA responded in several ways to these uncertainties. First, as explained in the preamble to the 316(b) rule, EPA engaged in a qualitative assessment of the benefits of the environmental protections at issue. Second, EPA developed lower and upper bound estimates of non-use benefits based on the Robb and Krinsky simulation technique and conducted sensitivity analysis with respect to various parameters (e.g., the size of the affected population) used in the analysis of non-use benefits. However, given the degree of uncertainty associated with the estimated national non-use benefits of the final 316b rule, monetized estimates of non-use benefits are not included in the benefit cost analysis for this rule.

Valuing Forage Species (incl non-use and non-landed)

EPA Should Only Include Nonuse Benefit Values If The Estimates Are Based Upon Sound Technical And Economic Methodologies

The EPA NODA provides an effort to develop methods that can be used to assess nonuse benefits from the proposed 316(b) rule and alternatives under consideration. As emphasized above, EPA itself expresses considerable skepticism about the validity of the specific studies. In conclusion, PSEG believes:

- benefit transfer can be a reasonable technique, but EPA's Single Study Approach is not an appropriate application;

- a rule-of-thumb approach has no conceptual basis; and

- meta-analysis has the potential to be a useful technique, but the studies used must be relevant to the policy case.

These findings suggest that the only benefit transfer methodology presented in the NODA that EPA should consider pursuing for its analysis of the Final Rule is the meta-analysis approach. However, in performing a meta-analysis, it is critical to adhere to the criteria set out in the EPA Guidelines for selecting appropriate studies. If the studies are not carefully selected, even an otherwise well-conducted meta-analysis will generate erroneous results. A review of the studies cited in the NODA reveals that none of the studies are applicable to the policy case for the purposes of a meta-analysis. Thus, a useful meta-analysis will require a new set of studies that meet the criteria outlined in the Guidelines. However, the apparent lack of studies that meet the basic criteria for meta-analysis makes the prospects of a useful meta-analysis problematic.

The potential implications of incorrect methodologies can be significant and are discussed below.

Incorrect Benefits Estimates Can Lead To A 316(B) Rule That Is Not In Society's Best Interest

Benefit-cost analyses provide a means of weighing the costs and benefits of alternative policies and thus provide guidance on policies that maximize net social benefits (Le., benefits minus costs). Inaccurate methodologies could lead to a 316(b) rule that does not maximize social welfare. (see, e.g., Harrison et al. 2000.) Overestimating compliance costs, for example, could cause regulators to implement a less stringent policy than that would maximize social welfare. Similarly, overestimating nonuse benefits could cause regulators to implement a more stringent policy than that which would maximize social welfare.

Incorrect EPA Methodologies Would Set Precedents And Lead To Inaccurate Site-Specific Benefit-Cost Analysis

The implications of inaccurate benefit assessments go beyond the 316(b) rule itself. Many of the critical 316(b) decisions will be made in the context of individual power plants. Inaccurate methodologies developed for the 316(b) rule can set precedents for these site-specific studies. The use of inaccurate nonuse benefit estimates could lead to inaccurate estimates for individual power plants, leading to individual 316(b) decisions that are not in society's interest.

EPA Response

For the final 316b rule analysis, EPA has changed its assessment of non-use values. As stated in the NODA, EPA agrees with the commenters that the 50% rule of thumb relies on outdated studies. In response to public comments, EPA agreed to undertake an improvement to the benefits transfer used in the analysis of non-use benefits of the 316b rule presented at proposal. Specifically, EPA developed a more rigorous regression-based meta-analysis that allows for estimation of the relative influence of various study, economic, and natural resource characteristics on willingness to pay (WTP) for non-use benefits. The results of such a regression-based meta-analysis make it possible to predict non-use WTP for aquatic resource changes as a function of site characteristics, the magnitude of environmental improvements, and study design attributes. Chapter A12, Non-Use Meta-Analysis Methodology, in the regional study document prepared for the analysis for the final Phase II rule provides detail on the meta-analysis approach to estimating non-use benefits of the 316b rule (see DCN #6-0003). Results of EPA's external peer review of its meta-analysis are provided in DCN #6-2500.

The Agency, however, recognizes that there are unavoidable uncertainties in monetizing non-use values for the ecological resources that would be protected by the final 316 (b) rule. EPA responded in several ways to the unavoidable uncertainties in monetizing non-use values. First, as explained in the preamble to the 316(b) rule, EPA engaged in a qualitative assessment of the benefits of the environmental protections at issue. Second, EPA developed lower and upper bound estimates of non-use benefits based on the Robb and Krinsky simulation technique and conducted sensitivity analysis with respect to various parameters (e.g., the size of the affected population) used in the analysis of non-use benefits. EPA considered the results of several different approaches to quantifying non-use values. However, given the degree of uncertainty associated with the estimated national non-use benefits of the final 316b rule, monetized estimates of non-use benefits are not included in the benefit cost analysis for this rule.

The Delaware Riverkeepers' Comments Mischaracterize PSEG's Estimates of I & E Losses at Salem

In its comments on the Proposed Rule, the Delaware Riverkeeper claimed that PSEG had underestimated entrainment and impingement losses at Salem (Delaware Riverkeeper comments, page 15), and that the underestimates were due to "assumptions, bias, errors and misstatements made by PSEG and its scientists." The Delaware Riverkeeper supported these allegations with references to reviews of Salem's 1999 Application. These reviews were prepared by ESSA Technologies <FN 46> ("ESSA Report"), Philip Goodyear<FN 47> ("Goodyear Report"), and Desmond Kahn<FN 48> ("Kahn 3/30/2000 Report", and "Kahn 9/26/2000 Memorandum") (Delaware Riverkeeper comments, page 18). PSEG categorically rejects these allegations and the purported bases for the allegations. Furthermore, PSEG prepared and submitted written responses to the ESSA Report, Goodyear Report, Kahn 3/30/2000 Report, and Kahn 9/26/2000 Memorandum, which have all been available from NJDEP as part of the administrative record for Salem's 2001 NJPDES Permit

The Delaware Riverkeeper cited the ESSA Report as concluding that PSEG underestimated biomass lost from the ecosystem by a factor greater than 2. In fact, PSEG did not present any estimates of biomass lost from the ecosystem in its 1999 Application. This baseless claim was completely refuted in PSEG's response to the ESSA Report<FN 49>, a copy of which is included as a reference to these comments. The Delaware Riverkeeper also cited the ESSA Report as concluding that PSEG overestimated natural mortality rates of young fish, which biased PSEG's cost-benefit assessments. As clearly documented in PSEG's response to the ESSA Report, ESSA's conclusion was erroneous and largely based on ESSA's misinterpretation of information presented in Salem's 1999 Application, and erroneous assumptions used in ESSA's analyses.

The Delaware Riverkeeper implied that the ESSA Report concluded PSEG's methods for estimating entrainment and impingement losses were unsound (Delaware Riverkeeper comments, page 16). In fact, ESSA commended PSEG for its efforts to avoid biases that could have been introduced by some sampling procedures:

"In order to complete the analysis of the loss of fish due to entrainment and impingement at the [S]tation, the investigators made a careful and substantial effort to fill gaps in the data and to adjust for known biases. Significant data engineering for entrainment losses had to occur before analyses could proceed. They should be commended for their efforts." (ESSA Report, page 6.)

The Delaware Riverkeeper also cited ESSA's concern regarding PSEG's use of multipliers to adjust upwards its estimates of entrainment. ESSA's concern on this matter was unfounded. PSEG's response to the ESSA Report identifies the flaws in ESSA's logic regarding PSEG's adjustment methods and demonstrates that ESSA's concern is completely unfounded.

It is important to recognize that all issues raised in the ESSA Report, which was commissioned by NJDEP, were fully addressed and resolved prior to the issuance by NJDEP of the 2001 NJPDES

Permit for Salem. The Delaware Riverkeeper participated actively in the administrative proceeding leading up to the issuance of the final permit, having testified at both hearing and having filed written comments on the Draft Permit. The Delaware Riverkeeper, however, did not file a challenge to the final NJPDES permit for Salem for an adjudication of the very issues being raised in its comments on the Proposed Rule.

The Delaware Riverkeeper alleged that PSEG's estimates of reductions in weakfish landings due to Salem operations were biased low because PSEG incorrectly assumed weakfish were subject to bycatch mortality in the south Atlantic shrimp fishery. The Delaware Riverkeeper cited the Kahn 9/26/2000 Memorandum as the basis for this claim. PSEG's response to the Kahn 9/26/2000 Memorandum <FN 50> addressed this issue, noting that Kahn's assertion regarding weakfish bycatch was not supported by any scientific data, and demonstrated that PSEG did not understate potential losses to the fishery. The Delaware Riverkeeper also erroneously claimed that PSEG's 12% overestimate of yield per recruit (in comparison to ASMFC's estimate of weakfish yield per recruit)<FN 51> would not translate into an overestimate of the number of fish caught by the recreational fishery. This claim is erroneous because yield per recruit is a function of mortality and weight at age, and mortality at age would affect the number of fish caught as well as the total weight of landings.

The Delaware Riverkeeper noted that PSEG did not estimate a conditional mortality rate ("CMR") for striped bass, and then erroneously concluded that this lack of an estimate of CMR biased PSEG's cost-benefit analysis. In fact, PSEG's cost-benefit analysis did not require estimates of CMRs as inputs, rather it relied directly on estimates of entrainment and impingement losses. Therefore, PSEG's cost-benefit analysis was in no way biased by the lack of a CMR estimate for striped bass.

The Delaware Riverkeeper cited the Kahn 3/30/2000 Report for its conclusion that the average CMR for striped bass was 32%, and was over 50% in some years. As fully documented in PSEG's response to the Kahn 3/30/2000 Report<FN 52>, this conclusion is wholly without scientific merit. PSEG's response to the Kahn 3/30/2000 Report demonstrates that the CMR for Delaware Bay striped bass is more likely to be less than 1%. Accordingly, all of the Delaware Riverkeeper's assertions (based on the CMR estimates from the Kahn 3/30/2000 Report) regarding the ecological and economic effects of Salem operations on the Delaware Bay striped bass are unfounded.

The Delaware Riverkeeper also briefly referred to the Goodyear Report, claiming that the Goodyear Report "joined in Dr. Kahn's concern about PSEG's failure to more vigorously attempt to obtain entrainment estimates for striped bass." However, the Goodyear Report was submitted prior to the Kahn reports, and therefore could not have --and did not -- offer any comments on the Kahn reports. PSEG's response to the Goodyear Report<FN 53> clearly explained the life history considerations and limitations of historical data that precluded development of CMR estimates for striped bass. Also, contrary to the Delaware Riverkeeper's assertion, PSEG did estimate entrainment losses for striped bass, and in fact, the Goodyear Report refers to those entrainment estimates for striped bass.

EPA Response

EPA has reviewed all of the comments provided by PSEG, and EPA stands by its analysis for the final rule. For this analysis, EPA averaged data from multiple facilities in the mid-Atlantic region, in addition to Salem, to develop a regional estimate of impingement and entrainment. EPA stands by this analysis.

Riverkeepers and Pisces Report Mischaracterize the Science Supporting the EEP and its Accomplishments

In its comments on the EPA's Proposed Phase II Rule, the Hudson and Delaware Riverkeepers (collectively referred to as the "Riverkeepers") level several objections to the use of restoration measures as a means to offset potential adverse effects of CWIS intake structures on fish and invertebrate populations. The Riverkeepers present many specific objections to restoration measures, using inaccurate or misleading references to the EEP. These objections include the following assertions: (1) that food and habitat are not limiting to fish populations in the Delaware Estuary,<FN 54> (2) that the success criteria used to evaluate the restoration project are flawed, (3) that Phragmites-dominated marshes are functionally identical or better than Spartina-dominated marshes for creating fish, (4) that PSEG's wetland restoration has failed, (5) that the restoration efforts only converted existing freshwater wetlands to saltwater wetlands, (6) that PSEG is unable to quantify the number of fish produced, and (7) PSEG's restoration has adversely affected horseshoe crabs.

Before responding to each of the above-listed criticisms, it is important to understand the regulatory background in which the EEP evolved and the regulatory concern it was designed to address. In 1993, PSEG formally proposed the EEP to address the NJDEP's concern about potential adverse effects of the operation of the CWIS at Salem on four fish species.<FN 55> The EEP was an innovative solution to an environmental issue, which was based on good science, sound ecological principles and good public policy. Through the EEP, PSEG has demonstrated a willingness and ability to drive not only technological developments but also environmental stewardship. The EEP incorporates short-term, near-field benefits of innovative fish protection technology with an estuary-wide habitat improvement project that will continue to provide ecological benefits far beyond the expected life of the Salem CWIS. PSEG maintains that the benefits associated with successful restoration and/or preservation of more than 10,000 acres of degraded wetlands far outweigh the benefits of other technology-based measures not required for installation under Salem's NJPDES permit.

Riverkeepers' Argument for Limiting Factors Is Flawed

The Riverkeepers allege that PSEG failed to provide scientific data indicating that food or habitat were limiting factors for the fish populations in the Delaware Estuary. Furthermore, their objections claim that there exists no data or information that would indicate such. The Riverkeepers' objections maintain that altering wetlands to increase food and habitat availability for fish is unlikely to have any effect on fish populations within in the estuary. This objection clearly indicates an insufficient understanding of estuarine ecology. Furthermore, and perhaps more significantly, it highlights faulty logic that is further biased by the Riverkeepers' fundamental position that 316(b) requires installation of closed cycle cooling systems at all power plants. Their assessment of EEP and their interpretation of the statute are equally flawed.

Contrary to the question that the availability of wetlands and the nutrients they provide is not a critical limiting factor for fish abundance, living space and food are demonstrably interrelated. In the wetlands, the risk of being eaten while obtaining food is likely to be lower than in other estuarine habitats. Furthermore, it is likely that the wetlands produce more fish than other habitats in the Estuary, as follows.

Aquatic populations may be limited by many environmental factors. A single factor usually operates as the critical limiting factor, but single factors do not limit populations for more than short periods of time over more than small areas. All of the parameters are simultaneously “critical limiting factors,” and any one can be limiting at a particular moment or in a particular place.

Because fish maximize their fitness (Mittleback 1981, Werner et al. 1983, Crowder 1984), factors which lower fitness can affect the success (or productivity) of a species. Critical limiting factors can take many forms, both abiotic and biotic. Abiotic factors include physical/chemical parameters such as temperature, salinity, nutrients and substrate composition. Biotic factors include competition for food and space, disease, and predation. In an estuary, limiting factors constantly vary over space and time. The physical/chemical factors set broad limits as to where a species may be found (Sanders 1968). Competition, disease, parasites, and predation set narrower limits on the whereabouts and physiological well-being of individuals.

The relationship of these factors produces predictable patterns in habitat selection, utilization and survival in estuarine fishes. However, habitat selection is also strongly influenced by .two biotic factors that control survival: foraging profitability and risk of predation. For a fish to grow, it must find food and, while doing so, not be eaten. Put another way, starvation and predation are sources of mortality which compete for fish (Werner 1986).

The stress from these sources of mortality is minimized in the marsh. The risk of an early life stage fish’s being eaten while obtaining food is likely to be lower in a tidal marsh than in many other areas of an estuary because the marshes and associated tidal creeks provide abundant food while serving as predation refugia for these early life stages (Boesh and Turner 1984). Although food supplies may be locally limiting in estuaries (Peters and Kjelson 1975, Laurence 1977, Bahr et al. 1982), the contrary is indicated in estuarine marshes (Deegan and Day 1984, Peters and Lewis 1984). Moreover, the seasonally warmer waters of the marsh creeks promote rapid growth rates in fish which reside there.

The presence of the dikes on the former diked salt hay farms precluded the exchange of fish .from the estuary and the vegetation on the former salt hay farms. The removal of these dikes and the reestablishment of appropriate hydrology increase the available aquatic habitat and increase available primary production.

Increasing available food will increase fishes’ growth rates, and increasing the growth rate will increase the survival rate of young fish. During the time that young-of-year occupy tidal creeks, they are likely to survive at higher rates than in open waters of an estuary (Weinstein 1985). For many species, this may result in greater contributions to the population of fall migrants than from other habitats in an estuary. In addition, rapid growth will result in larger individuals; combined with lower predation intensities, a very high rate of secondary production will be realized in the marsh ecosystem.

Thus, the critical limiting factors in the marsh may differ from the open estuary and the difference produces a more benign environment in the marsh, promoting rapid growth and enhanced survival. When the fish move to the estuary and coastal waters as larger individuals, they will benefit from the export of detritus and living biomass from the marsh. For some species, this food source will produce healthier adult fish prior to seasonal migrations and overwintering.

Footnotes

54 The Hudson Riverkeeper's specific objections to PSEG's restoration measures completed under the auspices of the EEP include:

"PSE&G's wetland experiment involves restoring, enhancing andlor preserving 10,000 acres of what PSE&G characterizes as degraded wetlands. The majority of those wetlands are dominated by the phragmites [sic] plant; restoration efforts include herbicide application, mowing and rescribed burning in order to remove phragrnites [sic] and replace it with spartina [sic] grasses. Some freshwater diked wetland are also being converted to salt marshes. The original argument supporting this program was that enhancement of these wetlands will increase fish production in the Delaware Estuary."

54 A consultant, Versar, Inc., hired by the NJDEP to review Salem's 1984 ' 316(b) Demonstration concluded based on two years of operational data and highly conservative, predictive models that Salem had the potential to cause long-term declines in four of the nine finfish RIS.

55 PSEG's Supplement to the Application for Renewal of Salem's NJPDES Permit No. NJ0005622, March 4, 1993.

EPA Response

EPA believes that removal of dikes from diked salt hay farms can result in a renewal of the hydrological connection between the marsh and the surrounding estuary. This connection renewal can result in an increase of salt marsh habitat for a variety of organisms. EPA believes that fish and other aquatic organisms in the estuary benefit to differing amounts from increases in salt marsh habitat, depending on the limiting factors acting upon the organisms and their particular habitat needs.

RFC: Performance/effectiveness of restoration

PSEG's Success Criteria Are Valid

With respect to the success of wetland restoration, the Riverkeepers assert that PSEG's evaluation methodologies and success criteria for the wetland restoration efforts do not include a determination of whether or not the fish populations of the River are benefiting from the wetland restoration efforts. The Riverkeepers highlight established restoration success criteria that focus on such parameters as change in vegetation coverage, algal productivity, and macrophyte productivity.

This statement is only partially true. PSEG's wetland restoration success criteria, as defined by site-specific management plans, are based on vegetative cover and hydrological conditions. Since the restoration project bases its premise on the creation of desirable intertidal habitat, the quantification of these factors is not only desirable, but also a logical necessity. The vegetative and hydrological success criteria developed for the restoration sites were established as measures to compare the form of the restored sites to nearby control sites as an overall measure of success. Furthermore, the success criteria and their supporting bases were reviewed by the Management Plan Advisory Committee prior to approval by NJDEP.<FN 56> Articles describing the success criteria and their bases were accepted and published in scientific peer reviewed journals<FN 57>.

Furthermore, the vegetative community and the stream morphology within a marsh system have a direct bearing on the quality of the habitat within the system. A marsh historically dominated by Phragmites can differ substantially from a marsh dominated by Spartina with respect to creek bank morphology, channelization, marsh plain hydroperiod and topography. Understanding these differences are vitally importantly in understanding how fish utilize marsh habitat and the relative contribution such utilization makes to the overall production of fish<FN 58>.

If vegetation were the only metric employed by PSEG in evaluating the success of wetland restoration, the Riverkeepers' objections might be justified. Beyond the vegetative and hydrological success criteria required by the NJDEP-approved management plans, however, PSEG has undertaken substantial efforts to understand, I characterize and quantify the success of the wetland restoration activities in producing fish. Much of this information is available in peer-reviewed literature (e.g. Able 1999, Able et al 2003, Smith et al 2003, Currin 2002, Teo & Able 2002).

These publications, as well as many others, document how scientists, including scientists conducting primary research at the PSEG sites, are making tremendous strides in describing the mechanisms by which primary production occurring in the marsh is transported first to tidal creeks and subsequently into the estuarine system. The processes involved are admittedly complex, and much work remains to be done; however, much has already been learned about the contribution to the forage and habitat base that healthy marshes provide (see Section III.A above). Fish abundance monitoring, food habits and habitat utilization research conducted at PSEG's formerly diked salt-hay farm restoration sites clearly demonstrate that the restored sites are performing as well as, or better than, relatively undisturbed reference marshes with respect to fish production. In particular, formerly diked salt-hay farms represent entirely new habitat to estuarine organisms and, as such, any fisheries production attributable to these sites is necessarily new production (see Section III.B, above).

Footnotes

56 The Management Plan Advisory Committee ("MPAC") was established as a requirement of Salem's 1994 NJPDES Permit. MPAC included representatives of USEPA Region II's Office of Wetlands, DNREC, NJDEP, the Delaware River Basin Commission and municipalities hosting restoration sites. It also included academicslindependent scientists with recognized expertise in marshes, marsh restoration andfor coastal processes, including a scientist nominated by the Delaware River.

EPA Response

EPA believes that there are uncertainties associated with the design, implementation, performance, and assessment of restoration measures. For a discussion of these uncertainties, see EPA's responses to comments 316bEFR.206.055 and 316bEFR.077.013. The requirements in the final rule are intended to help reduce uncertainties associated with restoration measures and enhance their overall performance.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

All restoration measures used to comply with the performance requirements of the final rule must meet the requirements described in sections 125.94 and 125.95 of the final rule.

RFC: Performance/effectiveness of restoration

Phragmites Sites Are Not Equivalent to Spartina Sites

With respect to Phragmites-dominated restoration sites, the Riverkeepers make multiple assertions in the following vein:

“PSE&G has failed to conduct the baseline data on the contributions of the phragmites [sic] stands to the food chain in order to make the necessary comparisons. It is very possible that the fish used the phragmites-dominated [sic] marshes in the same way and to the same degree as they would spartina-dominated [sic] marshes and therefore nothing has been truly gained by their efforts.” and:

“. . .PSE&G’s own data confirms.. .that phragmites-dominated [sic] marshes on the Delaware Bay contribute just as much basic nutrient material to into the food web as spartina-dominated [sic] marshes. As new data are generated, the general perception that regularly flooded phragmites [sic] marshes are less functional than the spartina [sic] marshes they replace does not appear to be upheld.” Clearly, these arguments are based upon the notion that marshes are merely a nutrient source, providing organic material for consumption within the estuarine system. At such a grossly simplistic level, the Riverkeepers’ argument could be persuasive; however, it misses the point. As previously stated, one of the fundamental differences between Phragmites-dominated and Spartina-dominated marshes is the value of these environments as nursery and refuge habitat<FN 59>

The significant effects that Phragmites colonization has on marsh habitat, particularly with respect to loss of intertidal habitat from marsh plain siltation, reduced reproductive capacity for marsh resident species (e.g., the mummichog, Fundulus heteroclitus) and loss of tidal tributaries is well-documented <FN 60>. To express marsh ecology as simply a process by which nutrient material is provided to the food web is to demonstrate a clear misunderstanding of habitat value and production potential.

The Riverkeeper acknowledges the potential differences in habitat quality between a healthy Spartina marsh and a Phragmites marsh, even when highlighting the supposed nutritive value of Phragmites. In footnote 119, the Riverkeeper quotes Rooth and Windham: "In comparison to a Spartina community, Phragmites enhances both mineral and organic decomposition, basically doubling the accretion potential of the marsh". In referencing such a statement, the Riverkeeper acknowledges that a Phragmites marsh accretes sediment at twice the rate of a Spartina marsh. The end result of this accretion, however, is the elimination of fish habitat. The accreting sediments fill the rivulets on the marsh plain, creating the table-top surface characteristics of Phragmites sites. Further, the accretion associated with Phragmites eventually reduces tidal exchange to the point where the very nutrients the Riverkeeper claim are beneficial are inhibited from being exchanged with the tidal tributaries. Thus, a long-term effect of sediment accretion in Phragmites -dominated marshes is the trapping of the nutrients necessary for aquatic production at the same time as intertidal habitat is being lost to sedimentation<FN 61>.

RFC: Performance/effectiveness of restoration

PSEG Marsh Restoration is Successful

Despite statements by the Riverkeepers, monitoring data indicate that PSEG's marsh restoration program is successful. As described in Salem's 1999 Application, Appendix G, Attachment G-2-4, PSEG has conducted extensive vegetation, hydrologic and biological monitoring programs. These monitoring programs are conducted, as is required by a biological monitoring plan ("BMP"). The BMP is reviewed by the Estuary Enhancement Program Advisory Committee <FN 62> ("EEPAC"), prior to approval by the NJDEP. EEPAC also reviews the results of these monitoring programs annually. The most recent data from the marsh sites indicate that the desired vegetation is being restored. The Dennis Township site met the Final Success criteria in 2000 and the Maurice River Township site reached success criteria in 2001. The remaining five marsh restoration sites are on a trajectory for success.

Footnotes

62 Salem's 2001 NJPDES Permit established a single advisory committee, EEPAC, which essentially combined the MPAC with the Monitoring Advisory Committee ("MAC"). The composition of the EEPAC includes the MPAC along with the governmental agency representatives with expertise in fisheries and academics/scientists with expertise in fisheries and population dynamics.

EPA Response

EPA believes that there are uncertainties associated with the design, implementation, performance, and assessment of restoration measures. For a discussion of these uncertainties, see EPA's responses to comments 316bEFR.206.055 and 316bEFR.077.013. The requirements in the final rule are intended to help reduce uncertainties associated with restoration measures and enhance their overall performance.

RFC: Performance/effectiveness of restoration

PSEG Marsh Restoration Has Not Replaced Diked Freshwater Wetlands with Salt Marsh

The Riverkeepers' contention that PSEG's marsh restoration program has merely converted diked freshwater wetlands into saltmarsh is untrue. As documented in Salem's 1999 Application (Attachment G, previously submitted to USEPA), all diked areas subject to restoration were salt-hay farms prior to the initiation of restoration, predominantly vegetated by salt hay (Spartina patens). Salt hay is not a freshwater wetland species. These areas, which were formerly open to the tides, historically were vegetated with smooth cordgrass (S. alterniflora) and salt hay. Dikes were constructed by agricultural interests to change the areas into predominantly high salt marsh for the agriculturally desirable salt hay. Prior to diking, these sites were subjected to twice-daily tidal inundation and were in direct hydrologic connection with Delaware Bay, experiencing a flux of nutrients and organisms that utilized the sites. The removal of the dikes has reestablished the twice-daily tidal inundation and reestablished the nutrient/organism fluxes.

Furthermore, to address areas of freshwater wetlands adjacent to the formerly diked salt hay farms that may have been impacted by restoration activity, PSEG was required to mitigate on a three-to-one basis for certain losses of freshwater wetlands pursuant to permits to allow restoration activities, issued by NJDEP.

At the Commercial Township Salt Hay Farm Wetland Restoration Site, PSEG proposed a freshwater wetland mitigation program consisting of 82.1 acres to offset the 24.8 acres of freshwater wetlands impacted by restoration activities. The 82.1 acres of mitigation included 67 acres of tidal wetlands that were to be converted to freshwater wetlands and 15.1 acres of upland area converted to freshwater wetland areas resulting from the landward movement of the tidal/upland interface <FN 63>. The freshwater wetland mitigation program was included as a condition in the NJDEP's Land Use Regulation Permit No. 0602-95-0002.3,.4,.5,.6,.7; dated September 11, 1996 and the U.S. Army Corps of Engineers Section 404 permit, CENAP-OP-R-199601947-24; dated September 14, 1996, issued for the restoration activities at the Commercial site.

At the Dennis Township Salt Hay Farm Wetland Restoration Site, PSEG was required by the NJDEP's Land Use Regulation Permit No. 0504-95-08.2,.3,.4.,.5; dated February 15,1996 and U.S. Army Corps of Engineers Section 404 permit, CENAP-OP-R-199500676-24; dated February 16,1996 to compensate for the loss of two acres of freshwater wetlands with the restoration of seven acres of former freshwater wetlands that were converted to coastal wetlands by previous salt hay farming activities. PSEG provides annual reports to NJDEP and the U.S. Army Corps of Engineers on an annual basis to document the progress of the freshwater wetland mitigation program.

Use of Replacement Costs (HRC and hatchery-based)

PSEG Estimated the Fish Production in the Marshes

Based upon monitoring of fish utilization of the marshes (Salem's 1999 Application, Appendix G, Attachment G-3, previously submitted to USEPA), there is scientific data on the species of fish, numbers of individuals, and their spatial and temporal occurrence in the marshes. These data were collected in both restored as well as reference marshes. Reference marshes are natural marshes or marshes that had been fully restored, which were located in proximity to the restoration sites (Salem's 1999 Application, Attachment G-2, Exhibit G-2-2.) Based on these data, PSEG demonstrated that the species, number of individuals, and spatial and temporal occurrence of these fish were equivalent (or in some instances greater in the restored marshes) in both the reference and restored marshes.

In addition, PSEG used the data to estimate total fish production on the restored salt hay marshes using bioenergetics modeling (Salem's 1999 Application, Appendix G, Attachment G-4). Bioenergetics modeling uses actual biological and physical data to estimate increased biomass for all fish in the marsh. This modeling did not address the primary production that is transported out of the marsh into the estuary. This includes particulate organic matter, dissolved organic matter, micro- and macro-invertebrates and fish too small or too large to collect in the sampling equipment employed. This production is utilized by organisms residing in the estuary.

EPA Response

EPA believes that there are uncertainties associated with the design, implementation, performance, and assessment of restoration measures. For a discussion of these uncertainties, see EPA's responses to comments 316bEFR.206.055 and 316bEFR.077.013. The requirements in the final rule are intended to help reduce uncertainties associated with restoration measures and enhance their overall performance.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant in determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

All restoration measures used to comply with the performance requirements of the final rule must meet the requirements described in sections 125.94 and 125.95 of the final rule.

RFC: Proposed use of restoration measures

Peg's Restoration Has Not Adversely Affected Horseshoe Crabs

The Hudson Riverkeeper cites the Pisces Report, which claims that Peg's marsh restoration program is having a negative impact on horseshoe crabs. Concern has been raised that the horseshoe crab population has declined. In addition a number of shorebird species rely on horseshoe crab eggs for food during their migration from South America to Canadian breeding grounds. The basis for this objection is early reports that horseshoe crabs were being stranded on Peg's Maurice River Township wetland restoration site ("MRT Site"), a formerly diced salt hay farm. Prior to Peg's commencement of any restoration activities, horseshoe crabs were indeed accessing the impounded area through breaches in the bay-front dikes that had occurred naturally prior to Peg's acquiring the MRT Site. These dike breaches resulted in higher than natural water velocities and the loss of vegetation on the site, which became dominated by mudflats. Many of these crabs were swept in on the flooding tide and were subsequently stranded on the acres of bare mudflat present in the area.

In 1996 and 1997, large numbers of horseshoe crabs were observed as being stranded on the MRT site (approximately 200,000 crabs were estimated to have died). In order to address allegations that the MRT Site was causing significant mortality to horseshoe crabs, PSEG retained nationally recognized experts<FN 64> in horseshoe crabs to evaluate the conditions at the MRT Site with respect to horseshoe crabs and to develop and implement a monitoring program to assess the effects of the MRT Site restoration on the horseshoe crabs.

PSEG began marsh restoration activities on the MRT site in 1997 outside of the horseshoe crab spawning season. Construction was completed in March 1998, prior to the 1998 horseshoe crab spawning season. During the 1998 spawning season only hundreds to a few thousand crabs were observed to be stranded. This number is modest in comparison to 240,000 crabs collected by hand-harvesters that year. The construction of tributaries within the site has resulted in water velocities within the site that are in the range of those in natural tributaries and is evidenced by the fact that stranding were reduced and crabs were using the constructed tributaries as they would natural tributaries (Salem's 1999 Application, Appendix G, Attachment G-2, Exhibit 12).

The successful restoration of the MRT site actually eliminated a condition detrimental to horseshoe crabs. Following restoration, horseshoe crabs were documented successfully reproducing on the banks of the constructed tributaries within the site <FN 65>. As a result, the NJDEP has declared the MRT Site area as a horseshoe crab sanctuary, and has prohibited the commercial harvest of these organisms within its boundaries.

The PSEG marsh restoration program has not resulted in a negative impact on horseshoe crabs. In fact, the restoration of the MRT site has eliminated a problem and resulted in newly expanded spawning habitat for an ecologically important species whose population is believed to be declining.

Footnotes

64 PSEG retained Drs. Carl Shuster retired from USFWS and professor at the Virginia Institute of Marine Science, Rober Loveland of Rutgers University and Mark Bottom of Fordham University in this regard.

65 Bottom, M. and R. Loveland. Horshoe habitat use at the Maurice River Township salt hay farm restoration site in Delaware Bay, New Jersey. 2000.

EPA Response

EPA believes restoration science continues to progress. Permitting authorities and permit applicants should consider net environmental benefit when assessing a particular restoration measure.

Salem

Salem Has Not Adversely Affected Threatened and Endangered Species

In their comments, the Riverkeepers criticize PSEG's record of threatened and endangered species encounters at the Salem facility. The Riverkeepers maintain that endangered and threatened shortnose sturgeon and sea turtles are killed at Salem and that data on these encounters have not been provided. With respect to endangered shortnose sturgeon, the Riverkeepers suggest that there must be unreported entrainment losses of this species if adult sturgeon are "getting caught on trash racks".

In 1990, NMFS held a formal consultation under Section 7 of the Endangered Species Act ("Consultation"). This Consultation addressed shortnose sturgeon, loggerhead turtle, Kemp's Ridley turtle and the green turtle. Based on the data and information provided in the Consultation, NMFS made a no jeopardy determination and issued incidental take numbers for the sturgeon and turtles. Subsequent Consultations have occurred to the present.

In accordance with the Consultation, PSEG reports any encounter with the endangered shortnose sturgeon at the Salem facility. These encounters are largely attributable to the impingement of already dead and/or decomposing organisms, often the result of gillnet by-catch or disease. Furthermore, the entrainment of a shortnose sturgeon has never been documented due to its reproductive strategy. Shortnose sturgeon spawn almost one hundred miles upstream of Salem and entrainable life stages of shortnose sturgeon occur far upriver from the influence of the Salem station. Only the substantially larger juvenile and adult shortnose sturgeon would be expected in the tidal portion of the estuary near the Salem Station.

Moreover, the comment that entrainable lifestages must be present if larger adult fish are being impinged demonstrates Riverkeepers complete lack of understanding of the most rudimentary concepts of fisheries biology; i.e., that different life stages of a given fish species utilize different water bodies and/or different habitats within a water body than other life stages of the same species. Likewise, it demonstrates a serious lack of understanding of the life history of the shortnose sturgeon. These fish spawn in primarily freshwater portions of tidal rivers; their eggs are demersal and adhesive, which limits their susceptibility to entrainment.

Although the death or injury of a shortnose sturgeon directly attributable to the CWIS is highly unlikely, any encounter with this species is nevertheless reported to NMFS and counts against the "incidental take" limits established by NMFS, even if the reported mortality was obviously not attributable to the Station's operations (e.g. due to the presence of gill net scars, propeller damage, skin lesions, or the deteriorated condition of the specimen).<FN 66>

The Riverkeeper states that endangered and/or threatened sea turtles have also been injured and killed at Salem. For example, the Hudson Riverkeeper states:

"The New Jersey permit record has information about the impacts to the federally 'threatened turtle populations injured and killed at Salem, and at one time required a turtle resuscitation program at that site.”

Since the Station began commercial operation in 1977 (Unit l), PSEG has had a program to report to the federal and state regulatory agencies of the collection of a sea turtle (or sturgeon). This program also included a sea turtle resuscitation program and a sea turtle and sturgeon recovery program (for either dead or live specimens). In the early 1990s' Salem's record of impingement of threatened and endangered sea turtles documented significantly increased numbers of encounters each year (approximately 40 turtles were encountered in 1990 and 199 1 combined). A satellite-tracking program for turtles recovered alive was also conducted during this period. Subsequent observations by Salem fisheries scientists led to a fundamental change in the summer configuration of the Salem CWIS. Historically, turtles sounding (diving) near the CWIS often surfaced behind the permanently installed ice barriers. Once behind these barriers, the turtles apparently had difficulty escaping.

After the mechanism by which turtles became trapped was understood, the ice barriers were removed during summer months.<FN 67> Subsequent to this change, sea turtle encounters dropped significantly (i.e., 0 - 1 encounters per year). Furthermore, the turtle encounters following the change in the deployment of the ice barrier are often the result of the impingement of turtles dead due to other sources of mortality (e.g., propeller strikes, disease).

Even though there has been a dramatic reduction in the number of turtles that are encountered at the Salem CWIS, Salem still must comply with its incidental take permit issued by NMFS. This permit limits the number of sea turtles (live or dead) taken each year. Contrary to the erroneous claims of the Riverkeepers, the sea turtle resuscitation program, the sea turtle and sturgeon recovery program and the obligation to report any incidental takes of these species to NMFS are still in effect at Salem, as mandated by NMFS under the 7 ESA consultation. In fact, resuscitation and identification guides are prominently displayed throughout the CWIS, and operators continue to receive training in these procedures. It is likely that the perception that this program was discontinued stems from the dramatic reduction in reportable turtle encounters since the change in ice barrier deployment.

Footnotes

66 It is worthwhile to note that Salem's incidental take permit limitation for the Salem Station also extends to PSEG's estuary-wide biological monitoring activities such as research trawling and seining for impace assessment purposes. Any collection of a T&E species during the conduct of these studies invokes the same handling and reporting requirements as an encounter at the CWIS, and counts toward the annual "take" limit.

67 The summertime removal of the ice barriers has subsequently become a condition of Salem's operation, as required by the United States Nuclear Regulatory Commissions consultation with the National Marine Fisheries Service under Section 7 of the Endangered Species Act. The observations of turtle behavior by Salem personnel led directly to the favorable modification to operating practices; thus, PSEG took a proactie and effective step in protecting the threatened and endangered sea turtles seasonally present in the Delaware Estuary.

EPA Response

EPA notes this information provided by PSEG on the impingement and entrainment of threatened and endangered species at Salem. Although the commenter acknowledges that some threatened and endangered species are impinged and entrained at Salem, EPA did not have access to any impingement and entrainment estimates for such species. Therefore, EPA did not include these species in its analysis.

Suggestions for Permit Writer Guidance on Proposals to Implement Restoration Measures

Introduction

USEPA is considering requiring the following practices during the development of restoration projects (68 Fed. Reg. 13542, col. 1):

1. documentation of sources and magnitude of uncertainty in expected restoration project performance;
2. creation and implementation of an adaptive management plan; and
3. use of an independent peer review to evaluate restoration proposals.

PSEG agrees that all three factors (uncertainty analysis, adaptive management, and peer review) may be useful for designing, assessing and managing restoration projects. PSEG recommends that the USEPA develop and issue guidance for Directors and permit writers to use during their review of proposals by cooling water users to implement restoration measures.

Based on its considerable experience with large-scale marsh restoration programs, PSEG offers the suggested guidance language presented below as an illustration of the types of information and levels of detail that would be helpful to include in a USEPA prepared guidance document.

II. Evaluation of Applicant Proposals

A. Application Contents

Applicants who propose to use restoration measures to meet the performance standards in § 125.94, must submit the following information as defined in § 125.95(b)(5) with their Comprehensive Demonstration Study for review and approval by the Director:

i. A list and narrative description of the restoration measures proposed for implementation;

ii. A quantification of the combined benefits from implementing design and construction technologies, operational measures and/or restoration measures and the proportion of the benefits that can be attributed to each;

iii. A plan for implementing and maintaining the efficacy of the restoration measures;

iv. A summary of any past, ongoing, or voluntary consultation with appropriate Federal, State, and Tribal fish and wildlife agencies regarding the proposed restoration measures; and

v. Design and engineering calculations, drawings, and maps documenting that the proposed restoration measures will meet the restoration performance standard at § 125.94td).

USEPA recognizes that it may not always be possible for Applicants to demonstrate quantitatively that restoration measures will achieve comparable performance; however, the Applicant must make a qualitative demonstration that such measures will maintain fish and shellfish in the waterbody at a level substantially similar to that which would be achieved under 5 125.94. Demonstrating "substantially similar performance" for habitat restoration measures where it is not scientifically possible to fully quantify the number or biomass of aquatic organisms expected to be produced through implementation of the restoration measures, can be difficult, but should not preclude a Permit Writer from accepting restoration measures when proposed by an Applicant. Fully quantifying the increased aquatic production from habitat restoration measures that result in water quality improvements, provide new aquatic habitat (e.g. opening impounded tidal marsh), or improve existing aquatic habitat (e.g. wetland restoration, artificial reef construction, re-establishment of submerged aquatic vegetation, wetland buffer conservation, and etc.) may not be possible, but suitable techniques are available to demonstrate "substantially similar performance." USEPA provides the following guidance to Permit Writers who may be reviewing a Comprehensive Demonstration Study that includes restoration measures as a component.

B. Evaluation Criteria

An Applicant may propose the implementation of restoration measures either, in lieu of, or in combination with, reductions in impingement mortality and entrainment. In addition, an Applicant may propose restoration measures to address only impingement and/or entrainment losses in excess of those acceptable under the Performance Standards defined by § 125.94. <FN 1>

The Comprehensive Demonstration Study must, at a minimum, include information and data on the following topics:

i. The percent reduction in impingement mortality and entrainment that would be achieved through the use of any design and construction technologies or operational measures that have been proposed;

ii. A demonstration of the benefits that will be achieved by implementation of the proposed restoration measures; and

iii. A demonstration that the combined benefits of the design and construction technology(ies), operational measures, and/or restoration measures will maintain fish and shellfish at a level comparable to that which would be achieved under § 125.94.

Whenever possible, an applicant 's Comprehensive Demonstration Study should include quantification of at least a portion of the benefits to be achieved by implementation of the proposed restoration measures. USEPA recognizes the difficulties in quantifying benefits associated with restoration measures; however, there are a number of methods of varying sophistication that can be applied, including, but not limited to: estimates of production from peer-reviewed scientific literature, production foregone calculations, bio-energetics modeling and ECOPATH modeling.

Mathematical modeling techniques can be used to quantify a portion of the fishery benefits that will result from implementation of most restoration measures. For restoration measures involving the stocking of hatchery-reared species, numbers or biomass of CWIS losses can be compared to the numbers or biomass of hatchery-reared organisms to be stocked. If the primary concern relates to the potential secondary effects on predator species of recreational or commercial fishery importance due to CWIS losses of a forage species; the level of stocking of predator species required can be determined through bio-energetic models which calculate the predator biomass that would be expected to result from consumption of the lost forage. <FN 2>

Similarly, the increased biomass of predator species of recreational or commercial importance attributable to the production of forage fish that results from restoration measures can be quantified through use of bio-energetic modeling. This approach has been applied to estimate the increased biomass of striped bass and weakfish from the production of river herring in the new habitat created through the installation of fish ladders on impoundments within the Delaware Estuary. <FN 3>

Mathematical modeling techniques such as bio-energetics modeling can be used for most restoration measures for which the number or biomass of forage or predator species expected to result from implementation of the restoration measures can be estimated. It is not necessary to conduct extensive monitoring to determine precisely the number of organisms or biomass produced as a result of the restoration measures. In most instances, sufficient scientific literature exists upon which to base credible estimates. The appropriate margin of safety for particular restoration measures can be determined by the Director on a case-by-case basis; and the required consultation with appropriate Federal, State and Tribal fish and wildlife management agencies specified by § 125.94(d) of the Preferred Option should provide sufficient input to the regulatory authority to ensure that an appropriate safety margin is applied.

Comprehensive ecosystem modeling using ECOPATH, or a similar type of model that tracks energy flow through an ecosystem is an approach that may be available in some instances (Christensen and Pauly, 1992; 1993; ECOPATH 2000). The ECOPATH model presents a mass balance of trophic exchanges for an entire ecosystem. It works by using estimates of biomass for each major species or their aggregation in functional groups representing trophic levels, then uses principles of energetics and trophic transfer to estimate the flux of energy from one level to another. This creates a steady-state solution that requires an input-output budget to balance for the ecosystem as a whole, and then calculates the rate of energy transfer required to balance that budget. ECOPATH has been used to describe the structure of food webs in 56 different ecosystems (Pauly and Christensen, 1995), and its applications have grown rapidly in the recent past to the point that there are now ECOPATH models for more than 90 different ecosystems (ECOPATH , 2000).

Biomass should be the common metric of assessment because biomass can be directly measured and compared across all levels of the food chain. Biomass can also be aggregated by trophic level for comparison to CWIS losses to capture the habitat-based benefits to multiple species resulting from restoration measures. Biomass is also the most suitable metric when the age or length-class of organisms lost at a CWIS are different than the age or length-class of organisms benefiting from a habitat restoration effort.

Regulatory agencies can further assure the performance of conservation measures by requiring the inclusion of safety margins within the restoration plans. The appropriate margin of safety for particular conservation measures should be determined by the Director on a site-specific basis. The margin of safety appropriate for a particular restoration measure should depend on the circumstances under which they are proposed. Factors such as: the degree of uncertainty concerning the adverse impact of CWIS operations (e.g., whether or not the aquatic populations demonstrate long-term trends of increasing abundance); the scientific understanding of the ecological benefits of the proposed conservation measures; the ability to monitor and quantify the ecological benefits of the proposed conservation measures; and the intended lifetime duration of CWIS should all be factored into decisions concerning the appropriate margin of safety to be applied. The required consultation <FN 4> with appropriate Federal, State and Tribal fish and wildlife management agencies specified by § 125.94(d) should provide sufficient input to the regulatory authority to ensure that an appropriate margin of safety is defined.

In circumstances when complete quantification of the benefits is not possible, the Comprehensive Demonstration Study should provide sufficient information and data to demonstrate "substantially similar performance." Restoration measures that can provide tangible results toward restoring and protecting the chemical, physical and biological integrity of the source water body can be demonstrated to provide "substantially similar performance" by expanding the analysis to focus on the ecosystem, community, and/or the population level benefits that will result from the proposed restoration measures. An analysis of ecosystem, community and/or population level benefits that will result from proposed restoration measures can be based on historical information relating to the source water body, scientific literature documenting the effects of restoration measures in other locations, or scientific information on the value of the particular type of habit proposed for restoration.

Restoration measures that are designed to restore water quality or habitat to the more productive state that previously existed, may be evaluated based on documented evidence concerning the ecosystem, community or population levels that were present under the prior conditions. If historical data and information is unavailable for the specific location, scientific literature documenting the ecological benefits provided by the environment conditions to be restored can be used to demonstrate "substantially similar performance".

For restoration measures that will result in the creation of new habitat, or where no data is available to document ecosystem, community and/or population characteristics prior to the adverse impacts being addressed by the proposed measures, the Comprehensive Demonstration Study will similarly have to rely on scientific literature documenting either the value of the habitat being restored or the overall ecosystem, community, or population level benefits to demonstrate "substantially similar performance."

An applicant 's Comprehensive Demonstration Study should also include a detailed plan for implementing and maintaining the efficacy of the restoration measures. The detailed implementation plan should contain sufficient information to fully evaluate an Applicant's proposal. In most cases, details concerning implementation will have already been worked out through consultation with the appropriate Federal, State and Tribal fish and wildlife agencies, and the Director should encourage all applicants to pursue such consultations before including restoration measures in any Comprehensive Demonstration Study.

Dependent on the type of restoration measures proposed, the Applicant may be unable to commit to a specific location or activity for the proposed restoration measures, Committing to a specific location prior to receipt of the Director's approval may be particularly difficult if the restoration measures require the purchase of land or the procurement of facilities. None-the-less, the Applicant should fully describe the proposed measures; provide details as to how the proposed measures will meet the Performance Standards; provide scientific justification concerning any calculations used to demonstrate compliance with the Performance Standards; provide schedules and time-frames for implementation of the proposed measures; and provide design and engineering calculations, drawings, and maps documenting the proposed measures.

The Comprehensive Demonstration Study should also contain details concerning the maintenance activities required during the term of the NPDES Permit to ensure that the efficacy of the restoration measures will continue. Whenever possible, the maintenance plan should include performance/success criteria that the Director can incorporate into the NPDES Permit as enforceable permit conditions. Applicants are encouraged to also work out these details through consultation with the appropriate Federal, State and Tribal fish and wildlife agencies. The Director or his designee can and should participate in these consultations to ensure that the restoration measures proposed will satisfy all interested parties.

Many of these details concerning proposed restoration measures will depend on the particularly type of measures proposed and the Director is encouraged to remain flexible as long as the proposed measures can be demonstrated to satisfy the Performance Standards specified in 125.94.

To assist the Director in evaluating proposed restoration measures, the USEPA suggests use of the checklist provided in Table 1. Dependent on the particular type of restoration measures proposed, specific items listed in Table 1 may or may not apply, but the list can be used to ensure that the Applicant's proposal includes the necessary critical elements.

Table 1. Factors to consider in evaluation of proposed restoration measures to ensure compliance with the Performance Standards specified in 125.94.
[see hard copy for table]

Footnotes

1 For example, an Applicant may be able to meet the § 125.94 Performance Standards for reduction of impingement mortality, but propose restoration measures to reduce entrainment losses.

2 For example, see PSEG 1999, Attachment G-4.

3 Id.

4 The conservation measures proposed by operators of the C WIS may also likely require the issuance of permits involving these same Federal, State and Tribal fish and wildlife management agencies. The Director or NPDES permitting authority can facilitate the necessary dialog between the interested regulatory parties who all become stakeholders in any proposed conservation measures to ensure that the outcome satisfies the differing objectives and requirements of all involved parties.

EPA Response

EPA believes there are uncertainties associated with the design, implementation, performance and assessment of restoration measures. For a discussion of these uncertainties, see EPA's response to comment 316bEFR.206.055. The use of adaptive management, peer review, and uncertainty analysis is intended to help reduce uncertainties associated with restoration measures and enhance their overall productivity (see EPA's responses to comments 316bEFR.307.047 and 316bEFR.311.022).

For a discussion of the usefulness of quantitative analysis, see EPA's response to comment 316bEFR.202.035.

EPA has incorporated many of the principles mentioned by the commenter in the requirements for restoration described in the final rule in sections 125.94 and 125.95.

EPA believes there are many methodologies available to permit applicants and permitting authorities for assessing and implementing restoration measures. For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

EPA believes the requirements for restoration measures provide permitting authorities and permit applicants with flexibility. However, any restoration measure must meet all of the requirements described in the final rule.

Determination of compliance

Introduction

PSEG Services Corporation ("PSEG") commissioned the preparation of this report which describe alternate approaches for compliance tests that would be required under USEPA's Proposed 316(b) Phase II rule for existing power plants [68 Fed. Reg. 17122-17225, April 9,2002] ("Proposed Rule"). On March 19, 2003, USEPA published a Notice of Data Availability ("NODA") requesting comments on new analyses the agency conducted since the close of the comment period on the proposed Phase II Rule as well as the entire record for this rulemaking. USEPA's Preferred Approach proposes to include national performance standards.

Four different performance standards are defined in the Preferred Approach (125.94(b)). The determination of which of the four performance standards would apply to each facility would depend on the facility's cooling system characteristics and on the source water body. The four performance standards are:

1. Intake capacity commensurate with the use of a closed-cycle, recirculating cooling system; or

2. Reduction of impingement mortality of all life stages of fish and shellfish by 80 to 95 percent from the calculation baseline if the facility.
a. has a capacity utilization rate less than 15 percent, or
b. has a design intake flow 5 percent or less of the mean annual flow from a freshwater river or stream; or

3. Reduction of impingement mortality of all life stages of fish and shellfish by 80 to 95 percent from the calculation baseline, and reduction of entrainment of all life stages of fish and shellfish by 60 to 90 percent from the calculation baseline if the facility
a. has a capacity utilization rate of 15 percent or greater, and withdraws cooling water from a tidal river or estuary, from an ocean, from one of the Great Lakes, or
b. has a design intake flow greater than 5 percent of the mean annual flow of a freshwater river or stream; or

4. Reduction of impingement mortality of all life stages of fish and shellfish by 80 to 95 percent from the calculation baseline if the facility withdraws cooling water from a lake (other than a Great Lake) or reservoir <FN 1>

This report addresses the issue of how the percent reduction in entrainment and/or impingement mortality, that would be required by performance standards 2, 3 and 4, would be estimated. Specifically, four alternative approaches for estimating percent reductions in entrainment and/or impingement mortality are described.

Compliance Tests Based on Percent Reduction in Entrainment and Impingement Mortality

Tests of compliance with the national performance standards appear to require estimates of the percent reduction in losses, although the Proposed Rule and the NODA do not provide specific details on how compliance with the performance standards would be determined. Algebraically, percent reduction in losses can be expressed as:

[see hard copy for equations]

Footnotes

1 This performance standard also includes the requirement that if the facility proposes to increase its design intake flow, the increased flow must not disrupt the natural thermal stratification or turnover pattern (where present) of the source water. except in cases where the disruption is determined by any Federal, State or Tribal fish or wildlife management agency(ies) to be beneficial to the management of fisheries.

EPA Response

Today's final rule offers five different compliance alternatives. However, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Alternate Approaches for Estimating Percent Reduction

The four alternate approaches for estimating percent reduction that are described in this report are:

1. Ratio of Losses: Before vs. After
2. Ratio of Ratios
3. Ratio of Mortality Rates
4. Weighted Average Flow Reductions

Each of these approaches is described in the following sections. <FN 2>

For each approach, separate estimates could be made for each taxonomic group (i.e., species with similar properties, with respect to the assumptions of each estimator), and a weighted average of all taxonomic-specific estimates computed as the final result.

A. Ratio of Losses: Before vs. After

This approach would be to estimate P based on an empirical estimate of losses for a period after the technology or operational measure was in place and an empirical estimate of losses for a period prior to putting the technology or operational measure in place:

[see hard copy for equation]

This method is flawed because interannual variability in the abundance of vulnerable organisms can introduce large biases. All other things being equal, the magnitude of losses depends on the abundance of vulnerable organisms in the withdrawal zone of the facility:

[see hard copy for equation]

Therefore, equation (3) would produce estimates that could be seriously biased, depending on the difference in abundance of vulnerable organisms in the two time periods (before and after):

[see hard copy for equations]

B. Ratio of Ratios

This approach relies on a covariate (i.e., an observable quantity that is proportional to the abundance of organisms in the withdrawal zone of the facility):

[see hard copy for equations]

C. Ratio of Mortality Rates

For technologies or operational measures that reduce the mortality rate of fish collected at the intake, the percent reduction in losses can be estimated without a direct estimate of losses. Because the reduction in losses is due to the reduction in mortality rate, the estimate of percent reduction in losses can be based on estimates of percent reduction in mortality rate:

[see hard copy for equations]

D. Weighted Average Flow Reductions

If for the purposes of demonstrating compliance with the national performance standards, it can be assumed (as stated in the Proposed Rule) that entrainment and impingement numbers at a facility are proportionate to intake flows (all other things being equal), then the percent reduction in losses can be estimated based on the schedule of flow reductions.

The annual losses can be viewed as a sum of weekly losses (the subscript, w, indicates calendar week):

[see hard copy for equations]

Applicability of Alternative Approaches

Due to the problem of potential biases, the Ratio of Losses approach should be evaluated carefully on a case-by-case basis before being used to test for compliance with performance standards. The remaining three approaches do not have the same potential for bias, and each would be an appropriate approach depending on the type of technology and/or measure under consideration. Table 1 contains a summary of the approaches that likely would be appropriate for testing compliance with performance standards for entrainment reductions; and Table 2 contains a summary of the approaches that likely would be appropriate for testing compliance with performance standards for reductions in impingement mortality.

Table 1.
Table 2.
[see hard copy for tables]

Footnotes

2 Letters (English and Greek) refer to parameters, hats (^) indicate estimates, and the notation, E[], indicates expectation.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

RFC: Test: benefits should justify the costs

Introduction

PSEG Services Corporation ("PSEG") commissioned the preparation of this report to respond to issues raised concerning the site-specific option included in the United States Environmental Protection Agency's ("USEPA," "EPA," or the "Agency") 316(b) Phase II rule for existing power plants [68 Fed. Reg. 17122-17225, April 9, 2002]. On March ,2003, USEPA published a Notice of Data Availability ("NODA") requesting comments on new analyses the agency conducted since the close of the comment period on the proposed Phase II Rule as well as the entire record for this rulemaking. USEPA's preferred approach proposes to include three compliance options, Compliance Option ID would allow for a site-specific determination of best technology available ("BTA") for minimizing adverse environmental impact ("AEI"). The ability to utilize the site-specific option is not automatic; an applicant must satisfy one of two prerequisites: the cost-cost test or the cost-benefit test.

Regarding the cost-benefit test, the following two key issues have been raised:

1) Are methods available for valuing all of the identified benefits?
2) How can the Agency be assured that all benefits of reducing entrainment and impingement mortality are identified and considered?

In response to the first issue, PSEG and Entergy commissioned National Economic Research Associates ("NERA") to prepare a white paper entitled white paper on the Use of Benefit-Cost Analysis in Site-Specific 316(b) Decisions Under the Clean Water Act. The NERA white paper discusses the economic methodologies available for assessing ecological benefits and demonstrates that valid methods are available for valuing all benefits that might result from reductions in entrainment and impingement mortality. It also provides a more detailed discussion on non-use values, in response to the NODA.

In response to the second issue, PSEG offers the approach suggested in the following sections of this report as a means to ensure that all benefits from reducing entrainment and impingement mortality would be considered in cost-benefit tests applied by facilities that request Compliance Option III.

Suggested Approach

PSEG believes that a comprehensive but tractable site-specific option can be implemented using the benefits analysis process documented in EPA's Guidelines for Preparing Economic Analyses (U.S. EPA 2000) ("Guidelines for Economic Analyses") when used in conjunction with a benefits identification process based on EPA's draft Generic Assessment Endpoints for Ecological Risk Assessments (US. EPA 2002). This approach can be applied successfully with EPA's Preferred Approach and does not hinge upon a determination of AEI.

Background

According to 125.94(a)(3) of the Proposed Rule, an applicant may demonstrate to the Director that a site-specific determination of best technology available for minimizing adverse environmental impact is appropriate for a site. According to 125.94(c) of the Proposed Rule, if the site-specific alternative is chosen, an applicant must demonstrate to the Director either that the cost of compliance with the applicable performance standards would be significantly greater than the costs considered by the Administrator when establishing the standards, or that the cost would be significantly greater than the benefits of complying with the performance standards.

The requirements for calculating the benefits of compliance with the standards are defined in 125.95(b)(6)(ii) of the Proposed Rule. These requirements state that the applicant must use a "comprehensive methodology" to ''fully value" the impacts of impingement mortality and entrainment and the benefits achievable by compliance with the applicable requirement of 125.94.

EPA's Guidelines for Economic Analyses describes types of ecological benefits typically addressed in environmental policy analyses and identifies valuation methods that can be used to monetize these benefits. Both use and non-use values are included in the guidance. To apply the guidance to a site-specific 316(b) determination, it is necessary to identify and quantify improvements in the quantity or quality of ecological resources that provide the benefits. According to EPA's Guidelines for Economic Analyses, this task should be performed by ecologists, using methods found in EPA's Ecological Risk Assessment Guidelines (US. EPA 1998) and other similar documents.

The Ecological Risk Assessment Guidelines ("ERA Guidelines") describe a process for designing, implementing, and documenting ecological risk assessments. This process begins with the identification of specific ecological entities and attributes, termed "assessment endpoints" by EPA, that are the focus of management action. To aid Agency risk assessors in using the guidelines, EPA has prepared a new draft document entitled Generic Assessment Endpoints for Ecological Risk Assessments. The intent of this document, which' was recently released for public review, is to provide Agency risk assessors with a list of assessment endpoints that are consistent with the Agency's programmatic goals, supported by legislative mandates, applicable to a wide array of environmental issues, and quantifiable using existing ecological assessment tools. This report shows how comprehensive benefits studies for site-specific 316(b) determinations could be designed by linking the assessment endpoints described in the Generic Assessment Endpoints for Ecological Risk Assessment to the benefits categories described in the Guidelines for Economic Analyses.

Rationale

The Guidelines for Economic Analyses are intended to establish a sound scientific framework for economic analyses of environmental regulations and policies, applicable to all agency programs. These guidelines have been reviewed by the EPA Science Advisory Board to ensure that they are scientifically sound and consistent with mainstream practices in environmental economics. The benefits and valuation methods discussed in Chapter 7 of the guidance should be adequate to support a comprehensive analyses of benefits associated with reductions in entrainment and impingement losses.

Although it has not yet completed agency review, the report on Generic Assessment Endpoints for Ecological Risk Assessments is similarly intended to establish a sound scientific framework for selecting ecological assessment endpoints that capture all relevant and significant environmental values that could be affected by a risk management action. The document is a product of several years of work by an EPA Technical Panel composed of experts drawn from across the agency, including the Office of Water. Although the document was not intended to provide a final, exhaustive list of all possible endpoints relevant to ecological risk assessment or benefits analysis, it should provide a reasonable starting point for identifying environmental values that could be affected by a reduction in entrainment and impingement losses.

Appendix B of the Generic Assessment Endpoints for Ecological Risk Assessments identifies correspondences between the generic assessment endpoints developed in the report and benefits categories drawn from a variety of published sources. The following table identifies similar correspondences between the generic assessment endpoints and the benefits categories shown in Exhibit 7-1 of the Guidelines for Economic Analyses. Because the four categories in Exhibit 7-1 are intended to be exhaustive of all possible types of ecological values, all of the assessment endpoints and associated benefits can be accommodated.

[see hard copy for table]

Summary of Suggested Approach for Identifying Ecological Benefits

The suggested approach begins with consideration of a full list of ecological endpoints and a full list of categories of ecological benefits. The approach then identifies a subset of endpoints and categories of benefits that are relevant to a specific CWIS through a sequential process of elimination.

The first step of the approach is the identification of relevant generic ecological endpoints, i.e., the types of endpoints that potentially could be affected by the CWIS. The second step is to identify site-specific ecological endpoints for each relevant generic ecological endpoints. The third step is to identify data and information sources that can be used to assess each site-specific endpoint. The fourth step is the determination of which site-specific ecological endpoints are adversely affected by CWIS, based on the data and information identified in Step 3. In the fifth step, the categories of ecological benefits that would be affected by each relevant site-specific ecological endpoint are identified. The final step is the quantification of effects of reductions in impingement and entrainment on the final site-specific ecological endpoints.

EPA Response

For EPA's response to comments on application of the cost-benefit test to assessing the value of alternative CWIS technologies, please see comment #316bEFR.005.020

Discussion of Site-Specific Approaches

Illustrative Example of Implementing the Suggested Approach

This section demonstrates, through an example, how the suggested approach can be implemented. The example, which is based on conditions at the Salem Generating Station ("SGS") on Delaware Estuary, is for illustrative purposes only. Accordingly, details are omitted to keep the example simpler and easier to understand.

As noted above, the suggested approach would begin by initially considering a full list of generic ecological endpoints and a full list of categories of ecological benefits. For this example, the list of generic ecological endpoints is taken from EPA's Generic Assessment Endpoints for Ecological Risk Assessments - External Review Draft (EPA/630/P-02/004A), and the list of categories of ecological benefits is taken from EPA's Guidelines for Preparing Economic Analyses (EPA 240-R-00-003). The following table depicts the initial set of endpoints and benefits categories that would be considered:

[see hard copy for table]

Step 1 - Identification of Relevant Generic Ecological Endpoints

This step would be conducted as a process of elimination, with all generic ecological endpoints initially included. For the SGS example, the following generic ecological endpoints would be eliminated from consideration for the reasons listed in the following table:

[see hard copy for tables]

Step 2 - Identification of Site-Specific Ecological Endpoints

For each generic ecological endpoint not eliminated from consideration in Step 1, site-specific endpoints would be identified in Step 2. This step includes identification of species of organisms and geographic areas potentially affected by the CWIS. For the SGS example, three categories of potentially affected species have been identified: (1) commercially and recreationally valuable fish and shellfish species, (2) forage fish and shellfish species, and (3) threatened and endangered species. Also for the SGS example, the geographic area under consideration is the Delaware Estuary. Accordingly, the following site-specific ecological endpoints are identified:

[see hard copy for table]

Step 3 - Identification of Information Sources

In this step, data and information requirements for determining whether the CWIS adversely affects each identified site-specific ecological endpoint are identified. Because the SGS has for many years been conducting environmental assessments to address environmental regulations, it already has compiled a wealth of information to address the effects of its CWIS on the relevant site-specific ecological endpoints. However, in general, some new data collection and analysis might be required. Sources of information to address the relevant site-specific ecological endpoints are listed in the following table:

[see hard copy for table]

Step 4 - Determination of Which Site-Specific Ecological Endpoints Are Adversely Affected by CWIS

This step, like Step 1, removes ecological endpoints from consideration by a process of elimination. An ecological endpoint would be removed from consideration only if positive evidence were available to support the contention that the CWIS did not adversely affect the endpoint. Data and information identified in Step 3 would be used in this step to determine whether the CWIS adversely affected each of the relevant site-specific ecological endpoints. This Step is not intended to be an assessment of the presence or absence of AEI. Rather, this step is intended simply to determine whether the operation of the CWIS would cause a negative effect on the endpoints. Accordingly, no definition of AEI is required.

For the SGS example, the data and information identified in Step 3 were collected and analyzed as part of assessments of the ecological effects of the SGS on the Delaware Estuary. Therefore, analyses needed to support determinations of the type and extent of effects of the SGS CWIS on the identified ecological endpoints have already been conducted, and the results of those analyses have been reviewed by regulatory agencies. The results of those determinations are summarized in the following table:

[see hard copy for table]

Based on the determinations summarized in above, the final list of site-specific ecological endpoints that would have to be included in the benefits assessment for SGS would be the following:

[see hard copy for table]

Step 5 - Identification of Categories of Benefits That Are Affected by Final Site-Specific Ecological Endpoints

As discussed in EPA's Guidelines for Economic Analyses, and in the NERA white paper, not all categories of ecological benefits would be affected by changes in each ecological endpoint. For example, an increase in the production of forage fish due to a reduction in entrainment would not affect market benefits because forage fish are not harvested by fisheries. However, an increase in the production of forage fish would affect the ecosystem service of trophic transfer by making more food available to predator and scavenger species of fish and shellfish. The purpose of this step is to identify which categories of ecological benefits would be affected by the final site-specific ecological endpoints.

For the SGS example, the following table lists the ecological benefit categories that would be affected by the final site-specific ecological endpoints (ie., the endpoints remaining after the elimination process of Step 5):

[see hard copy for table]

For commercially and recreationally valuable fish and shellfish, the market benefit that would be affected by an increase in population-level production (resulting from a decrease in kills of organisms) would be an increase in harvests. The non-market benefit that would be affected would be an increase in the catch rate in the recreational fishery. For forage fish and shellfish species, the indirect benefit that would be affected by an increase in population-level production (resulting from a decrease in killed organisms) would be an increase in the food available to predator and scavenger species of fish and shellfish.

It should be noted that if other ecological endpoints had been retained through the process of elimination, then additional categories of ecological benefits might have to be considered. For example, if the extirpation of a species could not be eliminated from consideration (e.g., based on analysis of empirical data on long-term trends in abundance), then non-use benefits related to the existence value of those species would have to be assessed.

Step 6 - Quantification of Effects of Reducing, Impingement and Entrainment

The final step of the suggested approach is to quantify the effects on the final site-specific ecological endpoints that would result from reducing impingement and entrainment.

For the SGS example, the effects of reduced impingement and entrainment on commercial harvests and recreational catch rates would be estimated using fisheries models and estimates of age-0 natural mortality rates for the affected species of fish and shellfish. The effects of reduced impingement and entrainment on trophic transfers by forage species would be estimated using production foregone models and estimates of trophic transfer efficiencies.

EPA Response

While EPA rejected a purely site-specific approach, EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

While a risk-based approach may be useful to a facility seeking a site-specific determination of best technology, EPA disagrees that a determination of whether an adverse environmental impact is occurring is a preliminary step in implementing 316(b). Please refer to the response to comment 316BEFR.313.001 for more information on EPA's position on minimum impacts at existing facilities.

RFC: Test: benefits should justify the costs

Introduction and Overview

The United States Environmental Protection Agency ("EPA", or "the Agency") is engaged in the development of rules to guide decisions regarding implementation of §316(b) of the Clean Water Act. The Agency has developed a Proposed Rule that includes the option of making site-specific demonstration of the best technology available ("BTA").

This White Paper develops general conclusions and recommendations regarding the use of benefit-cost analyses in §316(b) decisions. Specifically, we come to the following four major conclusions:

1. Benefit-cost analysis provides a sound methodological basis for informing decision-makers about §316(b) alternatives for individual sites.

2. Sound methodologies are available to quantify the dollar values of the principal benefits components that arise in individual cases.

3. Benefit-cost analysis can be implemented effectively.

4. The complexity (and cost) of the benefit-cost analysis can be tailored to the size of the potential environmental risks in each case.

Benefit-Cost Methodology Provides a Sound Conceptual Basis for Evaluating BTA Alternatives for Individual §316(b) Decisions

Although the French engineer Jules Dupuit developed the basic elements of benefit-cost analysis more than 150 years ago, the first major applications were developed in the 1930s to evaluate water resource projects (Portney 2002). The technique has been in widespread use for the half century since World War II as the principal analytical framework used to evaluate public decisions (Stokey and Zeckhauser 1978). The extensive experience with benefit-cost studies—as well as the decades of research on the conceptual and empirical underpinnings of specific applications—indicates that the benefit-cost methodology provides a sound basis for evaluating public policy alternatives, including those related to site-specific §316(b) BTA alternatives.

Benefit-Cost Analysis Helps to Organize Information on the Effects of §316(b) Alternatives

One of the fundamental contributions of a benefit-cost analysis is to ensure a reasoned, responsible accounting of all relevant positive and negative effects of alternative policy choices. The basic steps can be summarized as follows (adapted from Stokey and Zeckhauser 1978 and U.S. EPA 2000):

1. Identify §316(b) alternatives. Identify the technical alternatives, in this case, the possible methods of reducing fish losses at a given cooling water intake structure.

2. Determine the effects of alternatives. Use sound scientific and technical methodologies to determine the effects on society, both favorable and unfavorable, of the various alternatives. The favorable effects are considered benefits and the unfavorable effects are considered costs.

3. Value the effects to the extent feasible in dollar terms. Use sound economic methodologies to assess the social value of the various benefits and the social costs due to the technical alternatives, to the extent practicable. For effects that cannot practically be valued, provide quantitative or qualitative information.

4. Calculate net benefits and identify other effects of alternatives. Calculate the net benefits (i.e., benefits minus costs) of each alternative. Provide the additional quantitative and qualitative information for the alternatives as well.

5. Consider the sensitivity of the results to major parameters and uncertainties. Determine whether changes in basic parameters—such as the discount rate used to translate benefits and costs over time into present values—affect the results.

This organization of information provides decision makers with a careful sorting out of the various effects that alternatives have on social welfare, as measured by the values that households place on benefits and costs. In contrast, alternatives such as the use of various ad hoc criteria (e.g., required application of a certain technology) tend to obscure, rather than illuminate, the effects of alternative policies; requiring a specific control technology, for example, provides no information on whether the benefits of applying the technology in a specific situation would outweigh the costs, and, therefore, whether the technology installation is appropriate.

EPA Response

RFC: Test: benefits should justify the costs

EPA Comprehensive Guidelines for Benefit-Cost Studies Should Apply to §316(b) Decisions

The assessment of costs, benefits, and economic impacts of rules is mandated by Executive Order 12866, which also establishes a formal review process under which the federal Office of Management and Budget ("OMB") reviews regulatory impact assessments developed to support significant rulemakings. Under Executive Order 12866, OMB ordinarily has required complete benefit-cost analyses for any proposed or final rule with projected annual benefits or costs of $100 million or more. Thus, for many years, EPA has prepared a benefit-cost analysis for virtually every major regulatory action. Indeed, an economic analysis was a key part of EPA's 316(b) Phase II Existing Facility Proposed Rule (U.S. EPA 2002a, 2002b).

EPA also has provided important guidelines for conducting Benefit-Cost Analysis, first in 1983 (U.S. EPA 1983) and more recently in 2000 (U.S. EPA 2000). EPA's Guidelines for Preparing Economic Analyses (2000) (hereafter, EPA Guidelines or Guidelines) is a comprehensive document that provides detailed guidance on the key concepts involved in developing a benefit-cost analysis. The EPA Guidelines were thoroughly reviewed by the Environmental Economics Advisory Committee of EPA's Science Advisory Board, comprised of thirteen well-recognized economists

EPA Response

EPA agrees that EPA's Guidelines for Preparing Economic Analyses, United States EPA (EPA 240-R-00-003) are relevant. The Agency points out that the approach to benefit cost analysis of the final Section 316(b) Phase II rule is consistent with principles outlined in the EPA's Guidelines for Preparing Economic Analyses, United States EPA (EPA 240-R-00-003). For detail see the final Phase II Regional Studies Document (DCN #6-0003) and the final Phase II EBA document (DCN #6-0002).

RFC: Test: benefits should justify the costs

EPA Guidelines for Benefit-Cost Analysis Offer Useful Categories of Benefits and Costs That Can Readily Be Applied to §316(b) Decisions

Although developed for federal agency regulations, the EPA Guidelines provide a framework that can be applied to §316(b) decisions. As explained in the EPA Guidelines, a Benefit-Cost Analysis is constructed by considering the categories of benefits and costs that are applicable to the issue at hand, in this instance a §316(b) decision.

Benefits

The EPA Guidelines provide a framework for assessing benefits that emphasizes an "effect-by-effect" approach for valuing the benefits of an environmental program, such as the issuance of a §316(b) determination. (U.S. EPA 2000, pp. 62-66) As described in the Guidelines, this approach consists of three sequential stages: (1) identifying the physical effects of a prospective policy or possible decision; (2) quantifying the significant physical effects; and (3) estimating the values of these effects.

The Guidelines provide a convenient taxonomy of physical effects, separating them into human health benefits, amenities, ecological benefits, and materials damage. Figure 1 provides the detailed lists for the various categories.

Table 1. Benefit Categories in EPA Guidelines
[see hard copy for table]

The Guidelines provide a summary of the benefit categories relevant to an assessment of ecological benefits, the general category that is relevant for §316(b) decisions. As noted in Table 1, the ecological benefits that could potentially result from reductions in entrainment and impingement losses due to application of BTA to a cooling water intake structure can be divided into four categories:

1. market benefits associated with catching and consuming fish and other marine life;

2. non-market benefits associated with recreational fishing and other activities;

3. indirect benefits that feed into other activities valued by humans; and

4. nonuse benefits that include those benefits not associated with any direct human use; in concept, this category could encompass a general concern about the fate of marine life or ecosystems that would be affected by choices of BTA, apart from any direct or indirect effects on individual humans.

Figure 1, taken from the Guidelines, provides another way of organizing these categories based on how they are experienced and where they fall along a private good/public good continuum.

Figure 1. Summary of Classification Scheme from EPA Guidelines
[see hard copy for figure]

Social Costs

The other side of the ledger is represented by the costs to society of adopting a proposed program. The EPA Guidelines identifies five basic components of social costs:

1. real-resource compliance costs, which comprise the real resource cost to the entities that would have to undertake actions as a result of the policy in question;

2. government regulatory costs, which are costs to the government of monitoring, administering and enforcing compliance with the proposed policy;

3. social welfare losses, which are losses in producer and consumer surplus that can be attributed to the proposed policy's effects on prices and production of goods and services;

4. transitional costs, which include the value of resources displaced as a result of a new policy and the costs of reallocating these resources and could include the cost to society of the dislocation caused by unemployment, for example; and

5. indirect costs, which include any adverse effects on product quality, productivity, and innovation, and include changes in markets indirectly affected by the policy in question (U.S. EPA 2000).

The most significant component of the total costs for regulatory requirements typically is the value of the real-resource compliance costs. The EPA Guidelines, for example, state:

The largest fraction of direct social costs arises from the real-resource costs due to the new regulation. These new compliance costs arise from the installation, operation, and maintenance of new capital equipment, or are a result of changes in the production process that raise the price of producing the good. (U.S. EPA
2000, p.119)

In Short, Benefit-Cost Analysis Is Well-Suited to Developing the Benefit and Cost Information That should Be Considered as Part of a 316(b) Permit Process

Benefit-cost analysis is a sound methodology that has been developed over many decades to provide information on the effects of alternative public decisions, both for general rules and individual decisions. This sound methodology is well suited to BTA determinations for individual sites.

REVIEW OF ALL POTENTIAL BENEFIT CATEGORIES REVEALS THAT ONLY A RELATIVELY SMALL NUMBER OF CATEGORIES GENERALLY APPLY TO §316(b) BTA ALTERNATIVES

One of the major potential concerns with the application of benefit-cost analyses relates to completeness—how can we be sure that all relevant benefits and costs are included in the analysis? Indeed, this issue of completeness was raised by EPA in its overall national benefit assessment (U.S. EPA 2002a) and has been noted by various commenters critical of the use of benefit-cost analysis in §316(b) contexts (see, e.g., Ackerman 2002). These concerns tend to focus on the completeness of the benefit estimates rather than the completeness of the costs, and thus these comments address benefits rather than costs. (The roadmaps provided in the next section provide guidance for developing complete cost assessments.)

It is of course neither possible nor appropriate to establish a "perfection standard" for when a specific empirical assessment of benefits and costs is complete. Rather, the appropriate question is whether the analysis is sufficiently comprehensive to ensure that significant benefits or costs are not omitted in a particular application of a §316(b) benefit-cost assessment. With respect to benefits, this issue devolves into two questions:

1. Does the list of endpoints included in the benefit-cost assessment identify the vast majority of the potential benefits?

2. Do the specific methodologies that are used to value benefits account for the vast majority of the relevant benefits?

This section addresses the first of these questions both through reference to the EPA Guidelines—which provide an exhaustive list of potential benefit categories—as well as other economic literature. The next section addresses the second question, also using information in the EPA Guidelines supplemented by other economic literature.

The EPA Guidelines for Preparing Economic Analyses Provide an Exhaustive List of Potential Ecological Benefit Categories That Are Relevant for §316(b) Decisions

As noted above, EPA developed a broad classification of the potential benefits from environmental policies, including the categories that are involved, examples of each of the categories, and methods that are used to develop dollar values of benefits for each category. This classification is consistent with those that have been developed by economists in similar contexts (see, e.g., Freeman 1993). The benefits are divided into four major categories: (1) human health; (2) amenities; (3) ecological benefits; and (4) materials damage. The third category is the one relevant for §316(b) benefit-cost analyses.

Table 2 reproduces the classes of ecological benefits from the EPA Guidelines. Four subcategories of ecological benefits are identified:

1. market products;

2. non-market recreation and aesthetic effects;

3. indirect ecosystem effects; and

4. nonuse existence and bequest values.

Table 2. Benefit Categories Relevant for Projects Such as §316(b) Permits that Provide Ecological Benefits
[see hard copy for table]

Since the four categories are exhaustive—covering all possible ecological benefits—the next step is to determine which specific service flows are relevant for §316(b) investigations. As emphasized in the EPA Guidelines, this function is performed by environmental scientists (U.S. EPA 2000, p. 71).

The framework developed by EPA provides a process for sorting through the factors that are likely to be relevant in §316(b) decisions. Below, we offer general conclusions regarding each of the four EPA categories based upon the nature of the potential §316(b) effects and experience of scientists in performing the biological assessments of the effects of cooling water intake structures (AKRF, mc, and LWB Environmental Consulting, Inc., 2003, hereafter "AKRF-LWB 2003" and Barnthouse et al. 2002).

EPA Response

The commenter summarizes the classes of ecological benefits from the EPA Guidelines and states that "the framework developed by EPA provides a process for sorting through the factors that are likely to be relevant in section 316(b) decisions." EPA agrees with this statement.

For EPA's response to comments on the use of benefit cost analysis in the context of the section 316(b) regulation, please see comment #316bEFR.005.020.

RFC: Test: benefits should justify the costs

Commercial Fishing Benefits Are the Only "Market Benefits" Relevant for §316(b) Evaluations

The EPA Guidelines note that market benefits consist of primary products that are bought and sold as factors of production or final consumption products. Increases in the numbers of fish, the adults of which are caught by commercial fishermen and wind up being sold in various fish markets throughout the United States, if demonstrated, would constitute potential market benefits.

Thus, §316(b) evaluations should consider potential commercial fishing benefits. But this is the only plausible "market benefit" affected by 316(b) alternatives. The other service flows mentioned in the EPA Guidelines—fuel, fiber, timber, and fur— would not be affected by 316(b) alternatives and, thus, no other commercial categories would be relevant. Reducing impingement and entrainment would not increase fuel, fiber, timber, fur or other marketed goods and services

EPA Response

In the cost-benefit analysis for the final Section 316(b) Phase II rule, EPA only considers market impacts in the commercial fishing sector.

For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits please see the response to comment 316bEFR.005.029.

Recreational Fishing Benefits

Recreational Fishing Benefits Generally Are the Only "Non-Market Benefits" Relevant for §316(b) Evaluations

The EPA Guidelines note that recreational opportunities and aesthetic qualities provided by ecosystems also are experienced directly by individuals, albeit in a non-market setting. The Guidelines distinguish between two subcategories of benefits for consideration in Benefit-Cost

Analysis:

1. consumptive uses, such as recreational fishing and hunting; and

2. non-consumptive uses, such as wildlife viewing or boating.

Increases in the number of fish, including many species whose adults are valued by recreational anglers, if demonstrated, could yield potential recreational benefits. Thus, the consumptive use of recreational fishing will be relevant for §316(b) evaluations. In contrast, non-consumptive uses—such as wildlife viewing or boating—are not likely to be positively affected by §316(b) alternatives. There may be some rare exceptions if the increased fish populations affected households' wildlife viewing or boating experiences. Based upon the assessments in AKRF-LWB(2003) and Barnthouse et al. (2002), such non-consumptive uses are not likely to be affected by §316(b) alternatives.

Thus, §316(b) evaluations should consider recreational fishing benefits. The other non-market service flows mentioned in the EPA Guidelines—swimming, hiking, and scenic vistas—either would not be affected by §316(b) alternatives and thus would not be relevant or likely would be insignificant or even negative. It is possible, for example, that reducing the amount of heated water by installing a closed cycle system could decrease swimming enjoyment, in which case the change would constitute a cost rather than a benefit.

EPA Response

EPA disagrees that the 316(b) regulation will have no impact on non-consumptive uses such as wildlife viewing (including scuba diving) or boating. Improvements in aquatic habitat and the resulting increase in the number of fish are likely to enhance the recreational experience of recreational users other than fishers. For example, scuba divers prefer to visit locations with more abundant aquatic life; boaters often engage in secondary activities such as fishing; recreational experience of beach goers is likely to be enhanced by wildlife observation. The Agency, however, was unable to quantify or monetize these benefits due insufficient data. Instead, EPA discussed benefits associated with enhanced non-consumptive uses of the affected fishery resources qualitatively. See Chapter A9, Economic Benefit Categories in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003).

Ecological Evaluation Methodology

If Non-Adult Commercial and Recreational Fish Are Incorporated in Those Other Categories, Forage Fish Benefits Generally Would Be the Only "Indirect Ecosystem Service" Relevant for §316(b) Evaluations

The EPA Guidelines note that ecosystem benefits to users can include indirect benefits in the form of ecosystem services. The Guidelines provide examples of these indirect benefits for different types of ecosystems. For example, the EPA Guidelines note that estuaries provide nursery habitat for early life stage or juvenile fish and a refuge that indirectly provides benefits because the early life stage fish eventually yield adult fish that are valued for their commercial and/or recreational uses.

Biological modeling indicates that cooling water intake structure modifications can, in theory, lead to two general types of ecosystem services that provide indirect benefits, i.e., benefits beyond the adults valued as commercial or recreational species (AKRF-LWB 2003, Barnthouse et al. 2002):

1. Increases in the numbers of early life stages ("pre-adult") fish, some of which will grow to become adult fish valued for their commercial and/or recreational uses. The "preadult" group is the one noted specifically in the EPA Guidelines.

2. Increases in the numbers of forage fish, which provide additional food available to predator and scavenger species of fish and shellfish that are valued for their commercial and recreational values.

Thus, a complete benefit-cost analysis of §316(b) alternatives would develop estimates of any indirect benefits due to changes in the numbers of early life stage fish (for species valued for commercial and/or recreational values) as well as due to any changes in the numbers of various forage fishes. If, however, the calculations of commercial and recreational catch include estimates of the numbers of adults linked to the change in early life stage fish, the first of these sub-categories would be included in the "direct" benefit categories. In that case, only forage fish changes would be included as an indirect ecosystem effect in a §316(b) evaluation. Note that the many other indirect ecosystem services identified in the EPA Guidelines—climate moderation, flood moderation, groundwater recharge, sediment trapping, soil retention, nutrient cycling, pollination by wild species, biodiversity/genetic library, water filtration, soil fertilization, and pest control—do not seem relevant for §316(b) determinations.

EPA Response

As the commenter observes, EPA's estimates of foregone commercial and recreational yield resulting from impingement and entrainment implicitly include the early life stage fish that are ultimately recruited to the fishery. Fishery yield is the one direct use benefit category in EPA's analysis.

EPA evaluates indirect use benefits by estimating the contribution of forage species to yield as a result of the consumption of forage fish by harvested species using a simple trophic transfer model, as described in Chapter A5 of Part A of the Phase II Regional Analysis Document (DCN #6-0003).

Chapter A9 of the Regional Analysis Document (DCN # 6-0003) provides information on EPA's benefits methods for the final 316b Phase II rule. EPA disagrees with the commenter that recreational and commercial fishing are the only services of value that are provided by fish. In addition to their importance in providing food and other goods of direct use to humans, the organisms lost to I&E are critical to the continued functioning of the ecosystems of which they are a part. Fish are essential for energy transfer in aquatic food webs, regulation of food web structure, nutrient cycling, maintenance of sediment processes, redistribution of bottom substrates, the regulation of carbon fluxes from water to the atmosphere, and the maintenance of aquatic biodiversity (Peterson and Lubchenco, 1997 ,DCN #4-1899; Postel and Carpenter, 1997, DCN #4-1912; Holmund and Hammer, 1999, DCN # 4-1612; Wilson and Carpenter, 1999 DCN #6-2020). Examples of ecological and public services potentially disrupted by I&E include:

- decreased numbers of ecological keystone, rare, or sensitive species;
- decreased numbers of popular species that are not fished, perhaps because the fishery is closed;
- decreased numbers of special status (e.g., threatened or endangered) species;
- increased numbers of exotic or disruptive species that compete well in the absence of species lost to I&E;
- disruption of ecological niches and ecological strategies used by aquatic species;
- disruption of organic carbon and nutrient transfer through the food web;
- disruption of energy transfer through the food web;
- decreased local biodiversity;
- disruption of predator-prey relationships;
- disruption of age class structures of species;
- disruption of natural succession processes;
- disruption of public uses other than fishing, such as diving, boating, and nature viewing; and
- disruption of public satisfaction with a healthy ecosystem.

These services are not captured by a simple analysis of commercial and recreational fishing benefits. This is a significant concern in the context of the 316b rulemaking because some 98% of the species lost to I&E are not commercial or recreational fishery species.

General Comments on Valuation Approaches

Whether Nonuse Values Are Relevant Is Highly Site-Specific

The EPA Guidelines note that some benefit categories are not associated with any direct use by either individuals or mankind. These nonuse benefits may arise if individuals value an ecological resource without using it or even enjoying the option to use it in the future. The Guidelines note various circumstances in which nonuse benefits might arise.

-knowledge that the resource exists in an improved state;

-bequest values for future generations;

-altruistic values for others' enjoyment of the resource; and

-commitment to environmental stewardship.

Although these provide some sense of the circumstances that might give rise to nonuse values, they do not provide much guidance on when such values are likely to be significant. Indeed, because such values can be empirically estimated only with the use of "stated preference" (sometimes referred to as "contingent valuation") surveys—which are complicated and relatively expensive to develop and implement—it is important to determine the factors that lead to significant nonuse values.

The literature on nonuse valuation provides some guidance on the situations in which nonuse values may be significant. In his still-definitive text on measuring environmental and resource values, Freeman (1993) reviews the literature on nonuse values, considering the situations in which nonuse values are likely to be important. He notes that there is an important distinction between degradation of a natural resource and the risk of its destruction. Freeman establishes that nonuse values are not necessarily significant. He concludes by noting that, while the literature is unresolved on this issue, nonuse values are likely to be important when the resource in question is special or unique and the loss or injury is irreversible (or subject to a prolonged recovery):

Another important question is, when are nonuse values likely to be important? The long literature on nonuse values emphasizes the uniqueness or specialness of the resource in question and the irreversibility of the loss or injury. For example, economists have suggested that there are important nonuse values in preserving the Grand Canyon in its natural state and in preventing the global or local extinction of species and the destruction of unique ecological communities. In contrast, resources such as ordinary streams and lakes or a subpopulation of a widely dispersed wildlife species are not likely to generate significant nonuse values because of the availability of close substitutes. Moreover the literature does not suggest that nonuse values are likely to be important where recovery from an injury is quick and complete, either through natural processes or restoration (Freeman 1993, p. 162, emphasis added).

Thus, Freeman's (1993) review of this literature suggests two operative criteria for evaluating whether nonuse value for fish protection is likely to be important:

1. the resource is unique; and

2. the fish protection would prevent losses to the resource that would be irreversible or subject to a long recovery period.

If both of these criteria are not met, Freeman (1993) suggests that the nonuse values are likely not to be important. (Note that the issue of when nonuse benefits are likely to be significant is not addressed in the EPA Guidelines.)

With regard to §316(b) evaluations, these two factors clearly are empirical questions that would need to be assessed in individual circumstances. Recent biological assessments related to individual §316(b) assessments (AKRF-LWB 2003 and Barnthouse et al. 2002) indicate that fish protection alternatives would not lead to a given species being viable that otherwise would not be viable. Thus, in these cases, nonuse benefits would be unlikely to be significant.

Although there may be a temptation to include nonuse benefits as a category in §316(b) evaluations—because of the possibility that such benefits may be significant—it is important also to consider the costs and other difficulties of developing reliable information. As the EPA Guidelines indicate, in applying the benefit-cost framework, it is important to focus on key issues:

Focus on key issues. Resources should be focused on benefit categories that are likely to influence policy decisions. To use time and resources effectively, analysts must weigh the costs of conducting additional analysis against the usefulness of the additional information provided for decision-making. The analysis should devote significant time and resources to carefully assessing those benefit categories that are likely to influence the selection among policy options…[S]ome benefit categories may not be assessed either because they are expected to be small or because the costs or time needed to quantify them far exceed the time or resource levels appropriate for analysis of the particular policy. (U.S. EPA 2000, p. 65)

These considerations mean that it may not be necessary to evaluate nonuse benefits in many §316(b) benefit cost analyses, although there may be some specific situations in which nonuse benefits should be considered. Combining the Freeman (1993) criteria described earlier and the EPA Guidelines suggests that nonuse benefits should be assessed when two conditions are met:

1. information indicates that fish protection alternatives (a) affect a unique or special resource and (b) would remove an irreversible impact on the resource (or one subject to a long recovery period); and

2. the likely value of the information on nonuse benefits would be greater than the costs of developing the information.

In sum, it would be sensible to attempt to value nonuse benefits only if there is a strong reason to believe the benefits would be significant and that their inclusion would affect policy decisions, i.e., the choice of BTA in a particular case.

EPA Response

For the final 316b rule analysis, EPA has not included quantitative measures of nonuse values. The Agency, however, has explored several methods that indicate the potential significance of non-use values, including meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN # 6-0002).

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer; comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

Benefit Estimation Methodology

Sound Methodologies are Available to Develop Dollar Values for the Relevant §316(b) Benefit Categories

After relevant benefit categories are identified and scientists quantify the physical effects, dollar values of the benefits need to be developed. As noted above, the EPA Guidelines provide a useful means of categorizing the potential ecological benefits according to how they are experienced and where they fall along a private good/public good continuum. Figure 2 reproduces the figure from the EPA Guidelines, which we have supplemented by addition of the specific categories noted above as relevant for §316(b) evaluations. As EPA notes, this categorization helps direct analysts to suitable valuation methods.

Figure 2. Ecological Benefits Classification Scheme
[see hard copy for figure]

This section summarizes the methodologies that have been developed by economists to value these various effects, which are the methodologies recommended in EPA's Guidelines. Before discussing the specific techniques that are used to develop values for specific categories, it is useful to describe benefits transfer, a methodology for using the results of previous studies to develop dollar values for any type of benefit category.

The Benefit Transfer Approach Can Reduce the Cost and Increase the Reliability of Benefit Assessments When the Approach is Used Correctly

Benefit transfer techniques take advantage of the stock of existing studies—often done by academic or public agency researchers—by "transferring" the results of the various studies to a particular policy case.

The EPA Guidelines provide a concise statement of the advantages of the benefit-transfer approach. As the Guidelines note,

The advantages to benefit transfer are clear. Original studies are time consuming and expensive; benefit transfer can reduce both the time and financial resources needed to develop benefit estimates... Additionally, while the quality of primary research is unknown in advance, the analyst performing a benefit transfer is able to gauge the quality of existing studies prior to conducting the transfer exercise. (U.S. EPA 2000, p. 86)

The advantages of benefits transfer assume that the benefit transfer study has been appropriately undertaken, as discussed below, and relies on relevant studies.

The EPA Guidelines provide a list of well-established steps (consistent with the existing literature on benefit transfer methodologies) that should be carried out to develop a reliable benefit-transfer study.

These steps include the following:

1. Describe the policy case. This step involves describing the nature of the policy and the populations affected. In the context of §316(b) recreational benefit assessments, for example, this would involve identifying the types of fishing experiences and fishermen potentially affected.

2. Identify existing, relevant studies. The literature search to identify studies should include published studies, as well as the "gray" literature (government publications, unpublished research, works in progress).

3. Review available studies for quality and applicability. The quality assessment involves evaluating the soundness of the data and methods used. The applicability assessment involves determining whether the available studies are comparable to the policy case. Specifically,

-the basic commodities must be essentially equivalent;

-the baseline and extent of change should be similar; and

-the affected populations should be similar.

4. Transfer the benefit estimates. This step involves using the existing studies to develop the transfer estimate. Four types of benefit transfer methods are possible: (1) point estimates; (2) benefit function; (3) meta-analysis; and (4) Bayesian techniques.

5. Address uncertainty. This final step involves describing the various assumptions that are being made as well as other major sources of uncertainties in the benefit estimates.

The four methods of benefits transfer differ in their applicability and likely accuracy. The EPA Guidelines note that the direct transfer of a "point estimate" (i.e., exact value for a given benefit, such as the value per additional recreational fish caught) is not likely to be appropriate, because the specific circumstances that determine value are likely to differ. The benefit function method is likely to be more accurate because one would be able to substitute the site-specific features into the function. As the EPA Guidelines note, the most rigorous benefit approach uses meta-analysis, a statistical method of combining a number of valuation estimates that allows the analyst to develop a statistical function relating to variation in value estimates across studies; as with the benefit function approach, the site-specific values would be substituted into the resulting function. The Bayesian approach is a less common alternative to meta-analysis in which case study information is combined with prior information.

EPA Response

The comment summarizes EPA's Guidelines regarding the benefit transfer method and its proper application, and does not comment on specific aspects of EPA's analysis.

For the final Phase II 316(b) analysis, EPA has reduced its reliance on benefit transfer to estimate recreational fishing benefits. For detail on the benefits transfer approach used at proposal, see response to comment #316bEFR.075.504.

In addition, EPA no longer uses case studies of individual facilities. Instead, EPA has estimated regional models. For the recreational fishing analysis, benefit transfer is used for the inland region, and benefit function transfer is used for the North Atlantic region. EPA has estimated RUM models for all other coastal regions (Mid-Atlantic, South Atlantic, Gulf of Mexico, and California), and for the Great Lakes region. Where benefit transfer is used, EPA has followed generally accepted procedures, and has carefully applied benefit transfer methods.

For the North Atlantic region, EPA's benefit transfer uses the benefit function from the Hicks, et al. (1999), study recommended by several of those who commented as the most appropriate study for benefit transfer for the North Atlantic region (DCN #4-1603). By using benefit function transfer, EPA was able to make appropriate adjustments to Hicks' model, to estimate values for relevant changes in catch rates. This benefit function transfer follows accepted methods and was performed carefully to provide the best available estimates of values for changes in catch rates for the North Atlantic region.

For the Inland region, EPA did a benefit transfer using values from several studies. EPA generally followed its Guidelines for Preparing Economic Analyses for benefits transfer (BT) in developing a benefits transfer approach for the Inland region. The steps were followed as recommended in the Guidelines when using BT: (1) describe the policy case; (2) identify existing, relevant studies; (3) review available studies for quality and applicability; (4) transfer the benefit estimates; and (5) address uncertainty. Further information on the methods EPA used to estimate recreational fishing benefits for the Inland region is provided in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003). See Chapter H4: Recreational Fishing.

Commercial Fishing Benefits

Commercial Fishing Benefits Can Be Quantified Based Upon Readily Available Data on Commercial Fishing Prices

Benefits due to additional commercial catch can be developed using conventional economic analysis of the likely gains to producers (i.e., commercial fishermen, wholesaler and retailers) and consumers due to demonstrated changes in the commercial fishery. These analyses, however, are complicated by the "open access" nature of most commercial fisheries, which means that much (or all) of the potential additional producers surplus ("profits") due to increases in the productivity of the commercial fishery tends to be dissipated as fishermen respond by increasing fishing activity. This phenomenon has been dubbed "the tragedy of the commons" (Hardin 1968) because of the early "open access" example of grazing on the English commons—no individual owner ultimately gained any advantage from the common property because none had an incentive to maintain its productivity. The same effect occurs for commercial fishing in the form of "overfishing."

Increased Net Revenues to Commercial Fishermen

The beginning step for estimating commercial fishing benefits is a set of estimates of commercial fishing prices. Values for the ex vessel prices (i.e., prices that fishermen receive at the dock for their catch) of various commercial species are available from the National Marine Fisheries Service ("NMFS"), which publishes values annually. These values differ by location and of course vary over time and based upon other factors. Although it would be desirable to have projected prices—since commercial benefits, if any, from a §316(b) technology could extend into the future for several decades—such projected prices typically are not available and average prices in the recent past typically are used. Multiplying the set of commercial ex vessel prices times the demonstrated increase in commercial catch provides an estimate of the potential additional gross revenues to commercial fishermen due to the §316(b) alternatives.

The next step to estimate commercial fishing benefits is to estimate net gains to commercial fishermen, taking into account the additional expenditures required for the additional catch. These additional expenditures consist of the variable costs fishermen incur with additional catch, e.g., labor, fuel, and the like. Studies of commercial fishing suggest that variable costs are in the range of 50 percent of total revenues (see, e.g., Rettig and McCarl 1985). These values suggest that, ignoring effects of open access to commercial fisheries, net benefits to commercial fishermen would be about 50 percent of the additional ex vessel catch.

Implications of Open Access Commercial Fisheries

Taking into account the open access nature of commercial fisheries and other considerations means that the long-term benefits to fishermen are likely to be substantially less than these potential gains. Indeed, the traditional models of open access fisheries, which apply to commercial fisheries without binding quotas, indicate that all potential gains are eliminated, and thus the long-term gains to fishermen from additional commercial catch are zero.

It has been well established for almost 50 years that under an open access fishery, competition among fishermen will drive producer surplus to zero for all fishermen. <FN 1> Ocean fisheries are typically common property resources, with no one exercising control over them. Since no individual or group has the property rights to the fishery, no single fisherman can exclude any other from exploiting the fishery. As noted, this situation has been labeled “the tragedy of the commons” in a well-known article by Garrett Hardin (1968).

Under such circumstances, “externalities” associated with the use of the common resource by many independent producers result in a reduction in the productivity of that resource. In open access fisheries—which characterize most commercial fisheries affected by §316(b) cases—as more fishermen harvest fish from the water, the ability of the fish population to reproduce at the most profitable rate is compromised. The result is that the economic value of the resource—i.e. the producer surplus—is dissipated and even destroyed, because fish are harvested at a point where the marginal cost of harvesting them, including the effects on the future stock, is higher than the marginal benefit.

The economic inefficiencies associated with open access fisheries can be summarized as follows: <FN 2>

-too many economic resources are committed to fishing—more fishermen employ more boats and fishing effort than would be economically optimal;

-current fishermen therefore earn a substantially lower return on their efforts; and

-over-fishing reduces the stock below its optimal level, which in turn lowers future profits from fishing. <FN 3>

These considerations mean that an open access fishery will generate no producer surplus. For our purpose, the key implication is that changes in conditions at the fishery—such as a potential increase in the number of commercial fish available due to reduced I&E—will not lead to any change in producer surplus.

Freeman (1993) provides a graphical depiction of the implications of open access on producer surplus and illustrates that changes in environmental quality—such as a reduction in impingement and entrainment due to §316(b) controls—would not lead to increases in producer surplus to fishermen. Figure 3 shows the marginal cost curve and average cost curve for a given commercial fishery, along with the relevant demand curve. As Freeman notes, if the fishery were privately owned, the output and price would be given by the intersection of the marginal cost function and the demand curve, with price equal to Pm0 and quantity equal to xm0; fishermen would obtain a producer surplus in this case. An improvement in environmental quality—such as a reduction in impingement and entertainment at a power plant—would reduce the marginal cost (not shown) and lead to an increase in quantity, a decrease in price, and an increase in producer surplus to fishermen.

Figure 3. Welfare Measurement for Open-Access Resources: The Case of a Fishery
[see hard copy for figure]

The situation is very different in the case of an open access fishery. In this case, the economic incentives lead to a situation where the price (Pc) would be equal to average cost (not marginal cost), and thus where each fisherman earns zero profits. (Fishermen earn zero profit when average cost is equal to average revenue, i.e., price.) Freeman notes that for the same change in environmental quality in a fishery with open access, even if quality improves and fish become more abundant, "there is no change in producer surplus." The logic behind this result is that positive producer surplus would lead additional fishermen to enter the fishery, driving the price down to p1c and the quantity up to x1c. At this point, the producer surplus is again dissipated and no fishermen receive any producer surplus.

The graph shows that changes in environmental quality, therefore, have no effect on net producer surplus. Better fishing conditions shift the average cost curve outward to AC1x. This reduction in costs and temporary improvement in profit results in additional fishing effort by existing fishermen and by new entrants. The added effort increases fishing output <FN 4> and reduces the price of fish until the zero profit position is reached in the new circumstances. The net result is that the improved conditions do not yield long-term producer surplus gains to fishermen; the superior fishing conditions are dissipated by additional fishing effort (and price changes, to the extent that these occur).

Consumers Would Not Gain if §316(b) Alternatives Do Not Affect Commercial Prices

Figure 3 suggests that consumers would gain from the environmental improvement in the form of reduced prices for fish. This result, however, depends upon the demand elasticity; the more elastic the demand for fish, the smaller the welfare gain associated with the environmental improvement. <FN 4> Because small segments of a given market have more elastic demand curves than the market as a whole, consumer benefit from changes to small market segments will also be small or even negligible. As Freeman (1993) notes:

[I]f this fishery is small relative to the market and the demand curve is perfectly elastic, there is no welfare gain [from the improvement in environmental quality]. The physical improvement in productivity brought about by the higher water quality is entirely dissipated by the uneconomic competition of fisherman for the potential increase in rents.<FN 5>(Freeman 1993, p. 308-9)

Figure 4 illustrates the situation in which the effect is small relative to the overall market for fish-and thus demand is perfectly elastic. As discussed below, this is likely to be the case for §316(b) changes. The figure shows the shift in the average cost curve from AV0x to AC1x and the increase in the number of fish bought and sold. Because the average cost still equals the price, however there is no change in the profits to commercial fishers. Moreover, there is no change in consumer surplus, since the price remains the same. The technology additions may lead to additional fish caught and sold, but, even if they do, there is no increase in producer or consumer surplus, and thus no social benefits.

Figure 4. Welfare Measurement for Open-Access Resources with Perfectly Elastic Demand
[see hard copy for figure]

Implications for §316(b) Benefit-Cost Analyses

These considerations suggest that commercial fishing benefits from §316(b) site-specific alternatives can be estimated using the following steps.

-use biological models to estimate potential increases in site-specific commercial catch for relevant species;

-calculate the increased ex vessel value of the additional commercial catch based upon the relevant commercial markets;

-based upon the size of the commercial market, assess whether or not changes due to §316(b) alternatives are likely to result in any decreases in the prices consumers pay;

-assuming no changes in prices, calculate potential gains as bounded by zero and the increased ex vessel catch value; and

-if the preliminary results warrant additional analysis, develop estimates of the increased variable costs and develop more detailed estimates of the likely fraction of added commercial catch value likely to lead to long-run gains to commercial fishermen.

Footnotes

1 The classic article is Gordon (1954). The basic arguments are described in environmental and natural resource textbooks. See, e.g., Tietenberg (2000).

2 These inefficiencies are described as “economic over-fishing” as distinguished from “biological over-fishing,” in which fish are harvested faster than they can reproduce their population, leading to a decline in fish stocks.

3 Note that the increase in output from the additional fishing effort may be short-lived if the increased effort further diminishes fishing stocks.

4 See Freeman (1993). Freeman (1991) provides illustrative calculations of the magnitude of the effects of alternative demand elasticities on consumer surplus gains.

5 The term “rents” as used here is roughly synonymous with “profits.”

EPA Response

EPA assumes no change in effort but shifts in marginal costs curves, so additional expenditures may be minimal. For comments regarding biological modeling see responses to comments #316bEFR.005.009, #316bEFR.025.015, #316bEFR.029.105, #316bEFR.206.065, #316bEFR.305.003, and #316bEFR.306.506.

EPA selected a conservative range of 0% to 40% (i.e., producer surplus as percent of gross revenue) to represent all fisheries affected by the final rule, given the difficulty and uncertainty associated with estimating percentages for individual fishery markets. For EPA's response to comments on the methods used to estimate commercial fishing losses and benefits, please see the response to comment 316bEFR.005.029.

RFC: Test: benefits should justify the costs

Recreational Fishing Benefits Can Be Calculated Based Upon Benefit Transfer Techniques to Value Marginal Fish

Assessing the likely gains from increased recreational catch poses more difficulties than assessing commercial gains, since there are no published market values for recreational catch. Moreover, calculating recreational values is complicated by the need to develop estimates of the marginal value that anglers place on additional catch; this marginal value tends to decrease as expected catch increases and thus simpler estimates of the average values for recreational catch are not accurate (see, e.g., Tietenberg 2000). Nevertheless, appropriate benefit transfer techniques can be used to develop marginal values.

Recreational Anglers' Value for Additional Catch Decreases as the Catch Rate Increases

One of the major conclusions of economic theory and practice is that the value households place on additional amounts of a given good or services tends to decrease as they have more of the good or service; this feature leads to the downward sloping demand curve shown in economics textbooks (see, e.g., Mankiw 2003).

Recreational fishing demand studies show that this general principle applies to recreational fishing experiences and the value placed on additional recreational catch. These studies indicate that the additional value that recreational anglers place on additional catch decreases as the expected catch increases. Figure 4 illustrates this relationship for a given angler, showing the total value as a function of the catch rate.

Figure 5. Hypothetical Value per Angler Trip at Different Catch Rates
[see hard copy for figure]

Figure 6 shows the marginal value of additional fish as a function of the catch rate. This relationship shows that the incremental (or marginal) value of additional fish to recreational anglers is lower than the average value per fish caught. As a result, fishing values for §316(b) benefit-cost analyses should reflect the incremental (or marginal) value rather than the average value, because fish protection measures lead to small changes in catch for many anglers. Otherwise recreational values would be overstated.

Figure 6. Hypothetical Marginal Value of Additional Catch at Different Catch Rates
[see hard copy for figure]

Recreational Fishing Demand Models

Site-specific estimates of recreational fishing benefits could be developed by undertaking a site-specific study—an original study that would involve collecting primary data and statistical analyses to determine the increased willingness of recreational anglers affected by a given §316(b) decision to pay for additional fish. These data could be used to estimate a function such as that illustrated in Figure 1.

Numerous studies have been done to assess the value of potential recreational fishing benefits (see, e.g., Freeman 1993 for a partial list). These studies focus on the choices that recreational anglers may make to fish at a site. The basic notion is that anglers generally make their choices based upon the satisfaction gained from fishing at the site—based upon the quality of the fishing and other attributes—and the value of money and time given up.

As noted in the EPA Guidelines, the empirical recreational demand models generally fall into two groups:

1. Travel cost models. These studies use information on visits and travel costs to infer the value that anglers place on fishing. The simplest models involve trips to a single site. Surveys provide information on the residential location of visitors, generally showing an inverse relationship between distance traveled and fishing participation. The distance variable can be converted to a cost measure using information on out-of-pocket travel costs as well as the value that travelers place on travel time. Thus, one can use the visitor survey information to develop a demand function, with the number of trips being a function of the travel costs of reaching the site. This single-site model can be extended to multiple sites using information on visitation rates and the costs of visiting the alternative sites. The travel cost methodology, however, is not well suited to model choices among competing sites.

2. Discrete choice models. These models are designed explicitly to model choices that anglers make among competing sites. (These models are sometimes referred to as “random utility models” or RUMs.) The discrete choice models consider travel costs as one of the variables affecting the decision on where to fish; others include the expected catch rate as well as the availability of various facilities (e.g., boat ramps).

Benefit Transfer Techniques Can Be Used to Develop Estimates of the Marginal Value of Recreational Fish

A second strategy is to develop a benefits transfer approach. As noted above, a benefit transfer approach uses results from existing studies to develop results for the particular case. The benefits transfer approach is likely to be a superior approach to estimate recreational fishing benefits for §316(b) applications in situations where there are existing studies that can be used for the area. Original studies can be costly, particularly if many recreational fish species are affected by the facility and these fish migrate over wide ranges. An original study would require measuring the values of additional recreational catch for many species across the wide geographic range, often an impractical alternative.

As noted above, where multiple recreational valuation studies are available, the meta analysis technique is likely to produce the most reliable estimates of the values that recreational anglers place on the additional catch. The basic steps for a meta analysis of recreational fishing benefits are the following:

-Step 1: Obtain recreational fishing value studies. The first step is to obtain studies that estimate the additional value that recreational fishermen place on additional catch. These studies include both journal articles and published reports.

-Step 2: Determine relevant studies. The next step is to select studies that are relevant to fishing potentially affected in the particular situation. Studies would be selected based upon the type of fish, the fishery location and the mode of fishing.

-Step 3: Conduct a statistical meta-analysis of the marginal value of increased catch. This step uses the relevant studies and statistical estimation procedures to determine the relationship illustrated in Figure 6. (As noted above, this study is referred to as a meta-analysis because it uses results from many studies.)

-Step 4: Determine the marginal value per pound of fish. The final step is to use the results of the meta-analysis to calculate the appropriate marginal value for fish relevant to this study.

The results of the meta analysis—in conjunction with biological estimates of the numbers of additional recreational catch that may be attributable to §316(b) alternatives—will allow the calculation of the potential value to recreational anglers of a particular 316(b) BTA alternative.

Implications for 316(b) Benefit Assessments

These considerations suggest that recreational fishing benefits from §316(b) site-specific alternatives can be estimated using the following steps.

-use biological models to estimate increases, if any, in site-specific recreational catch by species;

-develop estimates of the marginal values of any additional recreational catch to the relevant anglers, i.e., the anglers whose catch would be reasonably likely to increase as a result of the §316(b) alternatives (Note that this geographic area may be wide due to the wide-range migration patterns of many fish species.); and

-use this marginal value (or values) and the biological estimates of potential changes in relevant fish populations to estimate the benefits that recreational anglers would obtain from the §316(b) technology.

EPA Response

For the final Phase II 316b analysis, EPA has reduced its reliance on benefit transfer to estimate recreational fishing benefits. In addition, EPA no longer uses case studies of individual facilities. Instead, EPA has estimated regional models. For the recreational fishing analysis, benefit transfer is used for the Inland region, and benefit function transfer is used for the North Atlantic region. EPA has estimated RUM models for all other coastal regions (Mid-Atlantic, South Atlantic, Gulf of Mexico, and California), and for the Great Lakes region.

EPA has followed standard, generally-accepted methods of RUM modeling, which do estimate marginal values. See responses to comments 316bEFR.041.452, 316bEFR306.320, and

316bEFR337.010 for additional details regarding EPA's RUM analysis.

Valuing Forage Species (incl non-use and non-landed)

Indirect Values for Forage Fish Can Be Estimated With Inputs on Commercial and Recreational Values

Many of the fish species that might be affected by CWIS are not valued either by commercial or recreational fishermen. Some of these affected fish, however, may provide indirect benefits to the extent that they provide forage for species that are valued directly. Thus, increases in forage fish populations result in gains to individuals, but only indirectly as a result of the predator-prey relationship.

These indirect benefits can be included in a §316(b) benefit-cost analysis using a combination of biological and economic information. The biological information consists of estimates of the likely increase in predator populations due to any increases in forage fish populations. The economic information consists of applying the values for predator populations—based upon their commercial and recreational values—to any additional gains.

Implications for 316(b) Assessments

The following steps can be used to develop estimates of indirect forage fish benefits due to §316(b) alternatives.

-identify the forage fish species relevant for various predators (commercial and recreational value) in the affected areas;

-using biological information and models, determine the likely increases in forage fish population due to various §316(b)technologies;

-using biological information and models, determine the likely increases in the numbers of various predators in the commercial and recreational catch due to any increases in forage fish; and

-using economic information and values, determine the values that commercial and recreational fishermen place on any additional commercial and recreational catch.

EPA Response

EPA has revised the methods for estimating losses associated with forage species. In a manner similar to that suggested by this comment, EPA translates foregone production among forage species into foregone production among harvested species that are impinged and entrained using an assumed trophic transfer ratio, and then translates foregone production among these harvested species to foregone yield. Further information on the methods EPA used to estimate forage losses is provided in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003). See

Chapter A5: Methods Used to Evaluate I&E.

Please see EPA's responses to comments on fish population modeling (#316bEFR.005.009), and the discussion of ecosystem benefits found in Chapter A9 of the Regional Study Document (DCN #6-0003).

RFC: Test: benefits should justify the costs

Nonuse Values Can Be Assessed

Assessing nonuse value is substantially more complicated and subject to considerably more uncertainties than the other benefit categories. As noted above, there are relatively few situations in which nonuse values are likely to be significant. Such cases are limited to those in which the fish protection alternative would affect a unique or special resource and protect a fish species that would otherwise be compromised in a manner that would not quickly be reversed.

If nonuse values are expected to be significant, the same two general approaches to valuation are possible, as noted above for recreational studies:

1. develop a site-specific study using the revealed preference (survey) methodology; or

2. use benefit transfer to assess nonuse values.

Although the general natures of these two types of studies are the same as those discussed above with regard to recreational benefits, assessing nonuse benefits is considerably more difficult as many commentators have pointed out (see, e.g., Freeman 1993).

The potential dilemma is well summed up in the conclusions regarding stated preference methods contained in the EPA Guidelines:

In conclusion, because of the issues raised here, among other factors, there is a divergence of views within the economic profession concerning whether stated preference methods can provide useful information on economic values and on validity of individuals' responses to hypothetical questions. Nevertheless, for goods providing nonuse value, stated preference methods may provide the only analytic method currently available for benefits estimation. (U.S. Environmental Protection Agency 2000, p. 85)

The difficulty of evaluating nonuse benefits, in conjunction with the fact that the conditions that would lead to significant nonuse benefits should not arise very often in practice for §316(b) cases, suggests a limited and cautious approach to attempting to quantify nonuse benefits.

Implications for §316(b) Assessments

The following steps can be used to develop estimates of nonuse benefits due to §316(b) alternatives.

-Using biological information, identify whether a unique or special resource is involved and whether the viability of any species would be affected by the §316(b) alternatives.

-If these conditions are met—and if the nonuse benefits are likely to be important to the §316(b) decision—develop estimates of the dollar value of nonuse benefits based upon one of two methods:

--Develop a well-designed, stated preference survey (contingent valuation) study to determine the willingness to pay of the relevant population for the relevant biological changes.

--If appropriate existing studies are available, use benefit transfer methods to assess the willingness to pay.

-If unique resources are not involved and if the viability of species would not be preserved due to the fish protection alternatives, assume that nonuse benefits are not relevant for the 316(b) alternatives.

This procedure follows the logic in Freeman (1993) regarding the situations in which nonuse benefits are likely to be significant and the EPA Guidelines' emphasis on only undertaking expensive studies if they are likely to influence the policy results.

EPA Response

EPA has not included quantitative measures of nonuse values for the final 316(b) rule benefit-cost analysis. However, EPA does not agree that it is appropriate to assume that non-use values are not relevant, and the Agency has provided several measures that indicate the potential magnitude of non-use values.

EPA does not agree that only unique or special resources have non-use values. For EPA's response to comments regarding non-use values for losses to common species please see the response to comment #316bEFR.306.302.

While EPA agrees that either a stated preference study or benefit transfer are necessary for evaluating non-use values. For EPA's explanation of why the Agency did not conduct an original stated preference survey, please see response to comment number 316bEFR.306.105.

RFC: Test: benefits should justify the costs

Steps in Developing a Site-Specific §316(b) Benefit-Cost Analysis

This section provides an example to illustrate the steps involved in developing a §316(b) benefit-cost assessment. Although not taken from any specific assessment, this example builds upon our experience developing site-specific §316(b) benefit-cost studies. This experience allows us to provide a roadmap for the concrete tasks involved in developing a site-specific benefit-cost analysis of §316(b) alternatives.

Overview of Benefit-Cost Steps

This example uses a series of steps consistent with EPA's Guidelines (2000) to estimate the benefits and costs of fish protection alternatives. The basic steps are as follows:

1. Identify §316(b) alternatives. The first step is to use technical information to identify the alternatives that could be installed and operated at the site and that would be effective in reducing impingement and entrainment of various species. These alternatives could include changes in the current cooling water intake structure as well as various means of reducing cooling water flow (e.g., seasonal reductions and types of cooling towers). These alternatives would be compared to a baseline alternative of making no modification.

2. Determine the impacts of alternatives. The next step is for technical experts to determine the physical impacts and to identify which effects are favorable (benefits) and which are unfavorable (costs).

3. Develop dollar values for costs and benefits. This step uses economic and technical information to assess the value of the various benefits and costs, to the extent feasible.

4. Calculate net benefits and identify other effects of Alternatives. The cost and benefit information is used to calculate the net benefits (i.e., benefits minus costs) of each alternative considered.

5. Determine the sensitivity of the results to key parameters. The final task of the benefit-cost assessment is to determine how sensitive the results are to key parameters, such as the discount rate.

EPA Response

For EPA's response to comments on application of the cost-benefit test to assessing the value of alternative CWIS technologies, please see comment #316bEFR.005.020.

RFC: Test: benefits should justify the costs

Roadmap for Estimating the Benefits of Fish Protection Alternatives

The nature of the available biological information affects the specific steps required to develop benefit estimates. For purposes of this example, we assume that biological information on the benefits for each of the §316(b) alternatives is developed for a set of fish species labeled "representative important species," or "RIS." (Use of RIS for assessments under §316(b) is endorsed by EPA as a means of prioritizing information on the affected species.) Note, however, that in this example the benefit assessment includes the value of non-RIS fish as well.

Roadmap for Benefit Assessment

The benefit assessment consists of developing separate benefit estimates for all of the relevant categories, and then summing the results for each §316(b) alternative. This example assumes that nonuse benefits are judged not to be significant, following the criteria outlined above, so that the assessed benefits consist of three categories: (1) commercial benefits; (2) recreational benefits; and (3) indirect benefits due to changes in forage fish populations.

Figure 7 illustrates the steps used to develop estimates of the benefits for each alternative. The following are overviews of the steps.

1. Estimate additional pounds of equivalent adults caught by commercial and recreational fishers. Biologists and engineers develop estimates of the changes in equivalent adult fish weight for each of the RIS under each of the alternatives considered. This weight includes the change in commercial/recreational fish weight due to changes in the abundance of forage RIS.

2. Divide overall catch between commercial and recreational fisheries. For each RIS, biologists and fisheries experts divide the total change in catch to the fishery between commercial and recreational fishers, using data on the relative weight of recreational and commercial harvest over each species' geographical range during a recent time period.

3. Determine wholesale commercial values. To estimate the value of commercial fishing benefits, develop data on wholesale prices (from the relevant fish market, as reported by the NMFS) that can be used to value RIS caught by commercial fishermen.

4. Assess recreational values. To estimate the value of recreational fishing benefits, conduct a meta-analysis of recent studies of the value of RIS and related species to recreational fishers. This analysis is used to determine the value that recreational fishermen would place on additional RIS fish catch.

5. Calculate benefits from increases in RIS. Use the quantities (from Steps 1 and 2) and values (from Steps 3 and 4) to calculate the annual benefits of changes in the commercial and recreational catch for the MS for each of the fish protection alternatives considered.

6. Determine additional pounds of non-RIS. Determine the change in equivalent adult fish weight (pounds) of non-RIS.

7. Calculate benefits from increases in non-RIS. To estimate a dollar value associated with increases in non-RIS, use the average commercial and recreational value (per pound) for all RIS to calculate the annual benefits from changes in non-RIS fish.

8. Compute annual benefits. Sum the benefits from RIS and non-RIS to produce an estimate of the total annual benefits

9. Aggregate to obtain present value of benefits. Aggregate the annual benefits over the remaining lifetime of the facility using the same discount rate used to calculate the present value of costs.

Figure 7. Roadmap for Estimating Benefits
[see hard copy for figure]

This methodology produces estimates of the present value of benefits for each of the alternatives as of a fixed date; in this example we use January 1, 2002.

EPA Response

This comment describes the methods used by the author in preparing an alternative analysis of benefits. EPA notes this comment. No other response is required.

Costs

Roadmap for Estimating the Costs

The costs of fish protection alternatives can be estimated in several detailed steps— corresponding to the more general steps 2 and 3 described above. The general methodology for estimating the costs is as follows:

1. Identify categories of costs to be evaluated. Identify the categories of costs that likely result from one or more of the alternatives considered. The costs identified comprise three sub-categories of real resource compliance costs (consistent with the general findings discussed earlier), one of which has two components:

a. Construction costs;

b. Operating and maintenance ("O&M') costs; and

c. Cost of lost power, including

1.Lost power from construction-related outages

2. Lost power after installation.

2. Estimate the value of each cost category. Using sound economic methodologies, develop quantitative estimates for each of the cost categories for each alternative.

The components of costs and the methodologies for evaluating them are described in the subsections below.

Roadmap for Construction Costs

Figure 8 illustrates the methodology that can be used to estimate construction costs for each of the alternatives. Construction cost is estimated in three steps.

1. Estimate overnight capital costs. Overnight capital costs are engineering estimates of the cost of installing the necessary structures and modifications using current prices for materials, equipment and labor, and assuming the modifications can be completed immediately (i.e. "overnight"). These cost estimates are necessarily site-specific.

2. Develop estimates of annual construction expenditures. The overnight cost estimates and information regarding the timing of expenses needed to complete construction for each of the alternatives are used to develop estimates of the annual expenditures associated with the capital costs of construction for each of the alternatives.

3. Compute present values. These annual costs are translated into present values using the relevant real discount rate, e.g., 7 percent as recommended by the Office of Management and Benefit (U.S. OMB 1992).

Figure 8. Roadmap for Estimation of Construction Costs
[see hard copy for figure]

Roadmap for Operating and Maintenance Costs

As seen in Figure 9, which illustrates the methodology used to calculate the present value of O&M costs, O&M costs can be broken into two categories: annual labor costs and other operating and maintenance costs, including annual component replacements.

1. Estimate annual labor costs. Multiply estimated average wage rate by estimates of additional annual manpower hours for each alternative.

2. Calculate annual component replacement costs. The cost of replacing equipment components as they wear out is developed.

3. Aggregate to obtain annual O&M costs. Develop estimates of the annual O&M costs for each of the alternatives during the remaining useful life of the facility.

4. Translate to present values. Annual costs are translated into present values using a relevant real discount rate.

Figure 9. Roadmap for Operating and Maintenance Costs
[see hard copy for figure]

Lost Power Costs

The power costs consist of two distinct components:

1. Capacity costs. Capacity costs are the social costs of the reduction in the net amount of capacity (i.e., kilowatts) that the facility is able to provide.

2. Energy costs. Energy costs are the social costs of reduced net energy production (i.e., kilowatt-hours) at the facility. Energy costs include the net value of lost power as well as the value of changes in air emissions, i.e., the net social cost or benefit due to changes in air emissions resulting from the decreased power generation at the facility and the increased power generation by other power generation plants to offset these losses.

These components need to be estimated for two situations:

1. Energy losses related to construction. These are the losses related to reduced system output for any increased time the facility is shut down-in order to construct and/or install the particular alternative.

2. Energy losses related to continuing operation. These are losses due to a decrease of net output at the facility, from decreased facility capacity, increased auxiliary power requirements, i.e., the energy used to operate the alternative, or seasonal flow reductions.

We describe the methodologies used to estimate costs in these two situations below.

Roadmap for Power Losses Due to Construction Outages

During a construction outage, no energy is produced for sale on the market and no capacity is available. The cost of capacity, energy, and air emissions depends upon the timing of the construction outages due to differences in seasonal demands and seasonal regulatory requirements.

The following steps can be used to estimate the social cost of power losses due to construction outages:

1. Estimate monthly capacity costs. Calculate monthly capacity costs by multiplying the quantity of lost capacity that would be induced by a construction outage by the market price for capacity in that month in the relevant market.

2. Calculate monthly costs of replacing lost energy with energy from other power generating sources. The monthly cost of lost energy can be calculated by multiplying monthly changes in net energy output during each of three load periods (weekday peak, weekday off-peak, and weekend) by the wholesale price for that month during that load period. These costs are estimated net of cost savings at the facility due to reduced fuel and variable costs during construction outages.

3. Estimate monthly costs associated with changes in air emissions. Calculate the air emissions component of energy costs using estimates of the marginal cost of SO2, NOx, and CO2 emissions from replacement power; these marginal costs are assessed using methodologies that depend upon the regulations governing the facility's emissions; the methods can include the cost of control, pollutant impact estimates, and/or the forecast price of allowances. Costs reflect the increases in emissions from other plants and decreases of emissions at the facility.

4. Compute annual power costs for each category. Sum the monthly cost estimates to obtain annual costs for lost capacity and lost energy production associated with construction.

5. Translate to present values. Annual costs are translated into present values using a relevant real discount rate.

Figure 10. Methodology for Value of Lost Power from Construction Outages
[see hard copy for figure]

Roadmap for Power Losses Due to Continuing Operation

Fish protection alternatives can cause a loss of net output through three basic mechanisms:

1. In creased auxiliary power requirements. Auxiliary power requirements reflect the additional in-plant power requirements due to the operation of the CWIS alternatives. Energy used in plant

operations is not available to meet energy demand.

2. Performance (heat rate) penalties. Fish protection alternatives may reduce the facility's power generation efficiency. For example, closed-cycle cooling systems create higher cooling water temperatures that in turn cause higher turbine backpressure. This higher backpressure reduces the amount of energy that can be produced.

3. Decreased facility capacity. Intake alternatives may change the total amount of power that can be generated by the facility. The seasonal flow reductions, for example, decrease the amount of power that can be generated during the flow reduction periods.

Each of these operating impacts would reduce the quantity of power generated at the facility, and, potentially, the quantity of capacity available. Figure 11 summarizes the methodology used to calculate the cost of lost power due to changes in continuing operations. These losses include capacity, energy, and air emissions costs. The methodologies are similar to those used to estimate losses related to construction outages.

Figure 11. Roadmap for Value of Lost Power from Changes in Continuing Operation
[see hard copy for figure]

EPA Response

The Agency reviewed the comment and referenced figures and notes that their "roadmap for estimating compliance costs" correlates well with the methodology utilized by the Agency for the final rule cost estimates, as discussed in the Technical Development Document

Facility & firm-level costs/Econ. Practicability

Roadmap for Considering the Implications of Qualitative Factors

Some categories of benefits and costs are not included in these roadmaps. These potential categories include the following:

-costs to the facility of obtaining the 316(b) determination;

-prototype test facilities (relevant for some technological options);

-field tests (relevant for some technological options);

-disposal of waste materials (relevant for some technological options);

-fish losses at other power facilities whose production would increase;

-aesthetic impacts associated with cooling towers (e.g., visibility effects);

-air emission costs, other than those included in the assessment; and

-land acquisition costs.

The benefit-cost assessment thus should include assessments of how significant these categories are likely to be in light of the quantitative results.

In addition to these omitted categories, the quantitative analyses do not take into account some factors that might change the biological or economic values used in the analyses. Biological studies identify two biological relationships that may be excluded (see AKRF-LWB 2003, Barnthouse et al 2002):

1. Natural biological compensation, which would reduce the effects of losses and thus reduce the gains from fish protection alternatives; and

2. Lags in adult fish production, i.e., the delay between fish protection and the development of fish large enough to be caught commercially or recreationally.

Both factors would tend to reduce the estimated fish protection benefits, since the effects would either decrease the fish gains or delay the time when benefits are received. (As noted below, delay in realizing benefits reduces the total value of benefits.

EPA Response

The commenter cites several categories of benefits and costs are not included in EPA's analyses:

-costs to the facility of obtaining the 316(b) determination;

EPA response: The Agency included costs to facilities of obtaining and subsequently obtaining reissuances of 316(b) permits. Included in the Agency's costs are those of the "comprehensive demonstration studies," which include the data collection necessary for determining the feasible technologies. See the ICR (DCN 6-0001) and Chapter B1 of the EBA in support of the final rule (DCN 6-0002).

-prototype test facilities (relevant for some technological options);

EPA response: The Agency includes costs for field-implemented pilot plant studies at facilities needing to install technologies to comply with the rule requirements. See the ICR (DCN 6-0001) and Chapter B1 of the EBA in support of the final rule (DCN 6-0002).

-field tests (relevant for some technological options);

EPA response: The Agency includes costs for field-implemented pilot plant studies at facilities needing to install technologies to comply with the rule requirements. In addition, the Agency has included costs for field testing of the biology and hydrology in and around the intake in the "comprehensive demonstration studies." See the ICR (DCN 6-0001) and Chapter B1 of the EBA in support of the final rule (DCN 6-0002).

-disposal of waste materials (relevant for some technological options);

EPA response: For cooling tower costs, the Agency's estimates included costs for waste disposal in the operation and maintenance costs. However, the final rule requirements are not based on cooling tower technologies. The technologies forming the basis of the final rule do not generate appreciable waste materials that need disposal.

-fish losses at other power facilities whose production would increase;

EPA response: Based on its electricity market model analysis (see Chapter B3 of the final EBA; DCN 6-0002), EPA believes that it is unlikely that material shifts in electricity production will result from the final Phase II rule. Even where such shifts might occur, EPA disagrees that those shifts are likely to result in an increase in fish losses at other power facilities. The requirements of the Phase II rule apply to all power facilities that operate a CWIS and withdraw at least 50 million gallons per day (MGD) of cooling water. Furthermore, EPA is working on a future regulation (Phase III) that may apply to those facilities that withdraw less than 50 MGD. EPA also notes that requirements for new facilities regulated under the Phase I rule are more stringent the Phase II regulation. As a result, even if production shifts were to occur as a result of the Phase II rule, the facilities that would experience increases production would either be subject to 316(b) as well (for other CWIS users) or would not cause any fish losses (for facilities that do not operate CWIS). EPA also notes that the benefits estimate was based on installation of compliance technologies only. EPA's benefit estimates do not take into account additional reduction in impingement and entrainment that would result from a reduction in production. As such, even if increased production at other facilities caused fish losses, there would be a commensurate reduction at those facilities with reduced production.

-aesthetic impacts associated with cooling towers (e.g., visibility effects);

EPA response: The Agency did not include costs for aesthetic impacts of cooling towers at proposal/NODA. However, the final rule requirements are not based on cooling tower technologies, and any costs associated with them would further support EPA's decision not to promulgate a rule that contains cooling tower requirements.

-air emission costs, other than those included in the assessment; and

EPA response: Additional air emissions are primarily associated with cooling towers. The final rule requirements are not based on cooling tower technologies, and any costs associated with them would further support EPA's decision not to promulgate a rule that contains cooling tower requirements.

-land acquisition costs.

EPA response: Land acquisition costs are primarily associated with cooling towers. EPA did not include costs for land acquisition of cooling towers at proposal/NODA. However, the final rule requirements are not based on cooling tower technologies, and any costs associated with them would further support EPA's decision not to promulgate a rule that contains cooling tower requirements.

In addition, the commenter claims that two factors would reduce the estimated fish protection benefits:

"1. Natural biological compensation, which would reduce the effects of losses and thus reduce the gains from fish protection alternatives; and

2. Lags in adult fish production, i.e., the delay between fish protection and the development of fish large enough to be caught commercially or recreationally."

For a response to comments on natural biological compensation, please refer to comment 316bEFR.025.015 in subject matter code 10.01.02.02. For a response to comments on lags in adult fish production, please refer to the discussion on discounting in comment 316bEFR.005.029 in subject matter code 10.02.02.

Benefit Estimation Methodology

Roadmap for Considering the Sensitivity of Results to Alternative Discount Rates

The benefit-cost study should evaluate the sensitivity of the results to alternative discount rates. The discount rate is used to translate the time streams of costs and benefits into “present values,” i.e., the total amount in a given year (“present”) that would be equivalent to the stream of costs or benefits. The discounting calculation reflects the fact that a given dollar of cost or benefit is valued more highly today than in the future. This discounting procedure allows decision-makers to compare two values—the present values of benefits and costs— rather than the two streams.

Although the concept of discounting is universally accepted, there are different estimates of the precise magnitude of the discount rate (i.e., the rate at which society trades off present and future costs or benefits). The EPA Guidelines note that the literature on the choice of discount rate is voluminous and technically complex (U.S. EPA 2000, p. 33). The OMB has prescribed a real discount rate of 7 percent in different years, to provide uniformity for federal evaluations. The EPA Guidelines recommend that benefit-cost analyses use alternative discount rates to evaluate the sensitivity of the results to the choice of discount rate.

Present values can be calculated for various discount rates intended to bound the range of plausible alternatives. The study could then assess whether the choice of discount rate affects the basic benefit-cost results.

EPA Response

In the regional study document for the final Section 316(b) Phase II rule, EPA presents benefits estimates assuming three discount rates: 0%, 3%, and 7%. See DCN # 6-0003 for detail.

In the EBA for the final Section 316(b) Phase II rule, EPA presents costs and benefits estimates assuming two discount rates: 3%, and 7%. See DCN 6-0002 for detail.

Benefit-Cost Assessments Are Not Overly Burdensome

The EPA has expressed concerns about the use of benefit-cost analysis, indicating that site-specific studies will be too burdensome, both to the facility owner and to the government agencies that must review the submissions. Indeed, EPA noted this concern in its Notice of Proposed Rulemaking and sought comments on how significant the concern is likely to be (67 FR 17167). The Agency also sought comments on how the workload of a site-specific approach could be streamlined to avoid such difficulties.

Earlier reports have considered the issues posed by study costs and how such concerns have been addressed in prior programs (Harrison et al. 2000 and National Economic Research Associates 2001). The key conclusions from those studies are the following:

-The potential gains from use of a benefit-cost approach to §316(b) decisions can be substantial, relative to a requirement that would impose uniform technology on all (or similarly situated) facilities;

-These potential gains are considerably smaller for small facilities, in which the costs and environmental effects are relatively small;

-These considerations mean that a tiered approach should be adopted for §316(b) benefit-cost assessments:

--Large and complex assessments should include a detailed benefit-cost analysis that would involve the development of new site-specific data and analyses,

--Small and simple assessments could use formulaic benefit-cost analysis that supplemented site-specific information with generic modeling.

-There are many precedents for this tiered approach in other programs as well as in other EPA regulations. These precedents include:

--EPA's noncompliance benefits program, in which a computer model ("BEN" model) was developed to provide methods of estimating the benefits a company achieved through noncompliance with an environmental requirement. These methods are less costly than those used in litigation, the alternative "tier."

--Natural Resource Damage Assessments ("NRDA") for Superfund assessments, in which two tiers are used to assess potential damages: Type A, for smaller releases, in which less expensive assessment methods are used; and Type B, for larger releases, which involve more detailed assessments.

-These precedents provide examples that EPA could use to develop a tiered system for site-specific benefit-cost assessments.

This report thus provides input into the methods that EPA could use to “streamline” the benefit-cost assessment. Streamlining would allow society to obtain the gains from site-specific assessments, without excessive burdens either to §316(b) applicants or to government agencies.

EPA Response

EPA agrees with the commenter that if a facility is seeking a site-specific determination of best technology available for minimizing adverse environmental impact on the grounds that costs are significantly greater than the benefits of complying with the otherwise applicable requirements of Sec. 125.94, a facility must use a comprehensive methodology to fully value the benefits achievable by compliance with the applicable requirements to reduce impingement and entrainment mortality. The Agency also agrees that a permittee and permit writers should consider the magnitude and the character of the ecological impacts from a facility in identifying the appropriate methods for conducting site-specific benefits cost analysis. See Section V of the preamble to the final Section 316(b) Phase II regulation for a discussion on site-specific determination of technology and for a discussion of the site-specific cost benefit test.

See also EPA's response to comment #316bEFR.005.020 on application of the cost-benefit test to assessing the value of alternative CWIS technologies.

RFC: Test: benefits should justify the costs

CONCLUDING REMARKS

Benefit-cost methodology provides a time-tested means of evaluating the gains and losses from §316(b) alternatives and thus clarifying what is at stake in §316(b) decisions. EPA has contributed substantially to the practical implementation of §316(b) benefit-cost analyses by developing its 2000 Guidelines, which provide guidance on the types of benefits and costs to be included and the appropriate methodologies that can be used to estimate them.

This White Paper builds upon the EPA Guidelines—and other economic literature—as well as upon practical experience with §316(b) benefit-cost assessments in order to evaluate how benefit-cost analysis can be used in site-specific §316(b) decisions. The following are the principal conclusions of this White Paper.

1. Benefit-cost analysis is well suited to developing the benefit and cost information on alternatives that should be considered as part of the §316(b) permit decision process.

2. In response to a concern that the benefit assessment may not be complete, a review of all potential benefit categories as reflected in the EPA Guidelines reveals that only a relatively small number of categories generally apply to §316(b) alternatives.

3. Sound and manageable methodologies are available to develop dollar values for this relatively small set of relevant benefit categories.

4. With regard to developing a complete benefit-cost analysis, previous experience with §316(b) studies provides the bases for a roadmap of concrete steps to develop comprehensive cost and benefit values for §316(b) alternatives.

5. In response to concerns that site-specific studies would be too burdensome (both to the facility owner and to the permitting agency), a previous report provides guidance on how a tiered approach—in which large and complex assessments include detailed analyses and small and simple assessments combine site-specific information and generic modeling—can be used to “streamline” §316(b) benefit-cost assessments.

EPA Response

See the preamble for a discussion of the site-specific compliance alternative.

For EPA's response to comments on application of the cost-benefit test to assessing the value of alternative CWIS technologies, please see comment #316bEFR.005.020.

For EPA's response to comments on application of the "significantly greater than" test to assessing the value of alternative CWIS technologies, please see comment #316bEFR.005.003.

Permit applications/implementation schedule

City Public Service is concerned about the amount of time that will be needed to comply with the rule once the it becomes final and is in support of compliance schedules. We currently have two permits that will expire at the same time on two different reservoirs, since the Texas Commission on Environmental Quality has implemented the basin permitting process. The expiration date could potentially be less than one year from the date the rules become final. Having two permits that have to be renewed at the same time would be stretching resources and personnel. In addition to the difficulties of preparing a renewal, the agency renewing permits would probably be overwhelmed.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

Option 3--Site-specific determination

Site-Specific and Flexibility:

FirstEnergy supports EPA's recognition that no single technology will be the "best available" in all cases and strongly encourages EPA to recognize the site-specific features that must be considered in 316(b) decisions. Site specific information that is available should be used such as successful 316(b) demonstrations based on sound science. Also the rule should maintain as much flexibility as possible and continue reliance on technically sound 316(b) decisions and successful 316(b) state programs. Maintaining flexibility in this rule will help to insure that the electric utility industry can meet the challenge of providing reliable, adequate and affordable electricity.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

With respect to existing state programs, the final rule provides for EPA approval of alternative State program requirements where such State NPDES requirements will result in environmental performance within a watershed that is comparable to the reductions of impingement mortality and entrainment that would otherwise be achieved under § 125.94.

With respect to previous 316 demonstrations, a goal of today's rule is to set national minimum performance standards that reflect the best technology available for minimizing adverse environmental impacts. Given that previous determinations of best technology available were not made in reference to the national performance standards, EPA believes that the Director should not rely entirely on historical determinations. EPA believes that these national requirements will promote more effective and consistent implementation of section 316(b) requirements, and ultimately minimize adverse environmental impacts associated with the use of cooling water intake structures by Phase II existing facilities.

Author Name Scott F. Brown
Organization FirstEnergy

Subject Matter Code 10.08

RFC: "Significantly greater" for eval. alt. req.

Benefit-Cost:

FirstEnergy believes that the technology that maximizes net benefit should be the guiding principle not a strict performance standard approach. And the benefit-cost analysis should be based on "greater than" not "significantly greater than" due to the site-specific factors at issue.

EPA Response

Section 316(b) does not impose a "maximize net benefit" standard, rather, it provides that any standard established under CWA sections 301 or 306 and applicable to a point source must require that the location, design, construction and capacity of cooling water intake structures reflect best technology available for minimizing adverse environmental impact. EPA has considered the site-specific compliance alternative for the reasons discussed in section VII of the preamble to the final rule. With regard to use of the "significantly greater" standard, see response to 316bEFR.006.003.

Author Name Scott F. Brown
Organization FirstEnergy

Subject Matter Code 21.01.04
Comprehensive demonstration study (7 parts)

Comprehensive Demonstration Studies:

If a 316(b) demonstration study was done in the past and has been successful, and the plant conditions have remained the same, then the regulatory agency should be allowed to reapprove the existing intake. Where there is data that shows a healthy aquatic community exists, the expense of a comprehensive demonstration study is not warranted.

EPA Response

EPA disagrees that a facility that conducted a 316(b) demonstration study in the past should be exempt from the application requirements of today's final rule. Many of these demonstration studies were conducted 20 years ago or more, and may no longer be representative of conditions at the facility. EPA is, however, allowing the use of existing data that is reflective of current conditions to support application studies. Please see response to comment 316bEFR.040.001 for details.

Additionally, under compliance alternative 2 (see 125.94(a)(2)), a facility may demonstrate that it already meets rule requirements if its existing design and construction technologies, operational measures, and/or restoration measures meet the performance standards at 125.94(b) and/or the restoration requirements in 125.94(c).

Determination of compliance

Compliance and Baselines

FirstEnergy supports the “as built” approach option for entrainment. Historical data should be allowed to be used if there is no reason to believe it is not representative. We support the recognition that consideration should be given for ‘moribund” fish in any calculations and believe that mortality for entrainment should be considered not just total entrainment.

EPA Response

EPA agrees that the “As-Built” approach is an acceptable method for establishing the calculation baseline. Please see EPA’s response to comment 316bEFR.343.011 for a discussion of factoring naturally dead or moribund organisms into the calculation baseline. For EPA’s position on the factoring of naturally dead or moribund organisms, please see EPA’s response to comment 316bEFR.306.116.

Permit applications/implementation schedule

Author Name Scott F. Brown

Organization FirstEnergy

Implementation and Compliance Schedule

FirstEnergy has concerns with the implementation schedule of the proposed rule. Facilities should be allowed to utilize a previously approved 316(b) study in their application renewal and absent a previous 316(b) study be given at least three years to evaluate a system, perform biological sampling, review technology options and implement a technology. Once a facility has selected a technology and installed and it is found the technology did not achieve the expected performance standard results, the facility should not be subject to immediate enforcement action until it has an opportunity to reevaluate options and implement any changes. Those facilities that have achieved the standard should not have to undergo a complete reevaluation every permit term.

EPA Response

EPA disagrees that existing BTA determinations should remain valid under today's final rule. Please see response to 316bEFR.040.001 for a discussion on the use of historical BTA determinations.

EPA has provided tremendous flexibility in today's final rule and offers five compliance alternatives with varied study requirements to facilitate application completion and speed permitting. For some facilities, EPA expects that technology installation and monitoring may be an iterative process which may require modifications to meet appropriate performance requirements. This process should be conducted in consultation with the Director; immediate enforcement action for an exceedance of the performance requirements under these conditions is not expected.

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to 316bEFR 041.126 for a discussion.

General statement of support

The New Regulation Continues to Have Many Favorable Features

EPA is to be commended for the considerable effort that has been put toward this regulation. There are a number of positive elements in the rule that we endorse and hope will be part of the final requirements. Among the provisions that will improve the overall 316(b) processes are:

- Cost and benefit tests to determine technology suitability;

- The option to use voluntary environmental restoration and enhancement measures to satisfy compliance requirements;

- The use of 'baseline' intake condition with no controls from which compliance is determined; and

- Allowances for plants with low utilization.

We appreciate that EPA has seriously considered the comments from the regulated community and recognized that the proposed rule needs further refinements. It is also good that the entire slate of issues in the proposed rule remains open for additional comments.

EPA Response

EPA notes the comment. No response necessary.

The Regulation Needs a Definition of 'Adverse Environmental Impact'

It seems clear that the final rule will not attempt to define 'adverse environmental impact'. We continue to believe this is an unfortunate lapse of regulatory oversight. The statutory language is clear. To have a rule that is based on the concept, repeatedly references it, purports to reduce it yet refuses to define it will not serve the process well.

Rather than focus on reducing an absolute number of organisms, EPA should recognize the importance of population-level impacts and accept that, as a matter of basic biology, (sometimes large) losses occur naturally with little or no effect on the health of aquatic populations. In its comments on the proposed Phase II rule, UWAG recommended the following definition:

"Adverse environmental impact is a reduction in one or more representative indicator species that [1] creates an unacceptable risk to the population's ability to sustain itself, to support reasonably anticipated commercial and recreational harvests, or to perform its normal ecological function and [2] is attributable to the operation of the cooling water intake structure."

EPA Response

EPA has chosen not to define the term "adverse environmental impact" in the final rule. Please refer to section VIII of the preamble to the final rule for more information.

Follow 1977 Guidance

The New Rule Should Encourage Site-Specific Regulation of Cooling Water Intake Systems

We strongly urge EPA to craft a rule that accepts the site-specific aspects of power plants, their cooling systems, the source water bodies, the surrounding environments and the affected populations of aquatic organisms. All of these factors intuitively argue for greater consideration of a site-specific application of this rule and less uniform, one-size-fits-all alternatives. The original 1977 guidance and regulations required site-specific considerations. There is no sound scientific or technical basis to change EPA's or Congress's 30-year record that promotes site-specific regulation of cooling water intake systems.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b) determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact at cooling water intake structures.

Option 3--Site-specific determination

Entrainment and impingement are largely determined by factors that vary from site to site. Just because the proposed rule distinguishes certain water body types, it does not mean that everything after that is the same and amenable to one type of solution. Power plants are still different, as are water bodies and their surrounding landscapes. In fact, one might suggest that no two plant sites are the same. Every locality has its distinctive environmental characteristics, independent of the facility. Aquatic populations vary and the technologies and control options that are feasible will not perform the same way in certain environments.

EPA Response

EPA recognizes the variability in site-specific characteristics and notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information. EPA also authorizes State Directors to allow facilities to demonstrate compliance by means of a TIOP, which among other things, helps address the variability in aquatic populations even at a particular site.

Comprehensive demonstration study (7 parts)

Prior (site-specific) determinations should be considered. Also, if there are data that already show there is so little entrainment or impingement that the community is not affected or the economic impact is exceeded by the cost of a comprehensive study, there should be no need for further evaluation.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule; however, existing data that is reflective of current conditions may be used to support studies. Please see response to comment 316bEFR.040.001 and the final rule preamble, section VIII.D. 2., Existing Programs and Determinations for details.

Additionally, under compliance alternative 2 (see 125.94(a)(2)), a facility may demonstrate that it already meets rule requirements if its existing design and construction technologies, operational measures, and/or restoration measures meet the performance standards at 125.94(b) and/or the restoration requirements in 125.94(c).

Technology Efficacy Database

Author Name Kenneth S. Johnson

Organization Constellation Energy Group

In the NODA @ P. 13539, EPA requests comment on the documents in the "Technology Efficacy Database", a collection of 148 references on the performance of the recommended intake control technologies. To quote from the FR notice,

"EPA requests comment on whether these data are of sufficient quantity and quality to support the determination that the proposed performance standards are best technology available and that the existing facilities can meet these standards by implementing design and construction technologies either singly or in conjunction with other design and construction technologies (including operational and restoration measures)."

At this time, we do not believe that enough of the proposed intake technologies have demonstrated experience at the operating plant level or under sufficiently representative hydrologic conditions. Until more experience is available to support BTA decisions, it may be premature to suggest that some technologies will meet the performance standards...especially if non-compliance is to be based on strict percent reduction requirements.

Also, while relevant historical and operations experience from other plants has value, we do not want to facilitate hasty decisions or encourage challenges based on a simplistic justification that would be as follows:

"This plant is on an estuary... it installed fine mesh screens and restored a wetland … you are on an estuary… you should do the same."

Experiences elsewhere are worthwhile but technology determinations are another of the many factors that clearly argue for site-specific determinations.

EPA Response

Please see response to comment 316bEFR.325.004.

RFC: Use of previous demonstration studies

EPA Should Make it Easier to Accept the Considerable Long-Term Data That Shows Many Plants Have Negligible Adverse Environmental Impact

Many states have already done extensive work to regulate the impact of cooling water intake systems. If some plants have not yet conducted studies and assessed the impact of their cooling water intake systems, EPA should not conclude this is a reason to make others revisit an issue that has been demonstrably resolved.

EPA Response

EPA has disallowed the use of historical determinations of BTA in today's final rule; however, existing data that is reflective of current conditions may be used to support the required studies. Please see response to comment 316bEFR.040.001 for details.

Proposed standards for Great Lakes

The Great Lakes and Estuaries Do Not Require More Regulation Based on Sensitivity to Cooling System Impacts

The Great Lakes are unique but that does not make them uniquely sensitive. Great Lakes fisheries are highly managed and consist largely of introduced and stocked species. The life history characteristics of the Great Lakes commercial and recreational fish of concern are not put at risk by power plant operations.

Similarly, burgeoning human development and the fishing pressures on the abundant populations of commercial and recreational species have impacted estuaries. That many estuaries continue to be productive in spite of over-fishing, pollution and habitat degradation suggests resilience more than sensitivity. It also suggests that, if the overall health or 'sensitivity' of certain, important waters are at issue, the EPA should place as much attention on more obvious threats to the sustainability of important species. Habitat losses, competition from introduced species, non-point source runoff and over-fishing all contribute [to a greater degree] to the loss of commercial and recreational species.

EPA Response

Please refer to the response to comment 316bEFR.025.013 for a discussion of the Great Lakes as sensitive waterbodies and a discussion of introduced and nuisance species.

EPA acknowledges that other factors such as overfishing or declining water quality may also affect fish populations. However, these factors do not diminish the increased potential for adverse environmental impact from cooling water intake structures in tidal rivers and estuaries.

Subject Matter Code 11.01

RFC: Proposed use of restoration measures

Author Name Kenneth S. Johnson

Organization Constellation Energy Group

Allowing Restoration and Environmental Enhancements is Good Policy

Mitigation can be a cost-effective way to offset the impacts of cooling water intake systems and a most reasonable alternative to many technologies. Congress has consistently promoted creation and restoration of wetlands in a number of laws. EPA should not accept the Riverkeeper position that restoration measures are “wholly unrelated” to intake structure technologies and therefore cannot be BTA. The State of Maryland has included mitigation measures as part of 316(b) settlement decisions and we hope the new national guidance will continue to encourage that option. The voluntary option should remain in the final regulation.

The NODA (@ p. 13542) requests comment on additional proposed requirements for the use of restoration measures.

- Documentation of sources and magnitude of uncertainty in expected restoration project performance;

- Creation and implementation of an adaptive management plan; and

- Use of an independent peer review to evaluate restoration proposals.

We agree with UWAG’S recommendations on the requirements. All three can be useful to evaluate and endorse a proposed measure but the degree to which each requirement is applied should depend on the specific project. Based on the environment and experience, some activities certainly have less uncertainty and should need less scrutiny.

EPA Response

In the final rule, EPA allows use of restoration measures to minimize or to help to minimize the adverse environmental impacts that derive from impingement and entrainment of aquatic organisms. For a discussion of EPA's authority to include restoration measures as a compliance option in the final rule, see the preamble to the final rule.

For a discussion of the nature of the requirements in the final rule, see EPA's responses to comments 316bEFR.307.047 and 316EFR.311.022.

Permit applications/implementation schedule

Utilities Need Clear Guidance Regarding the Effective Date and Implementation Requirements of the Rule

While we are certain this concern was a high priority comment in many of the responses to the proposed rule, the NODA seems to have done little to lessen the vagueness that detracts from the proposal in so many important places. This is a complex matter that requires the kind of guidance that EPA produced in 1977. We suggest that uniform approaches to this very site-specific activity are not possible without more comprehensive guidance.

CEG has a total of six facilities that would be regulated under this proposal. One nuclear facility has an NPDES permits that expires in December 2004. If the complete application package is due to the permitting agency 180 days before the permit expires (May, 2004), it is most unreasonable to expect to have all the elements of the Comprehensive Demonstration Study completed in time. We will have known the final regulatory requirements for only three months. EPA misses the point when they justify the 180-day requirement (68 FR 13584). This is not about the time that permit writers need to review such complex and extensive submittals. It is about the time the applicants need to prepare the package. In fact, the expanded submittal that permit renewals will become might argue for even more time to review the substantial additional material.. .after all, most states require the 180-day lead time already and have much less to address (by comparison).

Our concern is about the time we will need to develop the application package with all the elements that the Comprehensive Demonstration Study requires. Sufficient time must be allowed to bring together the necessary information. More important than that, the application must be prepared with the understanding that comes from the final rules. It is unreasonable and unfair to expect the commitment of resources that would be required to prepare the next round of Phase II permit renewal applications before we know what the final requirements will be.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

Determination of compliance

The Rule Needs a Better Definition of 'Calculation Baseline' and Guidance on How it is Determined

We agree with UWAG'S recommendations to factor full operation conditions into a fair baseline characterization. We particularly agree that the process should be consistent with the same, overly-conservative assumptions EPA uses to estimate CWIS impacts and benefits - all fish are alive and in good health when impinged and there is zero survival. To be consistent, the baseline assessment should apply the same assumptions.

We appreciate that there will be a hypothetical, rudimentary basis to which the proposed performance standards will be applied. However, there must be acknowledgement that many cooling water intake systems have always had features that are improvements on (or just different from) the 'baseline' condition. Apart from operational considerations, we still need guidance on how we are expected to factor biological phenomena and all the structural differences that most intakes have into an assessment of a condition that never existed before. EPA (and UWAG, for that matter) continues to address what the 'baseline' intake should look like and we suggest the greater uncertainty is how we determine the entrainment and impingement at such a facility.

EPA Response

EPA has clarified its definition of calculation baseline in today's final rule (see §125.93). For additional explanation of EPA's definition of calculation baseline, please refer to EPA's response to comment 316bEFR.034.013.

Comment ID 316bEFR.341.013

Author Name Kenneth S. Johnson

Organization Constellation Energy Group

Subject Matter Code 21.04

Determination of compliance

Determining Compliance

CEG agrees with UWAG and strongly suggests that the final rule clearly indicates what constitutes compliance with the numerical performance standards. If we complete the demonstration study and install the technology specified in the NPDES permit, we should be considered in full 'compliance'. If monitoring shows that the measures have not actually achieved the required reductions in impingement and/or entrainment, the facility should not be in violation and be penalized. The facility should be expected to evaluate and commit to additional measures to meet the performance standards.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan. EPA disagrees that a facility that is out of compliance should not be subject to enforcement actions.

Comment ID 316bEFR.341.014

Subject Matter Code 21.03

Monitoring requirements

Author Name Kenneth S. Johnson

Organization Constellation Energy Group

In the NODA @ p. 13585, there is some worrisome language that suggests perpetual reconsideration of 316(b) issues and compliance with every NPDES permit renewal. If a facility has installed and operates technologies that monitoring shows meet the new performance standards, the issue should be closed. The plant has met the BTA standard or its equivalent under the site-specific determinations. To recommend that each renewal application include information that demonstrates that conditions have not changed suggests that facilities may have to monitor constantly in order to have this information. This should not be necessary if the accepted technology has demonstrated that it meets the performance standard.

This same difficulty arises on p. 13586 with the issue of how much time a facility needs to come into compliance. If compliance is NOT just having BTA that is installed/operated/maintained but monitoring that demonstrates that it meets the percent reduction standards, we may have to monitor routinely.. .as we do for effluent limits. The Clean Water Act enforcement framework has fines for daily non-compliance. If we cannot show we are in compliance every day, how will we counter accusations that we are not? This is another reason why, once monitoring demonstrates that the performance standards are met, the issue should be closed.

EPA Response

Comment ID 316bEFR.341.015

Author Name Kenneth S. Johnson

Organization Constellation Energy Group

Subject Matter Code 21.09

Permit applications/implementation schedule

Finally, EPA has some suggestions @ p. 13584 to address the considerable feedback it got regarding how applicants will be able to get the substantial permit application package together when it is due in 2004, shortly after the rule becomes final. We would agree to at least a one-year delay and two years if new biological studies would have to be conducted. We continue to believe that an easy way to cleanly resolve this question would be to make compliance start with a renewed permit that specifically requires all the elements of compliance in the new five-year term. Field studies, economic assessments, technology selection, approvals, installation and compliance monitoring can all be done with the applicants and permit writers having the advantage of knowing the final requirements [and having a guidance manual and training available].

One option we do not want is a 'Compliance Schedule' (p. 13584). . .if that approach implies that the facility is not in compliance with the regulations. While EPA describes a process that is attractive and innocent enough, with the permit writer preparing a "reasonable" schedule that "will ensure the facility is brought expeditiously towards compliance", we do not want any presumption that our facilities are out of compliance now. With the understanding that considerable time will be needed to do all that is required, EPA should call the approach an "Implementation Schedule" and make it clear that the facility is not in a state of non-compliance during this intermediate stage.

EPA Response

See response to comment 316bEFR.025.019.

Comment ID 316bEFR.341.016

Author Name Kenneth S. Johnson

Organization Constellation Energy Group

Subject Matter Code 21.03

Monitoring requirements

Impingement of Moribund Organisms Must be Factored Into the Impact Assessment

There is no doubt that certain environments can produce conditions that result in mass mortalities of aquatic organisms. Cold shocks in winter and the presence or sudden movement of low oxygen water in the summer have caused fish kills in the vicinity of the Calvert Cliffs Nuclear Power Plant on the Chesapeake Bay. Such conditions have killed or irreversibly weakened thousands of vulnerable fish, which are essentially collected by the plant's intake system. If this happens during impingement sampling, the numbers collected can be overwhelming. However, since impingement monitoring is a sub-sampling process and the numbers are extrapolated to the longer period of plant operation, these episodic events can yield huge estimates of impinged organisms. The final guidance for determining impingement impacts must factor in the obvious influence of episodic events where dead fish are drawn into the plant intakes. Guidance should allow for the development of scientific methods that document such episodes (and ultimately discount this site-specific phenomenon from the impact assessment).

EPA Response

Please see EPA's response to comment 316bEFR.306.116 for an explanation of EPA's position on factoring naturally dead or moribund organisms. For EPA's position on upset or bypass provisions for episodic impingement mortality and/or entrainment events, please refer to the preamble to today's final rule.

Comment ID 316bEFR.341.017

Author Name Kenneth S. Johnson

Organization Constellation Energy Group

Subject Matter Code 7.02

Performance standards

The Final Regulation Should Allow Entrainment Survival to Determine Compliance With the Performance Standard

As with impingement, the performance standard for entrainment should be mortality. Mortality is what constitutes the adverse impact.. .and it can be argued that planktonic organisms that are killed are not as lost to the food web they support, as other parts of the system would be. Also, it seems EPA is going to rather extreme lengths to criticize the body of work on entrainment survival. While many of the utility studies are dated and some methodologies may not be exquisite, one is still left to wonder why EPA does not apply the same level of scrutiny to the studies that support its initiatives.

The assumption of 100 percent mortality is too conservative and is inconsistent with the proposed impingement standard. Also, there are considerations that should be factored into any given facility's impact assessment. If we understand that entrainment mortality is a combination of three primary factors - exposure to heat, biocides and physical stresses, there are site-specific issues to consider. Biocide use is infrequent. Most entrained organisms are not exposed to the chemicals. Some plants have very efficient or substantial condensers and do not reject as much heat to the cooling water. The maximum temperature increase at the Calvert Cliffs Nuclear Power Plant is 12°F, not a significant thermal shock to many organisms. Finally, while certain groups of organisms may be vulnerable to the physical stresses of entrainment, others are not. The foregoing simply supports what many studies have demonstrated.. .sometimes, a significant number of entrained organisms survive. We need a regulatory framework that honestly assesses impacts and has a valid basis for evaluating the controls that may be required.

EPA Response

EPA disagrees. Today's final rule sets performance standards for reducing entrainment rather than reducing entrainment mortality. EPA chose this approach because EPA does not have sufficient data to establish performance standards based on entrainment survival for the technologies used as the basis for today's rule. If entrainment survival were to be incorporated into any determination of compliance with the performance standards, then the actual performance standard that would need to be met would be higher.

Based on its review of all entrainment survival studies available to the Agency, EPA believes that its assumption of zero percent survival in the benefits assessment is justified. The studies reviewed are characterized by significant uncertainty and variability which complicates efforts to synthesize the various results in a manner that would provide useful generalizations of the results or application to other particular facilities for the benefits assessment. The primary issue with regard to these studies is whether the results can support a defensible estimate of survival substantially different from the value zero percent survival assumed by EPA. The review of the studies has shown that while some individual organisms may be alive in some of the discharge samples, the proportion of the organisms that are alive in the samples is highly variable and unpredictable. In addition, the studies contain various sources of potential bias which cause the estimated survival rates to be higher than the actual survival rates. For these reasons, EPA believes the current state of knowledge does not support reliable predictions of entrainment survival that would provide a defensible estimate for entrainment survival above zero.

RFC: Appropriateness of "significantly greater"

We Still Need a Better Definition of 'Significantly Greater'

The cost/benefit tests that make economic feasibility a part of BTA selection are one of the most important features of the proposed rule and CEG strongly supports their retention in the regulatory process. However, as we noted in our comments for the 2002 Phase II rule, such a subjective term is not the way to go. 'Significantly greater' is too vague, and clearly needs clarification.. .preferably as a measurable or quantifiable expression. Otherwise, we face different interpretations across the country and the potential for regulators to say, "the difference is not significant enough."

EPA Response

See responses to 316bEFR.006.003 and 018.009.

Response to Public Comment

---National Pollutant Discharge Elimination System--- Regulations Addressing Cooling Water Intake Structures for Phase II Existing Facilities

(40 CFR Parts 9, 122, 123, 124, and 125)

Response to Comments Submitted by:

Theresa Pugh

On Behalf Of:

American Public Power Association

Author ID Number:

316bEFR.342

Comment ID 316bEFR.342.001

Subject Matter Code 7.02

Performance standards

Cooling Towers

EPA's proposed rule is based on "performance standards'' that call for reducing impingement mortality by 80-95% and, for many facilities, entrainment by 60-90%. EPA has looked at available intake structure technologies and concluded that some of them can achieve these standards. The candidates are wedge wire screens, fine mesh screens with fish return systems, and aquatic filter barriers. However, APPA is concerned that certain parts of the proposed rule seem to imply that if these technologies cannot achieve the performance standards at a particular site, that cooling towers (closed-cycle cooling) might be required.

APPA believes that EPA does not (and should not) intend to require existing facilities to retrofit cooling towers, as demonstrated by several passages in the NODA. For example, EPA deliberately did not include costs for cooling towers in its economic analysis for the "preferred" option. Furthermore, other parts of the economic analysis that do consider cooling tower costs (as well as environmental side-effects to other media such as air pollution and feasibility problems due to space constraints), clearly show, that cooling towers should not be required at existing facilities.

APPA believes EPA should make it very clear in the final rule that cooling towers are not the "default" option to be required whenever the other alternatives cannot achieve the numerical standards. APPA believes, along with the National Rural Electrical Cooperatives Association (NRECA) that EPA should add the following language to the rule:

"Although existing facilities with closed cycle cooling will be deemed to have complied with this rule, this rule does not require closed cycle cooling systems to be installed on any existing facility, even if the intake structure technologies considered in this rulemaking cannot achieve the performance standards in practice. ''

EPA Response

Today's rule does not require any facility to retrofit its cooling system to include closed-cycle cooling (cooling towers), although EPA notes that this option remains available to any Phase II facility in order to satisfy the requirements of the regulation. If a facility were to adopt closed-cycle cooling (compliance alternative 1), it would be exempt from many of the additional elements required of facilities opting for one of the other compliance alternatives. EPA also notes, however, that today's rule preserves each State's right to adopt or enforce more stringent requirements.

With regard to this issue, EPA believes the language adopted in today's rule is sufficient and does not warrant further changes as proposed by the commenter.

Comment ID 316bEFR.342.002

Author Name Theresa Pugh

Organization American Public Power Association

Subject Matter Code 7.02

Performance standards

While APPA has not had an opportunity to assess each of the studies EPA cites, APPA believes that these studies show that the technologies EPA has identified (wedge wire screens, fine mesh screens with fish return systems, and aquatic filter barriers) will be deployable at appropriate sites, are capable of achieving appreciable reductions in impingement and entrainment. APPA believes that they will meet the proposed performance targets at many, if not all sites, as long as those targets are properly and reasonably applied.

While APPA believes that there may be some sites for which the performance standards are not achievable, APPA believes that the cost-cost and cost-benefit tests offer an appropriate means of resolving issues and setting alternative targets for those cases.

APPA believes strongly that there is no technology - even cooling towers - that

- can feasibly be deployed at each and every existing facility and

- would meet the proposed performance targets (as opposed to a flow reduction target, which is not the equivalent of a reduction in entrainment and impingement) at all sites.

EPA Response

EPA agrees with the commenter and notes that today's rule maintains the flexibility for facilities to opt for the most cost-effective means of satisfying the requirements of the rule.

Author Name Theresa Pugh

Organization American Public Power Association

Subject Matter Code 21.04

Determination of compliance

Nature and Implementation of the Performance Standards

As we have said in our previous comments, APPA believes that the performance standards provide useful targets for evaluating existing technologies, selecting and designing new intake technologies, and for evaluating and refining their performance after installation. We do not believe, however, that they should be incorporated directly into permits as enforceable limitations. As EPA's own technology performance data show, the performance of specific technologies will vary over time in response to widely varying biological, physical, and even chemical conditions within the waterbody. Unlike the case for pollutant discharges produced and controlled by a discharger, varying in-stream conditions - particularly the high natural variability of biological populations and communities - are not under the permittee's control, nor can the permittee reasonably be expected to anticipate and adjust for all such variations.

APPA believes that the appropriate means of using performance standards is as targets for technology selection and design and then as standards for assessing technology performance. The enforceable BTA permit requirements should be expressed as requirements to (1) identify a technology or technologies (or other measures) that will achieve the performance range (or an alternate range justified by the cost-cost or cost-benefit test) with appropriate operating and maintenance specifications adapted to the technology and the site; (2) install/operate, and maintain the technology in accordance with the technology specifications approved by the permit writer; (3) perform appropriate monitoring to gauge performance; and (4) refine or adjust operation, maintenance, or other factors as appropriate in light of initial monitoring.

EPA Response

EPA disagrees that performance standards should be used only as targets. EPA also disagrees that a facility that is out of compliance should not be subject to enforcement actions. However, EPA has provided a tremendous amount of flexibility in today's final rule for meeting 316(b) requirements, including 5 compliance alternatives (one of which is site-specific), and the option to demonstrate compliance with a Technology Installation and Operation Plan rather than with numeric performance standards (see final rule preamble). Furthermore, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see the preamble to the final rule and EPA's responses to comments 316bEFR.017.003 and 316bEFR.063.005.

Comment ID 316bEFR.342.004

Author Name Theresa Pugh

Organization American Public Power Association

Subject Matter Code 7.01

RFC: Three-option framework for determining BTA

APPA strongly believes that the U.S. EPA should expressly allow permittees and permit writers flexibility to develop appropriate site-specific performance evaluation requirements because of the inherent difficulties of working with aquatic populations in a regulatory setting.

This overall approach makes sense for a number of reasons. First, it is consistent with 316(b) and with EPA's interpretation and application of 316(b). Second, it would tend to minimize administrative burdens by avoiding controversy over the specific value chosen. Third, it would avoid the disincentive to innovate that a rigidly enforceable performance standard would create.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative. Please refer to the response to comment 316bEFR.338.002 for more information.

EPA disagrees with the commenter's statement about the historic interpretation of 316(b). Today's rule is the first major regulation for 316(b) for existing facilities; all other § 316(b)determinations for existing facilities to date have used a best professional judgment approach. The final rule does include a site-specific compliance alternative as one of the five alternatives available to facilities, creating a flexible regulatory framework. EPA believes that today's final rule will minimize adverse environmental impact associated with cooling water intake structures.

Author Name Theresa Pugh

Organization American Public Power Association

Subject Matter Code 21.04

Determination of compliance

Baseline

EPA introduced the concept of the “Baseline” as a starting point for assessing the performance of cooling water intake technologies. While EPA addressed the “Baseline” in the NODA, APPA joins other utility organizations including NRECA in expressing uncertainty as to how this “datum plane” is to be determined. As we expressed in our earlier comments on the proposed Phase II regulations, however, as long as EPA does not use the performance criteria as directly enforceable permit limitations, many of our concerns about how to accurately establish the baseline are reduced.

APPA continues to urge EPA to find a simple way of employing this concept in the final rule. One suggestion that has already been made is to assume zero percent reduction as the baseline condition (the intake without any control technologies) thereby giving full credit for the percentage reductions achieved by technologies that have already been added to the intake or for those that are to be added in the future in order to comply with the new BAT regulations.

EPA Response

EPA has clarified its definition of calculation baseline in today’s final rule (see §125.93). For additional explanation of EPA’s definition of calculation baseline, please refer to EPA’s response to comment 316bEFR.034.013.

Subject Matter Code 7.04

Streamlined Technology Option

Streamlined Technology Option

Part B, Section VII of the NODA addresses a “Streamlined Technology Option for Certain Locations” (68 Fed. Reg. 13,539 col. 2). EPA asks whether the following technology would qualify for streamlined application requirements:

Use of submerged wedge-wire screens where the cooling water intake structure is located in a freshwater river or stream, sustained countercurrents exist to promote cleaning of the screen face, and the design intake velocity is 0.5 feet per second ft/s) or less.

APPA is concerned not only with the potential capital costs imposed by the regulations, but also with the “transaction costs” of determining what to do and how to do it. We would therefore support this as a suggested way for meeting the technology requirements of the rule, as long as it is applied within the general context of the rule (including the option for cost/benefit assessment) and not as a ‘one size fits all’ requirement.

EPA Response

EPA agrees that the Approved Design and Construction Technology compliance option should not be applied to all facilities. For this reason, EPA has included the option as one of several from which a facility may select. Regarding how a facility will determine which option to choose, this ultimately will be up to the Director to decide. The Director will evaluate a facility’s permit application and make a determination, based on the facility’s intake structure, operational data, waterbody type, and existing protective technologies, of the most appropriate compliance option. EPA anticipates providing guidance to State permitting agencies to assist Directors in implementing the requirements set forth by today’s final rule. In addition, the Agency intends to develop implementation guidance for owners and operators to address how to comply with the application requirements, the sampling and monitoring requirements, and the record keeping and reporting requirements in these final regulations. Finally, State permitting agencies and permit applicants may refer to Draft Guidance for Evaluating the Adverse Impact of Cooling Water Intake Structures on the Aquatic Environment: Section 316(b) P.L. 92-500 (U.S. EPA, 1977), for additional guidance.

RFC: Proposed use of restoration measures

Mitigation

APPA strongly supports the concept of voluntary restoration as a way to offset any impacts caused by the cooling water intake system, Mitigation has become an accepted part of the wetlands program and is now being embraced by the Fish and Wildlife service as part of their new ESA Conservation Mitigation Banking program announced on May 8, 2003.

EPA Response

In the final rule, EPA allows use of restoration measures to minimize or to help to minimize the adverse environmental impacts that derive from impingement and entrainment of aquatic organisms. For a discussion of EPA's authority to include restoration measures in final rule, see the preamble to the final rule.

For a discussion of the extent to which restoration measures are voluntary, see EPA's response to comment 316bEFR.060.022.

Permit applications/implementation schedule

Realistic Timeline

APPA appreciates the EPA's willingness to consider the phasing in of the 316(b) program through the NPDES renewal process. A number of public power systems will have a NPDES permit renewal within two years of the EPA's final rule on 316(b) for existing facilities. This presents a difficulty for both state permit writers and public power system environmental managers.

APPA urges the EPA and the states to give adequate time to issue NPDES permit renewals after the 316(b) Phase II rulemaking is finalized so that there are no unnecessary delays in permit approvals and no uncertainty if the state permit writer may approve the NPDES renewal if the 316(b) program is not fully in place. APPA urges the EPA and states to provide for adequate time for 316(b) studies and data collection, etc. This compliance schedule should not imply that a public power system is not in compliance with the 316(b) program if it is not practical or possible to implement the 316(b) studies, data collection etc by the time of the NPDES permit renewal.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion. See also response to comment 316bEFR.025.019 and other responses in this subject code.

Benefits of reduced intake capacity

EPA made a huge error of omission in evaluating the cost/benefit of converting to closed-cycle cooling. EPA FAILED TO CONSIDER AND EVALUATE THE TREMENDOUS BENEFIT OF ELIMINATING ALMOST ALL HEAT DISCHARGE as a result of employing closed-cycle recirculating cooling as the Best Technology Available.

One of the reasons EPA gave for not requiring closed-cycle cooling at all or part of the power plants affected by Phase II rule was the cost. However EPA in its cost-benefit analysis of closed-cycle cooling FAILED to account for the benefits of a 95-99% reduction of the pollutant HEAT being discharged from these once-through cooling systems. This should have been presented in the "Economic and Benefits Analysis (EPA-821-R-02-001)," "Case Study Analysis (EPA-821-R-02-002)," and "Technical Development Document (EPA-821-R-02-003)," and the results incorporated in the decision for selecting the best technology available alternative. I believe had EPA done this that closed-cycle recirculating cooling would have been selected as the preferred alternative.

This is a humongous error of omission! On page 17136 of the Draft regulations (Federal Register Vol. 67, No. 68, April 9, 2002) EPA states that the volume of cooling water currently used by these facilities is 279 billion gallons per day. This is a HUGE volume of hot water being discharged daily, equivalent to a discharge of 431,677 cubic feet per second. To provide some context, the mean discharge of the Columbia River at the Bonneville Dam (the most downstream dam) in 2002 was 172,019 CFS, or 111.179 billion gallons per day. So the quantity of hot discharge water affected by this rule is equal to 2.5 Columbia Rivers of heat-polluted water!

Going to closed-cycle cooling would reduce this volume of pollutant discharge by approximately 95-99%. Taking the low figure, 95%, this would reduce the discharge of hot water to the Nation's waters by more than 265 billion gallons per day, eliminating a pollution discharge roughly equivalent to 2.4 Columbia Rivers per day! Yet EPA failed to calculate this as a benefit in its cost/benefit analysis!!!

EPA should remember that the goals of the Clean Water Act is the ELIMINATION of pollution discharges (33 USC 1241) and the title of the permit program is the National Pollutant Discharge ELIMINATION System (emphasis added). HEAT is a named pollutant under the Act and EPA should be seeking its elimination, especially where applying the technology will also have big entrainment and impingement mortality reductions.

The quantity of heat discharged to waters by a single once-through cooling systems is huge. For example, Indian Point 2 & 3, a 2000 MW nuclear station, discharges 332.9 billion BTUs per day. Two 1200 MW fossil-fueled stations, Roseton 1 & 2 and Bowline 1 & 2, each discharge 135.4 BTU/day<FN 1>. The ΔT varies from plant to plant, but it probably is 15° F or greater for most facilities. These few examples are indicative of the huge quantity of heat discharged daily in sum from all the facilities affected by the Phase II rule.

This discharge of this huge quantity of heat is itself should be considered additionally as one further "adverse environmental impact" to be minimized in meeting 316(b) in that it is a harmful aquatic impact to coldwater species; apart and separate from any 316(a) implications.

EPA should do the calculations to project the total "rejected heat" that will be eliminated by converting these large polluters regulated under the Phase II Rule to closed-cycle cooling. The volume of polluted water and the intensity of the pollutant heat eliminated in BTU and in ΔT should be calculated and presented, and the results incorporated into EPA's decision-making on the Best Technology Available selected in the final Phase II rule..

The value of eliminating this heat pollution should be given a value. The Technical Development Document presented an annualized cost estimated at $2.26 to $2.32 billion, for closed-cycle cooling at the subject facilities. However, it did not calculate the value of the concomitant benefit of eliminating roughly 69,725 billion gallons per year of heat pollution from these plants (279 billion gallons per day times 95% reduction from closed cycle times 365 days in a year). This seems like a really good value! To give this pollution elimination benefit a context relative to cost, EPA should compare it to the volume of water discharged from municipal sewage systems versus the dollars spent on building and upgrading sewage treatment plants (STPs) nationwide. I'd bet that the volume of water from STPs is comparable, or even less than the volume from of water from Phase II once-through heat pollution discharges! I'd also bet that hundreds of billions of dollars were spent on these STPs, which should be converted into same-year-basis dollars. And again, in going to closed-cycle cooling at Phase II power plants, the benefit of eliminating heat discharge is in addition to the benefits already calculated from the huge reduction in impingement and entrainment mortality!

Footnotes

EPA Response

EPA notes simply that section 316(a) of the CWA applies to heat discharge. Section 316(b) applies to cooling water intake. Therefore, in this final 316(b) rule EPA is not basing its regulatory decisions on heat discharge. The benefits of the cooling water intake national rule are from reduction in the impingement and entrainment of aquatic organisms.

However, the Agency has allowed in the final rule the ability of local authorities, where the local conditions warrant, to require more stringent requirements (potentially including cooling towers) than are required by this final rule. As such, the sections of the CWA may be applied in their proper instances and not be restrictive of each other.

As a matter of record, the Agency notes that the commenter's assessment of the water reducing potential of cooling towers on a national level is optimistic and misleading, when marine water performance is considered. As such, the Agency refers to comment response 316b.efr.404.034 for more discussion of the true water withdrawal reduction potential of closed-cycle cooling in marine environments.

Also as a matter of record, the Agency disagrees with the hypothetical methodology suggested by the commenter for assessing a potential benefit of a reduction in heat discharge: "compare [heat pollution] to the volume of water discharged from municipal sewage systems versus the dollars spent on building and upgrading sewage treatment plants (STPs) nationwide ." This methodology is not explained further by the commenter and simply does not make logical sense as presented. In the Agency's view, heat pollution is not directly related to the costs of building and upgrading sewage treatment plants. These are too disperse and unrelated entities, which the commenter fails to equate.

EPA has given unreasonable, exaggerated weight to potential for energy supply disruptions.

EPA also states it did not choose conversion to closed cycle cooling because "EPA also has serious concerns about the short-term energy implications of a massive concurrent conversion and the potential for supply disruptions that it would entail." This is unreasonable, as the simple, logical solution is to develop an "implementation plan" or "schedule for compliance" that would achieve the conversion with a minimum of disruption. Since the passage of the Clean Water Act more than 30 years ago many dozen industries and thousands municipal sewage systems have built treatment works, without major disruptions. Cooling system cut-overs can be scheduled during months of lower demand, and the dates of conversion to closed-cycle cooling could be spaced out in time to assure adequate power reserves. EPA did not require all municipal STP's to be brought up to standards overnight, "...massive concurrent conversion..." for Phase II facilities is an unreasonable concept. Such an unreasonable excuse should not be used as a rationalization for not having an orderly conversion to closed-cycle cooling.

Cooling system costs (e.g., dry, wet, recirculating)

EPA has erred in not considering the financial incentives available to facilities that upgrade to close cycle cooling and/or re-power.

There are a variety of business incentives which EPA should have considered in reducing the cost of converting to closed-cycle recirculating cooling systems, and for re-powering or replacing once-through cooling facilities.

There are federal and state tax credits or advantages available for investing in new equipment. States like New York, through its Environmental Facilities Corporation, have low-cost loans available from a revolving fund to help finance the cost of adding pollution control measures. Also, facilities located in certain targeted areas may qualify for other incentive programs, such as New York's Empire Zone program and similar incentive in other state. Various State and Local governments often have Industrial Development Authorities that provide financial mechanisms for lower cost loans and local property tax advantages.

For example, the conversion in Bethlehem NY of the boiler-fired, once-through cooled 400 MW Albany Steam Station to the re-powered combined-cycle, closed-cycle cooled 750 MW Bethlehem Energy Center was funded by the Bethlehem Industrial Development Authority with loan and tax advantages far superior to conventional corporate bonding, greatly reducing the cost of the conversion project. See part of the financial advantage at
http://albany.bizjournals.com/albany/stories/2001/06/04/daily27.html and
http://albany.bizjournals.com/albany/stories/2002/02/11/daily16.html

The resulting Bethlehem Energy Center will produce 47% more energy with a 97+% reduction in air pollution, a 98+% reduction in water use, and a greater than 99% reduction in impingement and entrainment mortality. See http://www.state.ny.us/governor/press/year02/june10_1_02.htm. The point is that there are lower-cost financing and substantial tax advantages to plants that modernize, and EPA Must include these economic incentives in any evaluation of conversion to closed cycle cooling.

EPA Response

EPA notes that the final Phase II rule does not contain requirements to retrofit cooling towers.

The commenter claims that EPA erred in its analysis of regulatory options at proposal by not considering possible financial incentives that facilities might use to reduce the cost of installing equipment needed to comply with the 316(b) regulation. The commenter argues that financing programs such as those available from the New York Environmental Facilities Corporation would reduce the cost of installing closed-cycle recirculating cooling systems and that EPA should have accounted for such programs as part of its analysis of regulatory options.

The commenter correctly identifies that, in some instances, financing programs, such as those offered by states under EPA's Clean Water State Revolving Fund (CWSRF) and other state-level financial assistance programs, might reduce the cost of obtaining the financial capital needed for installation of environmental compliance equipment. However, EPA does not agree that the Agency should have considered the effect of such programs as part of its analysis of regulatory options and compliance technologies at proposal or for the final rule.

Financing assistance programs, such as those offered by states under the CWSRF or other programs such as the New York program cited by the Commenter, provide loans with "better than market" terms to qualifying parties for certain environmental projects. The advantages of these loans are that they carry a lower interest rate than otherwise available to the borrower from conventional sources and may offer a longer repayment schedule than conventional loans. As a result, these loans may make a capital project more affordable to the borrower. While such financing programs might conceivably reduce the cost to some parties for installation of equipment to meet 316(b) regulatory requirements, it is unlikely that such reduced cost financing would be generally available to 316(b) facilities. Key reasons include:

- Such programs are generally available only to municipal borrowers. Private parties would thus not generally be able to obtain funds from the financing assistance programs. Even when funding may be provided to private borrowers, availability of these funds is generally limited to small business or other disadvantaged parties believed to have relatively weaker access to capital than private borrowers, generally.

- Because the total funding value of these programs is limited to the amount provided by public agencies, funding from the programs is subject to rationing, and strict project criteria must be met to gain access to the funds. Candidate borrowers have no assurance of receiving financing from the programs.

Because of these limitations on access to these funding programs, EPA judges that it would not be reasonable to assume the lower cost of financing that these programs might provide to some parties for its general economic/financial analysis of 316(b) regulatory options. While these programs might be available in specific cases, this could not be modeled at a national level. However, EPA expects that those facilities that have this lower cost loan advantage available to them will take advantage of it and will take it into account in the case of a cost-to-cost test.

EPA also notes that the financial benefit conferred by these programs is likely to have little effect on the total financial burden imposed on the complying party. These programs reduce the cost of the capital funds for installing compliance technology but do not the affect the cost of the required capital outlay per se. A difference in this one element of the total cost framework is not likely to materially affect the overall economic/financial burden of regulatory compliance, which includes the capital outlay, the cost of baseline and compliance studies, permitting and monitoring costs, ongoing operating and maintenance expenses, and repermitting costs.

Finally, EPA notes that these financing programs affect only the affordability of regulatory compliance to the complying parties, and have no affect on the total cost to society of regulatory compliance. The reduction in cost of financing provided by these programs does not reduce society's cost of allocating capital resources to the compliance projects. The true societal cost of capital remains unchanged.

Performance standards

EPA's proposed rule does not meet the requirement "that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact" as required by CWA section 316(b).

The 60-90% reductions in entrainment and the 80-95% reduction in impingement mortality are ranges in name only, in reality they are meaningless. As a practical fact, the bottom end of the range (the minimum reduction number) will be the only standard that permittees will have to meet.

There obviously is no penalty for exceeding 90% reduction in entrainment or a 95% reduction in impingement, so these upper numbers are in fact meaningless. So EPA's de facto standard is only a minimum of 60% reduction in entrainment a minimum 80% reduction in impingement mortality. This is not Best Technology Available. EPA stated on page FR 17142 that closed-cycle, recirculating cooling can reduce impingement and entrainment mortality by 98%. Thus EPA's proposed performance standard underachieves BTA by 38% for entrainment and 18% for impingement mortality just on the basis of capacity, before factoring in location, design, and construction.

Thus, EPA is proposing a standard of 60% entrainment and 80% impingement mortality reduction from a "worst technology available" calculation baseline shoreline intake. That is, EPA is in effect proposing a performance standard of "somewhat better than the worst technology available" which is a far cry from the "best technology available for minimizing adverse environmental impact" required under the law. EPA compounds this inadequacy by proposing "special dispensation" for intakes on artificial canals that may perform worse than the hypothetical baseline. They further dilute this bad proposed standard by giving credit for unproven and out-of-kind "restoration" efforts, whether successful or not. Thus, under EPA's proposed rule, reductions will be less than the poor 60% entrainment and 80% impingement mortality nominally proposed. This is unacceptable when optimizing just one factor, capacity, could achieve a 98% reduction of all species, irrespective of whether the species sensitive or robust, or in low or high populations that year.

But the plain language of CWA section 316(b) require the not just the capacity, but the location, design, construction, and capacity reflect the best technology available for minimizing adverse environmental impact. That is, the location and design and construction and capacity each reflect the best technology available. The word "reflect" means "to manifest as a result of one's actions" or "to realize" which means "to bring into concrete existence." EPA's proposed draft rules do not minimize adverse impact from any one of these 4 factors, when they should be minimizing impact from each and every one of them.

The approach should be to require capacity restrictions (such as closed-cycle cooling) and location measures (e.g., offshore placement if most entrainables are inshore) and design measures (e.g., 2-mm spaced wedgewire screening with approach velocity under 0.5 ft/sec) and construction features (e.g. seasonally-deployed appropriately sized Gunderboom MLES or equivalent with through-filter flows below 5 gpm/sq ft and pore size less than 0.4 mm) with a total reduction of impact of 99% or greater than EPA's baseline. Real-world examples of conversion or replacement with multiple factor optimization (capacity, construction, location, and design) are Bethlehem Energy Center (PSEG) <FN 3>, Reliant Astoria Station re-powering<FN 4>, and New York Power Authority's Poletti Station replacement<FN 5> in New York, and PSEG's Linden Generating Station in New Jersey. These replacements use fuel more efficiently often 55-60% efficient fuel use versus 30-35% for the plants they replace. They produce substantially less air pollution, for example, Bethlehem Energy Center reduces SO2 emissions by 97% and NOx emissions by 98% while increasing energy production 188%. Such a positive impact can be crucial in air quality nonattainment areas, where it can free up air emission reduction credits, or ERCS, which can either be retired or used to support increased development.

EPA Response

For a discussion on EPA's authority to promulgate today's rule and the basis for this action, please see the preamble.

For a discussion on the performance standards and their applicability and implementation under today's rule, please see section VII and section IX of the preamble.

EPA disagrees that it is required under section 316(b) of the Clean Water Act to identify a Best Technology Available (BTA) for minimizing adverse environmental impact for location and design and construction and capacity. EPA believes that the statute gives EPA the discretion to identify technologies that relate to any one of these so long as the result is a technology or suite of technologies that is economically practicable and minimizes adverse environmental impact.

Subject Matter Code 7.02

Performance standards

EPA should give NO CREDIT for angled screens as they do not reduce entrainment nor impingement mortality.

The concept that credit should be awarded for angled intakes is without merit. EPA should be asking the key question, "Does it work?" For cooling water intakes with conventional screens, approach velocities of 0.5 ft/sec or less, the answer is NO. For example, at the Oswego Harbor Power (formerly Niagara Mohawk Oswego Steam Station, 1,399 MGD), Unit 6 has 2 angled screens (approximately 45°) leading to a central fish bypass, while Unit 5 has conventional screens angled 90° to the flow. Counter to intuition, Unit 6, the angled screen, has higher impingement mortality than Unit 5.

Furthermore, the concept of a "guiding flow" is a fallacy in conventional cooling water intake screens operating at common flow velocities. The "bow wave" of an approximately 1 to 3 mm wire that comprises the screen is nil. See the work of Dr. Ian Fletcher for RiverKeeper who calculated the force vectors of angled screens. (I do not have a copy.)

EPA may be getting confused by some work at hydropower intakes involving angled louvers, pressure screens like Eicher or Modular Inclined Screens (MIS), angled bar racks, or the submerged traveling screens (STS) on large dams of the Columbia River system. The velocities, forces, and structures employed by such systems are far different from the 316(b) cooling water intakes. For example, angled louvers have been used in power canals at Holyoke MA (Holyoke Canal Louver Facility at the Hadley Falls) to divert herring, shad, and salmon to a fishway. These louvers are INCHES wide, are set at a steep angle to flow (15°), are operating in velocities around 2 ft/sec to create a bow wave on each slat, have a bypass attraction flow of about 5% of canal flow. The fish bypass flow is created by gravity (head) so that there is no pump to injure fish in the bypass. The louvers in the canal create resistance to the flow, which costs a loss in hydraulic head for the hydro project that, if this was a steam-electric station, pumps would have to be overcome by the cooling water pumps. Realizing that energy increases with the square of velocity, increasing the approach velocity by pumping from 0.5 ft/sec to 2 ft/sec would take 16 times as much energy! Such velocities are not typically needed for steam-electric condenser cooling.

Pressure screens such as the Eicher screen or the MIS require a 10% bypass flow. These screens also only work at high velocity, have a 1-2 mm gap wedgewire panel set at about a 15% angle of attack to the water flow, and literally strain out organisms, which slide up the wedgewire "ramp" into the bypass pipe. These are designed for outmigrating salmon and steelhead smolts, far more rugged fish than many impingable/entrainable organisms at typical steam-electric facilities. For example, see Portland General Electric's Sullivan hydroelectric station on the Willamette River (OR). Tests of an MIS on the Hudson River at Waterford proved disappointing on outmigrating blueback herring, from injuries from belly scutes catching in the slots as they slid up the screens. Besides needing a high water velocity, the 10% fish bypass flow is also an impressive quantity of water. For example, the 2,000 MW Indian Point 2 & 3 Nuclear Generating Station uses 2,800 MGD; a 10% bypass flow would mean pumping additional 280 MGD just for the fish diversion! This is not very likely configuration for a 316(b) cooling water intake. In comparison, a 1,080 MW combined cycle plant (Athens Generating Station, original evaporative closed-cycle configuration proposal) would use 7.5 MGD maximum with oil firing.

Angled bar racks at hydro stations have had some limited success for Atlantic Salmon on small rivers, but are unproven for other species. EPRI tests on a 5 ft wide test flume with bars set at 15% angle at 1-3 ft/sec intake velocities have had some limited success. However, extrapolating from a baffled 5 ft wide test flume to a 150 ft wide intake of a 1,000 MW nuclear unit is tenuous at best, and these studies are continuing.

Thus, no credit should be given for angled racks, as anything likely on a 316(b) cooling water intake will not provide any additional protection. The only exception should be where a site-specific study has demonstrated effectiveness at that specific intake site.

EPA Response

EPA notes that with the exception of compliance alternatives 1 and 4, no technology is pre-approved to satisfy the requirements of today's rule. EPA agrees with the commenter that the deployment of any one technology (in this case angled screens) will not automatically correspond to a decrease in impingement or entrainment.

Some data have shown that angled screens can be an effective means to reduce overall rates of impingement or entrainment, but, as with all technologies, results may vary from one site to another based on many contributing factors (see Chapter 3 of the Technology Development Document). Any design and construction technology, operational measure, or restoration measure selected to meet the performance standards in today's rule must be demonstrated to achieve the desired level of performance in order to be acceptable to the Director.

EPA appreciates the distribution of any data that might lead to increased understanding of the effectiveness of all technologies, including angled screens. In keeping with the preferred flexibility of today's rule, however, EPA has not precluded any technology from among the options available to Phase II facilities in meeting the performance standards.

Organization N/A

EPA should gibe NO CREDIT simply for placing an intake in deeper water as it does not assure lesser impingement or entrainment impacts.

EPA's proposal to give carte blanche credit for reducing impingement mortality and entrainment by simply locating an intake in deeper water is an unsupported assumption at best, and not true in all cases. The impacts depend on the ecology of the specific waterbody. For example, in Cayuga Lake (an oligotrophic finger lake in central New York State) placing a cooling water intake in relatively shallow water entrains and kills smelt and alewife, as at the AES Cayuga Station (formerly NYSEG Milliken Station). However, placing a cooling water intake in deeper water still entrains these species, but additionally entrains a critically important forage organism the mysid shrimp Mysis relicta, worsening the impact. (See studies performed for Cornell University's lake source cooling water intake.)

Placing an intake in the deep anoxic waters of some reservoirs may avoid entraining fish, but creates an anoxic discharge that may contain significant biochemical oxygen demand, and can violate dissolved oxygen standards in the receiving waters. (e.g. the discharge from Swinging Bridge Reservoir often violates dissolved oxygen standards in the receiving water, the Mongaup River when the intake water is drawn from the anoxic zone.) Thus, no credit should be simply given because an intake is deeper than the surface. Any consideration for credit should be based on site-specific studies and demonstrated effectiveness at that specific intake site.

EPA Response

EPA notes that with the exception of compliance alternatives 1 and 4, no technology is pre-approved to satisfy the requirements of today's rule. EPA agrees with the commenter that the mere location of an intake structure (in this case deeper, offshore waters) will not automatically correspond to a decrease in impingement or entrainment.

Some data have shown that offshore intakes located in deeper, less productive waters can be a means to reduce overall rates of impingement or entrainment, but, as with all technologies, results may vary from one site to another based on many contributing factors. Any design and construction technology, operational measure, or restoration measure selected to meet the performance standards in today's rule must be demonstrated to achieve the desired level of performance in order to be acceptable to the Director.

EPA appreciates the distribution of any data that might lead to increased understanding of the effectiveness of all technologies, including offshore intakes. In keeping with the preferred flexibility of today's rule, however, EPA has not precluded any technology from among the options available to Phase II facilities in meeting the performance standards.

Subject Matter Code 7.02

Performance standards

If EPA persists in using a "calculation baseline" cooling water intake, a of 3/8 in mesh traveling screen is an appropriate convention.

It is a fact that many old, harmful intakes have 3/8 inch screen, so there is a logic to support using 3/8 inch screen as a convention in EPA's baseline calculation. However the problem with the approach remains, instead of designing the best technology available EPA using a baseline of the Worst Technology Around, which does not satisfy the requirements of the law. If EPA insists on pursuing this course, then 3/8 inch screen is an appropriate convention for the baseline calculation.

EPA Response

EPA has modified the definition of calculation baseline to include 3/8-inch mesh as part of the baseline configuration.

Determination of compliance

It is critical that EPA's "Calculation Baseline" of operational measures reflect actual efficient flows, including reduced flows in colder seasons of the year that are standard operating practice in much of the US.

Baseline practices and procedures are those the facility would maintain in the absence of any specific measures for reducing impingement mortality and entrainment. This is very important quantification that must be made. Otherwise, once-through facilities will claim "bogus" reduction credits by claiming a baseline of running all pumps at 100% of capacity all the time. In reality, many plants operate at efficient flows to optimize fuel use and power production through the seasons of the year. That is, in the absence of any impingement/entrainment reduction efforts, powerplants in more northerly latitudes usually use a lower volume/minute of cooling water in the winter (when the water temperature is coldest), the highest flows in summer with the warmest water intake temperatures, and intermediate volumes/minute in the spring and fall. Permits will often permit a higher ΔT in different seasons, as water temperature drops further below the maximum lethal temperature of many organisms. The plants will use less than the maximum volume of intake water to save energy running unneeded pumps, and to avoid the problems associated with "over chilling" the steam/water condensate in the condenser. Consequences of over-chilling include:

- Making the condensate too cold, requiring more fuel to boil it again, reducing plant efficiency.

- Creating excessive vacuum in the condenser, which can cause premature leaks or failure, and

- Creating too great a vacuum (too low a backpressure) across the steam turbine, causing excessive steam velocity through the turbine. This is a problem because the steam can reach supersonic speeds, causing excessive erosion of turbine blades and shortening their useful life.

Thus EPA should require permittees to provide the baseline provide an honest profile of water use throughout the days of the year. These should preferably coupled with actual operation records, to show the volume of water pumped at different intake water temperatures or through the different months.

EPA Response

EPA has clarified its definition of calculation baseline in today's final rule (see §125.93). For additional explanation of EPA's definition of calculation baseline, please refer to EPA's response to comment 316bEFR.034.013.

Determination of compliance

EPA should not give "special dispensation" to facilities on canals or bays or other areas where the actual intake has higher impingement/entrainment than the "calculation baseline intake" on an open shoreline. (Page FR 13581)

EPA appears to have completely misplaced its priorities and thinking if it is looking to give an adjustment or "finagle factor" to facilities on canals (bays, constructed waterways) if they kill more fish than the hypothetical "baseline intake." If any facility is killing more fish, it needs to do more to minimize its impacts!! EPA's proposed "baseline intake" is already a really bad intake that is far from BTA; if the intake on the canal is performing worse than such a really bad baseline intake, it needs to be fixed. A plain reading of 316(b) states that the "... LOCATION, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact." If the current placement of the intake in the canal or bay causes killing of more fish, it is absurd to give a "special dispensation," it is EPA's duty under the law to remedy the location problem. No adjustment should be given if the location of an existing intake results in higher mortality than the calculated "shoreline intake baseline."

EPA Response

In today's final rule, EPA has accounted for situations where a facility may have much higher impingement mortality and entrainment rates than would be seen in the calculation baseline. As specified in the definition of calculation baseline (§ 125.93), EPA did not take the approach to give facilities credit when their intakes were located on a canal rather than on an open shoreline. EPA has tried to set a baseline not as a worst-case scenario, but rather at a baseline level, expecting that some facilities may have much lower impingement mortality and entrainment rates and some may have higher rates. EPA understands that aquatic organisms may tend to concentrate in canals, and has not given facilities the ability to take "credit" for having higher impingement mortality and entrainment rates relative to the calculation baseline. Instead, the calculation baseline would demonstrate that the impingement mortality and entrainment rates are elevated at that intake, and the facility would be required to "make up for the difference" between the actual configuration and the configuration described in the definition of calculation baseline.

Subject Matter Code 21.04

Determination of compliance

EPA should adopt The As-built approach with sampling in front of the existing intake for entrainment, but actual impingement counts on screens for impingement, and then take reductions against these numbers.

This seems like a more reasonable approach for entrainment of planktonic organisms that could not avoid the sampling gear. Gear like the pump sampler used in NY's Hudson River studies (4 inch pipe drawing water in the water column drawing water into a plankton net suspended in a barrel, with water being drawn into the barrel by a 4 inch trash pump whose intake is located downstream of the plankton net.)

For impingement, however, actual impingement off the screen collected from the screen washings should be used. No conventional sampling gear like nets or trawls used to estimate numbers will perform similar to a real intake, and sampling gear avoidance would make such results inaccurate and probably biased low.

Actual collections of impingement off the screens should be benchmarked to establish the percentage of impingeable-sized organisms actually recovered. That is, known numbers of marked dead organisms, covering a range of impingable sizes in sufficient numbers to assure statistical reliability, should be released upstream of the intake at a point where the current will carry all such fish to the intake screens. This should be done with traveling screens operating as well as not operating, as the hinge areas between the screens are one common place where fish can pass by the screen and otherwise not be counted. The number recovered off the screen by size class should be compared to the numbers released, and the resulting recovery efficiency should be used to expand for gear inefficiency.

EPA Response

With respect to the As-Built approach, see the preamble to the final rule. EPA has not specified in today's final rule how the sampling should be performed to determine the calculation baseline. The sampling methodology will be proposed by the permit applicant for review and approval by the Director.

Subject Matter Code 21.01.04

Comprehensive demonstration study (7 parts)

EPA SHOULD NOT accept data on impingement/entrainment from nearby facilities or waters as a substitute for sampling at the actual plant site as it is not comparable. Even very close plants have very different impingement/entrainment characteristics.

Each plant must be required to sample individually. Data from other sources is unacceptable for accurately quantify the impact of an individual plant, and to reduce this impact to meet Best Technology Available levels.

Intakes at even very close plants can have very different impacts. For example, the intakes of Roseton Station and Danskammer Station are located on the same west side of the Hudson River about 1,000 yards apart. However, Danskammer entrains roughly twice as many organisms per unit volume of water as Roseton, and their impingement characteristics are also quite different. If two intakes 1,000 yards apart can have such different results it makes no sense for EPA to accept data from other stations or waterbodies that are further apart and more different! Each plant must be required to sample individually and no substitutions should be accepted.

EPA Response

EPA disagrees that facilities should never be allowed to use existing data from facilities on the same waterbody. However, it is the burden of the facility to demonstrate that the data submitted is representative of the current physical and biological conditions in the vicinity of the cooling water intake structures of that facility, and to what extent the data is representative. Furthermore, the facility must be able to demonstrate that the data were collected using appropriate quality assurance/quality control procedures. EPA believes that with strict controls in place, that only facilities using truly representative data from other facilities will succeed in having that data approved by the Director.

Monitoring requirements

EPA should incorporate the ALL SPECIES in determining the percent reduction.

A “capacity” reduction, such as going from once-through to closed-cycle cooling would reduce impacts to ALL SPECIES, and that is the standard by which all other reductions should be judged. Furthermore, each individual collected by sampling should be identified to species and life stage. Where numbers are large, standard statistical sampling techniques should be used to assure numbers are estimated to a reliable level of precision. Species should not be lumped into a total combined count, nor weight, nor marginalized even further into a “dry weight.” Does a 5-kg carp (an exotic species) have the same ecological value as 5,000 1-g young-of-year shortnose sturgeon (an Endangered Species Act threatened species)? Or, say the millions of bay anchovy eggs that weigh a total of 5 kg, and which would have hatched to assure a forage base for the contemporaneous striped bass young-of-year age class production? The answer is that ALL are important, and all should be evaluated individually by identifying the impacts to ALL SPECIES and then taking action to reduce all these impacts.

Monitoring requirements

EPA should not use biomass from an outfall as an indicator of a facility's entrainment impact, it will grossly underestimate impact.

I take severe issue with EPA's proposal to measure biomass from an outfall as the measure of a facility's impact. I believe this would grossly under-represent the impact of the plant. Fish eggs and larvae are fragile, that is why they die going through once-through cooling systems. Does EPA really expect to be able to find and accurately quantify 100% of the biomass after it has been strained through an intake screen, abraded by passage through pipes, macerated by circulating water pump impellers, subjected to cavitation and pressure shear, cooked and cauterized by passage through a steam condenser, subjected to chlorine or other cooling solutions, and then discharged? Will it be of a size that won't be extruded through say ½ mm (505 micron) plankton nets? Yes there will be some recognizable fish parts, but there is a lot that would be reduced to "slime and eyeballs." This is recipe for underestimating impact and should not be used.

EPA Response

Subject Matter Code 10.01.02.01

EPA methods: age 1 equiv, yield, prod foregone

EPA's "Representative Species Approach" is fatally flawed as proposed.

The major flaw is that the permittee is proposing the representative species, which creates a "fox guarding the chicken coop" dynamic. That is, it is very easy to omit a species that may be suffering great impact to make the results more favorable to the permittee. EPA is only suggesting the permittee consult with the Director and Federal, State, and Tribal fish and wildlife management agencies. This completely inappropriate, these fish and wildlife management agencies should be the ones, along with the Director, identifying the species. The fish and wildlife resources belong to the People of the State or Tribe as a public trust resource, and the management of those resources is generally under the stewardship of the state or tribal fish and wildlife agency, with additional protections and treaty responsibilities of the Federal government under the stewardship of the US Fish and Wildlife Service and the National Marine Fisheries Service. The list should be the species identified by all these agencies to the Director, with the Director having the option of adding additional important species.

The 8 characteristics for "critical aquatic organism" contained in the 1977 guidance (DCN 4-0006) is still appropriate guidance to the Director and affected agencies. If the fish and wildlife agencies fail to comment, then the Director should propose the list of species based on the 8 characteristics for "critical aquatic organisms." The number of species should not be arbitrarily limited to 10-15; there may be good reason to have more.

In addition, the additional proposed language to change criteria number 8 as indicated on NODA page 13583 should be REJECTED. These public trust resources should not be subject to the potential for self-serving interest on the part of the permittee.

EPA Response

EPA agrees that facilities should provide accurate monitoring of species impinged and entrained, that the Director should be able to require additional information, and that other agencies (federal, state, and tribal) and the public should be included in the process. The Agency also agrees that the number of species subject to detailed analyses should not be a pre-determined number, but should depend on the species vulnerable to I&E at a given site.

Subject Matter Code 21.04

Determination of compliance

EPA should require counting ALL organisms, allowing discarding moribund or dead organisms that wash up on screens is an unacceptable bias and opportunity for bias or fraud.

Allowing removal of moribund or dead organisms from the screen counts is an unacceptable creates a loophole for fraudulent counts. Technicians counting the organisms should have the simple instructions to count ALL the organisms on the screen of a once-through cooling system. They should not have to divine how or when it died. If intake capacity was reduced by 95% or more by converting to closed-cycle cooling, the number of dead and moribund organisms impinged would be reduced by 95% or more, just like the live organisms. EPA is again further weakening its already weak proposed 80-95% impingement mortality “standard” unnecessarily and illogically.

Rather than letting individual organisms be removed arbitrarily as moribund or dead, the following procedure is recommended for doing counts of impinged fish over a specified sampling time period. First, the screens should be cycled and cleaned and any fish (alive or dead) should be removed from the collection basket. Then the timed collection period (day, week, hours, whatever) should commence, and all fish caught on the screens should be counted between the beginning and end of the collection period counted. This raw count should be expanded by the collection efficiency factor for the size organisms captured.

EPA Response

In today’s final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. It should be emphasized that the Director will have to approve any proposed methods for handling naturally dead or moribund organisms. Please see EPA’s response to comment 316bEFR.306.116.

Subject Matter Code 21.03

Monitoring requirements

EPA's proposal to quantify biomass instead of identifying counts by species and life stage does not meet CWA Section 101 goals of restoring biological integrity of the Nation's waters.

EPA's fixation on quantifying a biomass of organisms is especially troubling, as it trivializes and marginalizes the importance of these organisms as though they were a stick of driftwood. We remind EPA that their charge under the Clean Water Act is to restore the chemical, physical, and biological integrity of the Nation's waters. Reducing entrainment to a dry mass or wet weight does not adequately address the biological integrity of the ecosystem supported by the waterway (the biological integrity of the waters). Identifying organisms by species, life stage, and number begins to provide the information needed for assessing that biological integrity. All total biomass or total gross count irrespective of species should be summarily rejected as inadequate for evaluating whether a technology has minimized adverse environmental effects, as required under the plain language of 316(b).

Subject Matter Code 21.03

Monitoring requirements

Author Name William Sarbello

Organization N/A

EPA should not use an Averaging period in meeting reduction targets. Mortality should be summed over a whole year and the target must be met each and every year.

Averaging periods should not be used, the level of reduction should be required to be met or exceeded every year. Again, the yardstick should be closed-cycle cooling, which reduces the numbers of organisms killed by entrainment and impingement by a very high (95%+) percentage each and every year. This is irrespective of whether densities are high or low. EPA should expect nothing less from any other blend of technologies. The reduction percentage should be treated like any other annual standard. The disadvantage of choosing a multi-year averaging is that exceedances could continue for years before enforcement/corrective action could be taken, and then it would be too late. Reduction rate be determined and reported on a yearly basis.

Subject Matter Code 21.01.04

Comprehensive demonstration study (7 parts)

EPA should require "Comprehensive Demonstration Study" every permit cycle, as waters and biological communities continue to improve thanks to Clean Water Act caused improvements.

Evaluation studies should be done EVERY PERMIT CYCLE for facilities that have not converted to closed cycle cooling. The waters of the US are constantly improving as other dischargers do their fair share to clean up harm to the nation's waters. In the New York harbor area there have been tremendous increases in the numbers of species and numbers of organisms impinged and entrained at the Ravenswood, Astoria, and Polletti power plants. Species compositions on the Great Lakes have changed through recent times, with intentional and unintentional species introductions. Dramatic changes in the species impacted have been seen through time at the Fitzpatrick and Nine Mile Point 1 Nuclear Generating Stations on Lake Ontario. Furthermore, impact reduction technology is constantly improving, and effectiveness can be quite different for different species. For example, sound deterrent at the Fitzpatrick Nuclear Generating Station intake has been very effective for reducing alewife impingement/entrainment. However, during declines in alewife population, a greater proportion of the entrainment has been sticklebacks, which are not repelled by the sound deterrent. Thus, evaluation studies and evaluation this should be performed every permit cycle at a minimum.

A permittee that is concerned that additional costs of periodic studies to quantify their negative impact should consider that converting to closed-cycle cooling or equivalent levels of protection will result in long-term savings and certainty, as well as true meeting the Best Technology Available standard.

EPA Response

EPA agrees that the Comprehensive Demonstration Study should be required with every permit renewal cycle unless a facility demonstrates that conditions at that facility have not changed. Please see EPA's response to comment 316bEFR041.126. For an explanation of monitoring requirements, please see the preamble to today's rule and EPA's response to comment 316bEFR.307.027.

Organization N/A

Subject Matter Code 21.03

Monitoring requirements

Assertions that "the waters have not changed" should not be accepted, weaknesses in robustness of statistical tests make such hypothesis testing unreliable.

EPA should not accept the assertion that "conditions have not changed" in the source water body. Indeed, power plant monitoring experience in New York State in a wide variety of waterbodies (Finger Lakes, Great Lakes, estuaries, ocean harbor and sounds) suggests quite the opposite, that biological communities continue to change through time. Statistical tests are not neat and simple, there can be many ways to create a Type 2 or Beta error–accepting the null hypothesis of no change when there actually was change. Samples with a very large variance, like impingement/entrainment sampling data, will be more susceptible to a Type 2 error. Therefore, EPA should require sampling every permit cycle, and should consider monitoring every year.

EPA Response

Please see the preamble and EPA's response to comment 316bEFR.034.005 for EPA's position on conducting a Comprehensive Demonstration Study with each permit cycle.

Performance standards

General Comment

In the NODA EPA states that it has compiled a Technology Efficacy Database which is to serve as a compilation of data that supports the determination that the proposed performance standards are best technology available (page 13538). EPA goes on to state that based on a preliminary review of the available data, it continues to believe that the proposed performance standards are achievable (page 13539). Since the performance standards have yet to be thoroughly defined, i.e. representative species or all species, enumeration or biomass, etc. it is difficult to understand how EPA can state that the evaluated technologies will meet the standards. We believe, as does EPA, that the technologies evaluated do have the potential to meet the performance standards depending upon site-specific factors. We also believe that the projected performance of the technologies is promising, but projected performance does not equate to a reasonable certainty of compliance with a regulatory standard. This issue is significant when viewed from the perspective of permittees who will be held liable for failure to comply with a percent reduction performance standard when the performance of the technologies is uncertain. We urge EPA to structure the regulation so that the performance standards are targets or BMPs and not a directly enforceable standard.

EPA Response

EPA has discussed the range of technologies used to establish the performance standards (see Sections VII.B.2 and B.3 of the preamble to today's rule). Available data indicate that, when considered as a suite of technologies, barrier, and fish handling technologies are available on a national basis for use by Phase II existing facilities. These technologies exist and are in use at various Phase II facilities and, thus, EPA considers them collectively technologically achievable. For example, currently, 14 percent of Phase II existing facilities potentially subject to this final rule already have a closed-cycle recirculating cooling water system. In addition, 50 percent of the remaining potentially regulated facilities have some other technology in place that reduces impingement or entrainment. Thirty-three percent of these facilities have fish handling or return systems that reduce the mortality of impinged organisms. The fact that these technologies are collectively available means that one or more technologies within the suite is available to each Phase II facility. Economic practicability is discussed in Sections VII.B and XI.B of this preamble. See also response to comment 316bEFR.041.701.

EPA finds that the design and construction technologies necessary to meet the requirements are commercially available and economically practicable, because facilities can and have installed many of these technologies years after a facility began operation. Typically, additional design and construction technologies such as fine mesh screens, wedgewire screens, fish handling and return systems, and aquatic filter fabric barrier systems can be installed during a scheduled outage (operational shutdown).

Site-Specific Cost-Cost Comparison

Page 13525, EPA requests comments on the revised costing methodology and its relationship to the proposed site-specific cost-cost comparisons. We support the site-specific cost-cost comparison option as well as EPA's efforts in being as accurate as possible in determining financial impacts on affected facilities. In the April 9, 2002 proposal, EPA presented the site-specific cost-cost comparison option and outlined in a Technical Development Document, the costs that EPA considered for these purposes. This presented a straightforward approach for use by a permittee in evaluating the cost-cost option. With the new costing methodology the previous straightforward approach appears to be superseded. We ask that EPA present the new costs in a straightforward manner as possible similar to the April 9, 2002 concept.

EPA Response

Subject Matter Code 7.04

Streamlined Technology Option

Streamlined Technology Option

Page 13539, EPA invites comments on two variations of a streamlined compliance option that would reduce the information collection burden imposed on permit applicants. We support EPA in their efforts for a streamlined approach and ask that the following comments be considered.

Variation One - EPA would evaluate the effectiveness of specific technologies under specific circumstances. If, based on such an assessment, the Agency identifies technologies that are sufficiently protective and for which applicability conditions can be defined, EPA would promulgate regulations that allow for their use as a means of complying with Phase II section 316(b) requirements. Such a technology would be used to treat the entire cooling water intake flow and would not be used in combination with restoration measures to meet the performance standards. Monitoring would be required as necessary to verify that the technology is in fact achieving an acceptable level of performance.

This concept is sound but can be implemented in a manner that has a better probability of success. First, it is doubtful that approval of a technology by regulation is practical or expedient. Just the process of promulgating the regulation in the environment of 316(b) will be difficult as well as burdensome on the regulatory agencies. A better approach might be to approve the technology by issuance of a Technical Support Document or similar technical documentation. Second, if a permittee desires to include restoration in addition to an approved technology, then that should be acceptable. The permittee could simply get credit for Best Technology Available (BTA) for the portion of intake flow that is impacted by the preapproved technology. This credit could be allowed without the burden of the Comprehensive Demonstration Study. The remaining portion of flow could be addressed through restoration measures that are otherwise supported. Third, the monitoring should be conducted for informational purposes, not compliance purposes. If the technology has been established as being BTA then the permittee should not be liable if he has properly installed and maintained the technology but monitoring demonstrates that the performance standard percentages are not met.

EPA Response

Please refer to EPA's response to comment 316bEFR.307.027. See also the preamble to the final rule regarding the availability of restoration technologies. EPA also authorizes the use of a Technology Installation and Operations Plan for demonstrating compliance, subject to the Director's approval.

Comment ID 316bEFR.344.004

Author Name Charles R. Wakild

Organization Progress Energy

Subject Matter Code 7.04

Streamlined Technology Option

Variation Two - The Phase II regulations would establish the criteria and process for approving cooling water intake structure control technologies, but would allow the approval process to be carried out by the Director. The Director's draft determinations would be subject to a public participation process. After the public participation process the Director would then modify the State's implementing regulations to establish the technology as BTA for all eligible facilities.

The implementation process should be set up on a state basis similar to the process for a general NPDES permit. The approval criteria would be subject to the public participation process. Once the approval criteria are approved, the regulatory agency could then issue approval certificates (or denials) to the eligible applicants. As with the first variation, monitoring should be conducted for informational purposes, not compliance purposes. Again, if the technology has been established as being BTA then the permittee should not be liable if he has properly installed and maintained the technology but monitoring demonstrates that the performance standard percentages are not met.

EPA could possibly implement both variations. If so it should follow the above recommendations.

Any regulatory language in proposed §125.94(a)(4) and §125.95(c) should reflect the above concepts especially that monitoring should be for information purposes and not as compliance requirements. If a permittee is required to monitor a preapproved technology for compliance with the performance standards then the "streamlined" compliance option may be essentially undermined because most permittees will not install a preapproved technology if they are liable for its performance (or lack of performance).

EPA Response

In response to the comment that monitoring should be used only as a means of gathering data and not to evaluate compliance, EPA disagrees. For EPA's position on monitoring, please refer to EPA's response to comment 316bEFR.307.027. For EPA's response to the assertion that most permittees will not install a preapproved technology if they are liable for its performance, please refer to EPA's response to comment 316bEFR.317.009.

RFC: Performance/effectiveness of restoration

Restoration

Page 13542, EPA is considering requiring the following practices during the development of restoration projects:

- documentation of sources and magnitude of uncertainty in expected restoration project performance

- creation and implementation of an adaptive management plan

- use of an independent peer review to evaluate restoration proposals

Documentation of Uncertainty - Uncertainty in project performance is related to natural variations in both the restoration project and in the ecosystem that is affected by the restoration project. It is recognized that this uncertainty exists and it should be taken into account in determining the feasibility of a project. Prescribing how this uncertainty must be addressed is regulatory overkill and adds needless burden to the process.

EPA Response

EPA believes there are uncertainties associated with the design, implementation, performance and assessment of restoration measures. For a discussion of these uncertainties, see EPA's response to comment 316bEFR.206.055. The use of peer review, adaptive management, and uncertainty analysis is intended to help reduce uncertainties associated with restoration measures and enhance their overall productivity (see EPA's responses to comments 316bEFR.307.047 and 316bEFR.311.022).

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

EPA believes the requirements for restoration measures provide permitting authorities and permit applicants with flexibility. However, any restoration measure must meet all of the requirements described in the final rule.

Comment ID 316bEFR.344.006

RFC: Performance/effectiveness of restoration

Adaptive Management Plan

These plans serve a purpose, however they have the potential to elevate some restoration measures to intensive, expensive efforts that can rapidly reach a point of diminishing return. This could make effective restoration efforts less attractive and cause permittees to forego restoration efforts needlessly. We believe that if significant progress is made towards the goals of restoration, the permittee should be allowed to consider the efforts successful without further adaptive measures.

EPA Response

EPA believes there are uncertainties associated with the design, implementation, performance and assessment of restoration measures. For a discussion of these uncertainties, see EPA's response to comment 316bEFR.206.055. The use of adaptive management is intended to help reduce uncertainties associated with restoration measures and enhance their overall productivity (see EPA's responses to comments 316bEFR.307.047 and 316bEFR.311.022).

For a discussion of the limits on the resources expended on restoration measures, see EPA's response to comment 316bEFR.312.006.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

EPA believes the requirements for restoration measures provide permitting authorities and permit applicants with flexibility. However, any restoration measure must meet all of the requirements described in the final rule.

RFC: Performance/effectiveness of restoration

Peer Review

EPA's discussion of the Independent Peer Review process is somewhat ambiguous. From the discussion it appears that EPA is proposing to require permittees to consult with federal and state resource agencies and select a panel of multi-disciplinary private individuals that would review the restoration project plan prior to submittal. Selection of reviewers and alternates, coordination of review timeframes and logistics, consultation with federal and state resources agencies, all add expense and delay to the Comprehensive Demonstration Study with the benefits being questionable.

As a general comment, the addition of these practices for restoration projects will add additional time and effort in the process of compiling the Comprehensive Demonstration Study. EPA should consider this aspect when determining the overall time needed to prepare the Study.

EPA Response

EPA believes there are uncertainties associated with the design, implementation, performance and assessment of restoration measures. For a discussion of these uncertainties, see EPA's response to comment 316bEFR.206.055. The use of peer review is intended to help reduce uncertainties associated with restoration measures and enhance their overall productivity (see EPA's responses to comments 316bEFR.307.047 and 316bEFR.311.022). For additional discussion of the use of peer review, see EPA's response to comment 316bEFR.312.006.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

EPA believes the requirements for restoration measures provide permitting authorities and permit applicants with flexibility. However, any restoration measure must meet all of the requirements described in the final rule.

Subject Matter Code 21.04

Determination of compliance

A general comment - EPA defines the baseline calculation as an estimate of impingement mortality and entrainment. EPA also asks for comments on how to set a consistent and reproducible baseline. As stated in previous comments on the proposed regulation the biological variability on hourly, daily, monthly, seasonal, yearly and generational bases makes the baseline indeed an estimate. This estimate is also bounded by large confidence intervals. It seems irrational to make this gross estimate part of a more precise ratio (performance standard) that permittees are to be held legally liable to comply with in all circumstances. A more rational approach in dealing with this type of variability is to define the performance not as enforceable standards but as goals or BMPs.

EPA Response

EPA has provided a tremendous amount of flexibility in today's final rule for meeting 316(b) requirements, including 5 compliance alternatives (one of which is site-specific), and the option to demonstrate compliance with a Technology Installation and Operation Plan rather than with numeric performance standards (see final rule preamble section IX). Furthermore, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003.

Determination of compliance

Author Name Charles R. Wakild

Organization Progress Energy

Evaluating Compliance

EPA asks for comments on two approaches for determining compliance with the performance standards. These approaches are 1) an all species approach and 2) representative species approach. Additionally compliance may be determined by either enumeration or biomass.

We believe that a permittee should have the option of choosing between the two approaches of all species or representative species. That way a sound, site-specific approach that captures the highest net benefits can be implemented. If forced to choose between the two options, we believe a representative species approach is the better approach. Using a representative species approach provides insight into the impacts on the species that are the most important for the designated use of the waterbody which is what it is all about. It should be noted here that according to EPA's own regulations the setting of water quality standards and the determination of beneficial uses should take into account the use of the waterbody for industrial purposes (e.g. cooling water) as well as for protection and propagation of fish, and shellfish. A balance needs to be achieved between the two uses.

Count verses biomass - if either is acceptable the permittee should have the option of doing either or both.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Subject Matter Code 3.06.01

Withdrawal threshold of 50 MGD

Author Name Charles R. Wakild

Organization Progress Energy

Emergency Service Water Intakes

We recommend that EPA distinguish between primary cooling water intakes and emergency service water intakes at nuclear facilities. For example, at a certain facility, the primary cooling water system employs a natural draft wet recirculating cooling tower. The facility also employs an emergency service water system with an intake which normally operates a nominal amount of time to ensure that the system is in working order. However, this emergency intake has a design capacity greater than 50 MGD. We believe that an intake, regardless of design flow, that is used in this mode of testing for reliability should be excluded from the 316(b) regulation.

EPA Response

Permit applications/implementation schedule

Compliance Timelines

EPA requested comment on the Concentrated Animal Feeding Operations (CAFO) approach as well as other options for establishing an appropriate compliance timeline. The CAFO approach (disregarding the NPDES administrative requirements) requires that all CAFO facilities develop and implement a nutrient management plan by December 31, 2006 and that large CAFO facilities comply with the effluent guideline requirement (land application area) by the same date (68 Fed. Reg. 7184). Since the rule was published February 12, 2003, this provides a compliance time of almost 4 years.

In regard to a compliance timeline, some of the issues that are critical for us as a company are 1) being able to forecast necessary expenses for budgeting purposes, 2) being able to forecast needs for personnel resource allocation planning and scheduling, and 3) being able to coordinate potential intake modification construction with scheduled outages. These issues are critical not only in business practices but in successful compliance with the regulation. Consequently, EPA must structure the compliance timeline so that industry has adequate time to implement the above activities. A worst-case timeline for compliance with the regulation may take up to 5 years when regulatory agency approval time is factored in the process. Recognizing these necessities, we believe the CAFO approach with its 4 year timeframe is inadequate for successful compliance with the 316(b) rule due to the possible 4-5 year timeframe needed for studies/construction and the potential lack of adequate consulting/field resources needed if all industry crowds in compliance activities in a 4 year period. Consequently, the CAFO approach is not appropriate for 316(b) efforts unless the final compliance date is perhaps 2012.

In more recent effluent guideline activities:

- Coal Mining Category, Final Rule, January 23, 2002 (67 Fed. Reg. 3370)

- Iron and Steel Manufacturing Category, Final Rule, Oct. 17, 2002 (67 Fed. Reg. 64216)

- Centralized Waste Treatment Category, Final Rule, Dec. 22, 2000 (65 Fed. Reg. 81242)

- Pulp, Paper, and Paperboard Category, Final Rule, April 15, 1998, (63 Fed. Reg. 18505)

EPA has simply stated that existing dischargers must comply with limitations as soon as such requirements are imposed in their NPDES permits. Without becoming overly complicated and unrealistic with permitting reissuance scheduling, determining advance times for application development etc., EPA should follow an approach that is similar to the one listed above. This approach should allow the permittee and the permitting agency to work out a permitting method that adequately addresses compliance for existing facilities. This method would have the phase II regulations become effective at the end of a period of time (with interim milestones) that is decided upon by the permittee and the permitting agency. This would allow both the permittee and the permitting agencies to determine resource needs and scheduling without causing the permittee to be out of compliance as soon as the permit is issued.

Streamlined Technology Option

Performance Standards (VII)

Streamlined Technology Option for Certain Locations (B.) - The Comprehensive Demonstration Study (CDS) requirements outlined in the proposed rule are extensive, as well as time and labor intensive. Several of the CDS components require more than one year of preparation time and become especially problematic when preparing them for multiple facilities concurrently.

Allowing a facility to streamline the CDS process by choosing to install one of a group of specified technologies would decrease the burden to applicants and permit writers significantly. The two variations described in the NODA are a step in the right direction and be incorporated into the rule as options. The first variation would allow EPA to determine the effectiveness of impingement and/or entrainment reductions for technologies specified in the proposed rule, EPA would also identify conditions where the technologies would be expected to yield the prescribed results. Subsequently, a facility would be required to demonstrate the conditions will be met at the site and monitor the results following the implementation of the technology.

The second variation is especially beneficial because it allows the permitting agency, with oversight from EPA, to review and approve technologies for the streamlined approach. The final rule would identify control technology criteria required for approval and describe the process facilities would be required to follow in order to have a technology approved for the streamlined CDS process.

EPA Response

EPA believes that it has enabled facilities to potentially install one of a group of specified technologies under the Approved Design and Construction Technology option. Please see EPA' response to comment 316bEFR.333.004 for additional details.

RFC: Appropriateness of "significantly greater"

Cost Tests (VIII)

The proposed rule allows a facility to choose a site-specific determination if the costs are shown to be "significantly greater than" the costs or benefits determined by EPA. A definition of what constitutes "significant" was not provided. Even though this term is not precise, attaching a quantitative definition would restrict flexibility. Flexibility is essential; therefore Entergy requests a quantitative definition not be developed.

The EPA costs and benefits to be used by facilities when preparing their cost-cost or cost-benefit analyses and corresponding methodologies should be clearly defined so that accurate comparisons can be made. Facilities should also be allowed to incorporate into their cost-cost and cost-benefit comparisons any costs incurred to implement 316(b) measures/technologies prior to the promulgation of the final rule.

EPA Response

See response to 316bEFR.006.003. See the preamble to the final rule and the record for discussion of EPA's basis for the site-specific provisions in the final rule and the Agency's determinations regarding economics and costs for this rule. Also see 40 CFR 125.94(a)(5)(i).

Author Name Annette M. Holzer
Organization Entergy Services, Inc.

Subject Matter Code 18.03
Process for determining site-specific BTA

Proposed Rule - Other Cost Issues

The cost tests will involve a large amount of time and resources to complete for each technology; therefore we support UWAG'S approach (in their proposed rule comments) that if a technology can be proven "infeasible" through engineering analysis; a cost test should not be necessary. This will aid in streamlining the cumbersome process of permit renewal applications and analysis required by the state agencies. We have several facilities on the Mississippi River and some of the technologies listed in the rule may not be feasible due to the high flow rate of the river or for navigational reasons.

EPA Response

See section XI.H of the preamble to the final rule.

The cost to cost test does not pose any requirements on facilities for developing costs of compliance other than those the facility would do to comply with the rule in absence of the cost to cost test. If a facility determines that a technology is not feasible or will not meet the rule requirements, it is the facility's decision whether or not to pursue a full engineering cost analysis on these technologies. If a high flow rate precludes the use of a technology on a river, such as a net barrier, then the facility's judgment is used to determine this fact and the technology is not considered further for compliance with the rule. This is the same regardless of the existence or form of the cost to cost test.

RFC: Proposed use of restoration measures

Author Name Annette M. Holzer

Organization Entergy Services, Inc.

Restoration (B)

Voluntary restoration is an important component of the proposed rule. Restoration has been widely accepted as a mitigation strategy for environmental impacts and extending it to the NPDES program would be in line with past practices.

The language proposed within the NODA to be added to Section 125.95(b)(5)(ii) is appropriate, as it maintains flexibility, while defining expectations for compliance.

EPA Response

For a discussion of EPA's authority to include restoration measures in the final rule, see the preamble to the final rule.

For a discussion of the extent to which restoration is voluntary, see EPA's response to comment 316bEFR.060.022.

EPA acknowledges the commenter's statement on the language to be added at 125.95(b)(5)(ii).

Organization Entergy Services, Inc.

Subject Matter Code 21.04

Determination of compliance

Implementation and Other Regulatory Refinements (XI)

Definition and Methods for Determining the "Calculation Baseline " (A.)

- EPA seeks comment on specifications to be added to the definition of "calculation baseline". In general, "calculation baseline" should be defined as when the facility is at full operation with full flow. This keeps the definition clear and consistent and avoids confusion that would arise from times of the year when facilities do not run at full capacity or restrict flow. In regards to intake configuration and screen mesh size, the parallel shoreline intake and 3/8 inch mesh size are appropriate to be included in the definition.

EPA Response

EPA has clarified its definition of calculation baseline in today's final rule (see §125.93). For additional explanation of EPA's definition of calculation baseline, please refer to EPA's response to comment 316bEFR.034.013.

Comment ID 316bEFR.345.007

Author Name Annette M. Holzer

Organization Entergy Services, Inc.

Subject Matter Code 21.04

Determination of compliance

Another area EPA solicits comment is on the use of data from other facilities to determine baselines. Entergy has several facilities within the same waterbody and sharing data between them would provide a cost effective method to determine baselines. Of course, the use of data from other facilities should be required to undergo analysis by the permitting agency to ensure it is relevant to the other facilities prior to usage.

EPA Response

EPA agrees that under certain circumstances data from other facilities may be used to determine calculation baselines. Please see EPA's response to comment 316bEFR.343.011 for more details.

Comment ID 316bEFR.345.008

Author Name Annette M. Holzer

Organization Entergy Services, Inc.

Subject Matter Code 21.04

Determination of compliance

Options for Evaluating Compliance with Performance Standards (B.)

- EPA requests comment on two approaches (All Species Approach and Representative Species Approach) to measuring I&E reductions. Instead of requiring one or the other approach, EPA should provide guidance as to which approach will yield the most accurate results for particular situations. As mentioned previously, the site specific nature of reductions will necessitate different approaches at different facilities. Guidance will provide a road map for facilities to follow and obtain accurate results without restricting them to one type of approach.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Comment ID 316bEFR.345.009

Subject Matter Code 21.09

Permit applications/implementation schedule

Compliance Timelines, Schedules, and Determination (C.)

- It is important that EPA define a schedule for compliance with the rule. If the rule is effective the day after publication, many facilities would technically be in "violation" of the rule. A clear schedule for implementation would eliminate this problem. In order to comply with the rule, facilities must conduct the requisite sampling and then identify and install the appropriate technologies and verify that the technologies are functioning properly. All of this requires a considerable amount of time.

In UWAG'S August 7, 2002 comments to the Phase II Proposed Rule (67 FR 17122) it proposed a timeline for compliance. Basically, action by the facility would be determined by the amount of time before the expiration of the current permit. If a facility is three or more years away from expiration, a full application, including the Comprehensive Demonstration Study would be required by the application due date. If a facility is three years to one and a half years away from permit expiration, an abbreviated permit application would be due with a plan for data collection included. Lastly, if a facility was one and a half years or less away from permit expiration, there would be no application due until the next permitting cycle.

The above timeline allows facilities the time to conduct sampling and obtain valid results. In addition, it staggers the application process to ease the burden to permit applicants and permit writers and avoid permit renewal delays.

EPA Response

See response to comment 316bEFR.025.019.

Comment ID 316bEFR.345.010

Author Name Annette M. Holzer
Organization Entergy Services, Inc.

Subject Matter Code 21.04
Determination of compliance

Proposed Rule - Other Compliance Issues

- Many of the technologies in the proposed rule have not been extensively used and there is a potential for them to not produce the required percentage of reductions. If a technology is installed, maintained and monitored properly, and does not produce the percentage of reductions originally expected or required, a facility should not be considered to be out of compliance with their 316(b) requirements. Therefore, compliance measurement should be based upon factors that can be monitored and controlled; installation and maintenance. If a technology does not produce the percentage of reductions required, the facility should be permitted an appropriate amount of time to determine where the problem lies and propose a solution. This presents a problem with compliance.

EPA Response

In today's final rule, EPA has created a provision by which a facility may choose to demonstrate compliance with a Technology Installation and Operation Plan rather than with numeric performance requirements (please see preamble for a detailed discussion).

Performance Standards

Item VII.B of the NODA (68 FR 13539) - Streamlined Technology Option for Certain Locations, discusses the consideration by USEPA of two variations of a streamlined compliance option that would purportedly reduce the information collection burden imposed on permit applicants in exchange for them installing certain pre-approved technologies to reduce impingement and entrainment. In general, DP&L supports the concept of increased flexibility imparted to the regulated community in order to meet the impingement and entrainment reduction targets envisioned by the proposed rule.

USEPA states that it is in the process of assessing this option and has not completed a comprehensive review of control technology efficacy. With regard to the deployment of wedge-wire screens in certain freshwater applications (the only streamlined technology option presented in the NODA), the agency states “that the record would thus justify limiting the amount of site-specific information required to be collected to support of the use of this technology in freshwater systems.” In concept, DP&L supports the option of choosing to implement certain identified, pre-approved control technologies in exchange for streamlined permit application requirements. However, DP&L notes that no specifics are presented in the NODA as to what relief would be granted from the permit application requirements. Without details in the NODA on the option, it is impossible to determine it attractiveness as an alternative to the proposed Comprehensive Demonstration Study.

Furthermore, USEPA states that “at a minimum, monitoring would be required as necessary to verify that the technology is in fact achieving an acceptable level of performance.” DP&L understands that some post-installation monitoring is necessary. However, DP&L again notes that no details are presented as to what monitoring would be proposed, for how long and for what purpose. DP&L has a concern that should an entity voluntarily implement a “pre-approved” control technology and post-installation monitoring shows that for reasons not related to the facility, the performance standard is not achieved (80-95% impingement mortality reduction and 60-90% entrainment reduction), additional controls would be imposed at the site. If USEPA evaluates a particular control technology and determines it qualifies under the streamlined technology option and that technology is properly installed and maintained, no de-facto penalty should be meted out to the regulated entity in the form of additional control requirements to compensate for circumstances beyond its control. Yet that is exactly what USEPA considers at 68 FR 13540

[f]inally, where a facility plans to implement an approved technology, EPA expects that Directors would retain discretion to impose permit conditions necessary to ensure the technology meets applicable standards, as well as the ability to add permit conditions as necessary to ensure all Phase II existing facilities that pursue this compliance option meet section 316(b) standards.

Included in the same discussion within the NODA is a second variation whereby the Phase II regulations would establish the criteria and process for approving cooling water intake structure control technologies for eligibility under the streamlined technology option. DP&L commends the agency for considering this alternative as an incentive for the regulated community to develop and document both existing and new technologies. While no details are provided on the data requirements and process to be used to determine whether a particular technology satisfies the applicable performance criteria, the agency postulates that this would be up to the Directors of the individual permitting authorities, perhaps with USEPA oversight or approval. Here again, with no specifics presented in the NODA, the regulated community is unable to provide more than conceptual support/comments on the proposed variation.

EPA Response

In today's final rule, EPA specifies that those facilities that choose to comply using the Approved Design and Construction Technology option will only be required to submit the Design and Construction Technology Plan in § 125.95(b)(4) and the Verification Monitoring Plan in § 125.95(b)(7) (see § 125.95(b)). In answer to the second question regarding monitoring requirements, EPA has determined that the Verification Monitoring Plan must include a minimum of two years of monitoring to verify the full-scale performance of the proposed technology or operational or restoration measures. The Director may determine in some cases that more monitoring is necessary to determine the efficacy of a given technology or operational or restoration measures (see Verification Monitoring Plan in § 125.95(b)(7)). However, facilities not demonstrating compliance through the Verification Monitoring Plan must conduct monitoring in accordance with their Technology Installation
and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5). The Director may consider
additional monitoring requirements as well. Specific study parameters may be proposed by the applicant for review and approval by the Director.

With regard to the commenter's assertion that facilities choosing to comply with the Approved Design and Construction Technology option should not be penalized for failing to meet the performance standards, EPA notes that facilities may use a Technology Installation and Operation Plan, with the approval of the Director, to demonstrate compliance. However, EPA believes that ample evidence supports the capability of the wedgewire screen technology with the specifications and conditions outlined in § 125.99(a) to achieve the performance standards, so that EPA hopes that use of Technology Installation and Operation Plans will be minimal in connection with compliance alternative 4. See the Technology Development Document, Phase II Existing Facilities Final Rule Docket, DCN 6-0004. For more information on EPA's position with regard to the advantages to facilities choosing to comply through the Approved Design and Construction Technology option, please see EPA's response to comment 316bEFR.317.009. Finally, EPA thanks the commenter for supporting the Approved Design and Construction Technology option. EPA expect to provide guidance to permitting Directors to enable them to determine whether a proposed technology will meet the performance criteria specified by today's final rule.

RFC: Performance/effectiveness of restoration

Author Name Scott Arentsen

Organization Dayton Power and Light Company- Environmental Mgmt

Biology - Supporting Information

Item IX.B.2 of the NODA (68 FR 13542) - Adaptive Management discusses the possible requiring of adaptive management as part of a restoration project conceived and implemented in lieu of or in combination with installation of control technologies to reduce impingement mortality and entrainment. The agency's reasoning is that due to the uncertainty and evolving nature of restoration projects as an environmental management tool, adjustments may be needed to the project should monitoring indicate deviation of performance from accepted levels. DP&L understands the uncertainty of establishing performance criteria associated with environmental restoration projects and realizes that adjustments may be necessary as more experience and data are obtained for a particular site. However, DP&L is also concerned that this same uncertainty may contribute to unrealistic initial expectations for a restoration project which only after its implementation turn out to be unachievable. As a result, the regulated entity is potentially forced into a never-ending spiral of adaptive fixes to a site in an attempt to achieve goals that turned out to be unreachable. USEPA should recognize that the performance criteria for restoration projects may need to be adjusted once monitoring data provides information on actual project performance.

EPA Response

EPA believes there are uncertainties associated with the design, implementation, performance and assessment of restoration measures. For a discussion of these uncertainties, see EPA's response to comment 316bEFR.206.055. The use of adaptive management is intended to help reduce uncertainties associated with restoration measures and enhance their overall productivity (see EPA's responses to comments 316bEFR.307.047 and 316bEFR.311.022). Adaptive management involves identifying success criteria for a project and creating a plan for incorporating new information as it arises.

For a discussion of the limits on the resources expended on restoration measures, see EPA's response to comment 315bEFR.312.006.

For a discussion of the roles and responsibilities of the permitting authority and permit applicant for determining what is required to ensure a restoration measure meets the performance requirements in the final rule, see EPA's responses to comments 316bEFR.060.026, 316bEFR.212.001, 316bEFR.034.029, and 316bEFR.002.009.

EPA believes the requirements for restoration measures provide permitting authorities and permit applicants with flexibility. However, any restoration measure must meet all of the requirements described in the final rule.

Organization Dayton Power and Light Company-Environmental Mgmt

Subject Matter Code 21.04

Determination of compliance

Implementation and Other Regulatory Refinements

Item X1.B - Options for Evaluating Compliance With Performance Standards (68 FR 1358 1) discusses measuring compliance with the impingement and entrainment performance standards using either an All Species Approach or alternatively a Representative Species Approach. In discussing the representative species approach, USEPA states that it is considering two options for making the compliance determination, 1) total enumeration or 2) reduction in impingement mortality and entrainment for each species (68 FR 13583). In general, DP&L supports the concept of representative important/indicator species (or critical aquatic organisms) as a method for determining reduction in impingement mortality and entrainment at a particular location. However, DP&L has concerns with the species-specific option if it is not structured properly. If a subset of species out of the entire number present at a location is selected for determining compliance with the performance standard and compliance is determined by measuring the reduction in impingement mortality and entrainment for each species, there exists the very real possibility that a facility will be able to meet the performance standard for every species but one or two. In such a case, the facility could be found to be in non-compliance with the requirement based on a single species. The implications of such a finding are enormous ranging from enforcement actions to the requirement to install additional control technologies to reduce impingement mortality and entrainment, possibly for only a single class of organisms. The key to utilizing this approach is the proper selection of the representative important species such that they are truly representative of the waterbody in question and therefore are able to present an accurate picture of the local environment. DP&L urges the agency to take this into account should it include detail on any such option in the final rule.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see. e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Permit applications/implementation schedule

Item 1X.C - Compliance Timelines, Schedules, and Determination (68 FR 13584) includes a discussion of the issues of integrating the requirements of the proposed rule within the scope of NPDES permitting structure. Specifically, USEPA acknowledges comments on the proposed rule expressing concern that the proposed rule does not provide sufficient time for permittees to develop the information required to be submitted with an NPDES permit application. The NODA states at 68 FR 13585 that

EPA is considering and requests comment on whether the final rule should allow facilities required to apply for a permit renewal shortly after promulgation of the Phase II rule additional time to complete the studies associated with submitting a permit application. EPA is considering the following options: (1) Allowing applicants whose permits must be renewed in the first year after promulgation of the Phase II rule to submit application materials required by the Phase II rule one year after their current permit expires; and (2) allowing a two-year extension in the deadline for submitting Phase II application materials.

DP&L submitted extensive comments on the proposed rule expressing concern with the timing of the rule's final effective date vis-a-vis the requirement in the rule to submit the Comprehensive Demonstration Study as part of an NPDES permit renewal. DP&L appreciates the consideration USEPA has given to this issue as evidenced by the two options identified above. However, DP&L remains convinced that additional time is needed after the rule becomes final to allow the Comprehensive Demonstration Studies to be performed by the members of the regulated community whose NPDES permits are up for renewal. There are limited resources available in terms of expertise and manpower for conducting these types of complex and detailed studies. A properly planned and performed Comprehensive Demonstration Study could take several years to execute especially when one considers that permitting agency involvement is critical in the planning aspect of the effort and that little or no pre-existing data may be present at a majority of facilities to assist with study design and implementation. Therefore DP&L repeats its suggestion that the requirement to submit a Comprehensive Demonstration Study with NPDES permit renewal applications not be implemented until the 2nd permit renewal after the effective date of the rule.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

Permit applications/implementation schedule

Author Name Scott Arentsen

Organization Dayton Power and Light Company-Environmental Mgmt

In the same section of the NODA at 68 FR 13585, USEPA discusses that it is

considering whether to develop additional regulatory language that would allow the Director to relax the application information requirements if conditions at the facility and in the waterbody remain unchanged since the facility submitted their previous NPDES permit application, such that the information that they would submit would remain unchanged.

DP&L supports this effort. DP&L concurs that if facility operating conditions have not changed since the submission of the previous NPDES permit application, there is no reason to expect that the facility's impact on the local waterbody would have also changed and therefore permit application requirements could be relaxed. DP&L cautions however that conditions in the local waterbody may change from year to year independent of the facility's operation (due to natural population fluctuations and/or other influences). As a result, conditions in the waterbody may not "remain unchanged" and requiring a facility to conduct a full-blown Comprehensive Demonstration Study just because of natural year-to-year variations is not justified.

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to 316bEFR 041.126 for a discussion. Natural population fluctuations and/or other influences may be included in the facility's rationale/justification for reduced study requirements per 125.95(a)(3) of today's final rule.

Subject Matter Code 21.09

Permit applications/implementation schedule

USEPA also discusses in the same section of the NODA at 68 FR 13586 the issue of achieving compliance with the impingement and entrainment performance standards within the initial permit term and recognizes the difficulty of optimizing control technology performance due to natural variability in the biological community of the waterbody. USEPA states that it is

considering the need for regulatory language that would allow facilities time to come into compliance if they choose to install technologies to meet the performance standards in proposed 125.94. This would allow facilities a period of time to optimize technology(ies) so that they operate to minimize impingement and entrainment. EPA is currently evaluating and considering allowing six months, one year, two years, or five years (one permit term) for a facility to come into compliance after issuance of its permit.

DP&L supports the implementation of a compliance optimization period within the regulations. Clearly it is not reasonable to expect a facility to achieve compliance with the required performance standards immediately upon the installation of control technology(ies) at a facility given the significant uncertainty that exists in completing the Comprehensive Demonstration Study and the subsequent designing, installation, operation and maintenance of impingement and entrainment reduction devices/measures. While DP&L supports the inclusion of a compliance period in the regulations, DP&L emphasizes that too short of a compliance period is functionally equivalent to no compliance period at all. Six months or one year are simply not enough time to evaluate the effectiveness of impingement and/or entrainment reduction technologies at a facility before being exposed to enforcement actions on behalf of regulatory agencies. Even two years may not be sufficient time given the variability of the local waterbody conditions and populations. As a result, DP&L supports a five year compliance optimization period and requests that this be incorporated into the regulations.

EPA Response

RFC: Regulating limited capacity facilities

Item IX.D - Determining Capacity Utilization Rates (68 FR 13586) includes a discussion whereby USEPA is considering modifying the definition of "capacity utilization rate" so that it is based only upon the steam electric portion of a facility's capacity and actual production (excluding non-steam generators). The basis for this potential change is that only the steam electric portion of a facility's capacity utilizes cooling water and therefore has the potential for adverse environmental impact. DP&L supports this change.

EPA Response

The comment agrees with the Agency's final rule decision on the method for the determination of the capacity utilization rate threshold. The final rule reflects this method of determination.

Submittal of required information

NPDES Permit Application Data

To quote page 17154, third column, of the April 9, 2002 proposal "Of the 539 existing steam electric generating facilities that EPA believes would potentially be subject to the Phase II existing facility proposed rule, 73 of these facilities already have a recirculating wet cooling system (e.g. wet cooling towers on ponds). These facilities would meet the requirements under this option (to meet performance standards for reducing impingement) unless they are located in areas where the Director or fisheries managers determine that fisheries need additional protection."

Comment

This Company owns and operates one of these 73 facilities. It seems inappropriate to be subject to the same data submittal requirements as proposed by the modifications to 40 CFR 12.21(r) as the other 466 facilities. It is noted that because cooling towers are already in place, that this facility would be exempt from the (NPDES) application requirements of (r)(4), the Source Water Baseline Biological Characterization Data. However, we think that the data already submitted to EPA with EPA's January 14,2000, request, Detailed Industry Questionnaire Phase II Cooling Water Intake Structure, is sufficient to characterize this facility. Consequently, we are asking EPA to consider including an exemption in the proposed regulations for the submittal of additional data for utilities with a design intake structure of 50 MGD and that already utilize cooling towers.

The data previously sent in response to the above referenced request is extensive and would provide state (NPDES) permitting agencies significant information. EPA should reference the applicability of this data to the requirements of 40 CFR 122.2 1 (r). Would submittal of this data to state agencies meet the intent of the regulations? If not, what additional data would be required to be submitted? Such guidance may diminish our data submittal requirements and would provide guidance to state NPDES personnel.

It appears that even though a facility has installed cooling towers, there could be additional potential requirements per the Director or fisheries managers. We request that this uncertainty be removed from the proposed regulations

Finally, does the statement in (a)(l) "You must submit to Director.. ." mean submittal to an EPA Regional office or to a state agency? Is EPA taking authority from state agencies? Will there be double review of data submittals?

EPA Response

EPA is requiring that all existing Phase 2 facilities submit the information required at 122.21(r)(2),(3) and (5). If some of the information is duplicative of what was submitted in support of the Detailed Industry Questionnaire, the facility should make a copy of the required information and submit it with the later submission. No new studies are expected to be necessary if the facility is already employing cooling towers. The facility may also consult with the Director well in advance of permit expiration to verify the specific information required for 122.21(r)(2),(3) and (5). To clarify, the "Director" is only one entity, either a State Director in a State with NPDES program authority, or an EPA Regional Director if the State does not have program authority; only one review of the facility's application would ensue.

Subject Matter Code 3.06.01

Withdrawal threshold of 50 MGD

Design Intake Flow

The following definitions are listed on page 17130, middle column, of the April 9, 2002 proposal.

‘‘Design intake flow means the value assigned (during a facilities design) to the total volume of water withdrawn from a source water body over a specific time period.”

Cooling water intake structure means the total physical structure and any associated constructed waterways used to withdraw cooling water from waters of the U.S. The cooling water intake structure extends from the point at which water is withdrawn from the surface water source up to, and including, the intake pumps.

Additionally, Appendix 1. - Section 31 b (B) Phase II Existing Facility Rule Framework, page 17217, of the April 9,2002, proposal states, “Do you have a design intake flow of 50 MGD or more”.

Comment

For the one Company facility that EPA has listed as a Phase II facility, these definitions are contradictory. EPA has listed this facility based on the listed volume of the intake pumps. The pipeline that conveys water from the intake pumps at the intake structure has a significantly lower design (in mgd) than the intake pumps and this facility would not be a phase II facility. This has been operationally proven.

EPA should clarify that, when applicable, the lesser design value of an intake facility and conveyance structure vs. the design volume of intake pumps should be used to determine the 50 mgd threshold for applicability. Alternatively, EPA should provide guidance that a facilities design intake flow is not necessarily the flow associated with that of the intake pumps. Also, because of the importance of these definitions, it seems appropriate that they should appear in the regulations rather than in the preamble to the regulations.

EPA Response

Please see response to comment 316bEFR.019.003.

With regard to intake versus pump capacity, EPA notes that under § 125.93 of the final rule, design intake flow means the value assigned (during the facility’s design) to the total volume of water withdrawn from a source waterbody over a specific time period. Because numerous aspects of a cooling water intake or system can limit a facility’s intake flow, and because flow is a critical factor that affects the impacts posed by each facility’s cooling water intake structures, EPA has determined that it is more appropriate for the final rule to focus on a facility’s total design intake flow, rather than to conditional applicability of the rule on more specific parameters, such as intake capacity or pump design, which individually, do not fully account for total design intake flow.

Additional Time For Studies and Data Submittal

Page 13585, first column, of the March 19, 2003, proposal asks the following. "EPA is considering, and requests comment on, whether the final rule for a permit renewal shortly after promulgation of the Phase II rule should allow additional time to complete the studies (and perhaps data collection) associated with submitting a permit application." We note that the promulgation of the final rule is now scheduled for February 16, 2004.

Comment

We would favor the proposed option 2 - a two year extension in the deadline for submitting Phase II application materials. Reference is made to the circumstances surrounding EPA's recent two year extension of the effective dates for the SPCC regulations.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

Permit applications/implementation schedule

Reduction of Application Data Requirements for Unchanged Facilities

Page 13585, last column, of the March 19,2003, proposal states the following: “EPA is considering whether to develop additional regulatory language that would allow the Director to relax the information requirements if conditions at the facility and in the water body remain unchanged since the facility submitted their previous NPDES permit applications,. . .”

Comment

This makes sense. The conditions of intake structures and intake waters rarely change dramatically. However, EPA would need to define ‘unchanged’ and make specific references to what submittal information is sufficient for regulatory compliance (see our preceding comment No. 2 on NPDES Permit Application Data).

EPA Response

EPA agrees that a comprehensive demonstration study may not need to be conducted each time a permit is renewed. Please see response to 316bEFR 041.126 for a discussion. The Director will use best professional judgment when considering the justification for each element that the facility believes has remain substantially unchanged.

PROCEDURAL PERMITTING ISSUES

Our August 7, 2002 comments discussed practical considerations related to the implementation of Phase II requirements in renewal permits for existing facilities. We suggested that the rule should incorporate regulatory measures to reduce uncertainty over the timing of implementation. Specifically, our suggestions in included a fixed period of time after the rule becomes final to evaluate and meet requirements, and/or a allowing a 316(b) compliance schedule in the facility's renewal permit.

Section XI.C., "Compliance Timelines, Schedules, and Determinations" of the NODA confirmed that existing NPDES regulations allowing compliance schedules in permits apply to the proposed rule. The NODA also indicated that EPA is considering options for extending the compliance period by up to two years for facilities with permits that expire relatively soon after the Phase II rule becomes effective. We concur with the NODA that options allowing appropriate additional time for compliance when it is needed should be incorporated into the rule.

EPA Response

EPA has clarified timing requirements for the submittal of the required studies. See response to comment 316bEFR.034.066 for a discussion.

Non-aquatic impacts

ENDANGERED SPECIES ISSUES

Our comments in the August 7, 2002 correspondence also addressed concerns about the Florida manatee. The NODA did not appear to address these concerns in any direct manner. Rather than refer back to the previous letter, comments on manatee protection from the August 7, 2002 correspondence are provided again, as follows:

The Proposed Draft Rule seeks to protect endangered aquatic species by reducing losses due to impingement and entrainment from cooling water intake structures (CWIS) regulated under Phase II. To the extent that this beneficial effect will result from limitations on warm water discharges at once-through cooling water systems, serious harm may result for the Florida manatee, a very important endangered aquatic species in our State's waters. Unlike many other aquatic species, manatees are not impacted by impingement or entrainment from CWIS. On the contrary, manatees find refuge in the warm water discharge areas of some of Floridas steam electric power plants during cold days in the winter. It is estimated that two-thirds of the Florida manatee population uses these man-made warm water refuges on the coldest days. The situation presents a difficult case study in competing environmental benefits and impacts.

EPA Response

Thermal discharges are regulated under section 316(a) of the Clean Water Act. Today's final rule does not require wet cooling towers, and therefore, will not change levels of thermal discharge.

Comprehensive demonstration study (7 parts)

Comprehensive Demonstration Study

The Department believes it is appropriate for EPA to evaluate the effectiveness of technologies used to reduce impingement mortality by 80 to 95 percent and entrainment by 60 to 90 percent in the development of a Final Rule for Existing Facilities. Information derived from studies of a particular technology at one facility may be used to "streamline" compliance at another facility; the second facility could implement these technologies in lieu of a Comprehensive Demonstration Study. This streamlining could result in mitigative measures being implemented within a shorter timeframe, thereby protecting additional aquatic resources sooner. The Department recommends that verification studies be required in such cases to ensure that the technology is deployed and operated in a manner that achieves the desired results.

EPA Response

EPA agrees that today's final rule should include a "streamlining" alternative, and has therefore included the approved technology alternative, which is detailed at § 125.99.

Subject Matter Code 10.07.02

RFC: Appropriateness of "significantly greater"

The Department recommends against changing the monetary standard for consideration of mitigative costs. As stated in the Department's letter in response to the Existing Facilities Phase II Proposed Rule, published in the Federal Register on April 9, 2002:

Lowering the standard from "costs wholly disproportionate to benefits" to the much less stringent "costs significantly greater than site specific benefits" is problematic. The former criterion has been applied to facilities since the 1970s and is supported by a substantial body of case law, permit decisions and legal opinions. This gives it a great advantage over the latter criterion, which would be fraught with disputes over what is "significant" and to whom.

EPA Response

See responses to 316bEFR.006.003 and 018.009. EPA believes that these decision criteria can be developed for standards included in the final rule, just as they evolved for the standard used prior to formal 316(b) regulations.

RFC: Cost: benefit ratio for site-specific BTA?

The Department recommends against changing the monetary standard for consideration of mitigative costs. As stated in the Department's letter in response to the Existing Facilities Phase II Proposed Rule, published in the Federal Register on April 9, 2002:

State fish and wildlife resources would be at risk if the lower standard were used. In New York, all aquatic organisms belong to the State (Environmental Conservation Law 11-0105), which provides an additional reason for the State's protection of the resource against impacts from cooling water intakes. Rather than the widely-accepted "polluter pays" approach, the EPA-proposed rule weighs a generator's cost against a monetized value of fish and wildlife resources the generator does not own and to which it has no entitlement.

EPA Response

The final rule does not preclude states from implementing more stringent requirements or from implementing a program that is consistent with applicable state laws. Please refer to § 125.90 for more information.

Comment ID 316bEFR.402.004

Author Name Denise Sheehan

Organization New York State Dept of Environmental Conservation

Subject Matter Code 10.07

RFC: Cost: benefit ratio for site-specific BTA?

The Department recommends against changing the monetary standard for consideration of mitigative costs. As stated in the Department's letter in response to the Existing Facilities Phase II Proposed Rule, published in the Federal Register on April 9, 2002:

The value or "benefit" of State fish and wildlife resources is difficult to quantify. Whereas the costs of mitigative measures may be quantified using familiar accounting techniques, the task of placing an accurate dollar value on impacts to aquatic resources is rife with ecological and economic challenges; there is no widely accepted methodology. In contrast, by maintaining the "costs wholly disproportionate to benefits" analysis, generators would have to compare the incremental cost of controls with the dollars they earn selling electricity.

EPA Response

EPA agrees that developing a comprehensive measure of fish and wildlife resources is "is rife with ecological and economic challenges." However, the Agency points out that no methods are available for estimating either costs or benefits with perfect accuracy or without uncertainty. Therefore, informed decisions must be made with the best available information and analysis. Cost-benefit analysis provides such information. In addition, EPA points out that economic considerations should not strictly determine policy decisions, and that other factors should also be weighed. This supports the notion that EPA has significant discretion in weighing overall costs and benefits in evaluating various policy options.

RFC: Documented entrainment survival rate studies

Entrainment Survival

The Department agrees that caution must be used in interpreting the results of entrainment survival studies. Much of the research to evaluate ichthyoplankton entrainment survival has been conducted at facilities in New York State. These studies have demonstrated that survival rates are specific to species and to life stage. More important, the survival rates are specific to the facility being studied. Thus, any measure of entrainment survival must be based upon site-specific survival studies. Results from one facility should not be used to assess entrainment survival at another facility.

EPA Response

Please see response to comment 316bEFR.002.015 regarding the inclusion of entrainment survival estimates in site-specific benefit analysis.

Option: I&E reduction without regard to WB type

NYSDEC Preferred Alternative

The Department reiterates its preferred alternative: “Impingement Mortality and Entrainment Controls Everywhere” (as presented on pages 17158-17159 in Section VI (B) (4) of the Phase II Proposed Rule for Existing Facilities). The Department recommends that EPA adopt this alternative because it “levels the playing field” for all generating companies and because it offers flexibility in the selection of mitigation technology. The generators would be fully aware of what is required to meet the performance requirements of proposed Section 125.94(b) (3) of the Proposed Rule. EPA would establish the required level of performance but generators would be free to select any or a combination of techniques to achieve the performance level. This is the simplest alternative to implement and EPA’s analysis found that it provides the highest benefit to cost ratio (3.74:l). An additional advantage is that companies and regulators could direct staff and monetary resources to reducing impacts instead of studies and rebuttals. This alternative also responds to EPA’s request for comment on the “extreme burden” imposed on state agencies over past years by cost/benefit and site-specific determinations. Finally, the Department agrees with EPA’s statement that “This alternative would establish clear performance-based requirements that are simpler and easier to implement than those proposed and are based on the use of available technologies to reduce adverse environmental impact. Such an alternative would be consistent with the focus on use of best technology required under Section 316(b).”

Role of States and Tribes (alt./equiv. programs)

State Requirements

The Department supports those provisions that maintain states' abilities to impose more stringent limitations than those promulgated by EPA. The authority contained in Clean Water Act (C WA) Sections 401 (d) and 510 is necessary for states to conserve their natural resources and to enhance the welfare of the public who use and enjoy such resources. We have routinely exercised this authority with respect to generating facilities throughout New York. The Department notes that narrative statements made by EPA staff regarding Phases I and II of these regulations correctly describe how these CWA provisions are appropriately carried forward in both Phases I and II. [65 Fed. Reg. 49063,49079,49099; 66 Fed. Reg. 65320-321; 67 Fed. Reg. 17215.] We urge that EPA continue to recognize that the CWA clearly makes available to the States the authority to impose more stringent standards where necessary to protect, for instance, aquatic resources affected by cooling water intake structures.

EPA Response

EPA agrees and has preserved States' rights with the inclusion of 125.90(d) and 125.94(e). See response to 316bEFR318.006.

Performance standards

EPA's proposed rule is based on "performance standards" that call for reducing impingement mortality by 80-95% and, for many facilities, entrainment by 60-90%. EPA has looked at available intake structure technologies and concluded that some of them can achieve these standards. The candidates include wedge wire screens, fine mesh screens with fish return systems, and aquatic filter barriers. However, NRECA is concerned that certain parts of the proposed rule seem to imply that if these technologies cannot achieve the performance standards at a particular site, cooling towers (closed-cycle cooling) might be required.

We believe EPA does not (and should not) intend to require existing facilities to retro-fit cooling towers, as demonstrated by several passages in the NODA. For example, EPA deliberately did not include costs for cooling towers in its economic analysis for the "preferred" option. Furthermore, other parts of the economic analysis that do consider cooling tower costs (as well as environmental side-effects and feasibility problems), clearly show, we believe, that cooling towers should not be required at existing facilities.

NRECA believes EPA should make it very clear in the final rule that cooling towers are not a "default" option to be required whenever the other alternatives cannot achieve the numerical standards. EPA should add the following language to the rule: "Although existing facilities with closed cycle cooling will be deemed to have complied with this rule, this rule does not require closed cycle cooling systems to be installed on any existing facility, even if the intake structure technologies considered in this rulemaking cannot achieve the performance standards in practice."

EPA Response

Today's rule does not require any facility to retrofit its cooling system to include closed-cycle cooling (cooling towers), although EPA notes that this option remains available to any Phase II facility in order to satisfy the requirements of the regulation. If a facility were to adopt closed-cycle cooling (compliance alternative 1), they would be exempt from many of the additional elements required of facilities opting for one of the other compliance alternatives. EPA also notes, however, that today's rule preserves each State's right to adopt or enforce more stringent requirements.

With regard to this issue, EPA believes the language adopted in today's rule is sufficient and does not warrant further changes as proposed by the commenter.

Comment ID 316bEFR.403.002

Subject Matter Code 10.01.02

Methods to Evaluate I&E

Author Name James F. Stine

Organization National Rural Electric Cooperative Association

EPA makes a number of overly conservative assumptions when they estimate the number of organisms lost due to entrainment and impingement. For example, EPA assumes that entrainment survival is zero and EPA ignores important compensation responses that occur in natural systems. Even more importantly, EPA's attempt to estimate the "non-use value" of aquatic resources misses the mark. (Refer to UWAG's comments for a detailed discussion of these issues.) These flaws lead to a gross overestimation of the potential benefits of reduced entrainment and impingent which could in turn require companies to install inappropriate and unnecessary technologies. It is critically important for EPA to correct these problems before finalizing the rule.

EPA Response

EPA's reasons for assuming zero entrainment survival are detailed in Chapter A7 of the Phase II Regional Analysis Document (DCN #6-0003). See also response to Comment 316bEFR306.506.

See response to Comment 316bEFR.025.015 for a discussion of EPA's assumptions regarding biological compensation.

Regarding EPA's nonuse analyses, please see responses to Comment 316bEFR.338.046 and 316b.EFR.338.047 on EPA's meta-analysis and response to Comment 316bEFR on the habitat-based approach.

See response to Comment 316bEFR.074.201 for a discussion of conservative assumptions.

Available I&E technologies

While NRECA has not had an opportunity to assess each of the studies EPA cites, we believe that these studies show that the technologies EPA has identified (wedge wire screens, fine mesh screens with fish return systems, and aquatic filter barriers) will be deployable at appropriate sites, are capable of achieving appreciable reductions in impingement and entrainment, and will meet the proposed performance targets at many if not all sites as long as those targets are properly and reasonably applied.

EPA Response

Please see response to comment 316bEFR100.004.

Comment ID 316bEFR.403.005

Option 3--Site-specific determination

Author Name James F. Stine

Organization National Rural Electric Cooperative Association

While we believe that there may be some sites for which the performance standards are not achievable, NRECA submits that the cost-cost and cost-benefit tests offer an appropriate means of resolving issues and setting alternative targets for those cases.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Comment ID 316bEFR.403.006

Author Name James F. Stine

Organization National Rural Electric Cooperative Association

Subject Matter Code 7.03

Available I&E technologies

Equally important, we believe strongly that there is no technology - even cooling towers - that (1) can feasibly be deployed at each and every existing facility and (2) would meet the proposed performance targets (as opposed to a flow reduction target, which is not the equivalent of a reduction in entrainment and impingement) at all sites.

EPA Response

EPA agrees with the comment. Today's rule maintains the desired flexibility for facilities to determine the most cost-effective combination of design and construction technologies, operational measures, or restoration measures best suited to each individual facility.

Comment ID 316bEFR.403.007

Subject Matter Code 7.02

Performance standards

Author Name James F. Stine

Organization National Rural Electric Cooperative Association

As we have said in our previous comments, NRECA believes that the performance standards provide useful targets for evaluating existing technologies, selecting and designing new intake technologies, and for evaluating and refining their performance after installation. We do not believe, however, that they should be incorporated directly into permits as enforceable limitations. As EPA's own technology performance data show, the performance of specific technologies will vary over time in response to widely varying biological, physical, and even chemical conditions within the waterbody. Unlike the case for pollutant discharges produced and controlled by a discharger, varying in-stream conditions - particularly the high natural variability of biological populations and communities - are not under the permittee's control, nor can the permittee reasonably be expected to anticipate and adjust for all such variations.

Thus, NRECA believes that the appropriate means of using performance standards is as targets for technology selection and design rather than as standards for assessing performance. The enforceable BTA permit requirements should be expressed as requirements to (1) identify a technology or technologies (or other measures) that will achieve the performance range (or an alternate range justified by the cost-cost or cost-benefit test) with appropriate operating and maintenance specifications adapted to the technology and the site; (2) install/operate, and maintain the technology in accordance with the technology specifications approved by the permit writer; (3) perform appropriate monitoring to gauge performance; and (4) refine or adjust operation, maintenance, or other factors as appropriate in light of initial monitoring.

An additional facet of this approach is that EPA should expressly allow permittees and permit writers flexibility to develop appropriate site-specific performance evaluation requirements because of the inherent difficulties of working with aquatic populations in a regulatory setting.

This overall approach makes sense for a number of reasons. First, it is consistent with 316(b) and with EPA's interpretation and application of 316(b). Second, it would tend to minimize administrative burdens by avoiding controversy over the specific value chosen. Third, it would avoid the disincentive to innovate that a rigidly enforceable performance standard would cause.

EPA Response

Please see response to comments 316bEFR.307.064 and 316bEFR.029.040, as well as the preamble discussion of the Technology Installation and Operation Plan and its role in demonstrating compliance with today's rule.

Organization National Rural Electric Cooperative Association

Subject Matter Code 7.02

Performance standards

EPA introduced the concept of the "Baseline" as a starting point for assessing the performance of cooling water intake technologies. While EPA addressed the "Baseline" in the NODA, NRECA is concerned that a great deal of uncertainty remains in how this "datum plane" is to be determined. As we noted in our comments on the proposed Phase II regulations, however, as long as EPA does not use the performance criteria as directly enforceable permit limitations, many of our concerns about how to accurately establish the baseline are reduced. Nonetheless, we continue to urge EPA to find a simple way of employing this concept when they issue the final rule. One suggestion that has already been made is to assume zero percent reduction as the baseline condition (the intake without any control technologies) thereby giving full credit for the percentage reductions achieved by technologies that have already been added to the intake or for those that are to be added in the future in order to comply with the new BAT regulations.

EPA Response

For discussions on the basis for and implementation of the calculation baseline, please see response to comments 316bEFR.308.014 and 316bEFR.063.022, as well as the preamble to today's rule.

Subject Matter Code 7.04

Streamlined Technology Option

Part B, Section VII of the NODA addresses a “Streamlined Technology Option for Certain Locations” (68 Fed. Reg. 13,539 col. 2). EPA asks whether the following technology would qualify for streamlined application requirements :

Use of submerged wedge-wire screens where the cooling water intake structure is located in a freshwater river or stream, sustained countercurrents exist to promote cleaning of the screen face, and the design intake velocity is 0.5 feet per second (ah) or less.

NRECA is concerned not only with the potential capital costs imposed by the regulations, but also with the “transaction costs” of determining what to do and how to do it. We therefore support this particular technology as one possible way for meeting the requirements of the rule. However, our overall recommendation is for a more streamlined technology selection process -- a process that still fits within the general structure of the proposed rule (including the option for cost/benefit assessment) and does not attempt to identify a single “one size fits all” solution.

EPA Response

EPA believes that the Approved Design and Construction Technology compliance option as described in today’s final rule at § 125.99 is streamlined, and disagrees that this option constitutes a “one size fits all” solution. Rather, EPA believes that it has built tremendous flexibility into the Approved Design and Construction Technology Option, and expects that this will encourage and support innovation by industry and State Agencies (see § 125.99(2)(b)). For more details on the advantages of choosing to comply through the Approved Design and Construction Technology compliance option, please see EPA’s response to comment 31bEFR.306.062.

RFC: Proposed use of restoration measures

In response to further discussion of this topic in the NODA, NRECA continues to support the concept of voluntary restoration as a way to offset any impacts caused by the cooling water intake system. Mitigation has become an accepted part of the wetlands program and is now being embraced by the Fish and Wildlife service as part of their new ESA Conservation Mitigation Banking program announced on May 8, 2003.

EPA Response

In the final rule, EPA allows use of restoration to minimize or to help to minimize adverse environmental impacts that derive from impingement and entrainment of aquatic organisms. For a discussion of EPA's authority to include restoration measures as a compliance option in the final rule, see the preamble to the final rule.

For a discussion of the extent to which restoration is voluntary in the final rule, see EPA's response to comment 316bEFR.060.022.

Overview of I & E effects on organisms

COOLING WATER INTAKE STRUCTURES AND THEIR ENORMOUS IMPACTS ON FISH AND AQUATIC LIFE.

Every year, electric generating facilities kill the overwhelming majority of organisms in the more than 70 trillion gallons they withdraw from U.S. waters for cooling. This staggering mortality -trillions of fish, shellfish, plankton and other species, including some that are endangered or threatened -has harmed aquatic, coastal and marine ecosystems for decades, and has contributed to the collapse of some fisheries.

This excessive mortality occurs both despite and as result of the facilities' attempts to filter extraneous materials including fish from the cooling water stream. Aquatic organisms too small to be screened out are drawn through the cooling system and are killed by "entrainment." <FN 3> Larger organisms become trapped on intake screens and are killed or injured by "impingement." <FN 4>

Existing studies provide an incomplete picture of the severity of the impacts of cooling water intake structures (abbreviated as "CWIS"). Nevertheless, generators and government agencies, including EPA, have documented massive fish kills by power plants for decades in the U.S. and Europe. As just a few examples of this mortality:

- The Brayton Point Station in Somerset, Massachusetts on Mt. Hope Bay in the northeastern reach of Narragansett Bay killed between 7 million and 164.5 million menhaden and river herring each day in the summer of 1971 by entrainment;

- the Millstone Point Nuclear Power Station on Niantic Bay in Waterford Connecticut killed 36 million menhaden and blueback herring during a sixteen day period in 1972 by entrainment; and

- the Connecticut Yankee Plant on the Connecticut River in Haddam Neck, Connecticut killed 179 million fish larvae were per year from 1969-70.<FN 5>

The same EPA document also reported enormous impingement death tolls at power plants, such as:

- The Surry Power Station on the James River, Virginia destroyed 6 million river herring by impingement from October-December, 1972;

- the Millstone Point Plant's intake screens on Niantic Bay killed more than 2 million fish during the late summer and early fall of 1971;

- the Indian Point Electric Generating Station on Haverstraw Bay on the Hudson River in Buchanan, New York killed 1.3 million white perch and striped bass during one 9-1/2 week period from 1969-1970, with a predicted impingement death toll of 6.5 million fish per year; and

-the P.H. Robinson Plant in Galveston Bay, Texas impinged 7,191,785 menhaden, anchovy and croaker in one year from 1969-70. <FN 6>

In the preamble to the Phase II Proposal, EPA provided further examples of devastating impacts associated with impingement and entrainment at individual steam electric generating facilities:

-The Brunswick nuclear plant on the Cape Fear estuarine system in North Carolina, has entrained as much as 3-4 billion individual fish and shellfish at early life stages annually. Studies there have predicted an associated 15-35 percent reduction in populations, which may be altered beyond recovery <FN 7>

- On Florida's Gulf Coast, the Crystal River power plant seriously reduces forage species and recreational and commercial landings (e.g., 23 tons per year);<FN 8>

- On Lake Michigan, the D.C. Cook nuclear plant killed one million fish during a three-week study period.<FN 9>

- On New York's Hudson River, entrainment at five power plants (Indian Point, Bowline, Roseton, Lovett and Danskammer) predicted year-class reductions of up to 79 percent, depending on fish species. The generators' 2000 analysis of three of these plants completed in predicted year-class reductions of up to 20 percent for striped bass, 25 percent for bay anchovy, and 43 percent for Atlantic tomcod, even without assuming 100 percent entrainment mortality. These losses could seriously deplete any reserve or compensatory capacity needed to survive unfavorable environmental conditions.<FN 10>

- The Brayton Point facility in Somerset, Massachusetts withdraws 1.3 billions gallons per day from Mt. Hope Bay and has apparently caused an 87 percent reduction in finfish abundance since a 50 percent increase in its cooling water withdrawal in 1985. <FN 11>

- At the San Onofre Nuclear Generating Station on the Southern California coast, in a normal (non-El Nino) yeas-, 121 tons of midwater fish are entrained, causing a 34-70 percent decline in Pacific Ocean fish populations within 3 kilometers;<FN 12>

- The Pittsburg and Contra Costa Plants in the San Francisco Bay Delta in northern California can impinge and entrain more than 300,000 endangered and threatened species per year, including Delta smelt, Sacramento splittail, Chinook salmon, steelhead trout. <FN 13>

- More than 1,300 endangered sea turtles entered enclosed cooling water intake structure canals at the St. Lucie plant in Florida, resulting in mortality over a 9-year period.<FN 14>

The massive toll on U.S. ecosystems and fisheries has aggrieved commercial and recreational fishermen and other citizens who value these natural resources. Environmental advocates around the country have devoted substantial time and energy monitoring and fighting these impacts in the thirty years since Congress enacted the Clean Water Act.

For example, on New York’s Hudson River, environmental groups and fishermen’s organizations, including Riverkeeper, Inc., the Hudson River Fishermen’s Association, (Riverkeeper’s predecessor), the Natural Resources Defense Council, and Scenic Hudson, Inc., have been fighting for more than 30 years to reduce the massive entrainment and impingement at the River's six large once-through plants. Decades of fish kills from these facilities, including reductions in some year classes up to an estimated 79 percent, has sapped the recovery of one of the most valuable estuaries on the eastern seaboard, once a word-class fishery.

Similarly, the Brayton Point Power Station in Somerset, Massachusetts has obliterated the fisheries of Mount Hope Bay, which forms the northeast arm of Narragansett Bay. Mount Hope Bay, a federally designated essential fish habitat and a critical spawning and nursery area for many marine species, had a long history as a productive fishing ground for flounder, lobster, and shellfish. The Bay's legendary fishing productivity crashed in the mid-1980's, after the power plant increase in cooling water withdrawals approximately 45 percent. Environmental organizations, such as Save the Bay and its Narragansett Baykeeper and the Conservation Law Foundation, and Bode Island public agencies including the state Attorney General and Department of Environmental Management, have fought for years to force the plant to reduce its water withdrawals to restore the ecological health of Mount Hope Bay.

The Salem Nuclear Generating Station, in Salem County, New Jersey approximately 30 miles southwest of Philadelphia, withdraws over 3 billion gallons per day, more cooling water than any facility in the country, from Delaware Bay. A study commissioned by the New Jersey Department of Environmental Protection estimated that the Salem cooling water intake annually kills 375,000 white perch, 281,746 herrings (alewife & blueback), 305,000 spot, 61,100 Atlantic croaker, and 3,239 striped bass, 842,000,000 bay anchovy and 1,120,000 weakfish -four times as many bay anchovy and weakfish each year than are commercially caught in the Delaware Estuary.<FN 15> The Delaware Riverkeeper Network and the American Littoral Society have been fighting for years to cause Salem to reduce its massive death toll.

Similarly large aquatic mortality tolls have occur at numerous other locations around the country, including but not limited to the Big Bend plant in Tampa, Florida, the Duke Energy Plants in Morro Bay and Moss Landing, California, the Portero Plant in San Francisco Bay, many plants on the Great Lakes, and a great many others where environmental advocates continue to devote substantial time and energy to monitoring and fighting these impacts.

EPA also has placed in the docket for the Phase II Proposal a large collection other studies of fish mortality by entrainment and impingement at cooling water intake structures.<FN 16> In all, EPA currently has a database of impingement and entrainment data from more than 100 different facilities, ranging from the relatively low flow Palisades Plant in Michigan, which -after its 1974 closed-cycle retrofit -takes in 19.7 million gallons per day (mgd), to the nation's largest user of cooling water, the Salem Nuclear Plant in New Jersey which withdraws more than 3 billion gallons per day.<FN 17> EPA acknowledges that even the massive reported death tolls fail to account for the full extent of mortality to aquatic organisms:

Studies like those described ... may provide only a partial picture of the severity of environmental impact associated with cooling water intake structures. ....[T]he methodologies for evaluating adverse environmental impact used in the 1970s and 1980s, when most section 316(b) evaluations were performed, were often inconsistent and incomplete.. . <FN 18>

Footnotes

3 Entrainment occurs when relatively small fish and shellfish organisms, eggs, and larvae are drawn through the cooling

water intake structure into the plant’s cooling system, pass through its heat exchanger, and are discharged out of the facility. As entrained organisms pass through the cooling system they are subject to mechanical, thermal, and toxic stress including physical impactsh the pumps and condenser tubing, pressure changes caused by diversion of the cooling water into the plant or by the hydraulic effects of the condensers, sheer stress, thermal shock in the condenser and discharge tunnel, and chemical toxemia induced by antifouling agents such as chlorine. Few, if any, entrained organisms survive. 67 Fed. Reg. at 17136; see also U.S. EPA, Guidancefor Evaluating the Adverse Impact of Cooling Water Intake Structures on the Aquatic Environment: Section 316(b), P.L. 92-500, p. 1 (1977) (hereinafter “1977 EPA Guidance Manual”).

4 Impingement occurs when fish and other aquatic organisms become trapped on screening devices or other barriers installed at the entrance of the intake structure to prevent debris from entering the facility’scooling system. Impingement is caused by the force of water passing through the intake structure and can result in starvation and exhaustion (when organisms are trapped against an intake screen), asphyxiation (when organisms are forced against an intake screen or other barrier at the entrance to the cooling water intake structure by velocity forces that prevent proper gill movement or when organisms are removed from the water for prolonged periods of time), and descaling (when organisms are removed from an intake screen by a wash system). 67 Fed. Reg. at 17136; see also 1977 EPA Guidance Manual, p.1.

Benefits of reduced intake capacity

CLOSED-CYCLE COOLING IS AN AVAILABLE TECHNOLOGY WHICH WOULD DRASTICALLY REDUCE FISH KILLS DUE TO ONCE THROUGH COOLING

The enormous aquatic mortality caused by power plants intakes is almost entirely unnecessary. Readily available, affordable and common technology can eliminate more than 90% of the impact for those facilities using “once through cooling,” which requires extremely large quantities of water. Once-through cooling simply transfers the waste heat to the receiving waterbody. “Closed-cycle” cooling, in contrast, substantially recirculates cooling water because it uses a cooling tower transfer heat to the atmosphere by evaporation and convection.

As a result closed-cycle cooling systems use dramatically less water than once-though cooling systems, and thereby impinge and entrain a fraction of the aquatic organisms. The precise volume of water withdrawn by closed cycle systems depends on the size of the plant, type of electricity generation technology, and the source water salinity. On fresh water, closed-cycle systems generally reduce water usage by about 95% over once through cooling. That is, a plant which would extract 1 billion gallons per day (1000 mgd) of water if cooled by a once-through system, will require only about 5% of that amount or 50 mgd if cooled by an evaporative cooling tower instead.<FN 19>

Footnotes

19 Where State water quality standards limit chloride to a maximum increase of 10 percent over background and therefore require a 1.1 cycle of concentration (as opposed to 2.0), closed-cycle cooling may reduce intake volume by a still significant 70%, rather than 95% or more. EPA Phase II Technical Development Document ("Phase II TDD") at p. 4-1

Author Name Reed Super
Organization Riverkeeper, Inc.

Subject Matter Code 19.0
Dry Cooling

"Dry" closed-cycle (also known as air-cooled) systems are also available to reduce impacts even further. Dry-cooling uses radiator-type coils to transfer heat to air by convection. These systems recirculate virtually all their water. As a result, plants that use dry cooling have no visible plume or thermal discharge to waterways, and have much smaller water requirements. Hybrid cooling systems use both wet sections and dry sections in order to abate evaporation plumes present caused by wet cooling towers.

EPA Response

See "Energy Penalty Analysis of Possible Cooling Water Intake Structure Requirements on Existing Coal-Fired Power Plants" (June 14, 2002) for the Department of Energy's evaluation of the feasibility of dry cooling systems for existing power plants. The Agency agrees with the general findings of the Department of Energy's dry cooling evaluation. As such, dry cooling technologies are not appropriate to form any portion of the basis of this national rule. See response to comment 316b.EFR.022.002.

EPA notes that the commenter fails to distinguish that plume abating towers are similar to wet cooling towers in that they would face the same engineering hurdles of a wet cooling tower retrofit, but would exceed the cost of the wet cooling tower and increase the energy penalty marginally during periods of plume abatement. As such, the Agency generally refers to wet cooling towers throughout its response to comment and applies the same principles to hybrid wet-dry cooling towers about their unacceptable candidacy for forming the basis of the final rule.

Comment ID 316bEFR.404.004

Subject Matter Code 17.03.01

Ex. facilities converted to closed-cycle

Author Name Reed Super

Organization Riverkeeper, Inc.

Both the wet and dry closed-cycle cooling has been standard power plant technology for decades. As EPA reported last year, 100% of the combined-cycle plants built in the last 20 years and 88% of the coal-fired facilities built in the last 10 years have a closed-cycle recirculating cooling system. 66 Fed. Reg. at 28855-28856 (May 25, 2001). Retrofits of cooling towers on existing facilities are less frequent, but have been completed at a variety of power plants, including a gas-fired plant on a west coast estuary (Unit 7 of the 751 MW gas-fired Pittsburg Power Plant in Contra Costa County, California); a nuclear plant on a Great Lake (821 MW Palisades Nuclear Plant in Michigan), and coal-fired plants on eastern seaboard rivers (490 MW coal-fired Canadys Steam Plant and 346 MW Jefferies Coal Plant in South Carolina).<FN 20> Retrofits are also currently planned or underway at several other US facilities, including at the McDonough (520 Mw coal) and Yates (1250 MW, coal) plants on the Chattahoochee River in Georgia and at the Wateree Station (772 MW, coal) on the Wateree River in South Carolina. Several different retrofit options have been evaluated for some or all of the four units at the Brayton Point power station (1500 MW, coal/oil) in Somerset, Massachusetts, including unit-specific and/or multi-mode cooling towers.

Footnotes

20 67 Fed. Reg. 17155; Ohase II TDD, pp. 4-1 to 4-6

EPA Response

See response to comment 316b.EFR.404.034. EPA notes that the project of retrofitting a cooling tower to an existing facility is a much different engineering project than integrating the system into the construction of a new power plant. As such, the data provided by the commenter relating to the percentage of new power plants with closed-cycle cooling is irrelevant to this final rule, which applies to existing facilities.

Purpose of Rule (General, incl. bckgrd., history)

CWA SECTION 316(B) REQUIRES BEST TECHNOLOGY AVAILABLE

Section 316(b) of the 1972 Federal Water Pollution Control Act amendments ("Clean Water Act," "CWA" or the "Act") <FN 21> provides:

Cooling water intake structures

Any standard established pursuant to [Section 301 or Section 306 of the Act] and applicable to a point source must require that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact.<FN 22>

Congress enacted the BTA requirement in response to a number of well-profiled fish kills at power plants in the early 1970s. <FN 23> In fact, during debate over the Clean Water Act, Senator Buckley cited with approval two newspaper articles reporting a decision of the Atomic Energy Commission (AEC) to require Consolidated Edison to install closed cycle cooling at Indian Point.<FN 24> The articles noted that the plants withdrew massive amounts of water from the Hudson River, entraining thousands of organisms per minute, and that the AEC had ordered Con Ed to stop removing such large volumes of water from the River and to install cooling towers in order to abate these massive fish kills.<FN 25>

EPA Response

Please see the preamble to today's final rule and other documents in this record for an explanation of why EPA did not select the closed-cycle cooling for all facilities option.

Comment ID 316bEFR.404.006

Author Name Reed Super

Organization Riverkeeper, Inc.

Subject Matter Code 2.04.03

Define BTA as anything less than closed cycle

The integration of section 316(b)'s"best technology available" (BTA) requirement to minimize adverse environmental impacts with the effluent limitations under sections 301 and 306 indicates Congress's intent for national technology-based standards to control entrainment and impingement. EPA establishes industry-wide, nationally-uniform standards without regard to site-specific water parameters (such as receiving water quality) to govern the setting of individual NPDES permit limitations.<FN 26> Technology-based standards must bring all facilities up to state-of-the-art pollution control as quickly as possible (referred to as "technology forcing") and promote national consistency in NPDES permit limitations.<FN 27>

Congress chose the NPDES permitting program as the vehicle for minimizing adverse environmental impact by making the provisions of 316(b) applicable to any facility containing a point source.<FN 28> Section 316(b)'s explicit cross-reference to sections 301 and 306 further clarifies that cooling water intake standards are an integral component of the NPDES technology-based regulations. Section 301 mandates the "best available technology" for existing sources while the section 306 new source performance standard must reflect the "best available demonstrated control technology." 33 U.S.C. 1131l(b)(2)(A), 1316(a)(l). Congress' use of substantially similar statutory language in Section 316(b) underscores its intent to incorporate that section's limitations into the categorical standards of sections 301 and 306:

[T]he regulations issued under 316(b) are.. .closely related to the effluent limitations and new source performance standards of 301 and 306.. . It bears emphasis that 316(b)...requires 301 and 306 standards to deal with cooling water intake structures.. ..[The] regulations [are] issued at least in part under the same statutory sections, some of which limit intake structures, others, effluent discharges.<FN 29>

Significantly, the Court in the VEPCO case contrasted the similarity between Section 316(b) standards and effluent limitations with the fundamentally different statutory scheme for water quality standards.<FN 30>

EPA may comply with its Section 316(b) mandate in one of two ways. One option is to implement Section 316(b) by including national performance standards for cooling water intake structures in each national, industry-specific Section 301 and 306 standard. The other option is to implement Section 316(b) with a free-standing, overarching regulation that would apply to all categories of point sources subject to Sections 301 and 306 that utilize cooling water intake structures. Either of these two options is permissible <FN 31> EPA has chosen the latter.

But in either case, EPA's section 316(b) regulations specifying BTA for minimizing adverse environmental impact must be national, technology-based regulations effluent limitations under sections 301 and 306. The statutory integration of these sections, along with the spare and direct "best technology available" mandate, clearly indicates Congressional intent that EPA set nationwide technology-based standards for cooling water intake structures in the same fashion as for discharges of chemical pollutants.

Footnotes

26 See 40 C.F.R Parts 402-699. In waters which violate ambient quality standards, a more restrictive set of limitations may apply. See 33 U.S.C. $8 1312, 1313,40 C.F.R. Parts 130-131.

27 A primary objective of Congress in implementing nationally applicable standards was to avoid the “race to the bottom,” which commonly occurred in the absence of uniform national effluent limitations prior to the adoption of the Act, where states would compete to attract and maintain industries by relaxing control requirements. Purpose of Rule (General, incl. bckgrd., history)

HISTORY OF CWIS REGULATION

EPA has established effluent limitations under CWA Section 301 for existing sources in each of the industry categories which are major users of cooling water.<FN 32> However, none of these standards address cooling water intake structures. Unlike other sources of degradation to aquatic ecosystems controlled under the 1972 Clean Water Act amendments (such as discharges of pollutants), cooling water intake structures have uniquely avoided nationally uniform limitations. Instead, regulation of cooling water intake structures has long been relegated to ad hoc determination by individual permit writers exercising best professional judgment.

In 1976, EPA chose to promulgate a single regulation under Clean Water Act section 316(b), codified at 40 C.F.R. Part 402<FN 33> and applicable to all categories of point sources, rather than include a section 316(b) provision within all individual effluent limitations guidelines and new source performance standards under sections 301 and 306.

The operative section of the 1976 regulation, provided in full:

The information contained in the Development Document <FN 34> shall be considered in determining whether the location, design, construction and capacity of a cooling water intake structure of a point source subject to standards established under section 301 or 306 reflect the best technology available for minimizing adverse environmental impact.<FN 35>

In 1977, the United States Court of Appeals for the Fourth Circuit remanded the regulation back to EPA because EPA had violated the Administrative Procedure Act by failing to either publish the Development Document in the Federal Register or properly incorporate it by reference.<FN 36> As a result, the court did not address the validity of the regulation on substantive grounds. EPA subsequently withdrew the regulation, <FN 37> and although it reserved space in the Code of Federal Regulations, had not promulgated a new cooling water intake structure regulation until its December 18, 2001 publication of the Phase I new facility rule. The present proposal is EPA's first proposed rule for existing facilities since the 1976 regulation was set aside and then withdrawn in 1979.

In the absence of federal regulations, section 316(b) determinations have typically involved individualized ecological assessment and determination of best technology available for each proposed or renewed cooling water intake structure. The lack of categorical standards has resulted in uneven and conflicting regulation as well as enormous, unnecessary aquatic mortality, which runs contrary to the goals of the Clean Water Act and the direct mandate of section 316(b). The individualized assessments have typically relied on narrow and inaccurately applied population models, and have ignored other impacts on ecosystem health.

For 30 years, industry has used the threat of litigation and a variety of dubious interpretations of section 316(b) to avoid the imposition of BTA. A favorite strategy of industry is to threaten state permitting agencies with litigation in order to obtain a compromise settlement for limited mitigation or data gathering and study, rather than installing best technology. Even with extensive data collection, there has been continued disagreement among industry, permitting agencies, and environmental groups over ecological impacts.

The multiplicity of these individual determinations and the combination of ecological and mathematical/statistical expertise necessary to determine the complex population dynamics for individual species has granted industry a critical strategic advantage because of superior resources in these proceedings. This advantage is a key component in industry's strategy to avoid national technology based regulations. Industry's most common analytical tools in these individualized technical determinations are density-dependent models of fisheries populations. Cooling water users have for decades used arguments based on density-dependence to justify the destruction of large numbers of fish and crustaceans via impingement and entrainment at their CWISs. In many critical cases, mathematical models of density dependent compensation these models have been misapplied. As just one example, industry has misapplied commonly-used Ricker curves, originally developed for salmonid fisheries with intense competition for spawning space, is misapplied to the entrainment of other species which lack such intense competition.<FN 38> More fundamentally, typical compensation analysis relies on an ecologically baseless concept of "surplus production" which dismisses the ecological value of the tens of millions of fish which are a critical base of the food chain whether or not they grow to adulthood -even though their predators may be populated at far below their historic values.

On January 19, 1993, Riverkeeper, Inc.<FN 39> and a coalition of individuals and environmental organizations sued EPA in the United States District Court for the Southern District of New York, to obtain an order directing EPA to promulgate new cooling water intake regulations. Riverkeeper, Inc., et al v. Whitman, U.S.D.C.,

S.D.N.Y., Case No. 93 Civ 0314 (AGS).<FN 40> In 1995, plaintiffs and EPA agreed to a consent decree which among other things set forth a timetable by which EPA would take final action on regulations to implement Section 316(b).<FN 41> Under the consent decree entered by the court in 1995, EPA was required to propose regulations implementing Section 316(b) for all facilities no later than July 2, 1999, and to take final action with respect to the regulations no later than August 13, 2001.

EPA subsequently moved to amend the Consent Decree, claiming it was unable to meet the deadlines.<FN 42> Although the court found that EPA's "explanations for its previous delays do not justify modification of the Consent Decree," it extended the proposal deadline, on the ground that "the public interest does require that the decree be modified to enable EPA to produce a sound Regulation." <FN 43> The amended consent decree requires EPA to take final action on its Phase II regulation by February 16, 2004.

EPA Response

No response necessary.

THE CLEAN WATER ACT REQUIRES TECHNOLOGY-BASED AND TECHNOLOGY-FORCING STANDARDS TO RATCHET DOWN POLLUTION.

Congress enacted the Clean Water Act <FN 44>(CWA) in 1972 to “restore and maintain the chemical, physical, and biological integrity of the Nation’s waters.” 33 U.S.C. 1251(a). The CWA establishes a comprehensive regulatory program requiring all dischargers, including power plants, to obtain National Pollutant Discharge Elimination System (NPDES) permits for point source discharges. 33 U.S.C 1311. The permits contain standards, which are established by EPA through a system of technology-based limitations, supplemented by water-quality related limitations, which protect specific bodies of water.<FN 45> 33 U.S.C. 1312. The NPDES permit takes the applicable effluent limitations and other standards and turns them into the obligations borne by the individual polluting entity. NRDC v. EPA, 822 F.2d 104, 110 (D.C. Cir. 1987).

The intended effect of the Clean Water Act permit and effluent limitation process is to gradually reduce pollution and adverse environmental impact to the point of elimination. Indeed, Congress set a “national goal that the discharge of pollutants into the navigable waters be eliminated by 1985.” 33 U.S.C. 1251(a)(l). Congress understood that compliance with the Act would have economic consequences to industry and, accordingly, adopted a phase-in compliance scheme. That scheme uses increasingly more stringent effluent limitation guidelines and NPDES permits to ratchet surface water pollution down to zero. As explained by the court in NRDC v. EPA:

[T]he [Clean Water Act’s] regulatory scheme is structured around a series of increasingly stringent technology-based standards (beginning with the implementation of the best “practicable” technology (BPT) and progressing toward implementation of pollution controls to the full extent of the best technology which would become available (BAT). New sources would, again, be subject to the most stringent technology-based standards of all, namely “new source performance standards”. ... [T]he most salient characteristic of this statutory scheme, articulated time and again by its architects and embedded in the statutory language, is that it is technology-forcing.... The essential purpose of this series of progressively more demanding technology-based standards was not only to stimulate but to press development of new, more efficient and effective technologies. This policy is expressed as a statutory mandate, not simply as a goal.

NRDC v. EPA, 822 F.2d 104, 123 (D.C. Cir. 1987) (emphasis added).

Congress’s plan to eliminate surface water impairment requires that NPDES permits be made more stringent over time. Thus, it devised a three-phase implementation plan:

- For permits issued before EPA had completed the limitation guidelines, EPA was to use its “best professional judgment” (BPJ).<FN 46>

- By 1976, industries had to use the “best practicable technology” (BPT).<FN 47> Later, amendments to the Act extended the deadline for use of BPT to 1979.

- By 1981, industries had to use the “best available technology” (BAT), a much more stringent standard.<FN 48>

CWA section 316(b) requires NPDES standards for cooling water intake structures.<FN 49> Like sections 301,304 and 306 of the Act, section 316(b) mandates a best technology standard. Congress used the locution, “best technology available” (BTA), which is unique in the Clean Water Act, but is substantially similar to the Section 301 “best available technology” (BAT) standard. On its face, it is stricter than the Section 301(b) requirement to impose the “best technology available economically achievable” (BAT)<FN 50> because its spare and direct mandate contains no explicit cost component and does it require the consideration of the other factors relevant to BAT.<FN 51> Given the practically identical language and the application of the Phase II Proposal only to existing sources, the BTA requirement is as least as stringent, and possibly more stringent, than the section 301 BAT standard.

Footnotes

44 33 U.S.C. 33 1251-1387. The CWA is officially known as the Federal Water Pollution Control Act. It was amended in 1977 and 1987.

45 “Whenever a technology-based effluent limitation is insufficient to make a particular body of water fit for the uses for which it is needed, EPA is to devise a water-quality based limitation that will be sufficient to the task.” 33 U.S.C. 1312(a); see also NRDC v. EPA, 822 F.2d 104, 111 (D.C. Cir. 1987).

46 “Best professional judgment” (BPJ): Where EPA has not yet promulgated national effluent standards for a particular category of point sources, the permit writer must use, on a case-by-case basis, his or her best professional judgment to impose “such conditions as the permit writer determines are necessary to carry out the provisions of the Clean Water Act.” 33 U.S.C. 0 1342(a)(l)(B);NRDC v. EPA, 863 F.2d 1420,1424 (9” Cir. 1988).

47 “Best practicable technology” (BPT): BPT represents the “average of the best existing performance by plants . .. within each industrial category.” Kennecott v.EPA, 780 F.2d 445,448 (4” Circ.1985).

48 33 U.S.C. p 131l(b) (2) (A), (C), (D) and (F). BAT uses “the optimally operating plant, the pilot plant which acts as a beacon to show what is possible.” Kennecott v. EPA, 780 F. 2d 445,448 (4” Cir. 1985). For new sources, the strictest standard, “best available demonstrated control technology” (BACT) is required. 33 U.S.C. 6 1316.

49 “Any standard established pursuant to [Section 301 or Section 306 of the Act] and applicable to a point source must require that the location, design, construction, and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impact.” 33 U.S.C. 9 1326(b).

50 CWA 6 301(b)(2)(A); 33 U.S.C. 3 1311(b)(2)(A).

51 “Factors relating to the assessment of best available technology shall take into account the age of equipment and facilities involved, the process employed, the engineering aspects of the application of various types of control techniques, process changes, the cost of achieving such effluent reduction, nonwater quality environmental impact (including energy requirements), and such other factors as the Administrator deems appropriate.”33U.S.C.4 1314(b)(2)(B)

Require closed cycle cooling

CLOSED-CYCLE COOLING REDUCES WATER WITHDRAWALS AND FISH KILLS BY AN ORDER OF MAGNITUDE OR GREATER AND IS THEREFORE NECESSARY TO MINIMIZE IMPACT.

Capacity is the Critical Factor in Minimizing Adverse Environmental Impact.

CWA section 316(b) requires minimization of adverse environmental impact (AEI):

the location, design, construction, and capacity of cooling water intake structures [must] reflect the best technology available for minimizing adverse environmental impact.<FN 52>

The amount of water withdrawn by an intake is directly related to -and is the critical determinant of -the extent of adverse environmental impact. Consequently, section 316(b) requires a minimization of intake capacity.

Overview of I & E effects on organisms

On November, 9, 2000, Riverkeeper submitted to EPA a report prepared by Drs. Peter A. Henderson and Richard M. Seaby of Pisces Conservation, Ltd., that reviewed and evaluated the ecological basis for the proposed Phase I regulation.<FN 53> Drs. Henderson and Seaby reviewed literature and data on cooling water intakes from many power plants in freshwater, marine and estuarine water bodies in the U.S. and Great Britain, and concluded that there is a direct relationship between the volume of water pumped and the number of fish impinged and entrained.<FN 54> The following regression equations summarize the average correlation for all of the plants studied:

$I = 0.023(G+340.25)^{1.844}$
$E = 1.816(G+340.25)^{1.628}$

where “I” represents the number of fish impinged per year, “E” is the number of fish entrained per year, and “G” is gallons of water per second. The power function indicates a particularly sensitive relationship: increases in water withdrawal will result in a greater proportional increase in entrainment and impingement mortality.

As the Pisces Report explains:

It is impossible to remove any significant volume of water from a lake, reservoir, river or the ocean without also removing some of the organisms that are living within it. When water is extracted from healthy natural waters, to an over-riding degree the number of organisms killed be they fish, crustaceans or members of the plankton increases with the volume of water pumped.<FN 56>

As Drs. Henderson and Seaby explain in the Pisces Phase I Report, mathematical analysis of data from a large number of U.S. and European power plants show “no appreciable difference in overall catch rate over a wide range of habitats and geographical position.”<FN 57> As such, “pumping rate is considerably more important than locality and intake configuration in determining the number of fish either entrained or impinged.”<FN 58>

Pisces has expanded on its assessment of the relationship between cooling water flows and impingement and entrainment by incorporating data from many more U.S. plants into its regression equations, and by conducting a full statistical analysis and calculating the confidence intervals for its impingement regression equations. As a result of that analysis, the Pisces Phase II and NODA Report <FN 59> contains the following equations for impingement and entrainment, as a function of water withdrawals, for power plants located on Great Lake, other freshwater and estuary/marine waterbodies:

Impingement/Flow Relationship

Great Lakes: $I = 1.7023V^{1.778}$

Other Fresh Water: $I = 6 \times 10-8V^{3.1444}$

Ocean and Estuary: I = 0.1704V^1.5943

All Waters Combined: I = 0.4719V^1.8699

(Where I is the number of fish impinged per year and V is volume withdrawn in cubic feet per second.)

Impingement/Flow Relationship

Fresh Water: En = 2E + 07V0.1924

Ocean and Estuary: En = 457475V 1.1405

(Where En is the number of fish impinged per year and V is volume withdrawn in cubic feet per second.) These equations and the entrainment data are plotted in Figures 1 and 2 in the Pisces Phase II and NODA Report.<FN 60>

Indeed, EPA has agreed that impingement and entrainment levels are directly related to the volume of water withdrawn.

Benefits of reduced intake capacity

Closed-Cycle Cooling Minimizes Capacity and Fish Kills.

The difference in capacity between once-through cooling systems and closed-cycle cooling systems is enormous. "Once-through" cooling systems take water from a local body of water, use it to absorb heat from the facility (in the case of electric power plants, from the steam condensers), and discharge it back at an elevated temperature. In a once-through system none of the cooling water is recirculated and extremely large volumes are required.

Once-through systems generally consume on the order of hundreds of millions or billions of gallons of water per day. The Salem Generating Station in New Jersey uses more than 3.3 billion gallons of water per day at peak operation. Each reactor at the Indian Point facility in New York uses more than 1.4 billion gallons per day at peak operation. Once-through systems at modern combined-cycle fossil fuel plants will use somewhat less water, but the volumes for large plants of that type are still in the hundreds of millions of gallons per day (mgd).

"Closed-cycle" cooling, in contrast, involves significant or complete recirculation of cooling water. The volume of water used by either of the two primary types of closed-cycle systems is dramatically lower than for once-through cooling. In closed-cycle wet cooling systems (ie., evaporative cooling towers), cooling water is circulated through cooling towers to transfer heat to the atmosphere by evaporation, and is then recirculated through the plant to absorb heat. In closed-cycle dry-cooling systems (aka. air cooling) radiator-type coils are used to transfer heat to air passing over the coils. In dry systems, there is no water evaporation and virtually all water is recirculated. As a result, plants that use dry cooling have no visible plume and have much smaller water requirements. Plants with dry cooling systems have no thermal discharge to watersheds, only to air, and need to add additional water only occasionally for periodic system maintenance and cleaning. Where steam plume abatement is desirable, hybrid cooling systems are available that use both wet sections and dry sections.

The precise volume of water withdrawn by any of these systems depends on the size of the plant and the type of electricity generation technology . Generally, the higher the output of a power plant, the more cooling water is required.<FN 61> Most critical for BTA purposes, however, is that water requirements for the different cooling system categories vary by orders of magnitude.

The differences in both capacity and mortality between once-through cooling and closed-cycle cooling are particularly dramatic. Closed-cycle systems generally require only 2-5% as much water as once-through cooling systems. That is, a plant which would extract 1 billion gallons per day (1000 mgd) of water if cooled by a once-through system, will require only about 2-5% of that amount or 20 to 50 mgd if cooled by an evaporative cooling tower instead. Retrofitting evaporative cooling towers on a power plant that currently uses once-through cooling will therefore reduce water usage by approximately 95-98%. The reduction in water use from saline sources may in some circumstances be lower, but is still highly significant, at 70% or more, depending on the extent to which State water quality standards limit chloride increases.

Most significantly, this dramatic reduction in intake volume will directly reduce the mortality of aquatic organisms by a correspondingly large amount. Thus, power plants which currently slaughter billions of larval fish will generally destroy less than 5% (and possibly as little as 2%) of that total.

Footnotes

61 Section 3 of the Pisces I Report contains regression functions to describe the relationship between power output and cooling water requirements.

EPA Response

EPA points out that the commenter has mistakenly used the word "consume" in reference to cooling water intake, especially in the case of once-through cooling. This could be a misleading word usage, as the term "consume" implies that the water is lost, when in fact it is returned to the waterbody. Although the elevated temperature of once-through system discharges will ultimately increase the rate of evaporation of the receiving water, this effect is small. In many cases, the local water authority may require a facility to account for this water "consumption", but confusing this accounting with water "withdrawal" may lead to issues related to water scarcity. In the case of recirculating wet cooling, there is some mounting concern in local communities over the small degree of water consumption that occurs in the cooling system (through evaporation) that is correctly termed "consumption." Granted, there is a significant misconception among the industry and local authorities about the comparative water consumption between once-through and recirculating wet cooling, but is measurably different.

The commenter repeats in this comment a common omission related to cooling tower water withdrawal compared to once-through systems (as compared to once-through systems) in marine environments. In fact, the data presented by the commenter about the supposed performance of cooling tower systems is optimistically high even for the likely case of a retrofit for a freshwater cooling system. For more discussion on this topic see response to comment 316b.EFR.404.034.

Documented facility examples of CWIS impacts

As just one example of the massive reduction on fish deaths from converting to closed-cycle cooling, in early 2002, the Albany Steam Station on the Hudson River received approvals from New York State to repower the once-through, steam-cycle plant and convert to closed-cycle cooling. The Bethlehem Energy Center project, as it is known, will convert the existing 400 MW oil-burning facility to a 750 MW combined-cycle natural gas facility. The project will reduce Hudson River water withdrawals dramatically, by 98-99%, from the current 500 mgd to a maximum of about 8 mgd. (It will also reduce air pollution rates by 98%). The plant's owner, PSEG Power New York, Inc., has estimated that the reduction in intake capacity will reduce entrainment by 9899% from the current annual totals of 420 million eggs, 460 million yolk-sac larvae, 210 million-post yolk-sac larvae, and 130,000 juveniles.<FN 62>

Retrofitting to closed-cycle cooling drastically reduces water usage and fish kills through impingement and entrainment. This ratcheting down of impacts is exactly what was contemplated by Congress when it established the NPDES permitting system and the technology-based limitation requiring best technology available.

Available I&E technologies

All Other Technologies Are Significantly Less Effective.

While other technologies exist to reduce entrainment and impingement, none of them afford anywhere near the level effectiveness and reliability of closed-cycle cooling. Such technologies include, for example, Ristroph screens and fish return systems; wedgewire screens; fine mesh traveling screens; barrier nets; louver screens; angled screens; velocity caps; porous dikes; behavioral barriers; variable speed pumps; and microfiltration.

As the Pisces Phase II and NODA Report, submitted with these comments, details, these technologies vary in their effectiveness, but none of them come close to achieving the effectiveness and reliability of closed-cycle cooling.<FN 63>

Source data used by EPA

In the NODA, EPA reports that it has collected additional studies on intake screen and diversion devices and has assembled a database of such studies.<FN 64>Pisces reviewed the database and new studies and concluded that:

The new database provided by the EPA does not materially improve the knowledge on these different technologies. Some are studies of well-known methodologies (traveling screens etc) others are of very experimental technologies.

One of the most obvious facts to come from the new data is that most of the technologies produce large between-sites and between-species variations in reduction of I&E. It its therefore impossible to produce a meaningful average figure for the decrease due to a particular technology. The only exception is the effect of reducing the total amount of cooling water used.<FN 65>

EPA acknowledges the superiority and certainty of cooling towers in reducing impingement and entrainment:

The only technology effectiveness that is certain is reductions in impingement and entrainment with cooling towers.<FN 66>

As a result, these technologies cannot be considered as BTA or as substitutes form closed-cycle cooling technology. They can, of course, be considered as supplements which when used in conjunction with closed-cycle cooling may offer additional environmental protection and further reduce impact.

Sample facilities/technologies

In particular, one technology, the microfiltration device known as Gunderboom, is an experimental technology that cannot be considered as any component of a national BTA standard, certainly not in lieu of cooling towers. The only locations where Gunderboom has been tested are on the Hudson River at the Lovett Station Unit 3 and in an in-situ experiment in Bowline Pond conducted by Riverkeeper. Analysis of the monitoring reports of Gunderboom deployment at Lovett reports indicates that even after anchoring problems were corrected, the effectiveness of the filter fabric began to decline soon after deployment, and the material was ineffective after 5 to 6 weeks of use. The failure of the Gunderboom fabric at Lovett was likely related to biofouling, which blocks water flow through the material, thereby causing water and aquatic biota to overtop, tunnel under and/or rip through the fabric. As a result, exclusion rates comparable to the entrainment reductions offered by closed-cycle cooling cannot be achieved. Such success rate has never been achieved at Lovett or anywhere else. If anything, the Lovett reports demonstrate that Gunderboom material will foul and fail within a month or two of deployment.

As the Pisces Phase II and NODA Report explains, Gunderboom has never been proven to be effective at Lovett, except for very limited periods of time:

The only microfiltration system considered is the Gunderboom and the report makes it clear that the only data available come from the observations at Lovett GS. It is concluded that ‘Entrainment reductions up to 82 percent were observed for eggs and larvae and these levels have been maintained for extended month-to-month periods during 1999 through 2001.

This statement is a clear exaggeration of the observed effectiveness of the Gunderboom at Lovett GS. Overtopping, tunneling and rips have been observed during testing. For example, in the Lovett evaluation report for 1999 it is stated that “the divers documented a substantial gap along the bottom of the boom. The gap extended along the bottom of the boom for approximately 3 m and ranged in depth from 0.5 to 0.6 m".

It is clear in Table 2 of the Lovett 2000 report (above [in Pisces report]) that there was a gradual increase in entrainment through time. Further, there was also a series of events between May and August 2000 that resulted in short-term total failures. The efficiency of the Gunderboom was assessed by comparing the level of entrainment at unit 3 (protected by a Gunderboom) to that at unit 4 (unprotected). Thus a ratio above 1 for the number of fish entrained at unit 3 to unit 4shows that the boom was offering no protection. To achieve 82% effectiveness or better the ratio would need to be smaller than 0.18. As shown in the figure below this level of efficiency was only achieved for a short period during May 2000. It is therefore incorrect to conclude that it was achieved for extended month-to-month periods during 1999 through 2001. In fact from late July 2000 the Gunderboom was completely ineffective at reducing entrainment.<FN 67>

Because Riverkeeper suspected that the declining efficiency of Gunderboom has was related to biofouling, we commissioned original research on Gunderboom fabric with intervenor funds in the New York State Article X power plant siting proceeding for the proposed Bowline 3 facility (Case

No. 99-F-1164).<FN 68>The in situ experiment conducted in Bowline Pond by Pisces Conservation, with assistance from Carpenter Environmental Associates, demonstrated that when exposed to the Hudson River environment during the spawning season, the permeability of Gunderboom material progressively declines as a result of the growth of a biological community on the surface.<FN 69> In fact, after 29 days in the water, Gunderboom material which was subjected to an airburst cleaning system (as proposed for BEC) had only 4% of the permeability remaining, as compared to clean material.<FN 70> Fouling of the filter fabric can result in at least three biological problems: (1) fouling of the surface might reduce the area through which water can flow leading to velocity 'hot spots' where delicate animals may be pinned or pulled through the mesh; (2) increased flow resistance causes water to force another path across or around the barrier; and (3) establishment of a predatory community adapted to feed on any small animals drawn close to the fabric. <FN 71>

Because Gunderboom is an experimental technology, and has not been shown to be an effective substitute for closed-cycle cooling, it cannot be considered BTA.

Assumptions about I&E survival

Assuming 100 Percent Mortality of Entrained Organisms Is The Only Defensible Approach for These Regulations.

EPA is requesting comment on whether the current state of knowledge supports a defensible assumption of the extent of entrainment survival above zero percent to be used to calculate national benefits estimates.<FN 72>Entrainment survival is also an issue that permit applicants use, in part, to justify their use of once-through cooling, on the theory that a great percentage of entrained organisms will survive once-through cooling than would survive a cooling tower.

The only assumption consistent with the research to date on the subject is that organisms do not survive entrainment intact. As EPA correctly acknowledges:

[Existing studies entrainment survival] are characterized by significant uncertainty and variability.. . [T]he proportion of the organisms that are alive in the samples is highly variable and unpredictable.<FN 73>

Pisces has reviewed material on entrainment mortality in the record concludes that "the only safe assumption for the mortality of fish entrained in the cooling water flow is 100%."<FN 74> Among other things, Pisces explains that there is a paucity of studies on entrainment survival and much of the data is limited in significant ways. Further, while some studied organisms may not immediately perish upon being entrained, they are compromised and subject to latent mortality which often not captured in the studies conducted to date:

In other words, fish can take many days to die from the effects of entrainment. Most studies only present the immediate and 48 hour survival times, whereas the effect on larvae might be apparent over a much longer period than this. No experiment has ever shown exposed fish to recover to a mortality rate as low as the controls. <FN 75>

Moreover, entrained organisms are more subject to predation and, even if they survive entrainment, may be subject to long-term sub-lethal damage.<FN 76>

As Pisces explains, quantifying the mortality of eggs and larval fish caused by entrainment is very difficult. Mortality caused by entrainment is certain. The long-term survivorship of eggs and larvae is not. While some fish are alive after entrainment, it is not known unknown but how many will survive the longer-tern effects of increased predation, affected growth and disease. Given the amount of acute damage and the steady mortality subsequently observed, the increased likelihood of predation, and the long-term impacts of poor growth following trauma, all available evidence points to a very poor likelihood of reaching adulthood. The entrained fish are effectively lost to the population even if not immediately after the entrainment event. Combined with the difficulty of using existing survival data to predict the survival rates at another plant on a different water body, it is clear that the only path the EPA can follow with any degree of certainty is to assume 100% mortality for any entrained fish. <FN 77>

Cooling system costs (e.g., dry, wet, recirculating)

CLOSED-CYCLE COOLING IS AVAILABLE AND AFFORDABLE FOR EXISTING FACILITIES, AND WILL NOT ADVERSELY AFFECT ENERGY SUPPLY, RELIABILITY OR PRICES.

Closed-Cycle Cooling Is Virtually Ubiquitous For Modern Power Plants, and Has Been Retrofit on Numerous Older Plants.

Closed-cycle cooling is available technology for both new and existing facilities. For new plants, it is overwhelmingly the standard technology. In conjunction with the Phase I regulation for new facilities, EPA reported that 100% of the combined-cycle plants built in the last 20 years have a closed-cycle recirculating cooling system.<FN 78> For coal-fired facilities, 88% of the facilities built in the last 10 years have closed-cycle cooling.<FN 79> Likewise, for existing plants, EPA acknowledges that:

A closed-cycle recirculating cooling system is an available technology for facilities that currently have once-through cooling water systems.<FN 80>

In the 1970s, 1980s, and 1990s, facilities of various sizes and fuel types converted from once-though cooling to closed-cycle cooling. Specifically, EPA has reported the following cooling system retrofits: The 821 MW Palisades Nuclear Plant in Michigan converted to closed-cycle cooling in 1974;the 490 MW coal-fired Canadys Steam Plant in South Carolina, converted its once-through cooling system to a closed-cycle recirculating system in two steps, first Unit 3 in 1972 and then Units 1 and 2 in 1992; in 1985, the 346 MW Jeffries Coal Plant also South Carolina converted from once-through cooling to recirculating cooling towers; and finally, Unit 7 of the 751 MW gas-fired Pittsburg Power Plant in Contra Costa County, California, has converted to closed-cycle.<FN 81>

Retrofits are also currently planned or underway at several other US facilities, including at the McDonough (520 MW coal) and Yates (1250 MW, coal) plants on the Chattahoochee River in Georgia and at the Wateree Station (772 MW, coal) on the Wateree River in South Carolina. Several different retrofit options have been evaluated for some or all of the four units at the Brayton Point power station (1500 MW, coal/oil) in Somerset, Massachusetts, including unit-specific and/or multi-mode cooling towers.

In addition, other plants have converted from once-through cooling to closed-cycle cooling, or are planning to do so, while repowering and simultaneously improving the efficiency, air pollution rates, and total capacity of their plants. For example:

Reliant Astoria Repowering Project and the Bethlehem Energy Center in New York State are evidence that firms will seek to repower older, less efficient generating facilities and that such repowerings can include cooling towers as part of the repowered facility in place of once-through cooling. Such projects will provide significant environmental benefits in terms of reduced water usage and lowered air emissions and will offer substantial economic benefits for their owners.<FN 82>

EPA Response

The commenter confuses the term “available technology” with “best technology available,” in the Agency’s view. Simply because many cooling tower systems exists where they have been integrally constructed from the ground up along with a facility or during the extended process of repowering the facility has no bearing on the ultimately availability of this technology through retrofit to existing, operating plants. The Agency based its determination on best technology available on those candidates that could reliably be retrofitted to existing facilities and would not cause the potential 10 month construction downtimes as could the mandate of cooling towers to the facilities within the scope of the rule. As such, the technology of wet cooling towers, in addition to being appreciably less cost-effective in minimizing adverse environmental impact, would not be the “best technology available.”

The commenter provides no evidence that “numerous” examples of cooling tower retrofits have been conducted. Despite the fact that a handful of new examples exist of cases where cooling towers have been evaluated does not a robust data set make. In addition, the example cases referenced by the commenter are potentially being driven primarily by forces outside of impingement and entrainment by cooling water intakes, such as thermal discharge or water reliability/availability. In addition, the commenter does not provide persuasive evidence of the ultimate costs that could be realized by these planned or considered projects, nor evidence that the potential connection outages would ultimately be reasonable. As such, the commenter’s examples provide little information that supports their illogical viewpoint that cooling tower retrofit projects at existing facilities is the default best technology available.

Mkt-level impacts/Reliability/EO 13211: Energy Effects

A Retrofit Mandate Will Not Cause Energy Shortages.

A regulation requiring closed-cycle cooling for all existing facilities would not significantly affect U.S. energy supplies in the short-or long-term. Submitted with our August 2002 comments was a report by Synapse Energy Economics of Boston, Massachusetts. In its 2002 report, the “Synapse 2002 Phase II Report”, Synapse analyzed the energy impact of an all closed-cycle cooling rule, and concluded that there would be no adverse energy reliability impact from the implementation of an all-cooling tower regulatory option.<FN 83>

Adverse energy effects of such a regulation could conceivably result from one of three causes: plants going temporarily off-line to retrofit to cooling towers; reduced energy generating efficiency (sometimes called an “energy penalty”) from operating with a cooling tower; or the retirement of facilities. Synapse carefully analyzed each of these possibilities, and determined that none presents a significant problem.

First, Synapse calculated the percentage of national power capacity that would be off-line for retrofit at any one time. As EPA acknowledged in its Phase II proposal, the new cooling towers could be built while an affected facility is operating and the attachment of the new tower to the existing cooling system would have only a one-time effect, extending a planned maintenance outage by one month.<FN 84> Based on EPA’s estimates, Synapse notes that a national closed cycle cooling rule would cause 416 facilities, representing 33.1 percent of U.S. generating capacity, to add cooling towers. Since power plant cooling technology is dictated by 5-year NPDES permits, and since the design and construction of cooling towers can take several years, it is reasonable to assume that the facility outages required to connect these new cooling towers could and would be scheduled to occur throughout a five-year transition period. As a result, on average, only 0.5 percent of the nation’s electric generating capacity would be out of service at any one time as a result of the implementation of a national closed-cycle cooling rule.<FN 85>

The same would be true on a regional basis. Only 0.75 percent of the generating capacity in the ECAR and NPCC regions, on average, would be out of service at any one time. Again, this assumes that the extra month of downtime needed to connect the new cooling towers would occur randomly throughout the year. It is far more likely, however, that the extra downtime would be preferentially scheduled to occur during the off-peak seasons when capacity reserve margins are much higher. As a result, the implementation of a national closed-cycle cooling regulation would have even less of an effect on electric system reliability than these figures would suggest.<FN 86>

Second, the energy penalties will be minor. Even assuming EPA has correctly estimated the energy penalty at 1.7 percent, this is a minor reduction considering in light of existing and predicted reserve margins, and the additional capacity expected to come on line in the near future. Moreover, EPA has significantly overstated the energy penalty, as Synapse explained in detail. <FN 87>

Third, no generating capacity will be retired as a result of the implementation of the closed-cycle cooling rule. As explained below, based on the extremely high profitability of existing nuclear and fossil fuel plants, and the relatively minor costs of retrofitting cooling towers, it is unreasonable and unrealistic to assume that any facilities will close as a result of such regulation. If anything, a cooling tower mandate might cause some retrofitting facilities to simultaneously repower from older, less efficient single-cycle generating technology to modern, more efficient combined-cycle technology. On the Hudson River, the owner of the Albany Steam Station recently received approval to repower the plant, and in so doing will reduce cooling water intake by 98-99% percent, reduce air pollution rates by a similar percentage, while nearly doubling capacity. Thus, a closed-cycle regulation may cause an increase in capacity. <FN 88>

Even apart from repowerings that might be caused by such a rule, there are a number of other sources of additional, new capacity which will more than compensate for any reductions in available capacity. Thus, the extremely minor capacity reduction totals discussed above overstate the effect that the implementation of a closed-cycle cooling the regulation would have on electric system reliability. A significant amount of new capacity is scheduled to come on line nationwide in the next few years. - Further, there will be additional capacity available from already-scheduled repowerings of oil-, gas- and coal-fired facilities to combined-cycle plants. Synapse is aware of at least 17 coal-fired facilities have been or are planned to be repowered to use combined-cycle technology, in addition to many more repowerings from oil or gas, which EPA has reported. These repowerings could add thousands of additional megawatts of generating capacity to the national electric system and, thereby, improve system reliability while reducing water usage. Similarly, condenser upgrades improve performance in terms of fewer tube failures and lower forced outage rates. Thus, the facilities that have implemented condenser upgrades should be available for service for more of the year than they previously had been. This additional capacity can be expected to further enhance electric system reliability. <FN 89>

Moreover, there will be additional capacity available from the implementation of power uprates at nuclear power plants. A power uprate means increasing the thermal power produced by the plant. A power uprate increases the output of the plant at a relatively low cost. The U.S. Nuclear Regulatory Commission has approved more than 60 such power uprates of between 5 and 20 percent. Requests for additional uprates are currently under review by the NRC or are planned for submission in the near future. An average increase of 10 percent in the power levels of the nation's nuclear plants would add approximately 9,000 megawatts of additional capacity to the electric system. Likewise, many nuclear power plants will be extended beyond the current 40 year terms of their Nuclear Regulatory Commission-issued operating licenses. Therefore, there may be more generating capacity available over the next 30 to 50 years than has been assumed in the EPA analyses. <FN 90>

Footnotes

83 Synapse 2002 Phase II Report at p. 2.

84 In the NODA, EPA revised its estimate of the net downtime for retrofitting cooling towers at nuclear plants from 4 weeks to 7 months, and has apparently based this revision solely on the time it apparently took to retrofit the Palisades nuclear power plant in 1973-1974. 68 Fed. Reg. at 13525. Synapse analyzed EPA's net downtime revision and concluded that basing current retrofit downtime estimates on the experience at the Palisades plant 30 years ago is unjustified because, among other things: (1) the durations of refueling/maintenance outages at nuclear power plants have been significantly reduced during the past decade; (2) contrary to what the plant owner told EPA, it appears that the extended outage of Palisades was primarily due to factors other than the installation of the new circulating water system; (3) the Palisades retrofit could have been completed in significantly less time than it took; (4) the U.S. Department of Energy's National Energy Technology Center October 2002 retrofit report, prepared by Parsons Infl-astructureand Technology Group, concluded that, with proper planning and coordination with other planned outages, cooling tower retrofits at nuclear plants could be accomplished without loss of generating time. See Synapse NODA Comment, submitted herewith. Thus, EPA should not have revised the

estimated downtime to 7 months and should instead continue to base its calculations on a 4-week net downtime.

Organization Riverkeeper, Inc.

Subject Matter Code 9.01
Facility & firm-level costs/Econ. Practicability

The Cost of Closed-Cycle Cooling is Minimal to Industry, Would Not Cause Facilities to Close, and is Only Pennies per Month Per Household.

In the Phase II Synapse Report, Synapse analyzed and the costs of complying with regulatory options that require closed-cycle recirculating cooling systems and concluded that such costs would be extremely minor.

Based on EPA's own calculations, the compliance costs of an all cooling tower rule, would add cooling towers at 416 facilities, would increase the average price of generating electricity at the affected facilities by about one-tenth of one cent (known as a mill) per kilowatt hour. Since retail energy costs average about 8.5 cents per kilowatt hour, this represents only a 0.66 percent increase.<FN 91>

Whether the owners of affected facilities can pass these cost increases along to their customers is not certain in a deregulated market, although where a market clearing price system is in place, it is like they can. To the extent costs are passed on, the overall price paid by consumers for the electricity they use would reflect a blend of both the price of generating electricity at affected facilities and the price of generating electricity at nonaffected facilities. Consequently, the price of electricity actually paid by consumers would increase by less than the tenth of a cent per kilowatt hour. Indeed, as demonstrated by Synapse the average price increases to consumers caused by an all-cooling tower rule would be only one-twentieth of a cent (one-half mill) per kilowatt hour. As a result, an average consumer who uses 500 kilowatt hours per month would see his/her bill increase by only 28 cents per month if a closed-cycle regulation were adopted.

These extremely minor cost increases would also not cause any facilities to close. Based on its experience and previous work with power plants, Synapse believes that it is extremely unrealistic to expect that currently operating nuclear power plants will be retired as a result of the adoption of a flow reduction technology based regulatory options. This conclusion is based on (a) the improved performance and reduced O&M costs achieved at nuclear plants since the mid-l990s, (b) the fact that nuclear plants' low operating and fuel costs allow them to compete successfully in bid-based wholesale markets, and (c) the significant economic benefits that are available from relatively low cost investments in plant power uprates and operating life extensions.

For example, a recent Synapse analysis concluded that a $36 million investment in increasing the power level of the Vermont Yankee Nuclear Plant by 13 percent would result in a net present value benefit of $56 million (in 2001 dollars). A similar investment in extending the unit's operating life by twenty years would produce a net present value benefit of $253 million. With the opportunity for potential economic benefits of this magnitude, it is unlikely that any nuclear plant would be retired as result of the adoption of a closed-cycle retrofit mandate from the EPA.

EPA Response

Please refer to the response to comment 316bEFR.206.026 in subject matter code 9.01.

Section 316(b) Requires Closed-Cycle Cooling as BTA because it is the Best Technology in Use.

As explained above, the Clean Water Act's technology-based limitations were designed to force the iterative development of more protective technologies, and to ratchet down discharges and other impairments to water quality until they could be eliminated. Congress and numerous federal courts have emphasized this "technology forcing" character of the Act's categorical standards within the context of the section 301 BAT requirement. It is therefore well-settled law that BAT standards must require all existing facilities to match the environmental performance of the best performing, i.e., least polluting, least harmful, facility.

BAT must be "at a minimum, established with reference to the best performer in any industrial category." Conf. Rep. On S. 2770 (October 4, 1972), Legislative History of the Federal Water Pollution Control Act of 1972 at 170. "The BAT standard reflects the intention of Congress to use the latest scientific research and technology in setting effluent limits, pushing industries toward the goal of zero discharge as quickly as possible. In setting BAT, EPA uses not the average plant, but the optimally operating plant, the pilot plant which acts as a beacon to show what is possible." Kennecott v. EPA, 780 F.2d 445,448 (4th Cir. 1985), citing legislative history See A Legislative History of the Water Pollution Control Act Amendments of 1972, 93d Cong., 1st Sess. (Comm. Print 1973), at 798 (hereinafter "Leg. Hist."). See A Legislative History of the Water Pollution Control Act Amendments of 1972, 93d Cong., 1st Sess. (Comm. Print 1973), at 798 (hereinafter "Leg. Hist.").;

"[I]t is clear that Congress did not intend by that phrase [i.e., BAT] to limit the technology to that which is widely in use. ... 'It will be sufficient, for the purpose of setting the level of control under available technology, that there be one operating facility which demonstrates that the level can be achieved or that there is sufficient information and data from a relevant pilot plant.'" American Iron & Steel Inst. v. EPA, 526 F.2d 1027, 1058 (3d Cir. 1975), quoting legislative history. BAT must "utilize the latest technology to reach 'the greatest attainable level ... which could be achieved. NRDC v. EPA, 863 F.2d 1420, 1431 (4thCir. 1988).<FN 92>

The best-performer/optimally-operating-plant essence of BAT standards is illustrated by contrast with or "best practicable technology" or BPT standards.<FN 93>BPT was an intermediate technology standard which, under the CWA's three-step phase-in process, were completely replaced by the BAT standards in 1979. Under the obsolete BPT mandate, EPA set standards which represented the "average of the best existing performance by plants of various sizes, ages and unit processes within each industrial category or subcategory. This average is not based upon a broad range of plants within an industrial category or subcategory, but is based upon performance levels achieved by exemplary plants.'' Kennecott v. EPA, 780 F.2d 445,448 (4th Circ. 1985) citing EPA v. Nat'l Crushed Stone Ass'n, 449 US. 64,76 n. 15, 66 L. Ed. 2d 268, 101 S.Ct 295 (1980) (1980) quoting 39 Fed. Reg. 6580 (1974). "The distinction between 'best practicable' and 'best available' is intended to reflect the need to press toward increasingly higher levels of control. Kennecott v. EPA, 780 F.2d 445,448 (4th Cir. 1985)' citing legislative history.

Section 316(b)'s BTA mandate, which is at least as strict as BAT standards and clearly stricter that BPT, requires EPA to set extremely technology-forcing cooling water intake standards that reflect state-of-the-art controls. As with BAT, BTA requires EPA to look to the optimally-operating plant, Le., the best performer, and to bring all facilities up to the "best of the best" level. EPA has done this for many years for most industrial dischargers, including new and existing power plants.<FN 94> The Clean Water Act requires the same for cooling water intakes at power plants.

Require closed cycle cooling

Because closed-cycle cooling is the best technology for minimizing adverse environmental impact, is widely available for both new and existing plants, and will not cause adverse energy impacts, it is BTA for existing facilities. EPA has no discretion to determine otherwise. Indeed, for EPA to determine that a once-through plant is the “optimally operating plant, the pilot plant which acts as a beacon to show what is possible,’’ (Kennecott v. EPA, 780 F.2d at 448) would be arbitrary and capricious and not in accordance with law.

Subject Matter Code 2.04.03

Define BTA as anything less than closed cycle

COMPLIANCE COSTS ARE ONLY MARGINALLY RELEVANT TO THE DETERMINATION OF BTA.

The fact that closed-cycle cooling may cause facilities to incur higher compliance costs does not change the BTA determination. “Congress foresaw and accepted the economic hardship, including the closing of some plants, that [Clean Water Act] effluent limitations would cause.” EPA v. National Crushed Stone, 449 U.S. 64, 79 (1980). As the Supreme Court explained, Congress devised the Act with the economic consequences in mind:

Prior to the passage of the [Clean Water] Act, Congress had before it a report jointly prepared by EPA, the Commerce Department, and the Council on Environmental Quality on the impact of the pollution control measures on industry. That report estimated that there would be 200 to 300 plant closings caused by the first set of pollution limitations. Comments in the Senate debate were explicit: ‘There is no doubt that we will suffer some disruptions in our economy because of these efforts; many marginal plants may be forced to close.

Id. at 80.

Section 316(b) does not explicitly provide that EPA may take compliance costs into consideration at all when establishing national standards requiring that cooling water intake structures reflect the best technology available. In contrast, other provisions of the Act that mandate the establishment of technology-based standards, such as Sections 304 and 306, require EPA to consider costs, and those provisions further specify how costs are to be considered. <FN 95> Significantly, the United States Court of Appeals for the D.C. Circuit has consistently held that, without specific statutory authorization for considering costs, “the EPA is not permitted to consider the cost of implementing those standards” under the Clean Air Act. American Trucking Associations v. US EPA, 175 F.3d 1027, 1040 (D.C. Cir. 1999); see also Lead Industries Assoc. v. EPA, 647 F.2d 1130, 1148 (D.C. Cir. 1980). This is especially true where the other provisions of the same statute direct EPA to consider costs, as certain sections of the Clean Water Act do. In such cases, courts conclude that Congress only intended EPA to consider costs where it has explicitly so provided. Lead Industries Assoc., 647 F.2d at 1148. Under this authority, which applies with equal force to the Clean Water Act, EPA is statutorily precluded from considering compliance costs in the setting of Phase II BTA standards.

Despite the lack of explicit reference to costs in section 316(b), EPA has EPA has stated that “best technology available”’ should be interpreted as “best technology available commercially at an economically practicable cost"<FN 96> EPA appears to be equating role of costs under the BTA standard with the BAT standard, which is “best available technology economically achievable.” If EPA’s interpretation is correct, however, then EPA’s consideration of costs for BTA can be no more extensive than is permitted for BAT.

Congress’ goal to impose the strictest controls for existing facilities is manifested in the extent to which EPA may consider costs. In setting BAT standards, EPA may consider, among other factors, “the cost of achieving such effluent reduction,” 33 U.S.C 1314(b)(2)(B),but it cannot perform a cost-benefit analysis: “[I]f the effluent reduction is technologically feasible and economically achievable [to the industry as a whole], it must be employed.” 92 Cong. Rec. S.2770 (1972)(emphasis added).

Footnotes

95 See, e.g., Section 304(b)(l)(B): “Factors relating to the assessment of best practicable control technology currently available ... shall include consideration of the total cost of application of technology in relation to the effluent reduction benefits to be achieved,” Section 304(b)(2)(B): “Factors relating to the assessment of best available technology shall take into account ...the cost of achieving such effluent reduction,” and Section 306: “In establishing ... Federal standards of performance for new sources.. .the Administrator shall take into consideration the cost of achieving such effluent reduction.”

96 EPA’s interpretation lacks support because it is not based not on any judicial authority or a reading of the plain language of the Act. Instead, it rests on a single statement in the legislative history and on EPA’s own preamble to the 1976 rule.

Use cost-benefit tests

Several major U.S. industries, including the steel, chemical and mining industries, have filed lawsuits against the EPA's promulgation of effluent limitation guidelines, claiming that the agency had been unreasonable by failing to consider environmental compliance costs either in establishing technology guidelines or refusing to issue variances to such standards. In each instance, the EPA's steadfast refusal to give undue consideration to pollution control compliance costs was upheld by the courts.

Courts have upheld the BAT selected by EPA for a variety of industrial categories, even though EPA predicted that the BAT would cause economic displacement, including plant closures, associated job losses and other significant impacts. For instance, the Third Circuit upheld performance standards for existing sources, which are set in accordance with the procedures for BAT standards, even though "EPA estimated that compliance with the [standards] would force 14% of all indirect discharging plants to close and cause a 1.2% reduction in total industry employment." Chemical Mfrs. Ass 'n,870 F.2d at 250. As the court explained, "Congress clearly understood that achieving the CWA's goal of eliminating all discharges would cause 'some disruption in our economy,' including plant closures and job losses." Id. at 252. The Ninth Circuit has also upheld BAT that was projected to cause plant closures, observing, "Congress contemplated the closure of some marginal plants." See Association of Pacific Fisheries v. EPA, 615 F.2d 794, 818 (9th Cir. 1980);Rybacheck, 904 F.2d at 1291.

Furthermore, the BAT standard should represent "a commitment [by an industrial category] of the maximum resources economically possible to the ultimate goal of eliminating all polluting discharges." See EPA v. Nat' Crushed Stone Ass'n, 449 U.S. 64,74 (1980); see also NRDC v. EPA, 863 F.2d. at 1426.

The role of costs in BAT can be illustrated in contrast to the now-defunct BPT standards. To determine "best practicable technology," a cost/benefit analysis was appropriate. For such BPT standards, the Clean Water Act allowed EPA to consider, among other factors, "the total cost of application technology in relation to the effluent reduction benefits to be achieved from such application." 33 U.S.C. 0 1314(b)(l)(B). Thus, under the BPT standard, EPA considered cost as a function of effectiveness; when the cost to reduce additional effluent became disproportionate to the amount of reduction, the additional reduction was not required. Reynolds Metals Co. v. EPA, 760 F.2d 549, 554 (4 Cir.1985). As explained above, BPT was determined by averaging the best performing plants of various sizes, ages, and processes, and applying that average as the BPT standard for each industry at that time. Organic Chemicals and Plastics and Synthetic Fibers Category Effluent Limitations Guidelines, Pretreatment Standards, and New Source Performance Standards, 52 Fed. Reg. 42522 (III)(A)(1) (to be codified at 40 C.F.R. 414,416.) This was Congress' concession to industry to allow facilities to update and comply with approaching BAT requirements.

However, even under the less stringent BPT standard, an industrial polluter could not escape complying with the regulations based solely on inability to bear compliance costs:

Because the 1977 limitations were intended to reduce the total pollution produced by an industry, requiring compliance with BPT standards necessarily imposed additional costs on the segment of the industry with the least effective technology. If the statutory goal is to be achieved, these costs must be borne or the point source eliminated.

EPA v. National Crushed Stone, 449 U.S. 64,78 (1980).

Thus, even under the less stringent BPT standard, costs must have a minor role and a strict cost-benefit test was not required. In Chemical Mfrs. Ass'n v. EPA, 870 F.2d 177 (5th Cir. 1989), chemical manufacturers maintained that the cost-effectiveness of Best Practicable Technology rulemaking should be measured by a "knee-of-the-curve" test to determine the point at which costs rise steeply per pound of pollutant removed. Under such a test, they argued, the BPT rules were not cost-effective. In supporting EPA's interpretation of cost-benefit analysis and rejecting the chemical manufacturers' argument, the Court stated,

Congress intended Section 304(b) to give the EPA broad discretion in considering the cost of pollution abatement in relation to its benefits and to preclude the EPA from giving the cost of compliance primary importance.

Chemical Mfrs. Ass'n v. EPA, 870 F.2d 177,204 (5th Cir. 1989) (emphasis added).

Senator Muskie, the principal Senate sponsor of the Clean Water Act, described the "limited cost-benefit analysis" employed in setting BPT standards as being intended to "limit the application of technology only where the additional degree of effluent reduction is wholly out of proportion to the costs of achieving such marginal level of reduction .. .."I Remarks of Senator Muskie reprinted in Legislative History of the Water Pollution Control Act Amendments of 1972 (Committee Print compiled for the Senate Committee on Public Works by the Library of Congress) Ser No. 93-1, p. 170 (1973) [emphasis added].

Following the phase-out of BPT, cost could be considered only if the total elimination of discharge is impossible and, even then, only with regard to establishing the appropriate level of reduction for the best within the industry-the BAT standard. Reynolds Metals Co. v. United States EPA, 760 F.2d 549,553 (4th Cir. 1985); Texas Oil & Gas Ass'n v. EPA, 161 F.3d 923,928 (5th Cir. 1998), quoting Chemical Mfrs. Ass'n v. EPA, 870 F.2d 177,226 (5th Cir. 1989). Thus, for BAT (best available technology economically achievable) under Section 301, EPA must consider costs but no full cost/benefit test is permitted.

Because the standard applicable here is akin to the higher BAT standard, compliance cost is given even less weight. In American Iron & Steel Institute v. EPA, 526 F.2d 1027 (3rd Cir. 1975),members of the steel industry sought variances from BAT standards set by the EPA, claiming the cost of compliance was prohibitive. The Court, again relying on congressional intent, explained the standard for compliance cost analysis under BAT as follows:

In making the determination of 'best available' for a category or class, the Administrator is intended to apply the same principles involved in making the determination of 'best practicable' (outlined above), except as to cost-benefit analysis . . .While cost should be a factor in the Administrator's judgment, no balancing test will be required. The Administrator will be bound by a test of reasonableness. . . the reasonableness of what is 'economically achievable' should reflect an evaluation of what needs to be done to move toward the elimination of the discharge of pollutants and what is achievable through the application of available technology-without regard to cost.

Remarks of Senator Muskie reprinted in Legislative History of the Water Pollution Control Act Amendments of 1972 (Committee Print compiled for the Senate Committee on Public Works by the Library of Congress) Ser. No. 93-1, p. 170 (1973) (emphasis added). Finally, EPA must filly explain its cost analysis. See Kennecott, 780 F.2d at 456.

Define BTA as anything less than closed cycle

Technology years ago advanced to the point where impacts on waters of the U.S. from cooling water intake structures at existing power plants can be drastically reduced, as was both anticipated and required by the Clean Water Act. <FN 98> Aquatic and other environmental impacts from closed-cycle cooled stations are negligible. By reducing cooling water intake volume and fish kills by more than an order of magnitude, closed-cycle cooling clearly represents the best capacity technology available for minimizing adverse environmental impact, and the key component of the BTA determination. EPA has no discretion to disregard such an effective and proven technology in determining BTA.

Footnotes

Define BTA as anything less than closed cycle

THE PHASE II PROPOSAL FAILS TO MINIMIZE DAMAGE TO THE NATION'S AQUATIC AND MARINE RESOURCES IN VIOLATION OF THE CLEAN WATER ACT

The Clean Water Act requires EPA to determine the best technology available for minimizing the adverse environmental impact of cooling withdrawals, and set such technology as a national standard. The Phase II Proposal does neither. The performance standards fail to reflect the best technology available-in fact they recognize and permit the worst technology by far with respect to water withdrawal capacity-and the proposed site specific option obviates the national applicability of any such standards.

EPA Response

Subject Matter Code 7.02
Performance standards

The proposed BTA standard for in-scope facilities (i.e., those with intake flows of at least 50 mgd) is as follows:

- All facilities must reduce impingement 80 to 95 percent from the "calculation baseline";<FN 99> and

- Facilities must also reduce entrainment 60 to 90 percent from the "calculation baseline," unless their capacity utilization rate is less than 15 percent, or their design intake flow is less than five percent of the mean annual flow from a fresh water river or stream, in which case they have no entrainment standard.<FN 100>

These standards, however, apply only to facilities that choose the compliance alternatives referred to as Track I and Track II.<FN 101> Permit applicants may instead seek a site-specific BTA determination under Track III.<FN 102> Furthermore, under any of the three tracks, applicants may meet the applicable performance standard with "restoration measures" in lieu of technologies, if the restoration will result in comparable increases in fish and shellfish in the watershed. <FN 103>

Footnotes

99 The calculation baseline was defied at proposal as a once-through cooling system with no impingement or entrainment coqtrols. 67 Fed. Reg. at 17141. In the NODA, EPA has proposed a revised definition, which is discussed below.

100 Id. There are slightly different standards for lakes and reservoirs, other than the Great Lakes. 40 CFR Q 125.94(b)(4) [proposed].

101 Under Track I, an applicant may demonstrate that existing "design and construction technologies, operational measures, and/or restoration measures meet the performance standards." 40 CFR Q 125.94(a)(l) [proposed]. Under Track II, an applicant may demonstrate that existing and proposed "design and construction technologies, operational measures, and/or restoration measures meet the performance standards." 40 CFR 125.94(a)(2) [proposed].

102 40 CFR Q 125.94(a)(3)and (c)(l) [proposed]. To get a site-specific BTA determination, applicants must show that either (1) their compliance costs would be "significantly greater" than those EPA considered in promulgating these regulations; or (2) their costs would be "significantly greater" than the benefits afforded.

103 40 CFR 125.94 (d)[proposed].

EPA Response

For a discussion of the available compliance alternatives authorized by today's rule, please see the preamble.

Define BTA as anything less than closed cycle

Author Name Reed Super

Organization Riverkeeper, Inc.

This proposed BTA "standard" is illegal, both in the approach EPA took to select it and in the result. Furthermore, the compliance options negate any semblance of a national technology standard. EPA's Phase I1 Proposal violates the law and is unsound environmental regulation in at least the following respects:

- The "performance standard" is set with reference to technologies less protective than the best available, in contravention of CWA section 316(b) BTA requirement and the Clean Water Act's technology-forcing mandate.

- EPA employed a cost-benefit test (the "maximize net benefits" approach) to select BTA, thereby violating the Clean Water Act and Executive Order 12866,which require minimization of environmental impacts and prohibit cost-benefit analyses.

- Restoration measures cannot be used in lieu of technologies in a Clean Water Act technology-based requirement because they are not technologies that minimize impacts and they cannot reverse the damage caused by CWISs.

- Track III, which includes both an economic and a ecological variance, is unauthorized and illegal.

EPA Response

EPA has coordinated with OIRA in accordance with Executive Order 12866 and will complete any associated docketing requirements. EPA's final decisions with respect to this rule were made pursuant to, and consistent with the Clean Water Act. EPA has complied with all Administrative Procedure Act requirements regarding ex parte contacts during an informal rulemaking.

Comment ID 316bEFR.404.031

Author Name Reed Super

Organization Riverkeeper, Inc.

Subject Matter Code 2.04.01

Require closed cycle cooling

EPA must substantially revise its Phase II regulation to require facilities to reduce their cooling water intakes capacity to a level commensurate with closed-cycle cooling, must not allow restoration measures as a compliance option, and must only allow variances consistent with statutory and Supreme Court precedent. Any other result would be an abuse of discretion and not in accordance with law.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Comment ID 316bEFR.404.032

Subject Matter Code 2.04.03

Define BTA as anything less than closed cycle

Author Name Reed Super

Organization Riverkeeper, Inc.

THE NATIONAL TECHNOLOGY-BASED PERF'ORMANCE "STANDARD" DOES NOT REFLECT BTA IN PROCESS OR PRODUCT.

The 60 to 90 Percent Entrainment Reduction and 80 to 95.Percent Impingement Reduction Standards Are Based on Less Protective Technologies than the Best Available.

The proposal violates the Clean Water Act by basing the national BTA performance standard on technologies less effective than closed-cycle cooling, i. e. by continuing to allow once through cooling. EPA purports to require a 60 to 90 percent reduction in entrainment from the calculation baseline,"<FN 104> but the operative standard is the bottom of the range, i.e., 60 percent. This is because the proposed rule requires only technologies within or above the range, so any level of performance within the range, including 60 percent, would suffice.<FN 105>

Footnotes

104 40 CFR 125(b)(3) [proposed]. For facilities with a capacity utilization rate of less than 15 percent, and for facilities whose design intake flow is less than five percent of the mean annual flow of a fresh water river or stream, there is no entrainment standard at all. 40 CFR Q 125(b)(2) [proposed].

105 EPA set the lower end of the range (60 percent) to account for sites where the fragility of species would make them susceptible to perishing when coming in contact with the very technologies designed to protect them. The upper end of the range (90 percent) represents the maximum achieved with the technologies on which the standard is based. EPA is considering, but has not included in the Phase II Proposal, a requirement that.facilities achieve the greatest reduction, within the range, that is possible at their site. 67 Fed. Reg. 17141-17142. Unless and until such requirement is included in the rule, facilities have no requirement to reduce entrainment by more than 60 percent. EPA's anticipation that "facilities will select technologies or operational measures to achieve the greatest cost-effective reduction possible (within today's proposed performance range)," 67 Fed. Reg at 17142, is naive. As they have for decades, generators will much more likely seek to minimize section 316(b) compliance costs as much as possible.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

Author Name Reed Super
Organization Riverkeeper, Inc.

Subject Matter Code 17.03.03
Benefits of reduced intake capacity

EPA acknowledges that closed-cycle cooling would reduce entrainment significantly more than the 60 percent standard:

[C]losed-cycle, recirculating cooling systems (e.g. cooling towers or ponds) can reduce mortality from impingement by up to 98 percent and entrainment by up to 98 percent when compared with conventional once-through systems.<FN 106>

Furthermore, cooling towers are not only more effective, but are also more reliable (i.e., more certain in their effectiveness), as EPA has also acknowledged:

Installed technologies may not operate at the maximum efficiency assumed by EPA in its estimates of technology effectiveness.<FN 107>

The only technology effectiveness that is certain is reductions in impingement and entrainment with cooling towers.<FN 108>

RFC: EPA rationale to not require closed-cycle

Despite the clear superiority of cooling towers, EPA did not set the performance standard based on a closed-cycle recirculating cooling system.<FN 109> In light of the significant difference in effectiveness (98 percent <FN 110> compared to 60 percent), and the certainty afforded by cooling towers (fish kills are reduced in proportion to volume; other technologies are affected by a variety of poorly-understood factors), the 60 percent standard violates the Clean Water Act's best technology mandate.

The entrainment performance standard in the Phase II Proposal violates the Clean Water Act because EPA based it on technologies far more destructive than those in place at the best performing plants. In other words, the standard does not reflect BTA. Simply put, cooling towers are the best technology, while filter barriers, screens, and the like, are not. In fact, such barriers and screens do not address withdrawal capacity, the critical factor in entrainment, at all; instead they may be and should be a component of BTA in conjunction with closed-cycle cooling, as many U.S. power plants already do. Instead, the Phase II proposal would continue to allow once through cooling-the worst technology with respect to capacity-at all in scope facilities.

Footnotes

109 67 Fed. Reg. 17142. EPA based the entrainment standard on aquatic filter barrier systems, fine mesh wedgewire screens, fine mesh traveling screens with fish return systems, seasonal flow restrictions, variable speed pumps and other operational measures. EPA admits that full-scale performance data are not available for entrainment reduction. Id. While a closed-cycle cooling tower would meet the performance standard (see 40 CFR § 125(b)(l) [proposed] and 67 Fed. Reg.17142), it is not required.

110 Even the lower bound of cooling tower effectiveness, 70 percent in saline waters where State regulations limit recirculation, is still significantly better than 60 percent. And as Pisces notes, the saline waters where cooling towers reduce withdrawals less also limit the effectiveness of the alternate technologies EPA relies on. Pisces Phase II Report at pp. 39-45.

EPA Response

The commenter misrepresents the range of entrainment reduction typical of cooling towers in marine environments and of those technologies forming the basis of the final rule. The technologies forming the basis of the final rule will realize an entrainment reduction in the range of 60 to 90 percent, as documented and described in the efficacy discussion of the Technical Development Document for the final rule. The typical recirculating wet cooling tower will realize a reduction in entrainment ranging from 85 to 95 percent (see EPA-821-R-01-036), dependent on the waterbody type. And therein lies a flaw in the commenter's logic: they fail to consider that in estuarine and ocean environments that cooling towers do not always operate at a comparable level as in freshwater. As such, in the areas in most need of entrainment reduction, in the Agency's opinion, the comparison of cooling towers to those technologies forming the basis of this final rule is dramatically different than the unscientific and misleading comment. For marine environments, the true comparison of the range of expected entrainment reductions is 85 to 92 percent for cooling towers versus 60 to 90 percent for the intake technologies forming the basis of the final rule.

See response to comment response 316b.EFR.404.018 for more discussion of why cooling towers are not the best available technology for retrofitting to existing plants.

Comment ID 316bEFR.404.035

Author Name Reed Super

Organization Riverkeeper, Inc.

Subject Matter Code 7.02

Performance standards

The proposal's impingement reduction standard of 80-95%, which is effectively an 80% standard, also falls short of BTA for several reasons including, but not limited to, that by optimizing just one factor, capacity, closed-cycle cooling towers reduce impingement of all species by approximately 98% or more. In addition to closed-cycle cooling other impingement controls in the form of protective screening and fish return systems can be installed-as they already are at many closed-cycle facilities-which will reduce impingement by a far greater percentage than EPA's proposed performance standard.

EPA Response

EPA agrees with the commenter that minimizing flow will often achieve the greatest reduction of both impingement and entrainment. EPA has not, however, selected closed-cycle cooling as a component of today's final rule. EPA believes the performance standards in today's final rule are both economically and technologically achievable by most Phase II existing facilities while achieving the desired level of protection for aquatic communities.

Determination of compliance

EPA's Calculation Baseline Is Problematic.

In the NODA, EPA proposes the following new regulatory language:

Calculation baseline means an estimate of impingement mortality and entrainment that would occur at your site assuming (1) the cooling water system has been designed as a once-through system; (2) the opening of the cooling water intake structure is located at, and the face of the standard 3/8-inch mesh traveling screen is oriented parallel to, the shoreline near the surface of the source water body; and (3) the baseline practices and procedures are those that the facility would maintain in the absence of any operational controls, including flow or velocity reductions, implemented in whole or in part for the purposes of reducing impingement mortality and entrainment.<FN 111>

No calculation baseline is necessary for the Phase II rule. In fact, none was included in then Phase I rule, which properly expressed its BTA standards in terms of (1) maximum intake capacity commensurate with a closed cycle cooling system; and (2) a maximum intake velocity of 0.5 feet per second. See Phase I Rule, Track I. Likewise, in the Phase II rule, EPA should establish BTA capacity and velocity limits based on closed-cycle cooling with low velocity intakes, which would comply with the Clean Water Act and would obviate the calculation baseline. Closed-cycle cooling reduces impingement and entrainment by approximately 95% at every facility, as compared to operation of the same facility with once-through cooling. Thus, it is not necessary to define a hypothetical baseline facility for comparison.

Nevertheless, if EPA promulgates Phase II BTA standards in terns of percentage reductions, as it proposes, then some baseline is necessary from which to calculate the percentage reductions. In defining this baseline, for equity and consistency purposes, it is crucial not to give facilities credit for illusory reductions. For this reason, the new operational definition is a good one: “the baseline practices and procedures are those that the facility would maintain in the absence of any operational controls, including flow or velocity reductions, implemented in whole or in part for the purposes of reducing impingement mortality and entrainment.” If EPA’s hypothetical baseline plant could be assumed to be withdrawing cooling water at full capacity 24 hours a day, 365 days a year (whereas even many baseload plants run only 55 -70% of the time), then applicants could take substantial impingement and entrainment reduction credit (as much as 50% or more) for doing nothing other than operating according their normal business practices. That would further skew comparisons with closed-cycle cooling, which reduces impacts by 95% at every operational level. However, in practice it may be difficult to.

The baseline issues of intake location, orientation and screens are more complicated. As the Pisces Phase II and NODA Report points out, many facilities locate their intake structures below the surface and/or offshore for reasons other then reducing impingement and entrainment, such as to withdraw colder water, to maintain cooling flows during low water, or to account for significant tides.<FN 112> Thus, EPA’s definition will allow for impingement and entrainment reduction credit for what is nothing more than normal plant design. (Note that reductions from offshore intakes are not certain, as it is feasible for offshore intakes to catch as many, if not more, fish than an onshore intake, particularly in marine environments.)<FN 113> The problem is best illustrated with comparison to the reductions offered by closed-cycle cooling. Cooling towers will reduce impingement and entrainment by 95% at plants with onshore, offshore, deep water, shallow water intakes and at those with 3/8-inch traveling screens and every other kind of screen. Thus, there is no issue as to whether or not to credit the other various design and operational features which may cause reductions in impact.

Moreover, in addition from these import conceptual problems, there is a very tangible practical problem which makes EPA's calculation baseline impossible (or at least extraordinarily difficult) to implement in the context of a permitting proceeding. Unless a facility has been in fact built exactly like the hypothetical baseline facility, there is no way to accurately or reliably determine baseline impingement and entrainment. As Pisces explains, the variations caused by small changes in intake configuration can be very large or negligible and are very difficult to quantify, requiring considerable background knowledge of the local fisheries populations. Consider a facility with a deep water, offshore intake with Ristroph screens. Implementation of the performance standard and calculation baseline approach set forth by EPA will require permit writers to ascertain what the hypothetical baseline facility with an on-shore surface intake with 3/8 inch traveling screens would be. It addition, the permit writer would have to determine what operational characteristics the facility ''would maintain in the absence of any operational controls," which may also be difficult or impossible to determine. Then the permit writer must calculate the percentage reductions in impingement and entrainment resulting from the differences in plant configuration and operation (if any). If these reductions do not meet the performance standards, then the permit writer must determine whether proposed technologies or measures will provide the additional reduction (which, as we explain elsewhere, is in itself an impossibly difficult and uncertain task).

The "as built" approach EPA is considering would be an improvement in that it would not rely on hypothetical calculations. In addition, since cooling towers would reduce impingement and entrainment by 95% of all once-through facilities as they are currently built, a logical and consistent approach would be to require the percentage reductions as compared to the "as built" condition for all once-through facilities. In such approach, the facilities would simply conduct impingement and entrainment monitoring and then be required to reduce those levels by the performance standard percentages. Although it would not give credit for intake structure location or configuration, this would provide a consistent basis for comparison with cooling towers which provide roughly the same percentage reductions at all plants.

EPA Response

As discussed in the NODA, EPA considered many suggestions for the approach to determining the calculation baseline, and has clarified its definition of calculation baseline in today's final rule (see §125.93). For additional explanation of EPA's definition of calculation baseline, please refer to EPA's response to comment 316bEFR.034.013. EPA agrees that the "As-Built" approach is an acceptable method for establishing the calculation baseline. Therefore, a facility may choose to use the current level of impingement mortality and entrainment as the calculation baseline (see EPA's definition of calculation baseline at § 125.93).

Use cost-benefit tests

Author Name Reed Super

Organization Riverkeeper, Inc.

EPA and OIRA's Cost-Benefit Analysis Is Fundamentally-Flawed and Such Analysis May Not Legally Be Used as the Decision Criteria for BTA Determinations.

EPA Phase II Proposal, as modified by the NODA, relies heavily on cost-benefit analysis. At proposal, after attempting to estimate the total benefits and compliance costs of the proposed alternatives, EPA chose the option predicted to have the greatest net benefit. EPA thus replaced the Clean Water Act's BTA mandate with a cost-benefit decision-making criterion. Such use of cost-benefit analysis is not authorized by law; in fact, it is prohibited for BTA determinations. In determining BTA standards, EPA is required to give compliance costs no more than a minor role and may not use a cost-benefit analysis to mandate technologies less than the best available.

Furthermore, EPA's benefits analysis is deeply flawed in principle and in its lack of completeness. It significantly undervalues the environmental benefits of preventing fish kills. Indeed, it is impossible to represent environmental conservation in solely monetary terms.

EPA Response

See preamble to the final rule, particularly sections III, VII, and VIII, and supporting documents.

RFC: Cost-benefit in proposed provision 124.95

Cost-Benefit Analyses Are Inappropriate for Environmental Harms and Benefits.

Cost-benefit analysis for environmental regulations is deeply flawed and invariably produces biased and misleading results. Unlike compliance costs, which can be readily estimated, the environmental benefits-preventing the needless diminution of aquatic and marine fauna, and all the ecosystem effects-cannot and should not be monetized. Any attempt at monetizing environmental benefits will necessarily suffer from several systemic problems.<FN 114>

First, it is not possible to realistically value the benefit of healthy marine and aquatic faunal populations. Ecosystems are immensely complex systems. There is insufficient data to fully understand these systems and identify the benefits they provide, let alone to quantify them. It is an absurd conceit to attempt to accurately estimate the value of ecological integrity given the geologic time frame for the contribution and longevity of functioning ecosystems. Instead, if something cannot be quantified, cost-benefit practitioners ignore it and therefore assume it is equal to zero, as EPA has repeatedly done in the proposed rule.

Similarly, some environmental benefits such as support for human life and civilization, as well as goals such as happiness, security and aesthetic pleasure are impossible to monetize. Failing to account for such assets leads to absurd results. Cost-benefit analyses have been used to argue that cigarette smoking should be subsidized because shorted lives would decrease national health care costs for an aging population, and that standards for preventing exposure to lead by children are too high.<FN 115>

Third, by discounting long-term benefits, cost-benefit analyses trivialize the future and make environmental restoration seem cost-ineffective. But the very nature of environmental protection is to invest now to protect resources for coming generations as well as the present. But by discounting future benefits, cost-benefit analyses make any project that does not have an immediate payoff worthless. For example, some benefits of planting a tree will not come for many years until the tree had grown enough to provide fruit, shade, habitat, aesthetic pleasure, etc. But discounting those benefits may make them so small in present dollars that it never seems cost-effective to plant a tree, when it is obvious that such is not true.

Fourth, basing regulations on cost-benefit ignores transfers of costs and therefore misallocates social resources. Comparing total costs to total benefits without regarding who pays the costs and who gets the benefits allows the power industry to continue transfer its costs on the rest of society and the environment. One result of killing fish is that fisheries become stressed, and commercial fishers are put out of work. Cost-benefit analysis does not take this into account.

Finally, the cost-benefit analysis ignores the determination, reflected in repeated Clean Water Act mandates including section 316(b), that degradation of aquatic and marine ecosystems is unnatural and unnecessary for our survival and prosperity. Instead, it presumes the massive aquatic mortality caused by power plants as the baseline, and requires a demonstration of effectiveness simply to avoid unnecessary destruction and restore a more natural ecological function. The burden should be on power plants to prove why they should be allowed to appropriate wildlife from that system for their own purposes.

Thus, cost-benefit analysis of environmental degradation is fundamentally flawed conceptually. But even assuming arguendo that such analysis could be useful, EPA's estimate for the Phase II Proposal is hopelessly incomplete and inaccurate.

RFC: Cost-benefit in proposed provision 124.95

EPA's Cost-Benefit Analysis is Hopelessly Biased, Inaccurate and Useless.

As Dr. Ackerman explains in two comment letters on the Phase II Proposal and NODA, respectively, EPA's analysis of the benefits of reduced cooling water intake is seriously incomplete, and can be considered as no more than an extreme lower bound on the complete benefits. Cost-benefit analysis is designed to weigh the relevant costs of a proposal against the corresponding benefits. This process cannot yield a meaningful result unless the calculations of costs and benefits are both complete. In the private sector, a balance sheet that weighs all of a company's income against some of its expenditures does not provide a useful picture of the company's true financial condition. Likewise, in the public sector, a comparison of complete costs and incomplete benefits does not provide an accurate picture of net benefits to society. <FN 116>

EPA has, however, produced a comparison of complete costs and incomplete benefits in this case. The costs of reducing the impacts of cooling water intake are monetary costs for marketed goods and services, such as production and installation of screens, cooling towers, and other equipment, and as a result there are no categories of costs which are intrinsically difficult to express in monetary terms. <FN 117>

In stark comparison, the calculation of the benefits of reducing cooling water intake consists of reduced damage to aquatic ecosystems, which is difficult to measure and monetize. EPA's analysis focuses only on valuing the benefits of killing fewer fish, which is itself a complex problem. Market prices are available only for a few commercially valuable fish species, and commercial prices do not necessarily capture all the value of avoided fish mortality. Furthermore, avoided fish kills are far from the only significant benefits of reduced ecosystem damages, since many other organisms and environmental services are also affected. <FN 118>

In the preamble to the Phase II Proposal and in the supporting Economic Benefit Analysis (EBA), EPA lists the categories of benefits that have been omitted, and the reasons why the environmental impacts of cooling water intake structures the benefits of regulating them have been significantly underestimated:

- Facility-provided monitoring data, the basis for EPA's analysis, typically focus on only a subset of the species impacted by impingement and entrainment (&E), thus underestimating total losses.

- Monitoring data often pertain to conditions existing many years ago, before the Clean Water Act had improved aquatic conditions; if the numbers and diversity of fish were depressed by degraded water quality, estimates of I&E losses would be similarly low.

- Cumulative impacts of multiple facilities on the same fish population are often important, but have been considered only to a limited extent.

- Estimated recreational and commercial values include only the proportion of I&E losses that would have been caught, typically less than 20 percent of I&E mortality of recreationally and commercially valuable species.

- Secondary economic impacts such as effects on marinas, bait sales, and property values have not been included.

- Losses of invertebrate species such as lobsters, mussels, crabs, and shrimp were not included, even though these include commercially valuable species.

- Effects on fish-eating (piscivorous) birds were not included.

- Current fishing mortality rates often reflect already-depleted fisheries, as for example in the case of winter flounder near the Brayton Point facility, one of the EBA case studies.

- Forage species, accounting for the predominant share of I&E losses, are poorly documented, and their full ecological value to the food web is not considered.

- Non-use benefits are estimated only for recreational users, not for the population as a whole.

- Thermal impact reductions are not accounted for in some options, such as replacement of once-through cooling with cooling towers.<FN 119>

In addition, another portion of the EBA, Case Study Chapter A11, re-examines the areas of incompleteness from a different perspective, focusing on the ecological services that are disrupted by I&E, but are not addressed by conventional valuation methods. As explained in the EBA, those omitted or undervalued services include:

-decreased numbers of ecological keystone, rare, or sensitive species; decreased numbers of popular species that are not fished, perhaps because the fishery is closed;

- decreased numbers of special status (e.g., threatened or endangered) species; increased numbers of exotic or disruptive species that compete well in the absence of species lost to I&E;

- disruption of ecological niches and ecological strategies used by aquatic species;

- disruption of organic carbon and nutrient transfer through the food web; disruption of energy transfer through the food web;

- decreased local biodiversity;

- disruption of predator-prey relationships.

- disruption of age class structures of species;

- disruption of natural selection processes;

- disruption of public uses other than fishing, such as diving, boating, and birding; and

- disruption of public satisfaction with a healthy ecosystem.<FN 120>

In addition to these admissions by EPA, the scientists at Pisces have identified other areas of undervaluation in EPA’s benefits analysis. These issues are explained in the Section 3 of the Pisces Phase II and NODA Report, submitted herewith, and in Part IV .of these comments, below. The lists of omissions and underestimates presented here clearly demonstrate the incompleteness of the benefits analysis in this case. Complete costs are being compared to a limited subset of benefits, causing environmental protection to appear as though it is not cost effective, when in fact it is. As Dr. Ackerman explains, “All that can be concluded from this misleading, incomplete comparison is that true, complete benefits must he larger, and net social benefits larger as well, for each of the various options under consideration."<FN 121>

In the NODA, EPA has discarded much of its previous methodology for calculating monetized environmental benefits. In fact, most of the NODA is devoted to explaining EPA’s proposed new benefits methodology. As Dr. Ackerman explains in his NODA Comments, submitted contemporaneously herewith, while some of the NODA’s adjustments respond directly to Dr. Ackerman’s criticisms of the original analysis, additional methodological problems introduced in the NODA make it difficult to draw clear conclusions about whether EPA’s analysis has, on balance, improved.

Among other problems with the NODA methodology, Dr. Ackerman notes that EPA’s nonuse valuation of fish affected in the Peconic Bay estuary is highly incomplete; EPA inappropriately limits the geographic scope of its nonuse benefits analysis; and the NODA fails to consider key biological facts, including interdependence among species and precarious stock status for many populations. Minimal requirements for completing the analysis EPA has begun should include developing a use value for unharvested fish and completing the meta-analysis of existing studies on nonuse value. In addition, EPA must avoid placing an effective value of zero on categories of value the Agency does not have time or resources to analyze in detail. <FN 122> After careful review of the NODA, Dr. Ackerman concludes:

even if one accepts cost-benefit analysis as an appropriate means to determine the appropriate level of regulation for power plant cooling water intake systems, the magnitude of the omissions in the NODA renders the exercise meaningless. The difficulties encountered in the attempt at monetization of benefits underscore the need for other approaches to evaluation of policy options.

the shortcomings of the NODA illustrate the flaws in the methodology that EPA is now pursuing. The task of quantifying benefits will require significant further analysis, and involves methodological quandaries that will not be resolved easily. In our opinion, by converting its regulatory mandate into a lengthy and methodologically questionable program of data collection and analysis, EPA has failed to meet its responsibilities under the Clean Water Act.<FN 123>

118 Id.

119 Id. at pp. 4-5 citing EBA Chapter C1.

120 Id., citing EBA Case Studies, p. A1 1-2. In addition, though not acknowledged by EPA, its benefits analysis is also incomplete in that it makes no attempt to analyze or quantify the monetary benefits to the economy resulting from the investment by regulated companies in the environmental protection goods and services sector of the economy. In other words, if a company spends $1 million dollars to protect wildlife, that cost not only produces the wildlife protection benefits, but also provides jobs and income to the employees and firms that will design and build cooling towers, install other protective devices, and monitor their performance. It will also spur technological innovation and the development of new products and services that can be marketed worldwide.

EPA Response

EPA agrees with the commenter that the proposed rule analysis does not include all possible benefits of reducing environmental impacts from CWIS. It was not possible to develop a comprehensive value of entrained and impinged fish to an ecosystem due to the lack of available monitoring data by many facilities, the difficulties in characterizing all biological effects relevant to the affected ecosystems and the limited availability of valuation data. EPA attempted to reduce any potential misinterpretation of its benefits results by conducting a careful qualitative assessment of potential benefits and characterizing inherent limitations and uncertainties present in the benefits analysis prepared for the final Section 316(b) regulation. For detail, see Chapter A9, Economic Benefit Categories and Valuation Methods, in the regional study document prepared for the analysis for the final Phase II rule (DCN #6-0003). See also response to comment 316bEFR.206.047.

EPA also agrees with the commenter that comprehensive, appropriate estimates of total resource value should include both use and non-use values, such that the resulting total value estimates may be compared to total social cost. For the final 316b rule analysis, the Agency has provided several measures that indicate the potential magnitude of non-use values, including a peer-reviewed meta-analysis, the benefit transfer method, and break-even analysis. For detail on non-use valuation methods considered in the context of the final 316(b) regulation, see Chapters A12, C6, D6, and G6 in the final Phase II Regional Studies Document (DCN #6-0003); Chapter D1 of the final Phase II EBA document (DCN #6-0002) presents the break-even analysis. EPA has not included quantitative measures of nonuse values in the final 316(b) rule benefits cost analysis due to unavoidable uncertainty in monetizing non-use values for this rule.

Define BTA as anything less than closed cycle

The Use of Cost-Benefit as the Decision-Making Criterion Violates the CWA and EO 12866 Because the Law Requires Minimization of Adverse Environmental Impact, Not Maximization of Economic Benefit.

As explained above, Clean Water Act Section 316(b) requires EPA to adopt section 301 and 306 standards (ie., mandatory limitations to be included in NPDES permits) governing cooling water intake structures. Further, these standards must reflect best technology available to minimize adverse environmental impact. This is the approach mandated by the relevant statutory authority.

In contravention of that statutory authority EPA, at the behest of OIRA, used the “maximize net benefits” approach instead of the statutorily-mandated approach. It is apparent that this was the approach used, because EPA rejected an alternative option (Federal Register Option 3 / EBA Options 1 and 2) even though it reduced impacts to a greater degree than the proposed option and was cost-effective, i.e.,, benefits outweighed costs by a 3:2 margin, yielding net benefits of $255 million.<FN 124> EPA’s stated rationale for rejecting this option was as follows:

EPA notes that the incremental costs of this option relative to the proposed option ($413 million) significantly outweigh the incremental benefits ($146 million).<FN 125>

Put another way, EPA chose the proposed option because it had greater net benefits (using EPA’s flawed calculations) that the waterbody/capacity based closed-cycle option. That is the maximize net benefits approach.

Furthermore, it is clear that EPA adopted that approach because OIRA insisted upon it. The record clearly demonstrates that EPA had intended to propose the waterbody/capacity based closed-cycle option (Federal Register Option 3 / EBA Options 1 and 2), but was prevented from doing so by OIRA.<FN 126>

The fact the OIRA would seek to apply a “maximize net benefits” approach is perhaps not surprising since OIRA acts pursuant to Executive Order 12866, which refers to such an approach in its “Statement of Regulatory Philosophy and Principles.” However, what this section of the Executive Order says is:

In choosing among alternative regulatory approaches, agencies should select those approaches that maximize net benefits (including potential economic, environmental, public health and safety, and other advantages; distributive impacts and equity), unless a statute requires another regulatory approach.<FN 127>

In this case, the statute clearly requires another regulatory approach. As explained in great detail in Part II, above, the Clean Water Act requires the imposition of a series of increasingly-stringent, technology-based controls to ratchet down water quality impairments as close to zero as possible. Costs play a minor role in EPA’s best technology determinations. In promulgating BTA standards, EPA must minimize adverse environmental impacts, and costs are only relevant to the determination of whether the technology that minimizes impacts is economically achievable, or wholly disproportionate to the benefit. Since that is the regulatory approach mandated by Congress in the Clean Water Act, the statute trumps the Executive Order and the maximize net benefits principle of the EO 12866 is-by its own terms-inapplicable to Section 316(b) regulations.

As a result, EPA has, at the direction of OIRA, violated not only the Clean Water Act, but the Executive Order as well. Furthermore, the Phase II Proposal violates Section 1(b)(7) of Executive Order 12866 which states that the Agency "shall base its decisions on the best reasonably obtainable scientific, technical, economic, and other information.. ." because much of the biological data and some of the economic literature (e.g., on non-use benefits) is decades out-of-date.

Lastly, despite its claims of transparency, OIRA is concealing documents concerning its evisceration of the rule in violation of Section 6(b)(4)(D) of the Executive Order which requires OIRA to make available to the public, after a notice of proposed rulemaking is published in the Federal Register, "all documents exchanged between OIRA and the agency during review by OIRA under this section." (Emphasis added.) OIRA has failed to place all documents exchanged between OIRA and EPA in its public docket, claiming that OIRA interprets "all documents" to mean only those documents exchanged between officials at SES-level or higher. <FN 128>

Subject Matter Code 7.01.03

Option 3--Site-specific determination

THE COMPLANCE OPTIONS ARE ILLEGAL AND UNSOUND.

Despite describing the rule as a “national minimum ...technology-based performance requirement,"<FN 129> EPA has failed to set a national minimum standard for technology or performance. Instead of setting a protective, technology-based standard, the rule would adopt and codify many of the site-specific arguments which permittees typically use to avoid closed-cycle cooling requirements. Since even environmentally sympathetic regulators lack the resources needed to rebut, or in most cases fully evaluate, these arguments, the Phase II Proposal will allow applicants to continue to obstruct and delay needed technology upgrades.

The two primary components of the rule that circumvent the purported technology standard are: (1) allowing applicants to attempt to replace fish they kill through “restoration measures’’ instead of installing technology to reduce or eliminate (i.e. minimize) the impact; and (2) Track III, which allows applicants to obtain both a site-specific BTA determination and more lenient requirements than the national standard.

Subject Matter Code 11.01

RFC: Proposed use of restoration measures

Author Name Reed Super

Organization Riverkeeper, Inc.

Restoration Measures are Unreliable and Cannot Be Permitted In Lieu of CWIS Technology.

EPA is proposing to allow any and all in-scope facilities to use "restoration measures" in lieu of technology, whether they choose compliance option Track I (existing operation is BTA), Track II (existing plus proposed is BTA), or Track III (site-specific BTA determination).<FN 130> More specifically, the Phase II Proposal provides:

In lieu of, or in combination with, reducing impingement mortality and entrainment by implementing design and construction technologies or operational measures to comply with the performance standards specified in paragraph (b) of this section [for Tracks I and III or the Director's determination pursuant to paragraph (c) of this section [for Track III], you may, with the Director's approval, employ restoration measures that will result in increases in fish and shellfish in the watershed. You must demonstrate to the director that you are maintaining fish and shellfish within the water body, including community structure and function, to a level comparable to those that would result if you were to employ design and construction technologies or operational measures.. . <FN 131>

While such measures may beneficial in compensating for past harms to the aquatic environment, they cannot be used as a substitute for dry cooling because they do not constitute best available technology for minimizing adverse environmental impact from cooling water intake structures, which is what Section 316(b) requires. Furthermore, restoration measures do not replace or compensate for the fish killed by cooling water intake structures.

Footnotes

Role of Restoration

Restoration Measures are Unreliable and Do Not Replace the Fish Killed By CWISs.

Restoring aquatic habitat for fish, wildlife, and plant species maybe a worthwhile and environmentally beneficial activity. Throughout the country, extremely large areas of aquatic habitat have been destroyed by development, primarily by filling open water and wetlands. Restoration measures, if successful, can provide some level of mitigation for such development activities. However, restoration measures, whether successful or not, cannot replace the fish killed by impingement and entrainment at power plants.

EPA Response

For a discussion of the role of restoration in the final rule, see EPA's response to comment 316bEFR.206.052 and the preamble to the final rule.

Comment ID 316bEFR.404.044

Author Name Reed Super
Organization Riverkeeper, Inc.

Subject Matter Code 11.06
RFC: Performance/effectiveness of restoration

Habitat restoration measures have been employed most prominently in an attempt to mitigate impingement and entrainment at the Salem Nuclear Generating Station in New Jersey. It is therefore critically important to acknowledge that, as the Delaware Riverkeeper Network explained in its separately-submitted comments on the Phase II proposal, the mitigation experiment occurring on the Delaware at Salem is failing. PSE&G has been unable to demonstrate that its restoration effort for the fish kills at its Salem plan is providing any benefit whatsoever to the fish populations of the Delaware estuary. Thus, it cannot demonstrate that the restoration measures are in any way minimizing the impingement and entrainment of over three billion Delaware River fish. Indeed, PSE&G cannot even demonstrate that if it were successful in eradicating and/or controlling phragmites, that this success would be sustainable without continuous intervening action. In fact, the primary result of PSE&G's mitigation proposal is that the Salem facility continues to kill over three billion Delaware River fish a year while PSE&G is now also harming thousands of acres of marshland by spraying it with glyphosate only to have the targeted phragmites return. There has been no minimization of adverse impact at Salem, as required by section 316(b).

Because the PSE&G restoration project at Salem is being held up as a national model for section 316(b) compliance, it is important to understand why restoration and cannot address the concerns that section 316(b) is intended to address-i.e.. impingement and entrainment of fish. PSE&G's wetlands experiment involves restoring, enhancing and/or preserving 10,000 acres of what PSE&G characterizes as degraded wetlands. The majority of those wetlands are dominated by the phragmites plant; restoration efforts include herbicide application, mowing and prescribed burning in order to remove phragmites and replace it with spartina grasses. Some freshwater diked wetland are also being converted to salt marshes. The original argument supporting this program was that enhancement of these wetlands will increase fish production in the Delaware Estuary. PSE&G is, however, unable to demonstrate that their experiment, even if successful (which is doubtful at best), actually provides benefits to the estuary ecosystem. The numerous, fundamental problems with the restoration approach at Salem include the following:

PSE&G never provided scientific data indicating that food or habitat were limiting factors for the fish populations in the Delaware Estuary-and there is in fact no data or information that would indicate that this is in fact the case. Therefore, altering wetlands to increase food and habitat availability for fish is likely not to have any effect on fish populations in the estuary. <FN 132>

PSE&G's success criteria and evaluation methodology for its wetlands enhancement efforts do not include determining whether the fish populations of the River are benefiting from the wetlands restoration efforts. Instead their success criteria focus on change in vegetation coverage, algal productivity, macrophyte productivity, etc. <FN 133>

PSE&G has failed to demonstrate that even if it is successful at replacing the existing phragmites in these areas with other species of plants, that this change in vegetation is sustainable and will not be overrun by neighboring stands of phragmites within a matter of years.<FN 134>

PSE&G has failed to conduct the baseline data on the contributions of the phragmites stands to the food chain in order to make the necessary comparisons. It is very possible that the fish used the phragmites-dominated marshes in the same way and to the same degree as they would spartina-dominated marshes and therefore nothing has been truly gained by their efforts.<FN 135>

In fact, PSE&G's own data confirms, what other scientists have found, that phragmites-dominated marshes on the Delaware Bay contribute just as much basic nutrient material into the food web as spartina-dominated marshes. " As new data are generated, the general perception that regularly flooded phragmites marshes are less functional than the spartina marshes they replace does not appear to be upheld." <FN 136>

As a result, the Salem mitigation project, rather than being an example of why mitigation should be allowed, is actually a prime example of why it should not.

133 Id.

134 Id.

135 Id.

136 Id., citing Judith S. Weis, Habitat and Food Value of Phragmites australis and Spartina alterniflora, printed in New Jersey Flows, Water Resoruces Institute, Vol. 1, No. 1, Fall 2000. That article explained: "Efforts to restore salt marsh areas by replacing the undesired Phragmites with the desired Spartina are often justified by the assumption that the productivity of animal populations will be enhanced. However, evidence from the studies reported here as well as those of others (e.g. Fell et al., 1998; Wainright et al., 2000) does not support the general assumption that Phragmites leaf detritus is of poorer nutritional quality for estuarine consumers than that of Spartina." Phragmites is native to North America and has been found to be a component of Eastern U.S. marshes for 2000 to 4000 years at least. Multiple studies document that "Phragmites production is equivalent to the role of alterniflora production in the diet of key estuarine species" and that it is consumed by fish in the marsh. Phragmites has also been found beneficial in other ways with benefits beyond those provided by Spartina. For example they release less contaminants back into the environment than Spartina. "In comparison to a Spartina community, Phragmites enhances both mineral and organic decomposition, basically doubling the accretion potential of the marsh." "Phragmites function may actually exceed that of other wetland plants in ameliorating certain estuarine dilemmas like eutrophication and marsh loss." Rooth and Windham, Phragmites on Death Row: Is Biocontrol Really Warranted?, Wetland Journal, Vol, 12, No. I, Winter 2000.

Role of Restoration

Author Name Reed Super

Organization Riverkeeper, Inc.

In the Pisces Phase II Report, submitted in August 2002, the scientists at Pisces discuss habitat restoration projects at length. Pisces begins by noting that while creation of a salt-marsh may replace the destruction of a salt marsh, like-for-like restorations for impingement and entrainment are impossible on the community level. <FN 137> Further, with any restoration project, there is a considerable time-lag, between the original damage and the establishment of the new resource at its full potential. NOAA's Habitat Equivalency Analysis (HEA) states: "The principal concept underlying the method is that the public can be compensated for past losses of habitat resources through habitat replacement projects providing additional resources of the same type". (NOAA, 1995). Thus the origin of the restoration concept is to be as compensation for finite, existing discrete and quantifiable losses, rather than justification for continuing and future loss.<FN 138>

Pisces also reviewed the data from the Salem restoration project, among others, and found as follows:

In summary, the project sought to replace lost productivity, rather than address losses at source of particular species, such as the bay anchovy. It is unclear whether the enhanced productivity in the restored saltmarsh will in fact move through the food web to increase the number of bay anchovy, and other pelagic spawning species. What is more, the increased productivity could favour other species less sensitive to impingement and entrainment than the anchovy, resulting in a change in the species balance and increased predation on the target species.. . [T]there is strong evidence that it does not, and was not intended to, fulfill its stated aim of equivalency with the losses at the Salem plant. <FN 139>

In addition, Pisces noted numerous other negative attributes of the Salem restoration project, including:

- Any 'new fish' that are produced by the converted saltwater wetlands will also increase the number of fish that will become impinged, entrained and killed by the power plant;

- PSE&G ignores the lost productivity of the destroyed freshwater marsh, which while as productive as a salt marsh, nevertheless provides important habitat for many species.

- The Salem Estuary Enhancement Program has had a negative impact on species, such as the horseshoe crab, which have dramatically declined since 1993.<FN 140>

In its report, Pisces also reviewed a recent power plant repermitting proceeding in Mono Bay on the California coast in which California Energy Commission rejected habitat enhancement measures in large part because it was unclear as to whether these enhancements would directly aid the species most affected by impingement and entrainment. <FN 141>

Pisces concluded that there are very serious limitations of habitat enhancement as a means of mitigation for entrainment and impingement, particularly:

- Habitat equivalency analysis is primarily aimed at offsetting past losses or damage, rather than continuing loss;

- Considerable uncertainty exists as to whether equivalence can be focused on actual species harmed;

- Potential lack of availability of sufficient habitat to adequately offset losses or damage.<FN 142>

In the Pisces Phase II and NODA Report, submitted herewith, Pisces considered the potential for success and the drawbacks of various forms of restoration measures, including fish hatcheries, habitat replacement, removing barriers to fish migration and undertaking water quality improvements. Pisces' detailed comprehensive discussion concludes that:

there are no proven pathways by which Entrainment and Impingement losses can be mitigated by habitat enhancement methods. There is a tendency to trade sensible and worthwhile goals such as wetland enhancement against impingement and entrainment losses. However, there is little evidence that the improved wetland aids the populations most impacted by the power plants.

The restoration measures outlined above can only partly mitigate for the losses caused by I&E. They produce an increase in a few target species and do nothing to mitigate for the loss of the other species impacted. In addition, they may have other ecological effects which tend not to be fully quantifiable until after the event.<FN 143>

The general availability of restoration measures renders the proposal's performance criteria ineffective because their effectiveness is typically doubtful and impossible to accurately estimate. Restoration simply cannot replace the aquatic organisms killed by power plants. By including restoration measures as a compliance option in lieu of technologies and operational measures, EPA would give a seal of approval (an EPA imprimatur), thereby misleading the state permit-writers, applicants, and the public into believing that these measures can be effective, when they are not.

EPA Response

For a discussion of the uncertainties associated with restoration and of EPA's goals for restoration in the context of the final rule, see EPA's response to comment 316bEFR.206.055.

For a discussion of the some of the factors that should be considered when planning a restoration project, see EPA's response to comment 316bEFR.206.054. Permit applicants and permitting authorities should also consider the types of species and the number of organisms from each of those species a restoration measure is able to provide when assessing the feasibility of a restoration measure.

Restoration measures in place of technologies

Restoration Measures Cannot Play A Role In BTA.

The uncertainty and high failure rate of restoration measures-in addition to their inability to replace fish killed by impingement and entrainment-not only makes their inclusion in this rule poor policy, it is also a violation of the Clean Water Act. BAT requirements can not be predicated on an experimental technology. Rather, there must be at least one facility where the technology has been successfully employed. The same is true for BTA, which is substantially similar to BAT. In the case of restoration measures, EPA has no evidence of restoration measures having successfully replaced the fish killed by a power plant-certainly, there is no such evidence from Salem. As a result, restoration may not be a component of BTA.

Furthermore, restoration measures cannot legally be a component of BTA because such measures, such as fish hatcheries, fish restocking programs, removal of impediments to fish migration, and the enhancement or creation of wetlands are wholly unrelated to cooling water intake structures cannot be used to fulfill the requirements of section 316(b). Section 316(b)mandates that the location, design, construction and capacity of cooling water intake structures must reflect the best technology available. Restoration measures are not related to location, design, construction or capacity of-cooling water intake structures, and therefore cannot be a component of BTA. Rather these measures, when proposed in the section 316(b) context, seek to allow facilities to continue to indiscriminately kill life rather than make attempts to curb, or stop, the damage they are inflicting. As a result, they violate the mandates of section 316(b) of the Clean Water Act.

EPA Response

For a discussion of EPA’s authority to include restoration measures as an aspect of cooling water intake structure design technology in today’s rule, see section the preamble to the final rule as well as EPA's response to comment 316bEFR.056.003.

EPA acknowledges there are uncertainties associated with restoration measures (see EPA's response to comment 316bEFR.206.055). The requirements described in sections 125.94 and 125.95 of the final rule are intended to help reduce uncertainties associated with restoration measures and enhance their performance.

Define BTA as anything less than closed cycle

The Track III Variances (Both Economic and Ecological) Are Unauthorized and Illegal.

The Phase II Proposal contains includes two separate variances from the performance standards. In the Track III compliance option, applicants may seek a site-specific determination of BTA requirements for a particular site.<FN 144> There are two ways to obtain a site-specific determination:

- by demonstrating that the facility's "costs of compliance with the applicable performance standards ... would be significantly greater than the costs considered by the Administrator when establishing such performance standards" (the "economic variance"); or

- by demonstrating that the facility's "costs would be significantly greater than the benefits of complying with such performance standards" at the site (the "ecological variance").<FN 145>

These two variances are unauthorized and their availability in a categorical BTA rule is illegal for several important reasons: (1) these variances unreasonably deviate from the cost test EPA has applied for 30 years of 316(b) permitting determinations; (2) the variances are unauthorized under the Clean Water Act which makes no provision for variances from BTA standards and only limited provision for variance from BAT standards; (3) the ecological variance requires the same kind of biased and inaccurate cost-benefit analysis that EPA used in determining the standard, but on a local level. If, despite its superior resources and a lengthy rule-making schedule, EPA could not come close to providing a full and accurate monetization of benefits (see above), then state permit-writers will do an even more incomplete job with more limited resources and under the time pressure of a permitting proceeding; and (4) allowing permit standards for power plants to be determined on a site-by-site basis would allow industry to overwhelm state agencies and public intervenors with data that they will be hard-pressed to analyze, no less counter.

EPA Response

EPA disagrees. Today's rule in general, and the site-specific option in particular, will not impose a significant burden on states, tribes, local governments, environmental advocates, or the public. There is sufficient flexibility in the final rule that EPA expects facilities will use the site-specific compliance options infrequently.

RFC: Appropriateness of “wholly disproportionate”

First, the variances unreasonably deviate from EPA’s long-standing cost test. Even though section 316(b) contains no mention of compliance costs, EPA has always contended “that there should be some reasonable relationship between the cost of cooling water intake structure control and the environmental benefits associated with its use.”<FN 146> Based on a statement by one Congressman in the 1972 legislative history, EPA has long interpreted BTA to mean “best technology available commercially at an economically practicable cost.” In so doing, EPA claims to be implementing “congressional concern that the application of best technology available should not impose an impractical and unbearable burden.”’<FN 147> EPA has traditionally measured economic practicability by applying the “wholly disproportionate test” to compare the benefits of cooling water intake technology against marginal cost to the ratepayer, i.e., the incremental electricity cost. Under EPA’s traditional wholly disproportionate cost test, a cooling water intake structure technology would not be deemed to reflect BTA if the incremental costs of requiring the use of that technology are wholly disproportionate to the environmental benefits to be gained through its use.

But in the Phase II Proposal, EPA departs from the wholly disproportionate test, and includes two far more lenient variances. Whereas the wholly disproportionate test would require a deviation from best technology available only where the compliance costs would be unconscionable or “shock the conscience,” the new significantly greater than test is far more lenient. EPA has not demonstrated the requisite need rationale for this deviation. Certainly, no showing has been made that these variance are necessary to avoid an “impractical and unbearable burden” on industry. Rather, they improperly seek to minimize industry’s compliance costs in contravention of the mandate to minimize environmental impacts.

Use cost-benefit tests

Author Name Reed Super

Organization Riverkeeper, Inc.

Second there is no statutory authority for variance from section 316(b) standards. Unlike BAT standards which have statutory variances in section 301(c) (economic variance to delay timetable). and section 301(n) (fundamentally different factors variance), Congress did not provide for a variance from BTA. Congress also did not provide for variance from section 306 new source performance standards. In that context, The United States Supreme Court in E.I. DuPont v. Train found unequivocally that the Clean Water Act does not allow a variance procedure for new sources:

It is clear that Congress intended these regulations to be absolute prohibitions. The use of the word “standards” implies as much. So does the description of the preferred standard as one “permitting no discharge of pollutants.” It is “unlawful for any owner or operator of any new source to operate such source in violation of any standard applicable to such source.” 306(e). In striking contrast to 301(c), there is no statutory provision for variances, and a variance provision would be inappropriate in a standard that was intended to insure national uniformity and “maximum feasible control” of new sources.<FN 148>

As with new source performance standards, no variance from BTA standards may be allowed, because EPA lacks the statutory authorization to do so.

RFC: Cost-benefit in proposed provision 124.95

Third, the ecological variance will require a cost-benefit analysis on the local level, which will undoubtedly be as incomplete, misleading and useless as the national cost-benefit analysis prepared for this rule, except that, as explained below, industry will likely be able to use it to its advantage.

EPA Response

The final rule includes five compliance alternatives, including a site-specific alternative. See preamble to the final rule, particularly sections VII and VIII for a discussion of these alternatives. It also specifies the information a facility must develop to support the site-specific compliance alternative.

See also EPA's response to comment #316bEFR.005.020 on application of the cost-benefit test to assessing the value of alternative CWIS technologies.

Discussion of Site-Specific Approaches

Finally, site-specific BTA determinations will leave state agencies and interested citizens and groups at a significant disadvantage. In practice, it is at minimum a tremendous burden, and often impossible to review, comprehend, analyze and, where appropriate, refute, the enormous volume of information that applicants submit in support of their site-specific permitting demonstrations. In the absence of federal regulations, section 316(b) determinations have typically involved individualized ecological assessment and determination of best technology available for each proposed or renewed cooling water intake structure. This lack of categorical standards has resulted in uneven and conflicting regulation as well as enormous, unnecessary aquatic mortality, which runs contrary to the goals of the Clean Water Act and the direct mandate of section 316(b). The individualized assessments have typically relied on narrow and inaccurately applied population models, and have ignored other impacts on ecosystem health.

For 30 years, industry has used the threat of litigation and a variety of dubious interpretations of section 316(b) to avoid the imposition of BTA. A favorite strategy of industry is to threaten state permitting agencies with litigation in order to obtain a compromise settlement for limited mitigation or data gathering and study, rather than installing best technology. Even with extensive data collection, there has been continued disagreement among industry, permitting agencies, and environmental groups over ecological impacts.

The multiplicity of these individual determinations and the combination of ecological and mathematical/statistical expertise necessary to determine the complex population dynamics for individual species has granted industry a critical strategic advantage because of superior resources in these proceedings. This advantage is a key component in industry's strategy to avoid national technology based regulations. Industry's most common analytical tools in these individualized technical determinations are density-dependent models of fisheries populations. Cooling water users have for decades used arguments based on density-dependence to justify the destruction of large numbers of fish and crustaceans via impingement and entrainment at their CWISs. In many critical cases, mathematical models of density dependent compensation these models have been misapplied. As just one example, industry has misapplied commonly-used Ricker curves, originally developed for salmonid fisheries with intense competition for spawning space, is misapplied to the entrainment of other species which lack such intense competition.<FN 149> More fundamentally, typical compensation analysis relies on an ecologically baseless concept of "surplus production" which dismisses the ecological value of the tens of millions of fish which are a critical base of the food chain whether or not they grow to adulthood-even though their predators may be populated at far below their historic values.

Indeed, several state agencies commenting on the Phase I proposal, including New York, New Jersey and Michigan, cited the enormous burden they faced in trying to assess species and ecosystem effects caused by a particular power plant. The very purpose of categorical standards is to raise the technology determination to the federal level, and to produce national uniform technology standards that states will automatically apply, unless local water standards dictate inclusion of even stricter requirements. That is how Congress designed the Clean Water Act, and how it has functioned for 30 years. With the Phase II Proposal, EPA is attempting to rewrite the very core of the Nation's most fundamental water quality protection program. That misguided attempt will not survive judicial scrutiny.

Footnotes

149 See e.g. Draft Environmental Impact Statementfor State Pollutant Discharge Elimination System Permit Renewal for Bowline Point I & 2, Indian Point 2 & 3 and Roseton 1 & 2 Steam Generating Stations, December 1999, Appendix VI-4-B, relying on Ricker models to estimate the impact of entrainment on Atlantic tomcod young.

EPA Response

For a discussion of the framework of the final rule and EPA's reasons for authorizing five compliance alternatives, please refer to the preamble to the final rule. EPA disagrees that a large percentage of facilities will opt for a site-specific determination of BTA. Please refer to the response to comment 316bEFR.202.002 for more information. EPA recognizes that members of the public lack the resources, and sometimes, the expertise to refute the results of studies performed under today's rule. However, EPA hopes that by requiring the studies as part of the permitting process, the public will have a better opportunity to influence the outcome of permitting decisions under this rule.

Benefits of reduced intake capacity

THE BENEFITS OF CLOSED-CYCLE COOLING FOR ALL IN-SCOPE FACILITIES MORE THAN JUSTIFY THE RETROFIT COSTS.

As explained above in Part III, the Clean Water Act and Executive Order 12866 prohibit EPA from using cost-benefit analysis as the decision-making criterion for determining BTA standards. Nevertheless, a complete estimation of benefits would demonstrate that the monetary benefits and other ecological benefits of an all-cooling tower rule vastly exceed the costs. In his comments on the Phase II Proposal, Dr. Ackerman provides a more accurate, yet still conservative, estimate for just two of the dozens of areas that EPA admits it has undervalued benefits: non-use benefits and the value of fish not immediately landed by fisherman. The result of those two minor adjustments demonstrates that all of EPA's proposed options are cost-effective (i.e., benefits exceed costs), including the all cooling tower option (benefits exceed costs by $4.082 billion); the waterbody-flow-based cooling tower option (benefits exceed costs by at least $4.2 billion); and even the dry cooling option (benefits exceed costs by $7.728 billion). Notably, EPA's proposed option, which provides only 60 percent entrainment reduction, has the lowest net benefits ($3.764 billion). (See Part IV.A, below.)

Furthermore, there are a dozens of other aspects of the benefits analysis that EPA has undervalued or failed to value altogether. EPA has acknowledged many of these omissions in the preamble to the Phase II Proposal and in the EBA. In addition, as explained below and in the Pisces Phase II and NODA Report, there are myriad other significant shortcomings the benefits analysis, each resulting in an underestimation of benefits. The Pisces report demonstrates in worked examples how EPA could and should correct these omissions. Correcting for each of these undervalued aspects of the benefits analysis raises the benefits of each option, resulting in a further increase in the net benefits of the all cooling tower option. (See Part IV.B., below.)

In addition, because the costs of the cooling tower options are overstated, the net benefits of these options are actually larger, and the differential between them and the proposed option (which has no cooling towers) is even greater than adjustments to the benefits alone indicate. EPA should also make these appropriate downward adjustments to the compliance cost estimate for cooling towers. (See Part IV.C., below.)

Finally, the Habitat Replacement Cost (HRC) method of estimated benefits, which has drawn criticism from industry as overstating benefits, does in fact just the opposite. In light of the impossibility of quantifying and monetizing all the myriad, complex benefits of aquatic ecosystem protection, HRC provides a reasonable lower bound estimate of those benefits by measuring the cost to replace some, but not all of what is destroyed by power plants' cooling water intake structures. (See Part IV.D., below.)

EPA Response

See response to comment 316b.EFR.404.058 for a discussion of why EPA has NOT overstated costs of cooling towers.

The commenter proposes that the unlanded fraction of additional survivors has an ecological value that should be quantified. This is essentially the same comment that other commenters have made when referring to foregone "reproductive value" of I&E losses. EPA has responded to the comments about the valuation of the unlanded fraction in response to Comment 316bEFR.336.009. See also EPA's discussion of reproductive value in response to Comment 316bEFR.206.065. EPA has responded to the related issue of non-use values of fish in the response to 316bEFR.077.022.

The commenter makes a specific proposal that the unlanded fraction of additional survivors should be valued as 25% the landed value of the same species. However, the commenter provides no data to support this request.

Concerning the HRC method, please see EPA's response to Comment 316bEFR.005.035 and the document entitled "Habitat-based Replacement Cost Method" (Docket #6-1003).

See EPA's response to comment #316bEFR.206.047 on incompleteness of EPA’s analysis of the benefits of reduced cooling water intake.

See EPA's response to comment #316bEFR.005.020 on application of the cost-benefit test to assessing the value of alternative CWIS technologies.

Benefit Estimation Methodology

CORRECTING JUST A FEW EVIDENT AREAS OF INCOMPLETENESS RAISES NET BENEFITS DRASTICALLY.

In his August 2002 comments on the Phase II Proposal, Dr. Ackerman prepared an adjusted set of figures incorporating estimates of corrections to just two of EPA's many omissions and underestimate.<FN 150> Dr. Ackerman's first adjustment is for the underestimate of non-use benefits. As discussed above in Part III, EPA's estimation at proposal that non-use benefits would be only 0.5 times recreational benefits was based on extremely limited and outdated economic literature.<FN 151> Dr. Ackerman explained that a recent literature review finds that non-use benefits are on average 1.9 -2.5 times all use values, rather than 0.5 times recreational benefits alone, as EPA assumed. Further, 1.9 -2.5 times use value is still a conservative estimate for existence values of many natural ecosystem.<FN 152> To correct for EPA's underestimate in this area, Dr. Ackerman recalculated EPA's estimates assuming that non-use values are 2 times estimated recreational, commercial, and forage values.<FN 153>

Dr. Ackerman's second adjustment is for the unvalued fraction of the mortality of recreationally and commercially valuable species. EPA's methodology values only the fraction of those species that would have been caught in the absence of I&E mortality. That is, only the fraction of the fish that would have been caught are assigned any value; the rest are ignored, even though those same fish have the potential to be caught in subsequent years and to produce offspring which will yield increased catches in future years. The catch rate, or "landed fraction," is below 20% in every case, and below 10% in some cases. Thus, the great majority of impingement and entrainment mortality of the most valuable species is never valued.

The nonlanded fraction of these species -the ones that survive uncaught -have an obvious ecological, commercial, recreational and forage value. For one thing, most fish that are protected by CWIS technology, and that are not caught by fishermen, will still be available the next year to be caught fishermen in that year. These unlanded fish will not all disappear from the ecosystem, as EPA's models assume. Rather, many of them will be caught in future years, thus further increasing the commercial and recreational catch.<FN 154> Furthermore, these unlanded fish will reproduce, and their offspring is the source of the increased catch in future years. Since the fisheries in question are depressed (they are currently both fished and subjected to once-through cooling), the fish that are protected by CWIS technologies and not caught by fisherman will cause an increase in the population over time. Such increase will be larger than the first year increase attributable to the installation of a cooling tower, which after subtracting the nonlanded fish, is all that EPA has valued. <FN 155>

Unfortunately, EPA's available data do not presently allow for calculation of the present value of future reproduction of nonlanded fish; the calculation would be complex and would likely vary by species. Below in Part IV.B, we explain a worked example of such calculation prepared by Pisces. EPA should adopt such method for valuing the unlanded species. But for present purposes, it is reasonable to assume that nonlanded fish have a value that is significantly greater than zero. Thus, Dr. Ackerman has conservatively assumed that nonlanded fish have a value equal to 0.25 times the value

of landed fish of the same species.
Dr. Ackerman's spreadsheet adjusts for the percentage reduction in losses achieved by each EBA policy option, calculating national baseline losses, and benefits of each policy option, replicating EPA's values when using EPA's assumptions.

Dr. Ackerman recalculated the spreadsheet three times: in Scenario A, keeping all EPA assumptions and input data, except assuming that non-use value is 2 times recreational, commercial and forage value; in Scenario B, restoring EPA's non-use assumption but assuming that nonlanded recreational and commercial fish are valued according to the above equation; and in Scenario C, combining my two assumptions. Dr. Ackerman's results, as shown in his Table 1, are as follows:

- Estimated benefits of each policy option are more than doubled in Scenario A, relative to the estimates in the EBA;

- Estimated benefits of each policy option are roughly doubled in Scenario B; and

- In Scenario C, combining the two adjustments, benefits of policy options are roughly 4-6 times the estimates in the EBA.

When compared to "the costs of the policy options, as reported in the EBA, each of the three scenarios has significantly greater net social benefits. And, importantly, the order of policy options, ranked according to net social benefits, changes. EPA's EBA Option 5 -the dry cooling option -has the greatest net benefit in all three scenarios, as shown in Dr. Ackerman's Table 2. In Scenario C, combining the two adjustments, EPA's proposed option, Le. EBA Option 3, is the one that fares worst. Options 1,2,3a, and 4 all have net benefits of $4.1 -$4.5 billion in Scenario C.

Because Dr. Ackerman's rough estimates of these two changes have such a large effect on the outcome of the analysis, EPA should explore both issues in greater detail. Specifically, as Dr. Ackerman recommends:

- EPA should develop approaches to non-use value more consistent with the recent economic literature, to replace the outmoded "50% rule" used in the EBA; and

- EPA should develop plausible values for the nonlanded fraction of I&E fish mortality. The one thing we know for certain is that the current estimate of zero is not the correct value.<FN 156>

The effect of such adjustments is far from trivial. They would show that all options in fact have large net benefits, and that EPA's incomplete valuation of benefits misleadingly favors the option that actually has the lowest net benefits. As Dr. Ackerman explained in August 2002, it is critical that EPA carefully explore these corrections.

In the NODA, EPA discarded much of the benefits methodology it had relied on at proposal, in favor of a regional benefits approach. Nevertheless, from the limited information available, Dr. Ackerman estimates that the NODA calculations introduce little change in aggregate estimated benefits.<FN 157> As discussed above in Section 3 and in the Ackerman NODA Comments, the NODA benefits methodology, like that at proposal, significantly understates total benefits. One adjustment EPA should make correct one of many problems with the NODA benefit methodology is to reconsider its restriction of nonuse value to the population living very close to the plants in question. Instead, EPA should add to its nonuse value for the population in bordering countries by assuming that the use value per household in the rest of the country is even 10% as high as in the bordering counties (or alternatively, one could assume that 10% of the households in the rest of the country have a non-use value as high as those in the bordering counties). <FN 158> Such adjustment more than triples the total value of baseline losses due to North Atlantic impingement and entrainment. See Ackerman NODA Comments at p. 10.

Footnotes

150 Ackerman Phase II Comments, Section 2.

151 Indeed, EPA has admitted that it understated non-use benefits. In the preamble to the Phase II Proposal it acknowledged:
- Nonuse benefits are most likely understated using the 50 percent rule because the recreational values used are likely to be understated.
- The 50 percent rule itself is conservative (e.g., only reflects any nonuse component of total value to recreational users. It does not reflect any nonuse benefits to recreational nonusers). 67 Fed. Reg. 17193.

152 Ackerman Phase II Comment at p. 6.

153 Id.

154 Of course, not all unlanded fish will return. To fully calculate this, one would have to factor in the average lifespan of the fish and average survival rates during the lifespan.

155 For a discussion of a method of calculating the worth of commercial species that are protected from impinged and entrained by cooling towers but not caught by fisherman in the first year, see Pisces Phase II Report, pp. 34-38, which is discussed below.

156 Ackennan Phase II Comments at p. 8.

157 Ackerman NODA Comments at p. 3.

158 A similar calculation could be done using EPA's estimates for households within a 32.4 mile radius. The result would be even larger total values than the ones derived by Dr. Ackennan.

EPA Response

EPA agrees that ecosystems provide many difficult-to-value services and that assigning zero values to this services would misstate society's values. As stated in the NODA (Federal Register 68 FR 13522-13587), the rule-of-thumb approach to estimating non-use is not used in the cost benefit analysis for the final Section 316(b) Phase II rule. Instead, the Agency explored various alternatives to quantifying and monetizing non-use benefits, including benefits from non-landed fish. These alternatives include: meta-analysis, the benefit transfer method, and break-even analysis. For detail see Chapters A12, C6, D6, and G6 of the final Phase II Regional Studies Document (DCN # 6-0003) and Chapter D1 (break-even analysis) of the final Phase II EBA document (DCN #6-0002). However, in view of the uncertainties in estimating non-use benefits for this rule at the national level, the Agency presented a qualitative assessment of the non-use benefits of the environmental protections at issue in the final 316(b) benefit cost analysis.

EPA has responded to concerns regarding the Agency's non-use valuation methods in responses to a number of comments. For EPA's benefit transfer approach, please see EPA's response to comment #316b.EFR.307.061 regarding using habitat values to estimate values for fish; comment #316bEFR.304.002 regarding the soundness of value estimates used for non-use benefit transfer;

comment #316bEFR.304.004 regarding comparisons of population demographics between the study region and policy region; comment #316bEFR303.020 regarding the definition of users vs. nonusers; and comment #316bEFR.303.021 regarding the allocation of values for various wetland services. For EPA's meta-analysis please see EPA's responses to comments #316bEFR.338.044 regarding meta-analysis in general; comment #316bEFR.338.046 regarding the appropriateness of the studies selected, comparison of baseline and extent of change, and comparison of affected populations; and comment #316bEFR.338.047 regarding sensitivity analysis in EPA's meta-analysis. For EPA's response to comments regarding the break-even analysis, please see response to comment #316bEFR.306.106.

For EPA's response to comments that the Agency's benefit estimates are incomplete, please see the response to comment #316bEFR.206.047.

For EPA's response to the issue valuing the "unlanded fraction" of fish please see the response to comment #316bEFR.336.009.

EPA agrees with the comment that there is potential for the affected population in the study area to be greater than the households in counties abutting the affected water body and households within 32.4 miles of the affected water body.

Benefit Estimation Methodology

MANY OTHER ADJUSTMENTSARE REQUIRED AND WOULD FURTHER INCREASE THE TOTAL BENEFITS AND NET BENEFITS FOR ALL REGULATORY OPTIONS.

As explained in Part III, EPA's benefits analysis is drastically incomplete and undervalues the benefits of minimizing impingement and entrainment. While data limitations and other constraints make it difficult or impossible for us recalculate EPA's the entire benefits analysis (other than in the two areas addressed in Part IV.A, above), Pisces Conservation has begun that process. In their report, the scientists at Pisces have identified a number of areas -some in addition to those acknowledged by EPA-where the benefits analysis undervalues the resource. Further, they have illustrated how those errors could be corrected.

EPA Response

EPA agrees with the commenter that the proposed rule analysis does not include all possible benefits of CWIS, and that, therefore, the value of entrained and impinged fish to an ecosystem is likely to be underestimated. As stated in the NODA (Federal Register 68 FR 13522-13587), EPA attempted to expand its analysis of non-use benefits categories for the final Section 316(b) Phase II rule analysis. However, given the uncertainties in estimating national ecological benefits for this rule, the Agency limited its benefits assessment to the use benefits categories and presented a qualitative assessment of non-use benefits of the environmental protections at issue in the final 316(b) benefit cost analysis.

Data Issues

Baseline Impingement and Entrainment Is Significantly Higher than EPA Has Estimated

.

The first significant correction EPA should make is to considerably increase the baseline impingement and entrainment data. This is critical because EPA has quantified the number of fish saved by various technologies by multiplying an effectiveness factor. The resulting number of saved fish is then multiplied by the value of those fish so as to measure the monetary benefit of the fish saving technology. Putting aside for the moment the obvious problems (discussed in Part III above) of monetizing fish deaths avoided, it is clear that an accurate, current assessment of power plant fish kills is necessary as a starting point. But EPA's data significantly understates these fish kills and should be corrected in at least the following respects:

- EPA's I&E data is decades old, much of it from the 1970s and 1980s, even though fish populations, and therefore the numbers of fish impinged and entrained at power plants, has increased over and since that period of time, due largely to improving water conditions such as increased sewage treatment. EPA should increase the baseline I&E data to account for such increases, and predict future increases by extrapolating such trends into the future. (See Pisces Phase II Report at pp. 22-27.)

- EPA has failed to account for increases in flow at Salem and other similarly situated plants, even though the data clearly indicates that Salem has increased its intake flow in recent years and EPA has acknowledged that the currently larger flows are anticipated to continue. As a result, EPA should not use the average flow data or the corresponding I&E data at Salem (or at any other plant where an increase in flow is likely to continue). Rather, it should use the current and projected flow data, and the corresponding I&E totals. (See Pisces Phase II Report at pp. 2-7.)

- EPA assumed all fish impinged are age 1. In fact, fish are impinged at all ages. Older, larger fish are more valuable for two reasons. First, when landed by fisherman, they weigh more and therefore yield more revenue. Second, when not landed, they produce offspring which can increase the size of the population. An age 6 striped bass is much more fecund than an age 1 striped bass, and is therefore worth more biologically. As Pisces examples demonstrates, by assuming all fish are age I, EPA has undervalued impingement by between one and two orders of magnitude. EPA should adjust the impingement data to take into account the actual age of fish impinged. (See Pisces Phase II Report at pp. 5-19.)

-EPA's survival rates, which are key variables used to estimate the total mortality as age 1 equivalent numbers, are most likely too low, as they are based on historical data when populations were badly suppressed by environmental damage and over-exploitation. Changing the survivorship figures used in the age 1equivalent calculations can have a large effect on the numbers of age 1equivalents estimated to be entrained or impinged. More reliable estimates of age1-equivalencewould be obtained by increasing survival rates by 25%. (See Pisces Phase II Report at pp. 20-2 1.)

EPA Response

EPA recognizes that abundances of aquatic species, and therefore the numbers of organisms vulnerable to I&E, may have increased, decreased, or stayed the same at particular sites since the time of the available I&E studies or life history data. Unfortunately, it is uncertain how old data can be adjusted to reflect current conditions, particularly given the many variables that influence the growth of biological populations.

As is common practice for EPA's regulatory analyses, EPA did not consider projected future conditions in its 316b Phase 2 benefits analysis.

Regarding the age of impinged fish, please see response to Comment 316bEFR0.29.105.

Environmental Impacts

Endangered Species Are Harmed and Killed By CWIS To A Far Greater Degree Than EPA Estimated.

In its benefits analysis, EPA has assumed that only two U.S. power plants (Pittsburg and Contra Costa in San Francisco Bay) out of a total of 550 in-scope facilities impinge or entrain endangered, threatened or otherwise special status species. That is, of course, patently wrong. Since power plants cooling water intake structures generally suck in a cross-section of all species present in the waterbody, any plant located near the habitat or range of a rare or special status species is likely to be impinging and/or entraining individuals of that species. As Pisces explains, “It should be assumed that all power plants situated on estuarine and coastal sites will impact to some degree threatened or endangered (T&E) species."<FN 159> Reliable data on the extent to which species are harmed and killed is not likely to be provided by the power industry for two primary reasons: first, because T&E species are, by definition, rare, they will appear in samples in much lower frequency than common species; and, second, there is a strong disincentive for plant operators to report the taking of T&E species, which may be prohibited by Federal and/or state law.

Nevertheless, it is clear that power plants do kill endangered species. As the Delaware Riverkeeper Network explains in its comments, endangered and threatened sea turtles and shortnose sturgeon are killed at Salem. Precise figures on these kills have not been provided, but they have been acknowledged and documented on the public record. A December 1998 report prepared by the National Marine Fisheries Service (NMFS) stated that Salem impacts the federally endangered shortnose sturgeon. While not a comprehensive tabulation of impacts, the report stated that 8 shortnose sturgeon were discovered in trash bars at Salem, and estimated that up to 11 shortnose sturgeon are impinged at Salem each year. Although there were no findings regarding entrainment, if adults are getting caught on trash racks it is highly likely that juveniles, and younger, are also getting killed there. Endangered and/or threatened sea turtles have also been injured and killed at Salem. The New Jersey permit record has information about the impacts to the federally threatened turtle populations injured and killed at Salem, and at one time required a turtle resuscitation program at that site.<FN 160>

There is also additional data concerning T&E species harmed and killed at other power plants. For example, the San Francisco Bay Delta estuary includes the following special status species:

- Central Valley ESU steelhead -Oncorhynchus mykiss
- Central Valley fall/late fall-run ESU Chinook salmon -Oncorhynchus tshwytscha
- Central Valley spring-run ESU Chinook salmon -Oncorhynchus tshwytscha
- Delta smelt -Hypomesus transpacificus
- Green sturgeon -Acipenser medirostris
- Longfin smelt -Spirinchus thaleichthys
- Sacramento River winter-run ESU Chinook salmon -Oncorhynchus tshwytscha
- Sacramento splittail -Pogonichthys rnacrolepidotus <FN 161>

These species are vulnerable to I&E at many Bay and Delta power plants in addition to the Pittsburg and Contra Costa plants.

In Morro Bay, California, an April 2002 staff report of the California Energy Commission noted that the estuary used for cooling water by Duke Energy's Morro Bay Generating Station is inhabited or potentially inhabited by the federally endangered tidewater goby (Eucycloglobius newberryi) and the steelhead trout (Oncorhyrnchus mykiss).

Lists of T&E species could be complied for almost all ocean and estuarine sites. For example, in the Hudson Estuary both shortnosed (Acipenser brevirostrum) and Atlantic sturgeon (Acipenser oxyrinchus) have been impinged on cooling water intakes. At many ocean and lower estuarine sites young turtles are potentially vulnerable to entrainment. At one power plant proposed for New York harbor, several turtle species were listed as potentially present, including:

- Green sea turtle -Chelonia mydas
- Loggerhead sea turtle -Caretta caretta
- Leatherback -Dermochelys coriacea
- Kemp's ridley turtle Lepidochelys kempii
- Hawksbill -Eretmochelys imbriimbricata <FN 162>

Importantly, as Pisces notes in its report, as conservation measures for species such as sturgeons and turtles are successful, populations rise, resulting in extended ranges and the risk of higher impingement in future years. Thus, the fact that EPA is using old impingement and entrainment data reflecting the poorer water quality conditions of decades past has likely depressed the reported numbers of threatened and endangered species at power plants.

As a result, EPA’s implicit assumption that T&E species are killed only at the Pittsburg and Contra Costa plants is wholly unsupportable, with the result that the benefits analysis is falsely skewed downwards. EPA should collect all available data concerning impingement and entrainment of endangered species, and collect all data of T&E ranges in the waters where in-scope facilities are located, and revise its benefits analysis to account for impacts to T&E species at the majority of the 550 in-scope facilities.

Footnotes

159 Pisces Phase II Report at p.62.

160 See August 5,2002 comments of Delaware Riverkeeper Network.

161 Pisces Phase II Report at p 62.

162 With the exception of a few leatherbacks, most of the turtles in nearshore waters in the New York coastal region are small juveniles. The loggerhead is the most abundant, followed by the Kemp's Ridley. These two species, along with a few green turtles, move into harbours and estuarine waters, while the leatherback turtles remain along the coast and are rarely seen in embayments. Kemp's Ridley inhabits the shallower areas of Chesapeake Bay in search of blue crab, their preferred prey. Their preference for shallow waters and blue crabs makes the Kemp's Ridley the most likely sea turtle species to venture into the New York & New Jersey Harbor area. Similar lists would be produced for many east coast marine or lower estuarine power plants situated to the south of New York. Pisces Phase II Report at p. 63.

Benefit Estimation Methodology

EPA's Static Models Underestimate the Benefits of Minimizing Fish Kills.

EPA calculated the number of fish that would be protected from impingement and entrainment by the conversion to closed-cycle cooling. EPA then valued the commercial and recreational worth of those fish. For commercial fishing, it applied the traditional catch rate and valued only those fish that would be saved by a cooling tower, and then caught by a commercial fisherman. But all of the fish saved by the cooling tower have both ecological and monetary value. EPA's limited, static models do not however capture their value. As discussed above, Dr. Ackerman assigned those fish a value equal to 25 percent of the value of the landed fish. However, a more sophisticated method of valuing those fish is possible.

For step one of the analysis, assume that those fish are sterile and thus do not produce offspring. Although they escaped the fishermen in year one, the sterile, unlanded fish would still be in the waterbody in year two, year three, year four, and so on, up to the end of their lifespans, and would therefore be available to be caught by fisherman in those years. Thus, the available population would steadily increase during the lifespan of the species, at which point it would level off. EPA's static model assumes that the population increases only by the proportion of fish saved each year by the cooling tower, but it is clear that in a dynamic model, there are additional fish which will be landed, and therefore provide direct value simply because fish live much longer than one year.

For step two of the analysis, assume that the unlanded fish spawn, as they of course do. Because they are creating future generations of fish, the fish that are saved by a cooling tower and not landed by fishermen will during their lifespan, increase the population, thereby providing additional fish to be caught in subsequent years. Pisces has demonstrated with worked examples at Salem and Pilgrim a method for valuing these unlanded fish according to their reproductive value. At Salem alone, the commercial value of striped bass increased from about $56,000 per year to about $135,000 per year, which is a 141% increase. (See Pisces Phase I1 Report at p. 34-38.) Increases would be shown for all species at all plants, if EPA follows this method. EPA should recalculate its benefits analysis to take into account the value of fish that are not immediately landed and marketed.

EPA Response

The commenter proposes that the assessment should include consideration of reproductive value of fish killed by I&E. EPA has addressed this topic in its response to comment #EFR.206.065.

The commenter asserts that the assessment would be improved if the unlanded fraction of additional survivors should be valued at a rate of 25% of the value of landed fish. The basis of this assertion is not apparent, and EPA believes that the proposed method would not withstand scrutiny. EPA is currently investigating possible alternative methods for determining the value of unlanded fish.

Cooling system costs (e.g., dry, wet, recirculating)

BECAUSE EPA HAS OVERSTATED COMPLIANCE COSTS FOR COOLING TOWERS, IT SHOULD MAKE APPROPRIATE DOWNWARD ADJUSTMENTS TO ITS ESTIMATES.

As also explained in Part III, EPA has significantly overstated the compliance costs of the closed-cycle cooling regulatory alternatives. In its comments on the proposed rule, Synapse Energy Economics describes a number of areas in which EPA must revise its cost estimates, including the following:

- EPA should annualize the capital costs of adding cooling towers over a longer period than 30 years to reflect the likely expected operating lives of those towers.<FN 163>

- Rather than using the baseline (I.e., once-through) system intake flow of affected plants to size the needed recirculating cooling towers and associated conduit systems, EPA should instead use Nuclear Regulatory Commission data indicating that “recirculating cooling systems have lower condenser flow to MW ratios than once-through systems, regardless of age or other characteristics"<FN 164> to properly size and cost the cooling system conversions.<FN 165>

- EPA should have used the cost of the more standard fiberglass reinforced plastic material for new cooling towers at existing fossil-fired facilities to calculate the capital costs of wet cooling towers, rather than redwood towers, as EPA has acknowledged that fiberglass has become “relatively standard” for new facility installations.<FN 166>

- EPA should revise its equations to more accurately reflect the actual costs of building a cooling tower in light of the fact that the equations used by EPA to quantify the capital cost of a new cooling tower produce cost estimates that “in almost all cases” exceeded the actual project costs, sometimes by as much as 25 percent of the actual costs. <FN 167> In the alternative, if the EPA decides to continue to use these equations without revision, it should not apply a 20 percent “retrofit factor” when quantifying the cost of adding a cooling tower at an existing facility because the combined use of both the existing equations and the 20 percent retrofit factor leads to unreasonably high estimates for the capital costs of adding a new cooling tower at an existing facility.<FN 168>

- EPA should adjust the costs associated with condenser upgrades (which EPA assumed affected facilities would elect to undertake as part of cooling system conversions from once-through to recirculating systems) in order to reflect reductions in O&M costs. Such O&M cost reductions can be expected from upgrading to the new materials which are less susceptible to failure and should lead to fewer tube leaks and, consequently, lower repair and repair outage-related costs.<FN 169>

- EPA should have used a range of lengths of concrete-lined steel piping for cooling water make-up water and blowdown that is more typical of existing facilities instead of using a range that might only apply to a limited number of plants. <FN 170>

- EPA should cost out all applicable compliance strategies-several of these compliance strategies are likely to be less costly than the strategies for which the EPA has developed costs-in order to develop an accurate assessment of each option's costs. <FN 171>

- EPA should reflect the repowering of coal-fired facilities to combined-cycle technology-at least 15 if which have recently occurred or are planned-because the costs of complying with any of these options would be lower for a repowered facility than for the original coal-fired plant.

-EPA should adjust its energy penalty calculations in accordance with the detailed explanations provided by Synapse.<FN 172>

Furthermore, EPA should also adjust its compliance costs to account for the fact that the costs of regulation are: always overestimated in advance of their implementation.

Once adopted, regulations encourage new technologies and more efficient ways of complying. Once study found that 92 percent of the time (11 out of 12 cases) costs estimated in advance of regulation were more than twice actual costs. <FN 173> Another study found that advance cost estimates were higher than actual costs 50 percent of the time, and below actual costs only 11% of the time. <FN 174> Most strikingly, before the 1990 Clean Air Act Amendments, industry anticipated that sulfur reduction measures would cost $1,500 per ton. In 2000, the actual cost was less then $150 per ton, a 90 percent decrease. <FN 175> In the present case, once cooling tower retrofits become more frequent, market factors and competition will drive the costs down. EPA's cost figures should reflect that fact.

And finally, EPA's compliance cost estimates should be adjusted to reflect the likelihood that older fossil-fired facilities will be repowered instead of retired as a result a closed-cycle retrofit mandate. Two facilities in New York State (Reliant Astoria Repowering Project and the Bethlehem Energy Center) have recently sought to significantly upgrade their plants by retrofitting closed-cycle cooling at the same time that they convert to combined-cycle natural gas technology. These plants, and others around the Country, are evidence that firms will seek to repower older, less efficient generating facilities and that such repowerings can include cooling towers as part of the repowered facility in place of once-through cooling. Such projects will provide significant environmental benefits in terms of reduced water usage and lowered air emissions and will offer substantial economic benefits for their owners. It is reasonable to assume that at least some plants will respond to a cooling tower regulation in such manner, and their costs would decrease as a result of the increased efficiency and reduced cooling water needs from combined-cycle technology.

By making these adjustments, EPA would come closer to estimating the true costs and true net benefits of the closed-cycle alternatives.

EPA Response

The commenter is correct that the Agency annualized the capital costs of cooling towers over 30 years, based on the expected useful life of the cooling tower system. The expected life of cooling towers depends on the materials of construction, the chemistry of water in the cooling system, the site ambient conditions, the maintenance practices of the tower, and the design of the tower. As such, the Agency considered the expected life of 30 years to be typical based on consultation with the expertise of vendors and manufacturers of cooling towers. Nonetheless, the commenter provides no information or data that suggests to the Agency that a better selection than 30 years is available. For typical mechanical draft towers, the prediction of a 30 year useful life is justified and supportable.

The Agency believes that the commenter is mistaken in asserting that retrofitting to closed-cycle cooling presents the opportunity for once-through systems to reduce their condenser flows and therefore install a smaller cooling tower in return. As stated in comment 316b.EFR.306.403, a retrofit installation of cooling towers that would reduce the size of the condenser flow would be extremely costly and might entail even more downtime for construction (i.e., retrofitting the entire condenser system from single-pass configuration to a two-pass system) than if it were to utilize the existing condenser configuration. This is not to be confused with replacing condenser tube systems, which the Agency modeled for the proposal and NODA cooling tower methodology, but instead requires dramatic and costly changes to the condenser configuration and connecting buildings/piping. The commenter fails to prove that cooling tower retrofits can afford the opportunity for dramatic resizing of the condenser flows, and as such, the Agency cannot act upon the recommendation because its research reveals contradictory evidence of the commenter's unsubstantiated assertions.

The Agency notes that the capital costs of redwood cooling towers do not significantly differ from those of fiberglass reinforced plastic. The difference is roughly 2 percent in terms of average cooling tower portion of capital costs. In the analysis of the annualized capital costs of the waterbody based capacity reduction option presented in the NODA, a possible 2 percent difference in capital costs of a partial component of the capital costs is negligible. The Agency also refers to comment 316b.EFR.306.419.

The Agency disagrees fundamentally with the commenters request that the Agency decrease the capital cost equations for cooling towers due to the fact that EPA's empirical comparison revealed that the costs estimated by the Agency exceed those of other empirical cases by a minor margin in the majority of cases and a slight margin (25 %) in others. The Agency approaches the prospect of providing national costs by attempting to utilize typical installed cost estimates, yet maintaining a slight (very slight in this case) conservative approach to empirical comparisons. The slight difference between EPA's new facility cooling tower capital costs to new facility tower projects is also just a portion of the costs associated with retrofitting to cooling towers, as represented in the proposal and NODA analysis of the waterbody based capacity reduction option. The commenter's suggestion that EPA not utilize a retrofit factor is unjustified further. The Agency notes that in comparing its retrofit project cost estimates (i.e., those relying on EPA's cost methodology, which includes the 20 % retrofit factor, which has been criticized by many other commenters) to those for two real-life cases of cooling tower retrofit projects (as presented in DCN 4-2526 for the proposal) that the EPA estimates were reasonably close to those actually realized in the real cases, but the EPA costs did not exceed those of the real cases. Should the Agency have removed the 20 percent retrofit factor, the comparison to real-life empirical cases would fail to present a reasonable result.

The Agency included condenser upgrades for a portion of the possible retrofit cooling tower projects in the waterbody based capacity reduction option in order to account for the likely possibility that the increased pressure in the condenser tubing from a cooling tower. These condenser upgrades would provide for typical operation and maintenance associated with new condensers at new facilities. Because the Agency developed its O&M estimates for cooling towers based on its new facility model, there would be no basis to adopt the commenter's recommendation of reducing the O&M estimates from those developed for new condensers. If there is an argument to be made, it would be that the Agency should marginally increase the O&M estimates for the portion of the retrofit cases in which the Agency did not assign condenser upgrades, whereby the new facility oriented O&M costs might not account for the upkeep and maintenance necessary to maintain an older condenser set while simultaneously increasing the pressure. As such, the recommendation cannot be adopted by the Agency.

The Agency disagrees with the commenter's assertion that the range of lengths of makeup and blowdown piping assumed by the Agency is improper for the cooling tower retrofit analysis in the NODA. The commenter suggests that the Agency adopt lengths of piping "more typical for existing facilities," than that used by the Agency. The Agency points out that the makeup and blowdown piping assumptions by the Agency reflect realistic estimates for retrofit projects at existing facilities, as a retrofit project may require locating a cooling tower system a sizeable distance from a waterbody due to space and siting constraints that do not apply in the case of new facilities.

The Agency notes that it has costed a variety of compliance strategies for the NODA and final rule analysis. The commenter asserts that other options might be more affordable than those analyzed by the Agency, and yet does not provide any suggestions of what these "more affordable" strategies might be. As such, the Agency believes that it has analyzed a range of broad compliance strategies for implementing cooling tower retrofits, and even in the least stringent of these cases found the national costs to be unacceptable.

The Agency notes that commenter in recommending that the Agency account for the repowering to combined-cycle configurations (which could reduce flow in certain cases) fails to also recommend that the Agency account for the cases in which facilities add all new steam capacity which would have the effect of raising intake flow in certain cases. The Agency analyzed the potential repowering of facilities within the scope of the final rule and found that for as many facilities that could reduce intake flows through repowering to combined-cycle that an equal and opposing amount plan to increase their intake flows through adding additional power without converting to combined-cycle (see 67 FR 17113). Therefore, by recognizing that a balance of facilities projected to repower would increase as well as decrease intake flow, the Agency's approach to repowering is reasonable.

Regarding the energy penalty issues referenced by the commenter, the Agency notes that in the referenced report (authored by Synapse) the primary contention pertains to EPA's use of a 67 percent load factor for annual energy penalty calculation. The commenter does not contend EPA's use of a 100 percent maximum load for summer energy penalties, which comprise a portion of the modeled energy penalty for the NODA analysis of cooling tower options. The report claims that this has significantly overstated potential energy penalties from cooling tower retrofits and recommends that EPA utilize a higher load factor, one they believe to be more realistic. The commenter correctly points out that the Agency has chosen the 67 percent load factor and also that the Agency is wary that by selecting a load factor that is slightly less than a maximum factor that it has slightly raised a portion of the energy penalty component. However, the Agency notes that this is a reasonable assumption, as the Agency based its turbine penalty model on data from a single type of turbine and chose a slightly conservative value to represent a wide variety of real-life turbines and operating conditions. The Agency also notes that it utilized an assumption that new turbines would function equally well with retrofitted or older turbines, but this is not the case, which further emphasizes the need for a conservative approach to modeling turbine penalties. The Agency received a comparable detailed energy penalty study from the Department of Energy (see response to comment 316b.EFR.010.103, in which the results of the annual average energy penalty from their independent research on cooling tower retrofits correlate well with those derived and used by EPA in the NODA and proposal. In addition, the commenter contests EPA's use of the national average for California. The Agency believes this is a fair methodology, as the annual average temperatures expected in California would be well modeled by the national average for Seattle, Chicago, Jacksonville, and Boston.

Regarding the recommendation by the commenter that EPA adjust compliance costs "to account for the fact that the costs of regulations are always overestimated in advance of their implementation," the Agency does not believe that it can do so in good faith. The Agency notes that the vast majority of comments (all except those provided by the commenter and organizations representing the commenter) assert that the Agency has significantly understated the potential costs of retrofitting to cooling towers. Based on the lack of supported or well reasoned suggestions for lowering costs given in the comment, the Agency is not inclined to concede that cooling tower costs may be understated. In fact, the Agency believes that should its estimates of cooling tower costs change in any direction, there would be a sufficient basis to raise the costs based on its review of the variety of substantial data and studies included elsewhere in the Phase II comment database.

Finally, the commenter asserts that facilities would choose to repower versus shut-down if the final rule would require a "closed-cycle retrofit mandate." The basis of this assumption is evidently two cases of repowering facilities along the Hudson river. While the Agency acknowledges that these repowering facilities indeed are examples of repowering cases that may adopt closed-cycle cooling for their new power plant projects, the Agency fails to see these two examples as evidence that “should” it adopt a cooling tower retrofit mandate that all other plants would choose to repower rather than retire. In fact, the Agency fails to see how the commenter has shown how the examples are even proof that the two power-plants arrive at their decisions to repower versus retire based on a mandate to retrofit to cooling towers. The Agency believes that a wide variety of economic decisions would influence the decision of a facility to repower, and there is no credible evidence given by the commenter that shows that the vast majority of facilities facing critical financial difficulties across the country, through bankruptcies in many cases, would make a “repower versus retire” decision when faced with extreme capital cost requirements, the potential for extended connection outages, and high recurring operation and maintenance costs.

Use of Replacement Costs (HRC and hatchery-based)

THE HABITAT REPLACEMENT COST METHOD OF VALUATION PROVIDES A REASONABLE LOWER BOUND ESTIMATE OF MONETARY BENEFITS.

In several of its case studies, EPA uses calculations of habitat-based replacement cost (HRC) to value the benefits of the regulatory alternatives. Use of the HRC method is based on the following rationale: Natural ecosystems produce numerous interrelated benefits, some of which are difficult or impossible to quantify, as EPA has admitted in the preamble and EBA. Thus, given the constraints of time, resources, data and human ability to quantify complex systems, a simpler approach is to calculate -to the extent possible -the replacement cost of the ecosystem that provides the benefits.<FN 176>

As Dr. Ackerman explains in his report, restoration cost is used as a measure of damages under the Comprehensive Environmental Response Compensation and Liability Act (CERCLA) for Superfund sites; under the National Marine Sanctuaries Act; and under the oil spill provisions of the Clean Water Act. Use of restoration costs was explicitly upheld in State of Ohio vs. US Dept of Interior, in which the US. Court of Appeals for the District of Columbia Circuit held in the CERCLA context:

Congress established a distinct preference for restoration cost as the measure of recovery in natural resources damage cases.<FN 177>

Insurance companies frequently value damages to property at estimated replacement cost. Valuation of assets at replacement cost is also a common practice in macroeconomics, where depreciation is routinely valued at replacement cost. For example, for a marketed asset, market value (as opposed to book value) is set at the current replacement cost. Such valuation is essential in understanding investments. Likewise, any detailed analysis of capital costs focuses on “economic depreciation”, or the replacement cost of consumed capital, as distinguished from accounting measures of depreciation based on book value or tax laws.<FN 178>

HRC valuations are often more expensive than other approaches to valuation. However, this is to be expected in light of the incompleteness of valuation when each particular service or benefit must be separately estimated. A separately evaluated list benefits might, if thorough and complete, show higher benefits than HRC because nature is generally more efficient in producing “ecosystem services” than artificial replacements can be, and because restoration cannot not completely restore what was destroyed. But since EPA’s itemization of benefits is utterly incomplete and significantly undervalues the benefits of cooling towers, HRC provides a closer approximation of true benefits.

Despite its limitations, HRC is valuable contribution to the process of valuation and provides a reasonable lower bound estimate of benefits. As a result, Dr. Ackerman recommends that EPA explore HRC valuation of additional sites, to broaden the data and analysis used in the estimates of benefits in this case. Specifically he recommends that EPA revise and expand the EBA Case Studies Chapter A11, explaining and supporting HRC calculations, discussing the theoretical basis for HRC, and identifying categories of ecosystem value that are not measured by any other techniques.<FN 179>

Footnotes

176 It is not possible to fully replace the aquatic organisms and ecosystem that are destroyed by impingementand entrainment at power plants. Attempts at “replacing” fish and other aspects of the environmentmay provide some benefit to some species, but cannot duplicate the natural systems which were destroyed, as the Pisces Phase II Report explains at pp. 48-60. As a result, HRC will not value 100% of the loss, but only some portion of it.

Option 3--Site-specific determination

THE ALTERNATIVE SITE-SPECIFIC APPROACHES TO DEFINING BTA WOULD UNFAIRLY BURDEN THE PUBLIC AND WOULD CONTRAVENE THE CLEAN WATER ACT.

In the preamble to the Phase II Proposal, EPA requested comment on several site-specific regulatory alternative approaches for determining BTA. These alternative approaches operate on an even more case-by-case and site-specific basis than the Phase II Proposal, which has one site-specific compliance option, Track III. Four site-specific approaches are described in the preamble: an EPA-developed "sample site-specific rule," complete with proposed regulatory text; a site-specific alternative based on EPA's 1977 draft guidance; a regulatory approach suggested by the Utility Water Act Group (UWAG); and a regulatory approach suggested by the Public Service Electric and Gas (PSEG).<FN 180> Each of these approaches contravenes both the letter and the spirit of the Clean Water Act and should be given no further consideration by the Agency.

Require closed cycle cooling

EPA states that the site-specific approaches “would be based on the view that the location of each power plant and the associated intake structure design, construction, and capacity are unique, and that the optimal combination of measures to reflect [BTA] for minimizing [AEI] must be determined on a case-by-case basis.” <FN 181> But this is clearly wrong. Almost without exception, impacts from cooling water intake structures are reduced by between one and two orders of magnitude by conversion from once-through to closed-cycle cooling. While other additional measures may be appropriate based on location, adverse environmental impacts cannot be minimized without closed-cycle cooling, and thus cooling towers must be required unless they are wholly disproportionate to the benefits (e.g., the highly unusual circumstance where a plant is located in a waterbody that-has no fish).

Option: Site-specific determination of BTA

Any site-specific approach would favor industry stakeholders and present an unreasonable burden on environmentalists and local officials. As EPA correctly recognized in its Phase I preamble:

The historical case-by-case approach requires significant resources on the part of the regulatory authorities that must implement section 316(b) requirement. [It] requires that each regulated facility must develop, submit, and refine studies that characterize or estimate potential adverse environmental impact. Such studies can take several years to complete and require the support of a multi-disciplinary team. In addition, given the iterative nature of the assessment process, industry as well as EPA regional and State regulatory authorities must expend significant resources assessing study plans and methods for characterizing the environmental impact occurring at each facility and evaluating those data to determine what constitutes BTA for each specific facility. <FN 182>

EPA actually understates the burden. Public commenters and intervenors have few resources to evaluate even the initial multi-disciplinary impact studies and volumes of technical supporting documents regarding CWIS characteristics and ecosystem impacts, let alone the months or years of hearings typically needed to adjudicate scientific disputes. Local officials and environmental advocates whose resources are dwarfed by those of industry should not be forced to counter industry's elaborate and self-serving technical obfuscation on generally applicable protection principles.

Footnotes

182 65 Fed. Reg. At 49079.

EPA Response

EPA disagrees that a large percentage of facilities will opt for a site-specific determination of BTA. Please refer to the response to comment 316bEFR.202.002 for more information.

Subject Matter Code 2.04.05

Implement a site-specific alternative

Any approach that does not set specific national, uniform performance standards for the critical determination of capacity minimization would also violate the Clean Water Act. By leaving the BTA determination to the NPDES permit writer (state agencies in delegated states and EPA regional offices in non-delegated states), EPA would have abdicated its non-discretionary duty under Section 316(b) to set national BTA standards for generally applicable impact minimization parameters. Local agencies could require different technologies based on a variety of considerations outside the Clean Water Act, or could be forced to do so by the resources of industry applicants. The result of this approach would inevitably be that different facilities and states would have different BTA requirements for CWISs, thus ensuring inconsistent protection and potentially even reviving the "race to the bottom." To avoid creating a disincentive to power generators in a deregulated energy environment, or to avert fears of increased energy costs, states might be even more reluctant to establish stringent measures than they were in the pre-1972 context.

EPA Response

In today's rule, EPA explicitly provides that under section 510 of the CWA nothing in the rule precludes or denies the right of a state or political subdivision of a state or an interstate agency to adopt or enforce any requirement with respect to control or abatement of pollution that is not less stringent than those required by Federal law.

Subject Matter Code 2.04.02
Apply 316(b) before a det. of impact/AEI

Furthermore, the approaches suggested by industry would require the agency to define the phrase "adverse environmental impact" in section 316(b). The basic purpose of such a definition would be to require a determination of adverse environmental impact as a threshold before a permitting agency would even consider mandating BTA. Industry is trying to create an additional procedural hurdle to the regulation of cooling water intake structures, by requiring that a proposed CWIS attain a threshold of adverse impact before best technology can be required. That approach, however, is wholly unnecessary and inconsistent with the language of Section 316(b) and the structure of the Clean Water Act. <FN 183> The only threshold requirements for application of Section 316(b) standards are that facilities include a point source (which is a NPDES permit prerequisite), must be in an industry subject to Section 301 and 306 standards (which includes all significant users of cooling water), and must have a cooling water intake structure.

At the very least, determination of AEI as a threshold to regulation provides for months or years of delay, consuming the resources of agencies and intervenors alike, and in the case of existing facilities, unnecessarily continuing the slaughter of aquatic organisms. The New York State Department of Environmental Conservation ("DEC") has adopted the correct policy regarding adverse environmental impact as a regulatory threshold. DEC "considers the death of any fish at or through a cooling water intake to be an 'adverse impact.'"<FN 184> Like the NYS DEC, EPA should refuse to allocate public fish and wildlife resources to electric energy generators or other cooling water intakes. Congress drafted section 316(b) to minimize adverse impacts, and not merely to ensure the protection of a balanced, indigenous population as provided in section 316(a). In light of the Phase II Proposal's 50 MGD regulatory threshold (which assures that every in-scope facility will be one that causes adverse environmental impact) defining and determining the level of AEI should not create an unnecessary threshold to BTA regulation.

While it is not realistic to expect to save every fish, the killing of any aquatic life by cooling water intake structures is the adverse impact that EPA must minimize by requiring best available technology under section 316(b). Industries' proposed definition and threshold determination of AEI would complicate and delay this task.

Footnotes

183 For an in-depth discussion of why determination of AEI as a threshold to section 3 16(b) determination is both unnecessary and contravenes the Clean Water Act, see Super, R. W., and D. K. Gordon, Minimizing adverse environmental impact: how murky the waters?, The Scientificworld JOURNAL (2002) 2, 219-237.

Comment on new (Phase I) facility rule

THE SEGMENTS OF THE REGULATORY COMMUNITY DEFERRED TO LATER PHASES OF THIS RULEMAKING SHOULD BE REGULATED BASED ON IMPACTS, NOT TIMING.

Pursuant to the Amended Consent Decree in Riverkeeper v, Whitman, EPA's section 316(b) rulemaking has been divided into three phases. In Phase I, EPA is required regulate all new facilities using a cooling water intake structure; Phase II must address all existing power plants above a threshold level; and Phase III captures the power plants below the Phase II threshold, as well as existing non-power plant facilities. EPA has, however, made at least two deviations from that tri-furcated scheme, by deferring regulation of certain segments of the regulated community to later phases. In both cases, EPA claimed the deferral was necessary because it lacked adequate information on the relevant industrial group during the earlier regulatory phase.

Specifically, in the Phase I NODA EPA stated that it had not considered or projected impacts on offshore and coastal oil and gas drilling facilities in its Phase I proposal. <FN 185> As a result, EPA considered not including these facilities within the scope of the Phase I rule, and instead addressing them within the scope of the Phase II or Phase III rulemaking.<FN 186> In the final Phase I Rule, EPA determined that it would "propose and take final action on regulations for new offshore and coastal oil and gas facilities, as defined at 40 CFR 435.10 and 40 CFR 435.40, in the Phase III section 316(b) rule." <FN 187>

In addition, in the Phase I rule, EPA attempted to define "new facility" more narrowly than the definition under Section 306:

Modifications to an existing cooling water intake structure that do not serve the cooling water needs of a greenfield or stand alone facility in 40 CFR 122.2 and 122.29(b)(l), (2), and (4)(i.e., a facility that meets the definition of new source or new discharger and commences construction after the effective date of the rule) do not constitute a new facility subject to this rule. Thus, the definition of new facility under this rule is narrower than the definition of new source under section 306 of the CWA.

EPA's intent in defining "new facility" for purposes of the Phase I scope was to exclude any facility built at a site where there is currently an existing operation devoted to the same industrial purpose, regardless of whether its industrial process are substantially independent of the existing facility at the same site.'" For example, adding a new electric-generating unit (whether peaking or not) at an existing power plant site would not be a new facility under Phase I, but would be an existing facility under Phase II, under EPA staffs interpretation. <FN 190>

As with oil and gas extraction facilities, EPA chose to delay the regulation of these new source facilities from Phase I to Phase I1 because it lacked information during the earlier rulemaking phase:

EPA generally deferred regulation of new sources constructed on a site at which an existing source is located (see 40 CFR 122.29(b)(3)) until the agency completes analysis of its survey data on existing facilities.<FN 191>

Thus, with both deferrals, EPA has not claimed that the relevant segment of the regulated community should be subject to the same regulations as the facilities in the later phase, only that their regulations should be promulgated at the same time as the regulations for the facilities in the later phases. But EPA has ignored this important point in the Phase II proposal.

The Phase II Proposal makes no distinction in its thresholds or standards between existing facilities and those facilities that are new sources under CWA Section 306 and were purportedly not included as new facilities under the Phase I rule. But such facilities, because they are actually new facilities and are substantially independent from industrial processes at the existing facility on the same site, have the flexibility to install the technologies required in the Phase I rule. EPA has not established why these facilities should instead be regulated like existing facilities. Now that EPA has the survey data it was waiting for, it should do one of two things in promulgating the Phase II rule: either (1) amend the definition of new facility in 40 CFR 125.83 to make clear that such definition will be consistent with the new source definition under CWA section 306 with respect to substantially independent processes; or, (2) if these new source facilities are to be considered existing facilities for section 316(b)purposes, EPA should provide separate standards for them consistent with the new facility standards.

Similarly, in Phase III, when promulgating regulations for existing industrial and small power plant facilities, EPA should not subject new oil and gas extraction facilities to those same (likely, more lenient) regulations by default. Rather, EPA should either include new oil and gas extraction facilities in the definition of new facilities (and thereby subject them to the Phase I standards) or should provide separate appropriate standards for that industry. With respect to the environmental impacts of offshore oil rigs, it is clear that such structures act like artificial reefs and are therefore extremely effective at attracting fish, which would then be exposed to impingement and entrainment.<FN 192> Indeed, industry has claimed that their oil rigs make excellent fishing spots. Thus, stringent cooling water intake regulations are necessary to protect fish at these facilities.

189 Telephone conversation with EPA staff, January 31,2002.

190 Id. Whether the codified text of the Phase I regulations actually accomplisheswhat the preamble and staff claim to have intended is far from certain. Reading the regulations alone, the definition of new facility at 40 CFR 5 125.83 appears to be consistent with, not narrower than, the definition of new source under CWA Section 306 and 40 CFR 122.29 because the references and citations in the Phase I rule to “stand alone” and “greenfield” facilities (40 CFR 122.29(b)(l)(i),(ii), and (iii)) and the “substantially independent”test for stand-alone facilities have been incorporated into 40 CFR 125.83.

Organization National Marine Fisheries Service

Subject Matter Code 11.01

RFC: Proposed use of restoration measures

NOAA understands the practical differences between existing plants and proposed (new) plants. NOAA recognizes that it may be difficult to retrofit an existing plant with intake technology to meet performance standards. In that regard, NOAA believes that mitigation can have a greater role in Phase II rules than in those for Phase I. Technology should be the first choice in reducing an existing impact. However, if cost limits the retrofit of intake technology, mitigation such as habitat restoration should be considered to reduce the impact. Habitat restoration can be an important tool in aiding the recovery of fish populations and NOAA believes that this should be an option available to regulators.

EPA Response

No response is necessary.

General: cost tests

I am writing to clarify a point made in the second paragraph on page 11 of those comments. [see 316bEFR.328.008] EEI indicated that -- because it was unable to obtain facility-specific assumptions EPA used to generate its estimates of the nationwide cost of the proposed regulations -- EPA should not share this cost information with other regulators, "in particular for use as a starting point in developing permit requirements."

However, by making that comment, EEI did NOT mean for EPA to withhold the information from facility owners. Facility owners need information about EPA's technology and cost assumptions for their individual facilities for the purposes of applying the "cost-cost" test in the proposed rule. Therefore, EEI requests that the agency make available to each facility owner EPA's assumptions as to both the technology that would apply at the facility and the cost of that technology at the facility. EPA should make this information available to facility owners now and upon request at any time in the future.

As a member of the Utility Water Act Group (UWAG), EEI fully supports UWAG's interpretation of the cost-cost test, as set out in UWAG's comments on the NODA and the underlying proposed regulations. Properly applied, the cost-cost test must compare the cost of the technology that EPA assumed for a given facility in promulgating the rule with the cost of technology the facility would actually be required to adopt to meet the proposed rule's performance standards. The point of the cost-cost test is to allow for site-specific relief if a facility would otherwise bear a significantly greater cost than EPA assumed in analyzing the proposed rule. Thus, in order for facility owners to properly apply the cost-cost test, EPA needs to make the underlying technology and cost assumptions for each facility available to the facility owner.

EPA Response

EPA notes that it received this letter from the commenter far after the close of the notice of data availability open comment period. Due to the very delayed submittal of the information, EPA attempted as best as it could, considering the limited time frame, to fully consider the comments.

EPA has no legal obligation to respond to such late comments. See e.g., Personal Watercraft v. Dept. of Commerce, 48 F.3d 540 (D.C. Cir. 1995). Nevertheless, EPA has attempted to respond to these comments to the extent possible.

The Agency notes that the cost-cost test included in the final rule is implementable without the necessity to share facility-specific confidential information with the permit authority. EPA also notes that the permit authorities have the legal means to obtain facility-specific information in determining conditions of permits affecting said facilities, provided that the information is germane to the permit requirements or supporting analysis of the permit.

See response to comment 316b.EFR.410.001 for EPA's response to the referenced comment on the cost-cost test.

Role of States and Tribes (alt./equiv. programs)

Author Name Mike Huckabee

Organization State of Arkansas, Office of the Governor

States have been implementing section 316(b) for more than 30 years and have developed significant expertise in the regulation of cooling water intake structures, as have the power plant owners that would be directly affected by the proposed rule. The proposed rule has enormous potential cost and energy impacts for the regulated utilities and their customers.

The proposed rule presents an opportunity to fulfill EPA's commitment to an effective Federal-State partnership and a regulatory regime that is flexible, cost-effective, and based on sound science. To avoid substantial disruption to state water quality programs and to our electric energy supply, it is important that the EPA preserve flexibility in the proposed rule by allowing use of equivalent state programs, preapproved technology in defined circumstances, site-specific variations, reasonable methods for assessing costs and benefits of particular cooling water intake structure options without understating the costs or inflating the benefits, and habitat restoration as an option or adjunct to technology and operational measures.

EPA Response

EPA recognizes the potential impact to Directors and has developed today's final rule with tremendous flexibility. Existing State 316(b) programs may be approved under 125.90(c). The final rule provides an approved technology compliance alternative in 125.94(b)(4); a site-specific determination of BTA is also available for facilities whose costs may be significantly greater than EPA's estimated costs or whose costs may be significantly greater than the benefits of complying with the national performance requirements. EPA has also included the provision of the Technology Installation and Operation Plan in 125.94(d). EPA believes that these and other flexibilities in the final rule will help to avoid any disruption to State water quality programs and the electric energy supply.

Comment ID 316bEFR.407.002

Option: Reduce capacity comm. with closed-cycle

In addition, it is equally important that EPA not mandate the use of cooling towers or other particular technology or operational measures across-the-board at power plants that rely on cooling water. Such an across-the-board mandate would fail to recognize the substantial variation in circumstances at each plant, as well as in the feasibility and cost of various cooling water intake options. It would also stifle innovation and would substantially increase the costs of implementing 316(b) without producing corresponding benefits.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161) in today's final rule. Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

For a variety of reasons, EPA opted not to implement a regulatory approach based solely upon closed-cycle, recirculating cooling. Please refer to section VII.E of the preamble for more information on why EPA rejected this alternative.

Permit applications/implementation schedule

Author Name Mike Huckabee

Organization State of Arkansas, Office of the Governor

I also urge the EPA to provide transition provisions for the new rule, delaying its effective date for at least two years from the date it is issued, and allowing use of compliance schedules.

EPA Response

See response to comment 316bEFR.025.019.

Comment ID 316bEFR.407.005

Author Name Mike Huckabee

Organization State of Arkansas, Office of the Governor

Subject Matter Code 21.04

Determination of compliance

I also support clarification that indicator species can be used in determining biological impacts of intake structures, and that those impacts are to be evaluated at a population level. Further, when NPDES permits for these facilities come up for renewal, if circumstances have not fundamentally changed, little, if any, new information should be required of the applicant, and the renewal process should be quite streamlined.

EPA Response

In today's final rule, EPA has not prescribed the methods for determining compliance. Rather, the permit applicant may propose the parameters for determining compliance in the Verification Monitoring Plan (125.95(b)(7)), Technology Installation and Operation Plan (125.95(b)(4)(ii)), if selected, and, if applicable, the Restoration Plan required at 125.95(b)(5), for review and approval by the Director. For a discussion of how compliance is to be determined, please see, e.g., EPA's response to comment 316bEFR.017.003. For EPA's explanation of EPA's monitoring requirements, please refer to EPA's response to comment 316bEFR.307.027. Also please see the final rule preamble for a discussion of the Technology Installation and Operation Plan.

Comment ID 316bEFR.407.006

Author Name Mike Huckabee

Organization State of Arkansas, Office of the Governor

Subject Matter Code 21.05

Role of States and Tribes (alt./equiv. programs)

Water quality is site-specific, and the design, location, and circumstances of each power plant are unique. Therefore, a decision framework that allows permit applicants to point to site-specific factors in seeking a reasonable regulatory outcome will help produce the most cost-effective and environmentally beneficial outcomes. I encourage you to build on the solid foundation of state experience with site-specific decision-making regarding section 316(b) of the Clean Water Act. I am encouraged that the proposed rule recognizes the site-specific nature of the issue, providing several compliance options based on cost-benefit and cost-cost analyses and most importantly, rejecting any mandate for the use of one technology in a one-size-fits-all approach.

The EPA should consider fortifying the proposal to encourage States to maintain, promote, and refine existing programs that implement section 316(b), including an alternative that accommodates facilities that have already demonstrated no adverse environmental impact. That would streamline the hundreds of permits each state must administer, reduce permit backlog, and maintain the integrity of state programs in this area. In many cases, environmentally protective and responsible decisions have already been rendered in accordance with appropriate stakeholder input. To require these decisions to be re-evaluated and permits reissued is bureaucratic, unnecessary, costly, and counterproductive since there are additional water quality concerns that should be immediately addressed.

EPA Response

In today's final rule, EPA has included the site-specific determination of BTA as 125.94(c) in recognition of the unique characteristics that some sites may pose.
EPA has also included a mechanism to approve existing State 316(b) programs under 125.90(c). Please see response to 316bEFR.023.001. However, EPA disagrees with allowing historical determinations of BTA to be used to meet compliance requirements of today's rule. This issue is discussed more fully in the response to comment 316bEFR.040.001.

Organization Texas Commission on Environmental Quality

Subject Matter Code 21.08

Burden on permitting agencies (general)

TCEQ is aware of the need to mitigate the effects of entrainment and impingement of aquatic organisms in cooling water intake structures, but the agency is also concerned about implementation costs for state agencies responsible for the requirements under the National Pollutant Discharge Elimination System. In previous correspondence, the agency estimated that the costs for permit administration in Texas would be about $1,712,451 to $4,127,085 over the first five years, depending on the number of site-specific demonstrations. Representatives of electric generating utilities in Texas have indicated that most facilities will choose to conduct site-specific studies.

EPA Response

EPA is sensitive to the resource limitations of some States. Since proposal and NODA, EPA has added many efficiencies to today's final rule to assist in speeding implementation and reducing application burden. Please see EPA's response to comment 316bEFR.034.005. EPA has provided five compliance alternatives including a site- specific determination of BTA, with the Director's approval. Because of the multiple compliance alternatives and the availability of the Technology Installation and Operation Plan as discussed in the preamble to today's rule, EPA believes that most facilities will not seek compliance via a site-specific determination of best technology available. Only a handful of facilities are expected to pursue the site-specific determination of best technology available.

Comment ID 316bEFR.408.002

Subject Matter Code 8.02

Proposed standards for lakes and reservoirs

Author Name Kathleen Hartnett White

Organization Texas Commission on Environmental Quality

The majority of facilities in Texas that would be subject to the proposed regulations are constructed on reservoirs designed to be cooling water impoundments for a specific facility. These impoundments were constructed in the watersheds of relatively small streams that usually provide opportunities for public fishing and aquatic recreation. Many of the fisheries are maintained and manipulated by stocking a variety of non-native fish species. The regulatory histories, uses, and ecosystems of these cooling water impoundments are markedly different from natural lakes and larger mainstream impoundments.

EPA Response

Please refer to the response to comment 316bEFR.041.551 for a discussion of the biology of reservoirs.

Comment ID 316bEFR.408.003

Author Name Kathleen Hartnett White

Organization Texas Commission on Environmental Quality

Subject Matter Code 7.01.03

Option 3--Site-specific determination

Therefore, the agency has concluded that prescribing specific technology is inappropriate in this instance, and that rules governing this particular issue should address the unique characteristics, flora, and fauna present in the water body. The agency supports options that allow industries to choose appropriate specific technologies or present site specific data and studies to determine the best protective approach for the site. This approach could significantly reduce compliance and administrative costs and still protect sensitive aquatic ecosystems.

Once again, I appreciate the opportunity to submit these comments, and urge EPA to continue to consider flexible, site specific methods to achieve the requirements of Section 316(b) of the Clean Water Act.

EPA Response

EPA agrees that flexibility for permittees is an important consideration and notes that the final rule contains five compliance alternatives from which a permittee may choose. Please refer to the preamble for a discussion of the framework of the final rule.

EPA notes that the final rule includes a site-specific compliance alternative, which includes a provision for a cost-cost and cost-benefit test. Please refer to the response to comment 316bEFR.338.002 for more information.

Comment ID 316bEFR.409.001

Author Name Gary Myers

Organization Tennessee Wildlife Resources Agency

Subject Matter Code 11.01

RFC: Proposed use of restoration measures

The Tennessee Wildlife Resources Agency (TWRA) recommends the US Environmental Protection Agency (EPA) retain provisions for compensatory mitigation as a restoration and compliance option under Section 316 of the Federal Clean Water Act. In drastically altered aquatic systems, such as the Tennessee and Cumberland Rivers, compensatory mitigation is an option that can provide maximum ecological and recreational benefit. Restoration of waters for classified uses such as fish and aquatic life and recreation use, including sport fishing, are established goals of both federal and state water quality law.

Tennessee opted to include compensatory mitigation as part of the 316(b) consideration for the National Pollutant Discharge Elimination System (NPDES) John Sevier Steam-Electric Facility on the Holston River in Hawkins County, Tennessee. The Holston River at this location changes seasonally from riverine to reservoir depending on the surface elevation of Cherokee Reservoir, water temperature at this location is a function of releases from Ft. Patrick Henry Reservoir, and sediments in the John Sevier retention reservoir are contaminated by mercury from the former Olin Corporation facility in Saltville, Virginia. In this complex situation, compensatory mitigation was the preferred alternative for maximum ecological and recreational benefit.

Since 1977, mitigation ponds constructed at the TWRA Normandy Hatchery have produces more than 4.3 fingerlings of eleven sport fish species. These ponds will continue to produce fingerlings for the foreseeable future.

Between 1982 and 1995, TVA stocked over 5 million hatchery-reared walleye, saugeye, and paddlefish fingerlings, and over 1.5 million saugeye fry into Cherokee Reservoir. Throughout this period, paddlefish numbers in Cherokee continued to increase and the survival of stocked fish was good. Saugeye (a walleye x sauger hybrid, selected by the Tennessee Wildlife Resources Agency) demonstrated good to excellent growth and survival; a strong sport fishery was established. Stocked walleye also survived and grew to catchable size in Cherokee, and thereby a fishery was also established for that species. From 1993 until the present, TWRA, as a part of this restoration program, has stocked 67,275 blue catfish, 1,225,837 black crappie, 274,238 hybrid striped bass, 11,416 paddlefish, 472,259 sauger, 25,328 hybrid striped bass, 1,065,200 striped bass, 580,823 walleye, and 44,126 white crappie.

TWRA's 2002 estimate of value of stocked fisheries to Cherokee Reservoir anglers (daily expenditures only) as approximately $731,310. This is a conservation estimate for the single year 2002. This would equate to $7 million in recreational fishing on Cherokee Reservoir and the Holston River over the last decade. TDEC continues to review the status of the restoration project at its 5-year renewal of the John Sevier NPDES permit, and to document restoration success as part of the permit rationale. 316(b) mitigation for the John Sevier facility includes enhanced public access and recreation facilities. Utilization and enjoyment of the public use area is year-round, and provides a variety of recreational opportunities, including wildlife viewing, sportfishing, picnicking, and boat launching.

We highly recommend that EPA retain compensatory mitigation as an option under Section 316 of the Clean Water Act.

EPA Response

In the final rule, EPA allows use of restoration to minimize or to help to minimize adverse environmental impacts that derive from impingement and entrainment of aquatic organisms. For a discussion of EPA's authority to include restoration measures as a compliance option in the final rule, see the preamble to the final rule.

For a discussion of the role of ancillary benefits, see EPA’s response to comment 316bEFR.032.011.

For a discussion of the role of state program priorities, see EPA’s response to comment 316bEFR.099.029.

Subject Matter Code 10.1

General: cost tests

PROPER IMPLEMENTATION OF THE COST-COST & BENEFIT-COST TESTS IS ESSENTIAL FOR AN EFFECTIVE FINAL 316(B) RULE

Issue: A meaningful cost-cost test is one that ensures implementation costs bear a reasonable relationship to the site-specific and national costs EPA considered. It is an essential component of any effective final phase II 316(b) rule. The test provides the mechanism to balance general technology performance standards, site-specific circumstances and cost. The cost-cost provision was included in the proposed rule to ensure that the actual costs of meeting the performance standard ranges at a given site are not significantly greater than the costs the agency considered in developing those performance standards or have unacceptable unforeseen economic or social consequences.

EPA is considering a new option for implementing the cost-cost test. We have several significant concerns with this new approach. Specifically, we are concerned that:
1) This approach can result in the implementation of fundamentally different technology selections from those assumed by EPA in analyzing the impacts of the rule, rendering the agency's economic analysis used for justifying the regulation invalid;
2) This approach can result in a significant increase of transaction and compliance costs for states and permittees and;
3) This approach makes it more difficult for facilities and permit writers to justify alternative standards that take into account site-specific variations in cost and effectiveness – reducing the cost-effectiveness of the overall rule.

Background: EPA's proposed Phase II 316(b) rule includes two important provisions -- the "cost-benefit" and "cost-cost" provisions. Although both are crucial to the rule, this paper focuses on the cost-cost provision, addressing questions that have been raised about how the cost-cost provision should be properly applied. The application of tests such as these allows society's resources to be applied efficiently and results in better public policy than an approach that simply requires all facilities to meet uniform performance standards. However, how these tests are applied will determine their efficacy in individual permit proceedings. If these tests are not implemented correctly, the agency's purpose for including them in the proposed rule will be undermined.

EPA acknowledges that many features of cooling water intake structures (CWIS) affect the feasibility, cost and performance of environmental control technologies available to existing facilities. This is one of the reasons that EPA did not designate a single technology for installation at all facilities and chose to express its proposed numeric performance standards as ranges (e.g., 60% to 90% reductions in entrainment and 80% to 95% reductions in impingement mortality). These ranges reflect the inherent uncertainty in predicting the efficacy of a given technology at any one facility. See, e.g., Existing Facility Proposed Rule, 67 Fed. Reg. at 17,141 col. 3.

Because the Phase II 316(b) rule relates solely to existing power plants, any modifications to the CWIS entail a retrofit of the existing facility. This creates design constraints due to availability of land, location of other existing equipment, the nature of the existing intake design, the hydrological conditions (currents, velocity, sedimentation levels) in the source waterbody and site-specific factors (e.g., geology, soil type) that affect not only the type of technology available for installation at a given site but also the cost of installing and operating that technology.

Unlike traditional effluent limitation guidelines that are directed at reducing the amount of a pollutant in a wastestream, 316(b) is aimed at minimizing adverse impact on aquatic organisms present in the source waterbody. The types of organisms present and the natural fluctuations in both the number and types of organisms present are beyond the control of the permittee. These differences can result in differing levels of performance in reducing entrainment or impingement.

As EPA has recognized, these variations mean that facilities will need to identify best technology available (BTA) for meeting those performance standards. Moreover, there may be cases in which the cost of achieving those standards is significantly greater than the costs EPA considered or the value of the benefits likely to accrue.

EPA is currently considering two options on how best to implement the cost-cost test: (1) a comparison of costs EPA estimated for a facility against the costs that the permittee estimates for achieving compliance with the performance standard (Facility-Specific Test); and (2) a comparison of the costs the facility estimates for installing a given technology against the costs EPAwould have estimated for that technology had it applied that technology in its estimate of compliance costs for that facility (Technology Cost Test). The facility-specific cost test is the approach EPA outlined in the proposed rule; the technology cost test is not.

Discussion of Issues

I. Why is it essential to include the cost-cost test as part of the final Phase II § 316(b) Rule?

-The cost-cost test is a practical tool to address site-specific variability in costs: Many site-specific factors affect the feasibility, cost, performance and benefits of different fish protection technologies for cooling water intake structures. Although EPA compiled a substantial amount of information about CWIS technology performance generally, and about the features of Phase II facilities and their source waters, neither EPA nor the regulated community has yet done the site-specific studies necessary to determine which of the several technology alternatives that EPA considered (or others that EPA did not consider) is the "best available" for meeting the performance standards at any given site or set of sites. Recognizing the greater degree of variability inherent in this rulemaking when compared to a typical technology-based rulemaking, EPA included the “cost-cost” test in the proposed rule. The test allows the establishment of site-specific alternative limits in cases where the actual costs a facility would incur is significantly greater than the costs EPA considered. See, e.g., Existing Facility Proposed Rule, 67 Fed. Reg. at 17,221 col. 1.

-The cost-cost test is administratively simple: The cost-cost test provides a relatively simple means for permittees and permit writers to identify compliance costs that are beyond what the EPA considered to be reasonable in establishing the numerical standards. The cost-cost test also provides a clear baseline for the evaluation of alternative BTA selection.
-The cost-cost test complements the cost-benefit test: In classic regulatory analysis, the adoption of a standard should be based on a careful analysis of the benefits and costs of the options. The 316(b) guidelines allow a permittee to propose an alternative standard if it can show that the costs of

applying the performance standard exceed the benefits. The cost-cost test is an important complement to the cost-benefit test in cases where a detailed cost/benefit analysis may be difficult, expensive or time-consuming. In such cases, the cost-cost test can serve as a simple but effective proxy for a more complex benefits analysis. EPA's difficulties in estimating the national benefits of its proposals is clear indication that there will be a number of instances where a permittee cannot undertake a full benefit-cost analysis, but can nonetheless justify the need for a site-specific alternative performance standard through the use of the cost-coat test.

II. Why is it important to ensure that the test is applied comparing unit costs to unit costs?
-The rule must provide a known and defensible baseline as a basis for cost comparisons: For the cost test to function properly, it is crucial to know what costs to use as the baseline for the cost comparison. Unless the baseline costs are the same as, or at least bear some reasonable relationship to the costs EPA actually considered for each site, the cost-cost test will not serve the purpose for which it was intended. Ultimately, this will undermine the effectiveness, fairness, and legitimacy of the rule.
-A unit cost to unit cost comparison ensures that actual costs will remain consistent with EPA's economic analysis: To evaluate the costs and economic impacts of its preferred approach, EPA used available data and made judgments about which of the technologies would be most likely to achieve the performance standard for each affected facility, without regard to cost. Then, for each facility, EPA estimated the likely site-specific cost of the selected technology. The costs EPA considered ranged from $ 0 to around $23 million. EPA used the site-specific cost estimates, to assess (1) the effects of the performance standard on the economic viability of each facility, and the resulting risk of plant closures; (2) the effect of plant closures on local, regional, and national electricity supplies; (3) the total national cost of the rule and the regional and national economic impact of those costs. In short, the site-specific cost estimates, which are highly technology-dependent, are the foundation of EPA's entire national cost analysis, as well as of the local, regional, and national economic impact analysis. Because EPA's conclusions regarding the net benefits of the rule are dependent upon its facility level assumptions concerning technology assignments and associated costs, EPA must ensure that the cost-cost test is applied in a way that ensures that actual facility costs will not substantially exceed its estimates. Otherwise, the test will not serve its intended purpose: to ensure that the agency's approach to assessing technologies and setting performance standards does not result in costs that are in excess of the costs EPA considered in developing the proposed rule, or have unacceptable unforeseen economic or social consequences. Without such a comparison, EPA's claims of compliance with the Unfunded Mandates Reform Act and E.O. 12866 are meaningless.
-The technology cost test approach could significantly increase compliance costs: In the proposed rule, EPA stated its intent to implement the cost-cost test on a unit cost basis and not on a theoretical similar technology basis.
"To document that its site-specific costs would be significantly greater than those EPA considered, the facility would need to develop engineering cost estimates as part of its Comprehensive Cost Evaluation Study. The facility would then consider the model plants presented herein, determine which model plant most closely matches its fuel source, mode of electricity generation, existing intake technologies, waterbody type, geographic location, and intake flow and compare its engineering estimates to EPA's estimated cost for this model plant." See, Existing Facility Proposed Rule, Technical Development Document, Appendix A. p. A-1.
EPA is considering an alternative approach that would require a facility to compare the site-specific cost of installing a technology that would in fact meet the performance standard with the cost the agency considered for this same technology at a comparable facility. Under this approach, a facility

which concludes that it can only achieve the standard by installing a wedgewire screen at a cost of $20 million would not be eligible for alternative limits under the cost-cost test, because EPA may have estimated that this would be the cost of a wedgewire screen for a facility of that size. This could occur even if EPA had actually assumed that the facility could meet the standard using a barrier net costing $63,000.
Thus, under the alternate application of the cost-cost test EPA is considering, the national cost of implementation could be significantly higher than that estimated by EPA because the cost-cost test would no longer be implemented as EPA had originally contemplated it. It would be conducted on the basis of what EPA would have calculated a facility would spend to comply had the agency chosen the same technology, rather than on the basis of what EPA actually assumed the facility would spend to comply.
-The EPA proposed technology cost test could significantly increase transaction costs: The technology cost approach requires several steps that are not necessary under the facility-specific cost approach. These additional steps include the possibility of developing several different site-specific engineering cost and effectiveness estimates. Then, for each prepared cost estimate there would be cost variables that differ depending on construction materials, component sizes, etc. that would need to be considered. Transaction costs would be higher than the facility-specific cost approach because of: 1) the greater number of engineering estimates required and; 2) the time spent in discussions with the state over which technologies and cost variables are the most appropriate to consider. In essence, the technology cost test creates more work and ambiguity over the selection of appropriate technologies and the inclusion of "proper" cost factors.

III. The cost-cost test can be applied to ensure comparison of actual costs, and achieve environmentally protective, equitable, and administratively efficient results.

-The cost-cost test, properly applied, will not result in unjustified regulatory relief: The proposed cost-cost test reflects a simplified "numbers to numbers" cost comparison and will not relieve facilities of the obligation to meet a performance standard . The requirement for meeting an alternative performance standard would still apply. It simply will ensure that meeting the alternative standard will not cost a facility significantly more than EPA has estimated. Concerns that the test would enable facilities to justify doing nothing are unfounded.
-EPA concern over possible misuse of cost-cost test: EPA has consistently stated that site-specificity in the implementation of the 316(b) standards is key to achieving the performance objectives in a cost effective manner. Therefore, the test should not be viewed as a variance process; it should be considered a mechanism to optimize technology performance under site-specific circumstances. In the classic effluent guideline framework the performance and unit costs of technologies are better defined, there are fewer site specific variables, and there is a greater degree of control over the facility specific variables since the discharge is under direct control of the permitted entity in contrast to the 316(b) context where the permittee does not have control over the presence and behavior of aquatic organisms in the source waterbody.

[see hard copy for table]

EPA Response

EPA notes that it received this letter from the commenter far after the close of the notice of data availability open comment period. Due to the very delayed submittal of the information, EPA attempted as best as it could, considering the limited time frame, to fully consider the comments.

EPA has no legal obligation to respond to such late comments. See e.g., Personal Watercraft v. Dept. of Commerce, 48 F.3d 540 (D.C. Cir. 1995). Nevertheless, EPA has attempted to respond to these comments to the extent possible.

EPA first notes that the commenter is partly incorrect in stating that a “facility-specific cost test is the approach EPA outlined in the proposed rule.” In Appendix A of the proposal Technical Development Document the Agency states the following:

"The facility would...consider the model plants presented herein, determine which model plant most closely matches its fuel source, mode of electricity generation, existing intake technologies, waterbody type, geographic location, and intake flow and compare its engineering estimates to EPA’s estimated cost for this model plant."

In addition, regarding model plants the Agency stated the following in the NODA (68 FR 13527):

"the Agency utilizes as much information as is available about the characteristics of the hundreds of facilities within the scope of the proposed rule. By incorporating as many site-specific features as possible into the design and implementation of its costing approach the Agency has been able to capture a representative range of compliance costs at what it deems ``model facilities." However, the Agency did not have and will never have the opportunity to visit and study in detail all of the engineering aspects of each facility complying with this rule (over 400 facilities could incur technology-related compliance costs as a result of this rule). Therefore, although the Agency has developed costs that represent EPA's best effort to develop a site-specific engineering assessment for a particular facility, this assessment does not incorporate certain peculiarities that only long-term study of each
facility would bear out. Hence, the Agency refers to its approach as a ``model" facility approach."

Hence, contrary to the opinion stated by the commenter, the Agency has stated explicitly its view that facilities compare their compliance costs to a model facility cost that is representative of the costs considered by the Agency in developing the final rule.

Because of the uncertainty inherent in the necessary approach to modeling facility-level costs adopted by the Agency, the final rule includes a provision in the cost-cost test that, in essence, balances the facility-specific comparison requested by the commenter with a site-specific check open to both the permit authority and the facility. This site-specific check functions such that should a party have concerns about the results and basis for the facility-specific comparison that limited adjustments to EPA's technology-based costs be conducted. For more information on the Agency’s approach to the final cost test see section IX.H of the preamble to the final rule.

The Agency generally agrees with the suggestion made by the commenter’s organization (UWAG) for the NODA, as presented in comment 316b.EFR.307.033. The approach suggested in this comment is as follows: EPA should “make available information about what intake technology it chose for each facility, so that the facility can calculate EPA’s estimated cost for that facility by starting with EPA’s choice of technology and applying EPA’s own costing method. To know what the cost assigned by

EPA is, permittees and permit writers need to know (1) what technology (wedge wire screen, fine mesh screen, or aquatic filter barrier) EPA chose for each facility and (2) what EPA's costing method would estimate it to cost."

The Agency has adopted for the final rule an approach that utilizes the principles of the suggestions from the commenter. As such, the Agency has fulfilled this commenting entity's request from comment 316b.307.033, balanced the proposed methodology of comparing to "similar facilities", and provided a balance check in the chance that the necessarily broad-based EPA cost methodology did not account for certain site-specific conditions not apparent through the data available to the Agency for the costing effort.

The Agency notes that it met with the commenter to listen to their concerns relating to the cost tests. The Agency heard the perspective of the commenter as documented in the above comment, and considered thoroughly various means by which to provide the fairest and least arbitrary means for a cost-test implementation in the final rule. In the end, the comments above do not solve the fundamental issues of fairness and equality as they relate to implementation of a facility-specific (only) cost test. The Agency stresses that the above comment provides no discussion of the means by which the costs of the final rule have been developed and their uncertainties, and by ignoring this lynchpin subject to the relevance of the cost-cost tests the commenter fails to fully consider a fundamental aspect of the cost-cost test application. As such, the Agency must reconcile the means by which the costs were developed with the best application of the cost-cost test through its judgment and in consideration of the concerns raised by the commenter. In the end, the Agency believes that the hybrid cost-cost test relying on both facility to facility cost comparisons and a site-specific technology cost check equates to the most equitable and fair test for the facilities complying, the permit writers, and the environment.

Response to Public Comment

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Keynote Address

Alex Matthiessen, Executive Director, Riverkeeper, Inc.

Mr. Matthiessen presented a brief overview and history of Riverkeeper, Inc., and noted some of the milestones in the organization's efforts to protect the Hudson River, beginning with the group's first victory — stopping the Storm King pump storage facility. He explained that Riverkeeper favors the following flow reduction technologies: dry cooling at new facilities, retrofit wet cooling at existing facilities, repowering, use of degraded water sources, and seasonal flow reductions. The organization prefers not to promote the use of screening technologies because of maintenance and operational issues that can cause degradation of performance. He also referred to PSE & G's permit for its Bethlehem facility, where cooperation led to a success story: Air pollution and fish impacts will be reduced by more than 98 percent. Riverkeeper is also working with Mirant at Lovett on the evaluation of Gunderboom over the next 5 years.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

See comment 316bEFR.206.022 for a discussion of why EPA did not opt for closed-cycle cooling.

EPA conducted a full analysis for the Phase I rule and concluded that dry cooling was not an economically practicable option for new facilities on a national basis. Dry cooling systems use either a natural or a mechanical air draft to transfer heat from condenser tubes to air. In conventional closed-cycle recirculating wet cooling towers, cooling water that has been used to cool the condensers is pumped to the top of a recirculating cooling tower; as the heated water falls, it cools through an evaporative process and warm, moist air rises out of the tower, often creating a vapor plume. Hybrid wet-dry cooling towers employ both a wet section and dry section and reduce or eliminate the visible plumes associated with wet cooling towers.

For the Phase I rule, EPA evaluated zero or nearly zero intake flow regulatory alternatives, based on the use of dry cooling systems. EPA determined that the annual compliance cost to industry for this option would be at least $490 million. EPA based the costs on 121 new facilities having to install dry cooling. At Phase II proposal, EPA estimated that total social costs for dry cooling were $2.1 billion per year. Thus, this option would be more expensive than dry cooling for new facilities. The cost for Phase II existing facilities to install dry cooling would be significantly higher that the cost for new facilities to do so due to the complexities of retrofitting both the dry cooling equipment and components of the cooling system. At proposal, EPA estimated that 550 Phase II existing facilities would be subject to Phase II regulation. The cost would be significantly higher because existing facilities have less flexibility, thus incurring higher compliance costs (capital and operating) than new facilities. For example, existing facilities might need to upgrade or modify existing turbines, condensers, and/or cooling water conduit systems, which typically imposes greater costs than use of the same technology at a new facility. In addition, retrofitting a dry cooling tower at an existing facility would require shutdown periods during which the facility would lose both production and revenues, and decrease the thermal efficiency of an electric generating facility.

The disparity in costs and operating efficiency of dry cooling systems compared with wet cooling systems is considerable when viewed on a nationwide or regional basis. For example, under a uniform national requirement based on dry cooling, facilities in the southern regions of the United States would be at an unfair competitive disadvantage compared to those in cooler northern climates because dry cooling systems operate more efficiently in colder climates. Even under a regional subcategorization strategy for facilities in cool climatic regions of the United States, adoption of a minimum requirement based on dry cooling would likely impose unfair competitive restrictions for steam electric power generating facilities because of the elevated capital and operating costs associated with dry cooling. Adoption of requirements based on dry cooling for a subcategory of facilities under a particular capacity would pose similar competitive disadvantages for those facilities.

As explained in the preamble to the proposal, EPA does not consider performance standards based on dry cooling a reasonable option for a national requirement, nor for subcategorization under this rule, because the technology of dry cooling carries costs that would potentially cause significant closures for Phase II existing facilities. Dry cooling technology would also have a significant detrimental effect on electricity production by reducing the energy efficiency of steam turbines. Unlike a new facility that can use direct dry cooling, an existing facility that retrofits for dry cooling would most likely use indirect dry cooling, which is much less efficient than direct dry cooling. In contrast to direct dry cooling, indirect dry cooling does not operate as an air-cooled condenser. In other words, the steam is not condensed within the structure of the dry cooling tower, but instead indirectly through an indirect heat exchanger. Therefore, the indirect dry cooling system would need to overcome additional heat resistance in the shell of the condenser compared to the direct dry cooling system. Ultimately, the inefficiency (i.e., energy penalty) of indirect dry cooling systems will exceed those of direct dry cooling systems in all cases.

Although the dry cooling option is extremely effective at reducing impingement and entrainment, it is not economically practicable for existing facilities.

EPA notes the commenter's preference against screening technologies but disagrees that maintenance requirements should preclude their use to meet the requirements of today's rule. Proper operation and maintenance of any technology, including screening systems and closed-cycle systems is necessary for any permitted facility.

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Keynote Address

Charles Goodman, Senior Vice President, Research and Environmental Affairs, Southern Company

Mr. Goodman opened his address by indicating that he felt a need to find a balance between effectiveness and cost as they pertain to the protection of aquatic life from intake structures. He pointed out the work that EPRI and the industry overall have already done to address Section 316(b) of the Clean Water Act. The best solutions consider site-specific issues. Some 316(b) alternatives are associated with other environmental impacts, such as those associated with wet cooling. Goodman emphasized that a single, “one size fits all” solution is not the optimum one, but rather one that maximizes net benefits

EPA Response

EPA appreciates the comment. Today's rule maintains the desired flexibility for facilities to determine the most cost-effective combination of design and construction technologies, operational measures, or restoration measures best suited to each individual facility.

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Greg Seegert, EA Engineering, asked about the mathematical relationships that Reed Super, Riverkeeper, Inc., presented and the reliability of those relationships; he also asked whether Mr. Super could site an R2 value. Also, for Lovett, Mr. Seegert had understood that Mr. Super was dealing with entrainment but had used formulas from the Pisces paper, which are actually based on impingement. He asked Mr. Super to explain.

A. In answer to the second question, Mr. Super said that he showed formulas for the volume:impingement relationship as well as the volume: entrainment relationship, and used the volume:entrainment relationship for the Lovett numbers. Mr. Super deferred to Peter Henderson, a statistician, to answer questions about reliability of the mathematical relationships. He explained that the points were plotted using actual facility data, and that the resulting line was the best line that could be drawn.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Paul Martin, TRC Environmental, asked Mr. Super whether he had used the energy cost of running the cooling towers as part of the costs in calculating the energy penalty.

A. Mr. Super answered that there are two components to the energy penalty: backpressure and energy penalty associated with mechanical draft tower fans. He used the energy penalties on average as discussed in the USDOE reports to illustrate that the penalty is only a small percentage as compared with orders of magnitude of reduction in environmental impacts.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

For a discussion on the energy penalty associated with closed-cycle cooling systems, see comment 316bEFR.206.022.

The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Andy Turnpenny, Fish Guidance Systems, asked Mr. Super how he addressed climate impacts as traded off for fish impacts.

A. Mr. Super indicated that it often takes a small amount of one resource to protect another resource and that one must look at the relative benefits. He emphasized that it does not mean sacrificing air for water but rather taking advantage of huge benefits to water. If people were concerned about side effects of pollution technologies, there would be none, because all of the technologies (recycling, for example) require some smaller expenditure of other resources. These smaller impacts may be reduced by other methods.

EPA Response

Q. Geoff Grubbs, USEPA, asked Mr. Taft to speculate about which are the most promising emerging technologies and where R&D dollars should be spent, given future demands from population growth and resulting resource pressures from activities such as overfishing.

A. Mr. Taft indicated that there is a need for an improved understanding of technologies such as cylindrical wedge wire screens and aquatic filter barriers in order to know how to apply them nationally would be helpful. For example, combining technologies such as AFB for impingement together with fine mesh screens for entrainment, needs to be examined. Historically we have over studied certain technologies and under-studied others. There is a need to fill in these data gaps..

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

EPA welcomes and encourages the continued research and development of intake technologies to address current and future impacts from cooling water intake structures.

Q: Karen Patterson, Tetra Tech NUS, asked whether the state agencies have given thought to their ability to be involved, given resource restrictions.

A. Edward Radle, retired, New York State Department of Environmental Conservation (NYSDEC) – Steam Electric Unit, answered that New York State intends to be fully engaged in the effort. Michael Calaban, New York State Department of Environmental Conservation – Steam Electric Unit, added that the two positions vacated at NYSDEC by retirement have been filled. Mr. McLean indicated that, for Maryland, the Department of Natural Resources, Power Plant Research Program (Maryland DNR – PPRP) is funded outside of state funds, so they will have the resources to address the issues.

EPA Response

EPA recognizes and encourages the participation of states in developing and implementing 316(b) programs. EPA notes the programs mentioned by the commenter.

Q. Denny Smith, USDOE, asked Mr. Powers about the footprint of dry cooling towers vs. the footprint of wet cooling (in particular, size requirements and restraints). In light of the ratio, what would it mean for a typical 300-500 MW unit? Mr. Smith added that the cost for a new dry system unit would be equivalent to $50/KW. How would this impact retrofits?

A. Mr. Powers cited another case where the air-cooled condenser was not as long as the wet tower, and in this case footprint was not an issue. He mentioned that you would need to take into account which impact you were trying to minimize: height or length.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Gordon Hart, Performance Contracting, asked John Maulbetsch, Maulbetsch Consulting, questions regarding the graphs used in his presentation. In particular, he requested an estimate of the net present value (millions per year) for energy efficiency costs for dry cooling.

A. Mr. Maulbetsch answered that the assumed energy efficiency penalty was 1 percent and the basis for the 20-year net present value was a 5 percent discount rate at a $25/MW cost at a 100-MW facility— a fairly low cost.

Q. Mr. Hart pointed out that one of the benefits of dry cooling is that you get a steam turbine credit—which makes it significantly cheaper with dry-cooled than with a conventional unit. The graph implies that the dry-cooling turbine would be designed for a 5.5-inch with a conventional turbine. With such a configuration, Mr. Hart anticipated constantly tripping the turbine. With a dry-cooled system, Mr. Hart said that you would not be designing it with a conventional turbine, but rather with a modified unit.

A. Mr. Maulbetsch agreed that the option was available. First you would probably look at the conventional turbine simply because that's what has usually been purchased. You could use other turbines (such as the high-backpressure turbine, which to date has only been theorized). You do need to look at the total cost relative to the lifetime of the plant, and include energy penalty costs. It's a complex calculation.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. John Kelly, Entergy Nuclear Operations, asked whether anyone could address the additional hotel load: the additional usage of systems that would have to be installed for backfitting a plant. For example, the cost of running fans and the pumping needs of going to a higher head.

A. Mr. Maulbetsch said that he did have that data in his presentation but breezed over it because of time. He said that he would not normally include fans and pumping under the term “hotel load.” He explained that if you go from once-through cooling to a closed-cycle system, and keep the flow rate the same, you add to the system pressure because of having to pump to the top of the tower (20-45 feet). This can double the pressure drop in the loop, and adding the fans can get you to 1.5- 2.5 percent energy use, which is significant over a long period of time. As pertains to the issue of re-optimizing the flow, if you do it, it will raise the going-in costs of the retrofit. If you don’t do it, you will have higher costs over the lifetime of the plant, and this is a choice you will have to make.

EPA Response

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Comment. Dave Michaud, WE Energies, talked about a barrier net installation that they have had good success with. He reinforced statements by Dave Bailey (Mirant) regarding barrier nets, adding that in freshwater systems (hydropower plants, specifically, with ~600 cubic feet per second (cfs) flow), barrier nets (1) have been found to require bottom sealing and (2) generally do not have a problem with biofouling in freshwater, although the barrier nets he's familiar with are removed in winter conditions. Their original net is still in service after approximately 10 years, and with excellent results. Its useful life was expected to be only about 2 years. Operations and Maintenance costs typically run under $1,000 per year.

EPA Response

EPA notes the comment and recognizes the potential use of barrier nets to reduce impingement. For further discussion of barrier nets and their effectiveness, see Chapter 3 of the Technology Development Document.

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Deborah Littleton, USDOE, asked Mr. Bailey to explain the preferred options in the proposal, particularly options for the calculation baseline. For example, at Chalk Point, what would they do to meet the performance standards?

A. Mr. Bailey said that Chalk Point has some before and after data for baseline projections. They could remove the net (to simulate a calculation baseline), but this would be counterproductive. He felt that they should use the data developed as the facility was deployed, rather than introducing error associated with trying to calculate a hypothetical baseline.

Comment. Ken Strait, PSEG, added that Salem also has a lot of data to use. The question becomes how to apply the percent reductions, as the facility needs to retain maximum flexibility as to which method to use. They might prefer using a method with RIS.

EPA Response

EPA notes the comment and recognizes the potential use of barrier nets to reduce impingement. For further discussion of barrier nets and their effectiveness, see Chapter 3 of the Technology Development Document.

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Greg Seegert, EA Engineering, pointed out that there are a lot of difficulties associated with the establishment baseline. He referred to Mr. Bailey's data on blue crabs as evidence that population fluctuations can cause problems assessing effectiveness. He added that the hypothetical shoreline intake would be difficult to measure. For Mr. Bailey: How would one measure the calculation baseline? It doesn't include a measure of "at risk" population changes, such as the blue crabs near Chalk Point mentioned earlier. Generally, one could only tell by doing extra sampling (indexing). Also, Chalk Point has more data than most facilities. How would one compare data without access to ample data, such as state surveys or other index data? If you do not have the indexing data sets that Mr. Bailey had, how could you evaluate population variation?

A. Mr. Bailey said that one would need some sort of baseline for relative abundance. You would have to do your own before/after studies to measure relative abundance. The other option may be to modify half the screens and do a side-by-side comparison. One would have to consider the data in the mindset of before and after prior to installing a given technology. For example, the barrier net has to take into account relative abundance, whereas other technologies (such as screens) may be able to compare percent reduction values. This certainly needs to be considered further.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

For a discussion on the calculation baseline, please see response to comments 316bEFR.308.014 and 316bEFR.063.005, as well as the preamble to today's rule.

The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Tim Connor, USEPA, mentioned to Mr. Bailey that the barrier net costs in today's presentations were much lower than the costs mentioned in yesterday's presentation by Mr. Taft.

A. Mr. Bailey explained that these were 1981-1984 costs, so they would be higher in present value. It is unclear what site-specific factors may drive up costs at some locations.

EPA Response

EPA notes the comment and recognizes the potential use of barrier nets to reduce impingement. For further discussion of barrier nets and their effectiveness, see Chapter 3 of the Technology Development Document.

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Bart Ruiter, Dupont, asked Mr. Bailey what the follow-up monitoring costs are for these barrier nets.

A. Mr. Bailey answered that he was not sure. Some are at no cost, because the state performs these index surveys. Also, the trawling studies were part of an overall 316(a) study, so the specific costs are not clear.

Comment. Ken Strait, PSEG, added that Salem spends approximately $80,000 per year for impingement and entrainment monitoring.

Comment. Isabel Johnson, Golder Associates, Ltd., added that in 1996-9 dollars, costs were approximately $60,000 per year.

Comment. Robert Rieder, Detroit Edison Company, added that the barrier net at Luddington is approximately 2.5 miles long. Capital costs were $1.5 million and the nets are replaced every 4-5 years. Operations and Maintenance costs are about $1.3 million, because divers perform clean-in-place operations. Algae and zebra mussels are problematic at the site. Approximately $100,000 per year is spent on monitoring.

EPA Response

EPA notes the comment and recognizes the potential use of barrier nets to reduce impingement. For further discussion of barrier nets and their effectiveness, see Chapter 3 of the Technology Development Document.

The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Doug Dixon, EPRI, asked with respect to Ristroph screens, could they meet the 80 percent impingement standards for reducing the number of fish impinged? Given that the most frequently impinged fish are often sensitive species, would it be sufficient?

A. Ken Strait, PSEG: It depends on the method of calculation. For example, there may be no survival data for non-RIS fish. The screens would likely meet the standard for biomass, but maybe not for number of fish. It would depend upon how the guidance is written and how they want to assess it.

EPA Response

EPA notes the comment and recognizes the potential use of modified ristroph screens to reduce impingement mortality. For further discussion of modified ristroph screens and their effectiveness, see Chapter 3 of the Technology Development Document.

The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Randy Lewis, Cinergy, asked whether there has been any monitoring of the response of fish communities or populations after installing a technology.

A. Mr. Bailey replied that no extensive AEI studies have been done, but he would guess there would be no discernible response in either direction. They have spent $7 million on 316(b) demonstration studies, and not seen any discernable impacts.

Comment. Ken Strait, PSEG, said that no indications of long-term effect in either direction have been noted. He indicated that only one species is declining and it is all along the eastern coast.

Comment. Isabel Johnson, Golder Associates, Ltd., added that they haven’t done any population level studies since the 1980s.

EPA Response

Q. Gordon Hart, Performance Contracting, asked with respect to screen blockages at Salem and the potential for plant shutdowns, what plans are there to avoid those circumstances?

A. Ken Strait, PSEG, replied that Salem has had the highest debris loadings on record for the Delaware River and the screens are handling the loads well. The primary problem for Salem right now is related to "carryover," where debris ends up in the condenser.

The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Elicia Blumberg, Tetra Tech, asked Andy Turnpenny, Fawley Aquatic Research, and Jeremy Nedwell, with respect to noise deterrent systems, what impacts do they have on underwater noise pollution, especially on marine mammals?

A. Mr. Turnpenny explained that the systems usually use low frequency sound and are well contained, often within 25 meters of the source. Mr. Hartlepool has a seal colony nearby, so this has always been a design consideration for sound deterrent systems.

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Tom Englert, LMS, asked Chuck Coutant, Oak Ridge National Laboratory, whether he had some other results showing that the velocity vectors are still through the screen. With respect to angled screen flows, some papers have cast doubt on the existence of sweeping flows since the flow is still through the screen.

A. Mr. Coutant answered that yes, even though the theory shows the flow going through the screen, the empirical data show they do work, possibly because the fish detects the screen.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

EPA agrees that while flow obviously does go through the screens, laboratory analysis and in situ demonstrations (Brayton Point, San Onofre NGS) have shown success in diverting some species of motile fish from intake screens to return troughs or fish elevators. Data indicate that, similar to the effect of velocity caps, angled screens create a discernible change in current that some species seek to avoid. For more discussion of angled screens, see Chapter 3 of the Technology Development Document.

Q. Greg Seegert, EA Engineering, asked Steve Jinks, ASA Analysis & Communications, Inc. whether there are any studies on size-specific survival? These could impact biomass calculations for determining compliance.

A. Mr. Jinks replied that this issue hasn't been talked about. Usually, the results are inconsistent. Smaller impinged individuals do often have a low survival rate.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Mr. Seegert: What about the same issue regarding numerical abundance and those species being more sensitive?

A. Mr. Jinks: Intuitively, one would expect demersal and benthic species to be more tolerant, since they are more rigid, hard-bodied, and adapted for low dissolved oxygen. However, they did not study the numbers for that, but would expect that some facilities could expect problems with sensitive species.

Comment. Mr. Coutant: Facilities with sensitive fish species can avoid handling them entirely with angled screens or other technologies—one can guide a fish to a return instead of using a screen to handle them.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

EPA notes the success of angled screens in some applications and studies (Brayton Point, San Onofre) but cautions against assuming that angled screens will be successful for all sensitive species at all facilities. Angled screens, like all technologies, must be considered against the local conditions present at a facility. For additional information regarding angled screens, see Chapter 3 of the Technology Development Document.

Q. Dave Michaud, WE Energies, asked Peter Henderson, Pisces Conservation Ltd., and Mark Strickland, PSEG Services Corporation, about the light penetration at Lovett and Bowline. Is the water turbid or is there opportunity for light, and thereby for scavengers to colonize the material?

A. Mr. Henderson stated that he thought light at Lovett doesn't penetrate very far, so you won't see much algal growth further down. The same conditions exist for Bowline, partly due to algal blooms on the surface.

Comment. Matthew Raffenberg, Lawler, Matusky, and Skelly Engineers, LLP, added that biological growth occurs only in the photic zone, and the waters are typically turbid at those plants.

Comment. Mr. Strickland, indicated the same conditions exist at Bethlehem.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Gordon Hart, Performance Contracting, mentioned that William Dey, ASA Analysis & Communications, Inc., estimated through-screen velocity at 0.25 fps (feet per second), which is significantly less than the figure mentioned in a presentation by Steve Amaral, Alden Research Laboratory, Inc., this morning, which quoted 1-3 fps. Matthew Raffenberg's estimates, for the filter fabric barriers, according to my [back of the envelope] calculations were an order of magnitude lower than 0.25 fps. All of these estimates of velocities are very different. How are the areas selected to achieve these different velocities?

A. Mr. Dey said the velocity estimate of 0.25 fps was only important in terms of costing. Actually 0.5 fps is much closer to reality; 0.25 fps is very conservative for wedge wire.

A. Mr. Amaral, Alden Research Laboratory, Inc., clarified that he had spoken about the louvers in the morning (in response to the 1-3 fps comment). Biologically, this is based on what the fish can avoid as per their swimming speeds (this varies by species and size classes, as well as among technologies). He stated that they observed low impingement and entrainment rates at the 0.5 fps velocity. The estimates differ for louvers and wedge wire screens. Even in the higher channel velocities (1 fps, for example), some eggs and larvae demonstrated low impingement and entrainment rates.

Comment. Mr. Raffenberg added that the selection of flow was initially based on what could pass the Gunderboom fabric. That's how they developed their estimate of 5 gallons per minute (gpm). Gunderboom is working to develop different fabric types and probably can elaborate further.

Comment. Ed Radle, NYSDEC, commented that when experimenting with fabric viability, they pasted the fabric to a barrel, sunk the barrel, and pumped water out of the barrel at different rates. At a very low rate the particles settled to the side and sloughed off. They developed the 5 gpm/square foot criteria based on observations that material impinged on the fabric filter cloth would slough off and no cleaning system would be required. He cautioned that the lesson learned is that laboratory experiments rarely mirror what happens in the field.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Mr. Coutant, Oak Ridge National Laboratory, asked Peter Henderson: On biofouling tests that you mentioned in your presentation, was there flow? If it was static, at what point does the fabric itself become the impingement/entrainment problem?

A. Peter Henderson, Pisces Conservation Ltd. And Oxford University, replied that the example he gave was for static conditions where the only flow would be tidal movement. A contemporaneous study, done by Gunderboom using an airburst system, however, showed the same problems with colonization. There was appreciable growth. Mr. Henderson could not answer the second question; they are working on the issue of animals being pulled into the Gunderboom.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

Subject Matter Code 7.03

Available I&E technologies

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Q. Andy McCusker, Gunderboom Incorporated, stated that his background is in marine benthic biology. He found the Gunderboom results anomalous, as they have panels in place in the upper Hudson River, Sacramento River, and beaches in the Long Island Sound, which have been analyzed by third-party scientists, and have not demonstrated results similar to Mr. Henderson's. What they did find is an invasive species of hydroid. They would like to explain that the technology does not always demonstrate that level of biofouling.

Q. Kent Zammit, EPRI, asked Mr. McCusker, whether there is publicly available data for the panels that they tested at other sites. Second, are flows available as well for those panels? Third, can you comment on the effects of the backwashing system on minimizing biofouling in addition to the sedimentation?

A. Mr. McCusker explained that the panels at the other sites were static and did not have flows. Inspection results have not been made publicly available, but there are plans to do so.

A. Mr. Raffenberg explained, regarding the backwashing system described by Mr. McCusker, that the airburst system was in 4 feet of water and did not display the same kind of shaking of the fabric or expansion of the air bubbles that you get in 20-30 feet of water. Though it's site-specific, there is potential for the airburst system to reduce biofouling, particularly for Lovett.

Comment. Mr. McCusker explained that they observed a tube-building amphipod, Corophium, unsuccessfully attempt to perforate the airburst system.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

For a discussion of Gunderboom technology, see response to comment 316bEFR.077.027 and Chapter 3 of the Technology Development Document.

Author Name EPA Symposium on Cooling Water Intake Technologies

Organization

Subject Matter Code 7.03

Available I&E technologies

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Comment. Rick Wantuck, NOAA Fisheries in California, mentioned that there are presently four proposals in California for Gunderboom deployment. One has been formally permitted by his agency for a 5-year test program. All the questions that have been raised—biofouling in particular—are on Mr. Wantuck's mind, as are longevity and maintainability of the filter fabric. Other issues include debris impacts in flowing streams and anchoring in tidal environments. He concluded that this technology is worthy of more study and requires more evidence before it should be viewed as a panacea. In addition, it should be noted that the California proposals suggest year-round deployment, while New York based proposals are on a seasonal deployment basis.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

Organization

Subject Matter Code 7.03

Available I&E technologies

The following comment was made by an attendee during the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms held May 6 - 7, 2003, in Arlington Virginia, in response to presentations made during the symposium. The comment has been summarized based on notes taken at the symposium. Despite best efforts to capture the key points, this comment does not constitute a verbatim record.

Comment. Ed Radle, NYSDEC, stated that regarding maximum speed, the velocity at 5 gpm/ft2 is equivalent to 0.01 fps, which is extremely slow. The limit would be driven by the swimming speed of the larvae in question, and there is little available literature on that. The experiment he did with shad showed that they did not orient to the flow at all. Mr. Radle read a section from the journal Sea Technology, the 2001 issue called Aquaculture Beyond the Reef. In summary, their research found that while biofouling was an issue during early deployment, the assemblage of herbivores around the technology rendered scrubbing unnecessary in time. The herbivores fed upon Corophium and other biofouling organisms. He said that this was a sales pitch for Gunderboom.

EPA Response

EPA notes the comment and appreciates the participation of the commenter at the Symposium on Cooling Water Intake Technologies to Protect Aquatic Organisms.

For a discussion of Gunderboom technology, see response to comment 316bEFR.077.027 and Chapter 3 of the Technology Development Document.

Organization Collector Wells International, Inc.

Regarding 316b --sometimes we forget and try to reinvent the wheel. I am preparing to have a round table discussion of the 316b rule and the upcomming Power Gen show in Las Vegas. Upon review of the rule and alternate technologies I see now mention of collector wells used for cooling. Please refer to EPA doc 440/1-76/015-a Entitled "Development
document for best technology available for the location, design, construction and capacity of cooling water intake structures for minimizing adverse environmental impact" dated april , 1976. Hopefully this document was reviewed prior to promulagating many of the new regulations that will be soon in place. If the aquifer is sufficient to accept collector wells then the problems of fish and aquatic life forms go away.

EPA Response

EPA welcomes continuing investigation into the applicability of non-traditional technologies and technologies not widely deployed. EPA has not determined any technology to be universally applicable to all facilities under all circumstances in today's rule. Instead, EPA maintains a desired flexibility for facilities to meet the performance by opting for one of several design and control technologies, operational measures, and/or restoration measures. EPA has neither prescribed nor prohibited any single technology from the suite of alternatives available to facilities.

Response to Public Comment

---National Pollutant Discharge Elimination System--- Regulations Addressing Cooling Water Intake Structures for Phase II Existing Facilities

Subject Matter Code 17.03

Option: Technol. to reduce I&E regardless of WB type

I wish to make a last request that EPA consider selecting "Impingement Mortality and Entrainment Controls Everywhere" (as presented on pages 17158-17159 in Section VI(B)(4)). I believe this option could be efficiently implemented by our agency and would result in the most uniform and effective measures being required of all facilities.

EPA Response

EPA elected to not adopt any of the alternative technology-based options or the alternative site-specific approaches discussed in the proposed rule (67 FR 17154-17161). Please refer to section VII of the preamble to the final rule for further information as to why these options were not selected.

Comment ID 316bEFR.903.002

Author Name Larry Wilson

Organization NY DEC

Subject Matter Code 17.06

Option: Site-specific determination of BTA

I also request that in any case, EPA eliminate "Method 3"which would generate numerous studies and impose a substantial review burden on state agencies. Should this option remain I am concerned that all facility owners in New York would chose to make the case that the costs of any mitigation was too great. This would effectively incapacitate our unit of 4 people by burying us in economic reports we would be unable to evaluate or refute.

EPA Response

EPA disagrees that a large percentage of facilities will opt for a site-specific determination of BTA. Please refer to the response to comment 316bEFR.202.002 for more information.
