Courant Number and Mach Number Insensitive CE/SE Euler Solvers

Sin-Chung Chang
Glenn Research Center, Cleveland, Ohio
Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program Office plays a key part in helping NASA maintain this important role.

The NASA STI Program Office is operated by Langley Research Center, the Lead Center for NASA’s scientific and technical information. The NASA STI Program Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program Office is also NASA’s institutional mechanism for disseminating the results of its research and development activities. These results are published by NASA in the NASA STI Report Series, which includes the following report types:

- **TECHNICAL PUBLICATION.** Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA’s counterpart of peer-reviewed formal professional papers but has less stringent limitations on manuscript length and extent of graphic presentations.

- **TECHNICAL MEMORANDUM.** Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.

- **CONTRACTOR REPORT.** Scientific and technical findings by NASA-sponsored contractors and grantees.

- **CONFERENCE PUBLICATION.** Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or cosponsored by NASA.

- **SPECIAL PUBLICATION.** Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.

- **TECHNICAL TRANSLATION.** English-language translations of foreign scientific and technical material pertinent to NASA’s mission.

Specialized services that complement the STI Program Office’s diverse offerings include creating custom thesauri, building customized databases, organizing and publishing research results . . . even providing videos.

Abstract

It has been known that the space-time CE/SE method can be used to obtain 1D, 2D, and 3D steady and unsteady flow solutions with Mach numbers ranging from 0.0028 to 10. However, it is also known that a CE/SE solution may become overly dissipative when the Mach number is very small. As an initial attempt to remedy this weakness, new 1D Courant number and Mach number insensitive CE/SE Euler solvers are developed using several key concepts underlying the recent successful development of Courant number insensitive CE/SE schemes. Numerical results indicate that the new solvers are capable of resolving crisply a contact discontinuity embedded in a flow with the maximum Mach number = 0.01.

1. Introduction

The space-time conservation element and solution element (CE/SE) method is a high-resolution and genuinely multidimensional method for solving conservation laws [1–58]. Its nontraditional features include: (i) a unified treatment of space and time; (ii) the introduction of conservation elements (CEs) and solution elements (SEs) as the vehicles for enforcing space-time flux conservation; (iii) a novel time marching strategy that has a space-time staggered stencil at its core and, as such, fluxes at an interface can be evaluated without using any interpolation or extrapolation procedure (which, in turn, leads to the method’s ability to capture shocks without using Riemann solvers); (iv) the requirement that each scheme be built from a non-dissipative core scheme and, as a result, the numerical dissipation can be controlled effectively; and (v) the fact that mesh values of the physical dependent variables and their spatial derivatives are considered as independent marching variables to be solve for simultaneously. Note that CEs are nonoverlapping space-time subdomains introduced such that (i) the computational domain can be filled by these subdomains; and (ii) flux conservation can be enforced over each of them and also over the union of any combination of them. On the other hand, SEs are space-time subdomains introduced such that (i) the boundary of each CE can be divided into several component parts with each of them belonging to a unique SE; and (ii) within a SE, any physical flux vector is approximated using simple smooth functions. In general, a CE does not coincide with a SE.

Without using flux-splitting or other special techniques, since its inception [1] the unstructured-mesh compatible CE/SE method has been used to obtain numerous accurate 1D, 2D and 3D steady and unsteady flow solutions with Mach numbers ranging from 0.0028 to 10 [42]. The physical phenomena modeled include traveling and interacting shocks, acoustic waves, shedding vortices, viscous flows, detonation waves, cavitation, flows in fluid film bearings, heat conduction with melting and/or freezing, electrodynamics, MHD vortex, hydraulic jump, crystal growth, and chromatographic problems [2–58]. In particular, the rather unique capability of the CE/SE method to resolve both strong shocks and small disturbances (e.g., acoustic waves) simultaneously [11,13,14] makes it an effective tool for attacking computational aeroacoustics (CAA) problems. Note that the fact that second-order CE/SE schemes can solve CAA problems accurately is an exception to the commonly-held belief that a second-order scheme is not adequate for solving CAA problems. Also note that, while numerical dissipation is needed for shock capturing, it may also result in annihilation of small disturbances. Thus a solver that can handle both strong shocks and small disturbances simultaneously must be able to overcome this difficulty.

In spite of its past successes, there is still room for improving the CE/SE method. An example is the fact that, in a CE/SE simulation with a fixed total marching time, generally the numerical dissipation
increases as the value of the Courant number decreases from 1, its maximum stability bound. As such, in a case with a large Courant number disparity (e.g., a simulation with a highly non-uniform spatial mesh and a spatially independent time step), the performance sensitivity with respect to the Courant number can lead to a solution that is highly dissipative in a region where the local Courant number \( \ll 1 \). Another example is the fact that a CE/SE solution may become overly dissipative when Mach number is very small.

By using the fact that each CE/SE scheme is built from a non-dissipative core scheme, robust one-dimensional and multidimensional Courant number insensitive schemes were described in [50,52]. As a follow-up, new one-dimensional Courant number and Mach number insensitive CE/SE Euler solvers have been developed using several key concepts underlying the development of Courant number insensitive schemes. Numerical results indicate that the new solvers are capable of resolving crisply a contact discontinuity embedded in a flow with the maximum Mach number = 0.01. The rest of the paper is organized as follows. A review of the existing CE/SE schemes is given in Secs. 2–4. The new Courant number and Mach number insensitive schemes are described in Sec. 5. Numerical results are presented in Sec. 6. Conclusions and discussions are given in Sec. 7.

2. Review of the basic 1D CE/SE method

For simplicity, we review the existing CE/SE schemes for the PDE

\[
\frac{\partial u}{\partial t} + a \frac{\partial u}{\partial x} = 0 \tag{2.1}
\]

where \( a \neq 0 \) is a constant. Let \( x_1 = x, \) and \( x_2 = t \) be considered as the coordinates of a two-dimensional Euclidean space \( E_2 \). Then, because Eq. (2.1) can be expressed as \( \nabla \cdot \vec{h} = 0 \) with \( \vec{h} \overset{\text{def}}{=} (au, u) \), Gauss’ divergence theorem in the space-time \( E_2 \) implies that Eq. (2.1) is the differential form of the integral conservation law

\[
\int_{S(V)} \vec{h} \cdot d\mathbf{s} = 0 \tag{2.2}
\]

As depicted in Fig. 1, here (i) \( S(V) \) is the boundary of an arbitrary space-time region \( V \) in \( E_2 \), and (ii) \( d\mathbf{s} = d\sigma \vec{n} \) with \( d\sigma \) and \( \vec{n} \), respectively, being the area and the unit outward normal of a surface element on \( S(V) \). Note that: (i) because \( \vec{h} \cdot d\mathbf{s} \) is the space-time flux of \( \vec{h} \) leaving the region \( V \) through the surface element \( d\mathbf{s} \), Eq. (2.2) simply states that the total space-time flux of \( \vec{h} \) leaving \( V \) through \( S(V) \) vanishes; (ii) in \( E_2 \), \( d\sigma \) is the length of a line segment on the simple closed curve \( S(V) \); and (iii) all mathematical operations can be carried out as though \( E_2 \) were an ordinary two-dimensional Euclidean space.

To proceed, let \( \Omega \) denote the set of all space-time staggered mesh points in \( E_2 \) (dots in Fig. 2(a)), where \( n = 0, \pm 1/2, \pm 1, \pm 3/2, \pm 2, \ldots \), and, for each \( n, j = n \pm 1/2, n \pm 3/2, n \pm 5/2, \ldots \) Each \( (j, n) \in \Omega \) is associated with a solution element, i.e., \( \text{SE}(j, n) \). By definition, \( \text{SE}(j, n) \) is the interior of the space-time region bounded by a dashed curve depicted in Fig. 2(b). It includes a horizontal line segment, a vertical line segment, and their immediate neighborhood.

Let \( (x, t) \in \text{SE}(j, n) \). Then Eq. (2.2) will be simulated numerically assuming that \( u(x, t) \) and \( \vec{h}(x, t) \), respectively, are approximated by

\[
u^*(x, t; j, n) \overset{\text{def}}{=} u^n_j + (u^n_{x})_j (x - x_j) + (u^n_{t})_j (t - t^n) \tag{2.3}
\]

and

\[
\vec{h}^*(x, t; j, n) \overset{\text{def}}{=} (au^n_j (x, t; j, n), u^*(x, t; j, n)) \tag{2.4}
\]

Note that (i) \( u^n_j, (u^n_{x})_j \), and \( (u^n_{t})_j \) are constants in \( \text{SE}(j, n) \), (ii) \( (x_j, t^n) \) are the coordinates of the mesh point \( (j, n) \) with \( x_j = j \Delta x \) and \( t^n = n \Delta t \), and (iii) Eq. (2.4) is the numerical analogue of the definition \( \vec{h} = (au, u) \).

Let \( u = u^*(x, t; j, n) \) satisfy Eq. (2.1) within \( \text{SE}(j, n) \). Then one has \( (u^n_{t})_j = -a (u^n_{x})_j \). As a result, Eq. (2.3) reduces to

\[
u^*(x, t; j, n) = u^n_j + (u^n_{x})_j [(x - x_j) - a (t - t^n)] \tag{2.5}
\]
i.e., \( u^a_j \) and \( (u_x)^a_j \) are the only independent marching variables associated with \((j, n)\).

Let \( E_2 \) be divided into nonoverlapping rectangular regions (see Fig. 2(a)). As depicted in Figs. 2(c)–2(e), (i) two such regions, i.e., \( \text{CE}_- (j, n) \) and \( \text{CE}_+ (j, n) \), are associated with each interior mesh point \((j, n) \in \Omega\); and (ii) \( \text{CE}(j, n) \) is the union of \( \text{CE}_- (j, n) \) and \( \text{CE}_+ (j, n) \).

Given the above preliminaries, we are ready to describe the existing CE/SE solvers for Eq. (2.1).

### 2.1. The \( a \) scheme

Note that, among the line segments forming the boundary of \( \text{CE}_- (j, n) \), \( \overline{AB} \) and \( \overline{AD} \) belong to \( \text{SE}(j, n) \), while \( \overline{CD} \) and \( \overline{CE} \) belong to \( \text{SE}(j - 1/2, n - 1/2) \). Similarly, the boundary of \( \text{CE}_+ (j, n) \) belongs to either \( \text{SE}(j, n) \) or \( \text{SE}(j + 1/2, n - 1/2) \). As a result, by imposing two conservation conditions at each \((j, n) \in \Omega\), i.e.,

\[
\int_{S(\text{CE}_+(j, n))} \vec{h}^* \cdot d\vec{s} = 0 \quad \text{and} \quad \int_{S(\text{CE}_-(j, n))} \vec{h}^* \cdot d\vec{s} = 0, \quad (j, n) \in \Omega \tag{2.6}
\]

and using Eqs. (2.4) and (2.5), one can obtain two equations for the two unknowns \( u^a_j \) and \( (u_x)^a_j \). In fact, let (i) \( \nu \overset{\text{def}}{=} a \Delta t / \Delta x \), and (ii) for any \((j, n) \in \Omega\),

\[
(u_x)^a_j \overset{\text{def}}{=} \frac{\Delta x}{4} (u_x)^a_j \tag{2.7}
\]

then Eq. (2.6) implies that (i)

\[
u_j^n = \frac{1}{2} \left\{ (1 + \nu) u_{j+1/2}^{n-1/2} + (1 - \nu) u_{j-1/2}^{n-1/2} + (1 - \nu^2) \left[ (u_x)^a_{j+1/2}^{n-1/2} - (u_x)^a_{j+1/2}^{n-1/2} \right] \right\} \tag{2.8}
\]

and, assuming \(|\nu| \neq 1\), (ii)

\[(u_x)^a_j^n = (u_x)^a_j \quad (|\nu| \neq 1) \tag{2.9}\]

with

\[
(u_x)^a_j^n \overset{\text{def}}{=} \frac{1}{2} \left[ u_{j+1/2}^{n-1/2} - u_{j-1/2}^{n-1/2} + (1 - \nu)(u_x)^a_{j+1/2}^{n-1/2} - (1 - \nu)(u_x)^a_{j-1/2}^{n-1/2} \right] \quad (|\nu| \neq 1) \tag{2.10}
\]

The \( a \) scheme, i.e., the inviscid case of the \( a-\mu \) scheme [1,3,9], is formed by Eqs. (2.8) and (2.9). Note that, because

\[
\frac{\partial u}{\partial x} = \frac{\Delta x}{4} \frac{\partial u}{\partial x}
\]

if \( \bar{x} \overset{\text{def}}{=} x / (\Delta x / 4) \), the normalized parameter \((u_x)^a_j^n\) may be interpreted as the value at \((j, n)\) of the derivative of \( u \) with respect to the normalized coordinate \( \bar{x} \). Also note that the superscript symbol “a” in the parameter \((u_x)^a_j^n\) is introduced to remind the reader that Eq. (2.9) is valid for the \( a \) scheme.

The review of the \( a \) scheme is concluded with the following remarks:

(a) Even though it is introduced to model a single PDE (i.e., Eq. (2.1)) with a single dependent variable \( u \), the \( a \) scheme is formed by two coupled discrete equations (i.e., Eqs. (2.8) and (2.9)) involving two independent numerical variables \( u^a_j \) and \( (u_x)^a_j \). It is shown in [1] that Eqs. (2.8) and (2.9) are consistent with a pair of PDEs with one of them being Eq. (2.1).

(b) The \( a \) scheme has the simplest stencil, i.e., a triangle with a vertex at the upper time level and the other two vertices at the lower time level. Furthermore, the number of the independent marching variables associated with a mesh point \((j, n) \in \Omega\) is equal to the number of the mesh points at the \((n - 1/2)\)th time level that are part of the stencil. Note that the same relation also holds for many 2D and 3D CE/SE schemes [7,8,41].

(c) As shown in [3], the two amplification factors of the \( a \) scheme are identical to those of the leapfrog scheme. As a result, the \( a \) scheme is non-dissipative and it is stable if \(|\nu| < 1\) (see the additional discussions given in Sec. 2.2).

(d) Note that derivation of Eqs. (2.8) and (2.9) can be facilitated by the following observations: because \( u^a(x, t; j, n) \) is linear in \( x \) and \( t \), it can be shown that the total flux of \( h^* \) leaving \( \text{CE}_- (j, n) \) or \( \text{CE}_+ (j, n) \)
through any of the four line segments that form its boundary is equal to the scalar product of the vector \( \mathbf{h}^* \) evaluated at the midpoint of the line segment and the “surface” vector (i.e., the unit outward normal multiplied by the length) of the line segment.

(e) Because, for any \((j, n) \in \Omega\), the total flux of \( \mathbf{h}^* \) leaving each of \( CE_- (j, n) \) and \( CE_+ (j, n) \) vanishes (see Eq. (2.6)), \( CE_- (j, n) \) and \( CE_+ (j, n) \), \((j, n) \in \Omega\), will be referred to as the conservation elements (CEs) of the \( a \) scheme. In addition, because \((i) \) the vector \( \mathbf{h}^* \) at any surface element lying on any interface separating two neighboring CEs is evaluated using the information from a single SE, and \((ii) \) the unit outward normal vector on the surface element pointing outward from one of these two neighboring CEs is exactly the negative of that pointing outward from another CE, one concludes that the flux leaving one of these CEs through the interface is the negative of that leaving another CE through the same interface. As a result, the local conservation relations Eq. (2.6) lead to a global flux conservation relation, i.e., the total flux of \( \mathbf{h}^* \) leaving the boundary of any space-time region that is the union of any combination of CEs will also vanish. In particular, because \( CE(j, n) \) is the union of \( CE_- (j, n) \) and \( CE_+ (j, n) \),

\[
\int_{S(CE(j,n))} \mathbf{h}^* \cdot d\mathbf{s} = 0, \quad (j, n) \in \Omega \quad (2.11)
\]

must follow from Eq. (2.6). In fact, it can be shown that Eq. (2.11) is equivalent to Eq. (2.8).

(f) In addition to the non-dissipative \( a \) scheme, as will be shown, there is a family of its dissipative extensions in which only the less stringent conservation condition Eq. (2.11) is assumed [3]. Because Eq. (2.11) is equivalent to Eq. (2.8), for each of these extensions, \( u^n_j \) is still evaluated using Eq. (2.8) while \( (u^c_j)_n \) is evaluated using an equation different from Eq. (2.9).

2.2. The \( a-c \) scheme and the \( c \) scheme

To proceed, consider any \((j, n) \in \Omega\). Then \((j \pm 1/2, n - 1/2) \in \Omega\). Let

\[
u^n_{j+1/2} \overset{\text{def}}{=} u^{n-1/2}_{j+1/2} + (\Delta t/2)(u^n_t)_{j+1/2}^{n-1/2} \quad (2.12)
\]

With the aid of Eq. (2.7) and the fact that the Courant number \( \nu \overset{\text{def}}{=} a \Delta t / \Delta x \), a substitution of the relation \((u^n_t)_j = -a(u^n_x)_j\) into Eq. (2.12) results in

\[
u^n_{j+1/2} = (u - 2\nu u_x)_{j+1/2}^{n-1/2} \quad (2.13)
\]

Note that, to simplify notation, in the above and hereafter we adopt a convention that can be explained using the expression on the right side of Eq. (2.13) as an example, i.e.,

\[
(u - 2\nu u_x)_{j+1/2}^{n-1/2} = u_{j+1/2}^{n-1/2} - 2\nu(u_x)_{j+1/2}^{n-1/2}
\]

Also note that, by definition, \((j \pm 1/2, n) \notin \Omega \) if \((j, n) \in \Omega\). Thus \( u^n_{j+1/2} \) is associated with a mesh point \( \notin \Omega \). The reader is warned that similar situations may occur in the rest of this paper.

According to Eq. (2.12), \( u^n_{j+1/2} \) can be interpreted as a first-order Taylor’s approximation of \( u \) at \((j \pm 1/2, n)\). Thus

\[
(u^c_x)_j^n \overset{\text{def}}{=} \frac{\Delta x}{4} \left( \frac{u^n_{j+1/2} - u^n_{j-1/2}}{\Delta x} \right) \quad (2.14)
\]

is a central-difference approximation of \( \partial u / \partial x \) at \((j, n)\). Note that: \((i) \) the superscript “\( c \)” is used to remind the reader of the central-difference nature of the term \( (u^c_x)_j^n \); and \((ii) \) by using Eqs. (2.13), (2.14) and (2.10), one has

\[
(u^c_x)_j^n = \frac{1}{4} \left[ (u - 2\nu u_x)_{j+1/2}^{n-1/2} - (u - 2\nu u_x)_{j-1/2}^{n-1/2} \right] \quad (2.15)
\]
\begin{align}
(u_x^c - u_x^a)_{j}^{n} = \frac{1}{2} \left[ (u_x^c)_{j+\frac{1}{2}}^{n} - (u_x^a)_{j-\frac{1}{2}}^{n} \right] - \frac{1}{4} \left( u_x^{n+\frac{1}{2}}_{j+\frac{1}{2}} - u_x^{n-\frac{1}{2}}_{j-\frac{1}{2}} \right) 
\end{align}

The \( a-\epsilon \) scheme is formed by Eq. (2.8) and
\begin{align}
(u_x^c)_{j}^{n} = (u_x^a)_{j}^{n} + 2\epsilon (u_x^c - u_x^a)_{j}^{n}
\end{align}

where \( \epsilon \) is a real number. Obviously the \( a-\epsilon \) scheme reduces to the \( a \) scheme when \( \epsilon = 0 \). Also, for the case \( \epsilon = 1/2 \), Eq. (2.17) reduces to
\begin{align}
(u_x^c)_{j}^{n} = (u_x^c)_{j}^{n}
\end{align}

Because \((u_x^c)_{j}^{n}\) represents a central-difference approximation, hereafter, to simplify its frequent references, the special \( a-\epsilon \) scheme with \( \epsilon = 1/2 \) will be referred to as the \( c \) scheme.

To proceed, several key remarks about the \( a-\epsilon \) scheme are presented:

(a) At each mesh point \((j,n) \in \Omega\), Eqs. (2.8) and (2.9) are the results of Eq. (2.6). Because Eq. (2.17) does not reduce to Eq. (2.9) except in the special case \( \epsilon = 0 \), at each mesh point \((j,n) \in \Omega\), generally the \( a-\epsilon \) scheme satisfies only the single conservation condition Eq. (2.11) (which is equivalent to Eq. (2.8)) rather than the two conservation conditions Eq. (2.6). However, because \((u_x^c)_{j}^{n}\) generally is present on the right side of Eq. (2.17), the \( a-\epsilon \) scheme generally will still be burdened with the cost of solving two conservation conditions at each mesh point. The exception occurs only for the special case \( \epsilon = 1/2 \) (i.e., the \( c \) scheme) in which Eq. (2.17) reduces to Eq. (2.18).

As it turns out, implementation of a multidimensional Euler version of the \( c \) scheme does not require inverting any system of equations while a similar implementation involving a version of any other \( a-\epsilon \) scheme \( (\epsilon \neq 1/2) \) generally requires inverting, per mesh point and per time step, a system of several linear equations (to be exact, a system of eight and fifteen equations, respectively, for 2D and 3D Euler equations) \[7,8,41\]. As such, it is much more cost effective to use a multidimensional Euler version of the \( c \) scheme than using that of any other \( a-\epsilon \) scheme. Partly for this reason, extensions of the \( c \) scheme have been used extensively.

(b) For the \( a-\epsilon \) scheme, it is shown in \[3\] that the principal and spurious amplification factors per \( \Delta t \), respectively, are \((\lambda_+)^2\) and \((\lambda_-)^2\) with
\begin{align}
\lambda_{\pm}(\epsilon, \nu, \theta) \stackrel{\text{def}}{=} \epsilon \cos(\theta/2) - i\nu \sin(\theta/2) \pm \sqrt{(1 - \epsilon) \left[ (1 - \epsilon)\cos^2(\theta/2) + (1 - \nu^2)\sin^2(\theta/2) \right]}
\end{align}

Here (i) \( i \stackrel{\text{def}}{=} \sqrt{-1} \), and (ii) \( \theta, -\pi < \theta \leq \pi \), is the phase angle variation per \( \Delta x \). In addition, it is shown that (i) the necessary and sufficient conditions for the stability of the \( a-\epsilon \) scheme are
\begin{align}
0 \leq \epsilon \leq 1, \quad \text{and} \quad |\nu| < 1
\end{align}

and (ii) the \( a-\epsilon \) scheme becomes progressively diffusive as the value of \( \epsilon \) increases from 0 to 1. Note that, unless specified otherwise, in the remainder of the paper the ranges of \( \epsilon, \nu \) and \( \theta \), respectively, are defined by Eq. (2.20) and \( -\pi < \theta \leq \pi \).

(c) Let \( k \) be a constant. Then \( u = e^{ik(x-\alpha t)} \) represents a plane wave solution to Eq. (2.1). For this solution
\begin{align}
\text{the exact amplification factor per } \Delta t
\end{align}

\begin{align}
def e^{ik[x-\alpha(t+\Delta t)]} = e^{-ika\Delta t} = e^{-i\nu\theta}
\end{align}

where \( \theta = k\Delta x \).

(d) According to Eq. (2.19), \[|\lambda_{\pm}(0,\nu,\theta)|^2\], the amplification factors of the \( a \) scheme (which corresponds to the case \( \epsilon = 0 \)) per \( \Delta t \), have the following properties:
\begin{align}
||\lambda_{\pm}(0,\nu,\theta)||^2 = 1
\end{align}
\[
\lim_{\nu \to \pm 1} [\lambda_+ (0, \nu, \theta)]^2 = e^{\mp i \theta} \tag{2.23}
\]
\[
\lim_{\nu \to \pm 1} [\lambda_- (0, \nu, \theta)]^2 = e^{\pm i \theta} \tag{2.24}
\]
and
\[
[\lambda_\pm (0, 0, \theta)]^2 = 1 \tag{2.25}
\]

On the other hand, \(e^{-i \nu \theta}\), the exact amplification factor per \(\Delta t\), has the following properties:

\[
|e^{-i \nu \theta}| = 1 \tag{2.26}
\]
\[
\lim_{\nu \to \pm 1} e^{-i \nu \theta} = e^{\mp i \theta} \tag{2.27}
\]
and
\[
e^{-i \nu \theta} = 1 \quad \text{if} \quad \nu = 0 \tag{2.28}
\]

For the \(a\) scheme, Eqs. (2.22)–(2.28) imply that: (i) the two amplification factor of the scheme, and the exact amplification factor all have the same constant absolute value (= 1) and, thus, the scheme is non-dissipative; (ii) in the limit of \(|\nu| \to 1\) (i.e., \(\nu \to 1\) or \(\nu \to -1\)), the principal amplification factor is identical to the exact amplification factor and, thus, the former has no dissipative or dispersive error in this limit; (iii) also in the limit of \(|\nu| \to 1\), the phase angle associated with the spurious amplification factor is exactly the negative of that associated with the exact amplification factor and, thus, the spurious amplification factor has a large dissipative error in this limit except when \(|\theta| \ll 1\) (i.e., when the wavelengths of the errors \(\gg 1\)); and (iv) when \(\nu = 0\), the two amplification factors of the scheme, and the exact amplification factor are all equal to 1 and, thus, the two amplification factors of the scheme have no dissipative or dispersive error if \(\nu = 0\). Because the accuracy of a scheme is essentially hinged on the behaviors of the principal amplification factor [1], according to the facts stated above, \(the a\) scheme tends to become very accurate when \(|\nu|\) approaches 1 or 0. However, the short-wavelength errors associated with the spurious amplification factor (which could be introduced at \(t = 0\) as a result of an inaccurate initial-value specification [1]) may appear in a solution as persistent (i.e., non-dissipative) numerical wiggles when \(|\nu|\) approaches 1 [1,9].

(e) According to Eq. (2.19), \([\lambda_\pm (1/2, \nu, \theta)]^2\), the amplification factors of the \(c\) scheme (which corresponds to the case \(\epsilon = 1/2\) per \(\Delta t\)), have the following properties:

\[
\lim_{\nu \to \pm 1} [\lambda_+ (1/2, \nu, \theta)]^2 = e^{\mp i \theta} \tag{2.29}
\]
\[
\lim_{\nu \to \pm 1} [\lambda_- (1/2, \nu, \theta)]^2 = -\sin^2(\theta/2) \tag{2.30}
\]
and
\[
[\lambda_\pm (1/2, 0, \theta)]^2 = \frac{1}{2} \left[ 1 \pm \cos(\theta/2) \sqrt{2 - \cos^2(\theta/2)} \right] \tag{2.31}
\]

For the \(c\) scheme, Eqs. (2.27)–(2.31) imply that: (i) in the limit of \(|\nu| \to 1\), the principal amplification factor is identical to the exact amplification factor and, thus, the former has no dissipative or dispersive errors in this limit; (ii) also in the limit of \(|\nu| \to 1\), the spurious amplification factor has large dissipative and dispersive errors; and (iii) when \(\nu = 0\), both the principal and spurious amplification factors generally have large dissipative errors but no dispersive errors. According to the facts stated above, like the \(a\) scheme, the \(c\) scheme also tends to become very accurate when \(|\nu|\) approaches 1. However, unlike the \(a\) scheme, the errors associated with the spurious amplification factor of the \(c\) scheme generally do die out rapidly when \(|\nu|\) approaches 1. Also, in sharp contrast to the \(a\) scheme, the \(c\) scheme becomes highly dissipative when \(\nu\) approaches 0.

From the above discussions, one concludes that:
(a) The advantages of the $a$ scheme include: (i) it is non-dissipative throughout the range of $\epsilon$ and $\nu$ defined in Eq. (2.20); and (ii) when the value of $|\nu|$ is close to 0 or 1, the scheme is very accurate. On the other hand, its disadvantages include: (i) because it is non-dissipative, its extensions for nonlinear equations generally are unstable; (ii) when the value of $|\nu|$ is close to 1, the short-wavelength errors associated with the spurious amplification factor will not die out rapidly and, therefore, appear in a solution as persistent numerical wiggles; and (iii) comparing with the $c$ scheme, it costs more to implement.

(b) The advantages of the $c$ scheme include: (i) when the value of $|\nu|$ is close to 1, it is very accurate and the short-wavelength errors associated with the spurious amplification factor also die out rapidly; (ii) because it is dissipative, its extensions for nonlinear equations generally are stable; and (iii) in terms of ease of implementation and computer cost, it is much more superior than any other $a$-$c$ scheme. On the other hand, the $c$ scheme has a serious disadvantage, i.e., it is very dissipative when $\nu$ approaches 0.

In Sec. 3, it will be shown that new solvers of Eq. (2.1) can indeed be constructed such that they possess all the advantages but none of the disadvantages listed above. Specifically, each of these solvers will be formed by Eq. (2.8) and a new equation in which $(u_x^n)_j$ is evaluated using a simple central-differencing procedure similar to that used to obtain $(u_x^n)_j$. In addition, $(u_x^n)_j$ so obtained will be (i) identical to $(u_x^n)_j$ in the limit of $|\nu| \to 1$, and (ii) identical to $(u_x^n)_j$ when $\nu = 0$. As such, each of these new solvers (i) is comparable to the $c$ scheme in ease of implementation; (ii) becomes the $c$ scheme in the limit of $|\nu| \to 1$; and (iii) becomes the $a$ scheme when $\nu = 0$.

### 2.3. The $w$-$\alpha$ scheme—a special wiggle-suppressing scheme

If discontinuities are present in a numerical solution, any $a$-$c$ scheme such as the $c$ scheme is not equipped to suppress numerical wiggles that generally appear near these discontinuities. To serve as a preliminary for future development, here we shall briefly review an extension of the $c$ scheme which was introduced as a remedy for this deficiency [3,35].

To proceed, let

$$
(u_{x-})_j^n = \frac{\Delta x}{4} \left( \frac{u_j^n - u_{j-1/2}^n}{\Delta x/2} \right) \tag{2.32}
$$

and

$$
(u_{x+})_j^n = \frac{\Delta x}{4} \left( \frac{u_{j+1/2}^n - u_j^n}{\Delta x/2} \right) \tag{2.33}
$$

i.e., $(u_{x-})_j^n$ and $(u_{x+})_j^n$ are numerical analogues of $\partial u / \partial x$ at $(j, n)$ evaluated from the left and the right, respectively. It can be shown that

$$
(u_x^n)_j = \frac{1}{2} (u_{x-} + u_{x+})_j^n
$$

i.e., $(u_x^n)_j$ is the simple average of $(u_{x-})_j^n$ and $(u_{x+})_j^n$. As such, the $c$ scheme can be extended by replacing $(u_x^n)_j$ in Eq. (2.18) with an weighted average of $(u_{x-})_j^n$ and $(u_{x+})_j^n$. In other words, the resulting extension is formed by Eq. (2.8) and

$$
(u_x^n)_j = (w_{-})_j^n (u_{x-})_j^n + (w_{+})_j^n (u_{x+})_j^n \tag{2.35}
$$

where $(w_{-})_j^n$ and $(w_{+})_j^n$, the weight factors associated with $(u_{x-})_j^n$ and $(u_{x+})_j^n$ respectively, must satisfy the condition

$$
(w_{-})_j^n + (w_{+})_j^n = 1 \tag{2.36}
$$

at all $(j, n) \in \Omega$. In addition, the expression on the right side of Eq. (2.35) represents an interpolation (rather than an extrapolation) of $(u_{x-})_j^n$ and $(u_{x+})_j^n$ if and only if

$$
(w_{-})_j^n \geq 0 \quad \text{and} \quad (w_{+})_j^n \geq 0 \tag{2.37}
$$

For real variables $x_-$, $x_+$, and $\alpha \geq 0$, let $W_-$ and $W_+$ be the functions defined by: (i) $W_-(x_-, x_+; \alpha) = W_+(x_-, x_+; \alpha) = 1/2$ if $x_- = x_+ = 0$; and (ii)

$$
W_-(x_-, x_+; \alpha) = \frac{|x_+|^\alpha}{|x_-|^\alpha + |x_+|^\alpha} \quad \text{and} \quad W_+(x_-, x_+; \alpha) = \frac{|x_-|^\alpha}{|x_-|^\alpha + |x_+|^\alpha} \tag{2.38}
$$
if either \( x_- \neq 0 \) or \( x_+ \neq 0 \). Furthermore, let
\[
(w_\pm)_j^n = W_\pm((u_{x-})_j^n, (u_{x+})_j^n, \alpha)
\]
(2.39)

Then \((w_-)_j^n \) and \((w_+)_j^n \) so defined satisfy Eqs. (2.36) and (2.37) and have the property that
\[
(w_-)_j^n = (w_+)_j^n = 1/2 \quad \text{if} \quad \alpha = 0 \quad \text{or} \quad |(u_{x-})_j^n| = |(u_{x+})_j^n|
\]
(2.40)

Note that: (i) to avoid dividing by zero, in practice a small positive number such as 10\(^{-20} \) is added to each of the denominators in Eq. (2.38); and (ii) the special cases of Eq. (2.38) with \( \alpha = 1 \) and \( \alpha = 2 \) are used in the slope-limiter proposed by van Leer [59], and van Albada et al. [60].

An extension of the \( c \) scheme is formed by Eqs. (2.8) and (2.35) with \((w_-)_j^n \) and \((w_+)_j^n \) being defined by Eq. (2.39). Because it involves an weighted average which is dependent on a parameter \( \alpha \), hereafter the scheme is referred to as the \( w-\alpha \) scheme. Let \( \alpha > 0 \) and \(|(u_{x-})_j^n| \neq |(u_{x+})_j^n| \). Then Eq. (2.38) implies that, of \((u_{x-})_j^n \) and \((u_{x+})_j^n \), the one with smaller absolute value is associated with an weight factor \( > 1/2 \). This observation coupled with Eqs. (2.34)–(2.37) leads to the conclusion that, of \((u_{x-})_j^n \) and \((u_{x+})_j^n \), \((u_{x})_j^n \) will have an algebraic value closer to the one with smaller absolute value if \((u_{x})_j^n \) is evaluated as an weighted average of \((u_{x-})_j^n \) and \((u_{x+})_j^n \) according to Eq. (2.35). As a result, \((u_{x})_j^n \) so evaluated has a smaller absolute value than that evaluated using Eq. (2.18). In turn, numerical wiggles or overshoots can be annihilated by the additional numerical dissipation introduced as a result of this local “flattening” of \((u_{x})_j^n \). It has been shown numerically that the extension is stable if \(|\nu| < 1 \) and \( \alpha \geq 0 \). Moreover, as a result of Eqs. (2.18), (2.34), (2.35) and (2.40), (i) the extension reduces to the \( c \) scheme when \( \alpha = 0 \); and (ii) even if \( \alpha > 0 \), the extension behaves very much like the \( c \) scheme in any smooth solution region (where the condition \((u_{x-})_j^n = (u_{x+})_j^n \) more or less prevails) or at a solution extremum (where the condition \((u_{x-})_j^n = -(u_{x+})_j^n \) more or less prevails). As such, the wiggle-suppressing power of the extension takes effect only if \( \alpha > 0 \) and only in a solution region where \(|(u_{x-})_j^n| \) and \(|(u_{x+})_j^n| \) differ substantially.

3. The \( c-\tau \) and \( c-\tau^* \) schemes

In this section, the ideal solvers of Eq. (2.1) mentioned at the end of Sec. 2.2 will be constructed. As a preliminary, we shall show that \((u^\tau_x)_j^n \) can also be cast in a central-difference form when \( \nu = 0 \).

To proceed, note that by assumption \( a \neq 0 \). Thus \( \nu = 0 \) if and only if \( \Delta t = 0 \). Because \( |(w)_j^n| = |(b)_j^n| \) (see Figs. 2(c,d)) when \( \Delta t = 0 \), the two conservation conditions given in Eq. (2.6) for the case \( \nu = 0 \), respectively reduce to the following conditions: (i) the flux leaving \( CE_+(j, n) \) through the top face \( AF \) is equal to that entering the same \( CE \) through the bottom face \( BD \); and (ii) the flux leaving \( CE_-(j, n) \) through the top face \( AB \) is equal to that entering the same \( CE \) through the bottom face \( CD \). According to Remark (d) given at the end of Sec. 2.1, the flux leaving \( CE_+(j, n) \) through the top face \( AF \) is equal to the value of \( u^* \) at the midpoint of \( AF \) (evaluated using the marching variables at point \( A \)) multiplied by \( |AF| \), while that entering it through the bottom face \( BD \) is equal to the value of \( u^* \) at the midpoint of \( BD \) (evaluated using the marching variables at point \( E \)) multiplied by \( |ED| \). With the aid of these observations and the fact that \( |AF| = |ED| \), the above condition (i) implies that, when \( \nu = 0 \), the value of \( u^* \) at the midpoint of \( AF \) evaluated using the marching variables at point \( A \) is equal to that at the midpoint of \( ED \) evaluated using the marching variables at point \( E \). As such, the first conservation condition in Eq. (2.6) is equivalent to
\[
(u + u_x)_j^n = (u - u_x)_j^{n-1/2} \quad (\nu = 0)
\]
(3.1)

if \( \nu = 0 \). Similarly, by using the above condition (ii), it can be shown that the second conservation condition in Eq. (2.6) is equivalent to
\[
(u - u_x)_j^n = (u + u_x)_j^{n-1/2} \quad (\nu = 0)
\]
(3.2)

if \( \nu = 0 \). Because Eqs. (2.8) and (2.9) (which form the \( \alpha \) scheme) are equivalent to Eq. (2.6) if \(|\nu| \neq 1 \), they must be equivalent to Eqs. (3.1) and (3.2) when \( \nu = 0 \). In fact, by substracting Eq. (3.2) from Eq. (3.1), one obtains Eq. (2.9) where \((u^\tau_x)_j^n \) is the reduced form of Eq. (2.10) for the case \( \nu = 0 \), i.e.,
\[
(u^\tau_x)_j^n = \frac{1}{2} \left[ (u - u_x)_j^{n-1/2} - (u + u_x)_j^{n-1/2} \right] \quad (\nu = 0)
\]
(3.3)
Moreover, by summing over Eqs. (3.1) and (3.2), one has the reduced form of Eq. (2.8) for the case \( \nu = 0 \).

With the aid of Eq. (3.3) and the facts that: (i) \((u - u_x)_{j+1/2} \) and \((u + u_x)_{j-1/2} \), respectively, represent an approximation of \( u \) at the midpoint of \( ED \) and that at the midpoint of \( CD \) (see Fig. 2(c,d)); and (ii) the distance between the two midpoints referred to above is \( \Delta x/2 \), it becomes obvious that, for the special case \( \nu = 0 \), \((u_x)_j \) is indeed a central-difference approximation of \( \partial u/\partial x \) at \((j, n - 1/2) \) (which coincides with \((j, n) \) when \( \nu = 0 \)). QED

According to the above discussions, construction of the ideal solvers defined at the end of Sec. 2.2 is hinged on finding central-difference approximations for \((u_x)_j \) such that each approximation (i) becomes \((u_x)_j \) in the limit of \( |\nu| \to 1 \), and (ii) reduces to the expression on the right side of Eq. (3.3) when \( \nu = 0 \). As a result of these observations, these new solvers can easily be constructed as the subschemes of the \( c-\tau \) scheme, a new class of CE/SE solvers for Eq. (2.1) to be described immediately.

### 3.1. The \( c-\tau \) scheme

To proceed, refer to Fig. 3. Here \( M^+ \) and \( M^- \) denote the midpoints of \( AB \) and \( BC \), respectively. Also \( P^+ \) and \( P^- \) are two points on \( BF \) that satisfy the following conditions: (i) \( P^+ \) coincides with \( M^+ \) if and only if \( P^- \) coincides with \( M^- \); (ii) \( P^+ \) is to the right (left) of \( M^+ \) if and only if \( P^- \) is to the left (right) of \( M^- \); and (iii) \(|M^+P^+| = |M^-P^-|\), i.e., \( M^+P^+ \) and \( M^-P^- \) have the same length. In addition, let the parameter \( \tau \) be defined by: (i) \( \tau = 0 \) if \( P^+ \) coincides with \( M^+ \); (ii) \( \tau \Delta x/4 = |M^+P^+| \) if \( P^+ \) is to the right of \( M^+ \); and (iii) \( \tau \Delta x/4 = |M^-P^-| \) if \( P^- \) is to the left of \( M^- \); and (iii) \( \tau \Delta x/4 = -|M^+P^-| \) if \( P^- \) is to the right of \( M^- \).

Moreover, let

\[
u(P^+) \overset{\text{def}}{=} [u + (\Delta t/2)u_t - (1 - \tau)u_x]_{j+1/2}^{n-1/2}
\]

and

\[
u(P^-) \overset{\text{def}}{=} [u + (\Delta t/2)u_t + (1 - \tau)u_x]_{j-1/2}^{n-1/2}
\]

With the aid of Eq. (2.7), it is seen that \( u(P^+) \) is a first-order Taylor’s approximation of \( u \) at \( P^+ \) evaluated using the marching variables at point \( E \), while \( u(P^-) \) is a first-order Taylor’s approximation of \( u \) at \( P^- \) evaluated using the marching variables at point \( C \). Also note that, by using the relation \((u_t)_j = -a(u_x)_j\), Eqs. (3.4) and (3.5), respectively, can be simplified as

\[
u(P^+) = [u - (2\nu + 1 - \tau)u_x]_{j+1/2}^{n-1/2}
\]

and

\[
u(P^-) = [u - (2\nu - 1 + \tau)u_x]_{j-1/2}^{n-1/2}
\]

At this juncture, note that \( P^+ \) and \( P^- \) generally lie outside of SE\((j+1/2, n-1/2)\) and SE\((j-1/2, n-1/2)\), respectively. Yet here, by definition, \( u(P^+) \) and \( u(P^-) \) are evaluated as though \( P^+ \) and \( P^- \) lie within \((j+1/2, n-1/2)\) and \((j-1/2, n-1/2)\), respectively. At first glance, the current practice is inconsistent with a previously established rule. However, as explained by the reasons given below, the definition of \( u(P^+) \) and \( u(P^-) \) is perfectly legitimate:

(a) Recall that solution elements were introduced such that the boundary of a CE can be divided into several component parts with each of them belonging to a unique solution element. As such, the flux over a component part that belongs to a special solution element, say SE\((j, n)\), can be unambiguously determined in terms of the marching variables at the mesh point \((j, n)\). In other words, in related to evaluation of any flux conservation condition over any CE, Eqs. (2.3)-(2.5) can be applied only to a point \((x, t) \in SE(j, n)\).

(b) On the other hand, \( u(P^+) \) and \( u(P^-) \) introduced here have nothing to do with flux evaluation. In fact, they will be used only in the construction of some numerical analogues of \( \partial u/\partial x \) at \((j, n)\).
To proceed, note that: (i) the mesh point \( (j, n) \) (i.e., point \( A \) depicted in Fig. 3) is the midpoint of \( P^{-}\) and \( P^{+} \), and (ii) \( |P^{-} - P^{+}| = (1 + \tau) \Delta x / 2 \). Thus

\[
(\tilde{u}_x^n)_{j}^{\tau} \triangleq \frac{\Delta x}{4} \left( \frac{u(P^{+}) - u(P^{-})}{(1 + \tau) \Delta x / 2} \right) \quad (\tau \neq -1)
\]  

represents a central-difference approximation of \( \partial u / \partial x \) at the mesh point \( (j, n) \). Thus the new scheme formed by Eq. (2.8) and

\[
(u_x^n)_{j}^{\tau} = (\tilde{u}_x^n)_{j}^{\tau}
\]  

represents a solver for Eq. (2.1). Because (i) \( (\tilde{u}_x^n)_{j}^{\tau} \) represents a central-difference approximation of \( (u_x^n)_{j}^{\tau} \), and (ii) the approximation is associated with the parameter \( \tau \), hereafter the new scheme will be referred to as the \( c-\tau \) scheme.

To explore the \( c-\tau \) scheme, note that Eqs. (3.6)-(3.8) can be combined to yield

\[
(\tilde{u}_x^n)_{j}^{\tau} = \frac{1}{2(1 + \tau)} \left\{ [u - (2\nu + 1 - \tau)u_x]_{j+1/2}^{n-1/2} - [u - (2\nu - 1 + \tau)u_x]_{j-1/2}^{n-1/2} \right\} \quad (\tau \neq -1)
\]  

Moreover, by using Eqs. (2.10), (2.16) and (3.10), one has

\[
(\tilde{u}_x^n)_{j}^{\tau} = (u_x^n)_{j}^{\tau} + \frac{2\tau}{1 + \tau}(u_x^n - u_x^{\tau})_{j}^{n} - \frac{\nu(1 - \tau)}{2(1 + \tau)} \left[ (u_x^n)_{j+1/2}^{n-1/2} - (u_x^n)_{j-1/2}^{n-1/2} \right]
\]  

By comparing Eq. (3.11) with (2.17), one concludes that the \( c-\tau \) scheme generally is different from the \( a-\epsilon \) scheme. In fact, a special case of the \( c-\tau \) scheme can be turned into that of the \( a-\epsilon \) scheme and vice versa if and only if either (i) \( \tau = 1 \) or (ii) \( \nu = 0 \). For the case \( \tau = 1 \), Eq. (3.11) implies that \( (\tilde{u}_x^n)_{j}^{\tau} = (u_x^n)_{j}^{\tau} \). In other words, the \( c \) scheme is the special case of the \( c-\tau \) scheme with \( \tau = 1 \), a fact that can also be deduced from the observation that the points \( P^{+} \) and \( P^{-} \) depicted in Fig. 3, respectively, coincide with points \( F \) and \( B \) (i.e., the mesh points \( (j + 1/2, n) \) and \( (j - 1/2, n) \)) if \( \tau = 1 \). On the other hand, it is seen that, when \( \nu = 0 \), the \( c-\tau \) scheme become the \( a-\epsilon \) scheme with \( \epsilon = 2\tau / (1 + \tau) \). In fact one can further deduce that \( c-\tau \) scheme reduces to the \( a \) scheme if and only if \( \nu = \tau = 0 \).

Because the \( c-\tau \) scheme is formed by two rather complicated equations (i.e., Eqs. (2.8) and (3.9)) involving two parameters \( \nu \) and \( \tau \), it were not expected that its von Neumann stability conditions could be cast into an explicit analytical form. However, it is shown rigorously in [55] that the \( c-\tau \) scheme is von Neumann stable if and only if

\[
\nu^2 \leq 1, \quad \tau \geq \tau_o(\nu^2), \quad \text{and} \quad (\nu^2, \tau) \neq (1, 1)
\]  

where

\[
\tau_o(s) \overset{\text{def}}{=} \begin{cases} 
0 & \text{if } s = 0 \\
\frac{4 - s - 2 \sqrt{2(2 - s - s^2)}}{s} & \text{if } 0 < s \leq \frac{3}{11} \\
\frac{s - 1 + \sqrt{1 - 2s + 5s^2}}{2s} & \text{if } \frac{3}{11} \leq s \leq 1 
\end{cases}
\]  

Note that:

(a) It can be shown that [55]: (i) \( \tau_o(s) \) is continuous at \( s = 0 \); (ii) \( \tau_o(s) \) is consistently defined at \( s = 3/11 \); (iii)

\[
\lim_{s \to \frac{3}{11}} \tau_o'(s) = \frac{d\tau_o(s)}{ds} = 121/90
\]

where \( \tau_o'(s) \overset{\text{def}}{=} d\tau_o(s)/ds \); (iv) \( \tau_o(s) \) is strictly monotonically increasing in the interval \( 0 < s < 1 \); (v) \( \tau_o(1) = 1 \); and (vi)

\[
s < \tau_o(s) < \sqrt{s}, \quad 0 < s < 1
\]  

(3.14)
(b) For any given fixed value of \(|\nu| < 1\), the \(c-\tau\) scheme tends to become more dissipative as the value of \(\tau\) increases from \(\tau_0(\nu^2)\), its minimum stable value.

(c) The function \(\tau_0\) defined here is different from the function \(\tau_0\) defined in [52]. In fact, for any \(\nu \in [0, 1]\), the value of \(\tau_0(\nu^2)\) defined here is identical to that of \(\tau_0(\nu)\) defined in [52]. Because the analytical \(\nu-\tau_0(\nu^2)\) relation depicted in Fig. 4 here is virtually identical to the numerical \(\nu-\tau(\nu)\) relation depicted in Fig. 4 of [52], the analytical stability conditions given here are in complete agreement with those generated numerically and stated in Eq. (3.12) of [52].

With the above preliminaries, the ideal solvers of Eq. (2.1) defined at the end of Sec. 2.2 will be constructed in Sec. 3.2.

3.2. The \(c-\tau^*\) schemes

The value of \(\tau\) used in the \(c-\tau\) scheme generally can be chosen independent of \(\nu\). Here we will introduce a subset of the \(c-\tau\) scheme in which \(\tau^*\) is a function of \(\nu^2\) for each member of this subset. As a preliminary, note that, by using the properties of \(\tau_0(s)\) presented earlier, it can be shown that there exist infinitely many choices of a strictly monotonically increasing smooth function \(h(s), 0 \leq s < 1\), which possesses the following properties:

\[
\begin{align*}
  h(0) &= 0; \quad \lim_{s \to 1^-} h(s) = 1; \quad \text{and} \quad h(s) \geq \tau_0(s) \quad \text{if} \quad 0 < s < 1 \quad (3.15)
\end{align*}
\]

For each function \(h(s)\) that satisfies the above conditions, each member of the subset referred to earlier is defined using the relation

\[
\tau = h(\nu^2) \quad (\nu^2 < 1) \quad (3.16)
\]

Note that, using the definition of \(h\) and Eq. (3.16), one can easily infer from Fig. 3 a simple relation between the value of \(\nu^2\) and the locations of \(P^+\) and \(P^+\), i.e., as the value of \(\nu^2\) increases from 0 to 1, \(P^+\) will move away from \(M^+\) and edge toward the mesh point \((j + 1/2, n)\) while \(P^-\) will move away from point \(M^-\) and edge toward the mesh point \((j - 1/2, n)\). Also note that, by using the above preliminaries, one can show that:

(i) \(\tau = 0\) if \(\nu = 0\) \quad (3.17)

(ii) \(\lim_{\nu^2 \to 1^-} \tau = 1\) \quad (3.18)

and (iii) \(\tau \geq \tau_0(\nu^2)\) \quad (\nu^2 < 1) \quad (3.19)

Recall that (i) \((\tilde{u}_x)_j^n = (u_x^j)_n\) if \(\tau = \nu = 0\); and (ii) \((\tilde{u}_x)_j^n = (u_x^j)_n\) if \(\tau = 1\). As such, Eqs. (3.17) and (3.18) imply that, for each member in the subset, (i) \((\tilde{u}_x)_j^n = (u_x^j)_n\) if \(\nu = 0\); and (ii) \((\tilde{u}_x)_j^n = (u_x^j)_n\) in the limit of \(\nu^2 \to 1^-\). In other words, all members in the subset are ideal solvers in the domain \(\nu^2 < 1\). Moreover, by using Eq. (3.12) and (3.19), one can also show that these ideal solvers are also stable in the same domain. Hereafter, each of these ideal solvers will be referred to as an ideal \(c-\tau^*\) scheme.

Corresponding to infinitely many choices of \(h\), there are infinitely many different ideal \(c-\tau^*\) schemes. In particular, because

\[
h(s) = \sqrt{s} \quad (0 \leq s < 1) \quad (3.20)
\]

is a legitimate choice (see Eq. (3.14)), Eq. (3.16) implies that an ideal \(c-\tau^*\) scheme can be defined using the relation

\[
\tau = |\nu| \quad (\nu^2 < 1) \quad (3.21)
\]

Any ideal \(c-\tau^*\) scheme described above meets all the requirements of an ideal solver defined in Sec. 2.2. However, because of stability problem, an ideal \(c-\tau^*\) scheme and its multidimensional extensions may not be robust enough for some complicated real-world applications. To overcome this difficulty, we introduce a special \(c-\tau\) scheme which is defined by Eqs. (2.8), (3.9), and (3.10) with

\[
\tau = \beta |\nu| \quad (\beta \geq 1; \nu^2 < 1) \quad (3.22)
\]
where $\beta \geq 1$ is an adjustable parameter. For this scheme, Eq. (3.17) is also valid. Thus it becomes the nondissipative $\alpha$ scheme when $\nu = 0$ and, therefore, it will not become overly dissipative as $\nu \to 0$ (i.e., the scheme’s numerical dissipation is Courant number insensitive). Moreover, because $\beta \geq 1$, Eqs. (3.12) and (3.14) along with the comment (b) given following Eq. (3.14) imply that the scheme is stable if $\nu^2 < 1$ and it becomes more dissipative (i.e., more stable) as the value of $\beta$ increases. However, also because $\beta \geq 1$,
\[
\lim_{|\nu| \to 1^-} \tau = \beta \geq 1
\]  
(3.23)

As such, except for the case $\beta = 1$, the scheme does not become the $c$ scheme in the limit of $|\nu| \to 1^-$, i.e., it does not meet all the requirements of an ideal solver.

Note that, unless specified otherwise, in Sec. 4 we consider only the cases in which either Eq. (3.16) or Eq. (3.22) is assumed.

4. Extensions of the $c$-$\tau^*$ scheme and related weighted averagings

To proceed, let
\[
(u_x^-)_j^n = \frac{\Delta x}{4} \left( \frac{u_j^n - u(P^-)}{(1 + \tau) \Delta x/4} \right)
\]  
(4.1)

and
\[
(u_x^+)_j^n = \frac{\Delta x}{4} \left( \frac{u(P_+^n) - u_j^n}{(1 + \tau) \Delta x/4} \right)
\]  
(4.2)

Because $\nabla P^- = \nabla P^+ = (1 + \tau) \Delta x/4$ (see Fig. 3), it is easy to see that $(u_x^-)_j^n$ and $(u_x^+)_j^n$ are two one-sided difference approximations of $\partial u / \partial x$ at the mesh point $(j, n)$ with one being evaluated from the left and another from the right. Also, it follows immediately from Eqs. (3.8), (4.1) and (4.2) that
\[
(u_x)_j^n = \frac{1}{2} \left[ (u_x^-)_j^n + (u_x^+)_j^n \right]
\]  
(4.3)

Moreover, by (i) substituting Eqs. (2.8), (3.6) and (3.7) into Eqs. (4.1) and (4.2), and (ii) using Eqs. (3.10) and (3.17), one arrives at the conclusion that
\[
(u_x^-)_j^n = (u_x^+)_j^n = (u_x)_j^n \quad (\nu = 0)
\]  
(4.4)

when $\nu = 0$.

With the above preliminaries, several extensions of the $c$-$\tau^*$ scheme will be constructed in the following subsections.

4.1. Scheme w-1

A comparison of Eqs. (4.1)–(4.3) with Eqs. (2.32)–(2.34) reveals that an obvious extension of the $c$-$\tau^*$ scheme can be obtained by replacing $(u_x^-)_j^n$ and $(u_x^+)_j^n$ in Eqs. (2.35) and (2.39) with $(u_x^-)_j^n$ and $(u_x^+)_j^n$, respectively. In other words, the new extension is formed by Eq. (2.8) and
\[
(u_x)_j^n = (w_+)_j^n (u_x^-)_j^n + (w_+)_j^n (u_x^+)_j^n
\]  
(4.5)

with
\[
(w_\pm)_j^n = W_\pm ((u_x^-)_j^n, (u_x^+)_j^n, \alpha)
\]  
(4.6)

Because the scheme is the first extension of the $c$-$\tau^*$ scheme in which $(u_x)_j^n$ is expressed as a weighted average of $(u_x^-)_j^n$ and $(u_x^+)_j^n$, for simplicity, hereafter it will be referred to as Scheme w-1. It has been shown numerically that Scheme w-1 is stable if $|\nu| < 1$ and $\alpha \geq 0$.

Note that, as a result of Eqs. (2.38), (4.4) and (4.6), one concludes that, for any given $\alpha \geq 0$, $(w_-)_j^n = (w_+)_j^n = 1/2$ if $\nu = 0$. In other words, for Scheme w-1, the “weighted” average on the right side of Eq. (4.5)
becomes a simple average if \( \nu = 0 \). According to an explanation given in the last paragraph of Sec. 2, this implies that Scheme w-1 will lose its capability to suppress wiggles or overshoots when \( \nu \) becomes small. For this reason, even though the Euler version of Scheme w-1 performs much better than that of the special scheme referred to in Sec. 2.3 in its ability to resolve shocks and contact discontinuities crisply in a wide range (from 1 to less than 0.001) of the global Courant number (i.e., the maximal value of local Courant numbers), it has a serious shortcoming, i.e., wiggles or overshoots can appear near a discontinuity in a generated solution when the local Courant number there becomes extremely small. In the following, it will be shown that this weakness can be overcome by simple modifications of Eq. (4.6).

4.2. Scheme w-2

A new scheme, referred to as Scheme w-2 is formed by Eqs. (2.8) and (4.5) with \((\frac{w}{\sum})^2_j\) being given by Eq. (2.39). In other words, although \((u_{x-})^2_j\) is still constructed as a weighted average of \((\bar{u}_{x-})^2_j\) and \((\bar{u}_{x+})^2_j\), the associated weight factors \((\frac{w}{\sum})^2_j\) are evaluated using \((u_{x-})^2_j\) and \((u_{x+})^2_j\). Because the last two parameters, respectively, are identical to the special cases of \((u_{x-})^2_j\) and \((u_{x+})^2_j\) with \(\tau = 1\) (see Eqs. (2.12), (2.32), (2.33), (3.4), (3.5), (4.1), and (4.2)), their values do not vary with \(\nu\). As such, \((\frac{w}{\sum})^2_j \neq 1/2\) and therefore the weighted average on the right side of Eq. (4.5) will not turn into a simple average when \(\nu = 0\).

In other words, Scheme w-2 is still capable of annihilating the numerical wiggles near a discontinuity even if \(\nu\) becomes small. It has been shown numerically that Scheme w-2 again is stable if \(|\nu| < 1\) and \(\alpha \geq 0\).

Note that a possible drawback of Scheme w-2 is that the relation \(|u_{x-}^2_j| < |u_{x+}^2_j| \rightarrow |\bar{u}_{x-}^2_j| > |\bar{u}_{x+}^2_j|\) does not automatically follow from \(|\bar{u}_{x-}^2_j| < |\bar{u}_{x+}^2_j| \rightarrow |\bar{u}_{x-}^2_j| > |\bar{u}_{x+}^2_j|\) and vice versa. As a result, at some local mesh points, it may happen that, of \((\bar{u}_{x-}^2_j)^n\) and \((\bar{u}_{x+}^2_j)^n\), the one with smaller absolute value may not be associated with a weight factor > 1/2. According to a discussion given in the last paragraph of Sec. 2, this implies that there is no guarantee that, at all localities, the weighted-averaging induced numerical dissipation will be available to suppress wiggles or overshoots. Despite this possible failing, fortunately it has been demonstrated numerically that, not only are they capable of suppressing wiggles or overshoots robustly, Scheme w-2 and its Euler extensions are also highly accurate.

In the following, schemes that overcome the weakness of Scheme w-1 and also avoid the theoretically possible failing associated with Scheme w-2 will be constructed using new weighted-averaging formulae more advanced than that given in Eq. (2.38).

4.3. New weighted-averaging techniques

To pave the way, first we shall discuss a limitation of Eq. (2.38) as a generator of weight factors.

Let \(x_{\pm} \neq 0\). Then, for a given \(\alpha > 0\), obviously \(W_{-} \rightarrow 1/2\) and \(W_{+} \rightarrow 1/2\) as \(x_{\pm} \rightarrow 1\). As such, when \(x_{\pm} \neq 0\) is very close to 1, then both \(W_{-}\) and \(W_{+}\) will be very close to 1/2 unless \(\alpha \gg 1\). As a result, in case that (i) \((\bar{u}_{x+}^2_j)^n \neq 0\), (ii) \(|(\bar{u}_{x+}^2_j)^n/(\bar{u}_{x-}^2_j)^n|\) is very close to 1; and (iii) Eqs. (4.6) is assumed, then the only way to prevent the weighted average that appears on the right side of Eq. (4.5) from becoming almost a simple average is to increase the value of \(\alpha\) used. However, this approach may be impracticable because numerical evaluation of a quantity such as \(x^n\) for any real number \(x\) generally is hampered by round-off errors and thus becomes highly inaccurate if the value of \(\alpha\) becomes too large, say 100. It is the purpose of this subsection to introduce new weighted-averaging techniques that do not have the limitation discussed above.

For motivation, note that Eqs. (4.5) and (4.6) can be expressed as

\[
(u_{x-})^2_j = w_1 x_1 + w_2 x_2
\]  

and

\[
w_1 = \frac{s_1}{s_1 + s_2} \quad \text{and} \quad w_2 = \frac{s_2}{s_1 + s_2} \quad (s_1 + s_2 > 0)
\]  

respectively if

\[
x_1 \overset{\text{def}}{=} (\bar{u}_{x-})^2_j \quad \text{and} \quad x_2 \overset{\text{def}}{=} (\bar{u}_{x+})^2_j
\]

\[
w_1 \overset{\text{def}}{=} (w_{-})^n_j \quad \text{and} \quad w_2 \overset{\text{def}}{=} (w_{+})^n_j
\]
Equation (4.7) represents an weighted average of only two values \( x_1 \) and \( x_2 \). However, for the sake of generality, weighted averages of two or more values will be considered in the following development.

To proceed, let (i) \( N \) be an integer \( \geq 2 \), (ii) \( s_\ell, \ell = 1, 2, \ldots, N \), be given positive numbers, and (iii)

\[
\begin{align*}
    w_\ell & \overset{\text{def}}{=} \frac{s_\ell}{S}, \quad \ell = 1, 2, \ldots, N \quad \text{(4.12)}
\end{align*}
\]

where

\[
S \overset{\text{def}}{=} \left( \sum_{\ell=1}^{N} s_\ell \right) > 0 \quad \text{(4.13)}
\]

(Note: to streamline the following development, here we assume that \( s_\ell > 0, \ell = 1, 2, \ldots, N \), instead of \( s_\ell \geq 0, \ell = 1, 2, \ldots, N \), as could be inferred from Eq. (4.11). However, without causing any practical harm, one can add a very small positive number, such as \( 10^{-20} \), to each member of a set of nonnegative numbers and turn all of them into positive numbers.) It follows from Eqs. (4.12) and (4.13) that

\[
\begin{align*}
    \sum_{\ell=1}^{N} w_\ell &= 1, \quad \text{and} \quad 1 > w_\ell > 0, \quad \ell = 1, 2, \ldots, N \quad \text{(4.14)}
\end{align*}
\]

As such,

\[
W \overset{\text{def}}{=} \sum_{\ell=1}^{N} w_\ell \cdot x_\ell \quad \text{(4.15)}
\]

is an “interpolated” weighted average of the real numbers \( x_\ell \). Note that, unless specified otherwise, hereafter \( \ell = 1, 2, \ldots, N \) is assumed.

Let

\[
\delta_\ell \overset{\text{def}}{=} w_\ell - \frac{1}{N} \quad \text{(4.16)}
\]

Then

\[
\begin{align*}
    w_\ell &= 1 - \frac{1}{N} + \delta_\ell \quad \text{(4.17)}
\end{align*}
\]

Also, with the aid of Eq. (4.14), Eq. (4.16) implies that

\[
\sum_{\ell=1}^{N} \delta_\ell = 0 \quad \text{(4.18)}
\]

Note that \( W \) becomes the simple average of \( x_\ell, \ell = 1, 2, \ldots, N \), if all \( \delta_\ell = 0 \). Thus the set \( \{\delta_1, \delta_2, \ldots, \delta_N\} \) provides a measure of how far the weighted average is deviated from the simple average. In the following, a simple way to adjust this deviation will be introduced.

Let

\[
\delta_{\min} \overset{\text{def}}{=} \min\{\delta_\ell\} \quad \text{and} \quad \delta_{\max} \overset{\text{def}}{=} \max\{\delta_\ell\} \quad \text{(4.19)}
\]

Then Eq. (4.17) and the fact that \( 1 > w_\ell > 0 \) for all \( \ell \) imply that

\[
1 > \frac{1}{N} + \delta_{\max} \quad \text{and} \quad \frac{1}{N} + \delta_{\min} > 0 \quad \text{(4.20)}
\]

Let some \( \delta_\ell \neq 0 \) (i.e., the case with all \( w_\ell = 1/N \) is excluded). Then Eq. (4.18) implies that \( \delta_{\max} > 0 > \delta_{\min} \). The last inequality and Eq. (4.20) can be combined to yield

\[
1 - \frac{1}{N} > \delta_{\max} > 0 > \delta_{\min} > -\frac{1}{N} \quad \text{(some \( \delta_\ell \neq 0 \)) \quad \text{(4.21)}}
\]
Note that an immediate result of Eq. (4.21) is

\[
\sigma_{\text{max}} \overset{\text{def}}{=} \min \left\{ \frac{1}{\delta_{\text{max}}^i} \left( 1 - \frac{1}{N} \right), -\frac{1}{N \delta_{\text{min}}^i} \right\} > 1
\]

(some \( \delta_i \neq 0 \))

(4.22)

Given any adjustable real parameter \( \sigma > 0 \), let

\[
\delta_i' \overset{\text{def}}{=} \sigma \delta_i
\]

(4.23)

Then Eq. (4.18) implies that

\[
\sum_{i=1}^{N} \delta_i' = 0
\]

(4.24)

In turn Eq. (4.24) and

\[
w_i' \overset{\text{def}}{=} \frac{1}{N} + \delta_i'
\]

(4.25)

imply that

\[
\sum_{i=1}^{N} w_i' = 1
\]

(4.26)

As such, \( w_i', i = 1, \ldots, N \), form a new set of weight factors. From Eqs. (4.23) and (4.25) one also concludes that the disparity of the weight factors (i.e., the deviation of the values of the weight factors from \( 1/N \)) will be amplified (reduced) if \( \sigma > 1 \) (\( \sigma < 1 \)).

The condition that

\[
1 \geq w_i' \geq 0
\]

will be imposed in the current development. With the aid of Eqs. (4.19), (4.23), and (4.25), and the original assumption that \( \sigma > 0 \), one concludes that Eq. (4.27) is true if and only if

\[
1 \geq \frac{1}{N} + \sigma \delta_{\text{max}} \quad \text{and} \quad \frac{1}{N} + \sigma \delta_{\text{min}} \geq 0
\]

(4.28)

For the special case that in which all \( \delta_i = 0 \), one has \( \delta_{\text{min}} = \delta_{\text{max}} = 0 \) and thus Eq. (4.28) is true always. On the other hand, for the case that some \( \delta_i \neq 0 \), Eqs. (4.21) and (4.22) imply that Eq. (4.28) is equivalent to

\[
\sigma_{\text{max}} \geq \sigma \quad (\text{some} \ \delta_i \neq 0)
\]

(4.29)

Let some \( \delta_i \neq 0 \). Then, according to Eq. (4.22), \( \sigma_{\text{max}} > 1 \). Moreover, \( \sigma_{\text{max}} \) increases as \( |\delta_{\text{max}}| \) and \( |\delta_{\text{min}}| \) decrease. In fact, \( \sigma_{\text{max}} \to +\infty \) as \( \delta_{\text{max}} \to 0^+ \) and \( \delta_{\text{min}} \to 0^- \). Thus the range of the values of \( \sigma \) allowed becomes larger when \( |\delta_{\text{max}}| \) and \( |\delta_{\text{min}}| \) become smaller. Note that, when \( W \) defined in Eq. (4.15) almost becomes a simple average (i.e., when \( |\delta_{\text{max}}| \ll 1 \) and \( |\delta_{\text{min}}| \ll 1 \), the disparity of the weight factors must be sharply amplified such that the weight average

\[
W' \overset{\text{def}}{=} \sum_{i=1}^{N} w_i' x_i
\]

(3.30)

will deviate substantially from the simple average. In this case, the larger range of the values of \( \sigma \) allowed meets the need to use a larger value of \( \sigma \). In practice, the value of \( \sigma \) used can be generated using a preset formula as long as the generated value is less than or equal to \( \sigma_{\text{max}} \). For the case that the value generated using the preset formula is larger than \( \sigma_{\text{max}} \), \( \sigma = \sigma_{\text{max}} \) is assumed.
As an example, consider the \( N = 2 \) case in which \( x_1 \) and \( s_1 \), \( \ell = 1,2 \), are defined by Eqs. (4.9) and (4.11). It was explained earlier that, for this case, \( w_1 \rightarrow 1/2 \) and \( w_2 \rightarrow 1/2 \) as \( \nu \rightarrow 0 \). In other words, the weighted average \( w_1x_1 + w_2x_2 \) almost becomes a simple average when \( |\nu| \ll 1 \). To prevent this from happening, the weight factors \( w_1 \) and \( w_2 \), respectively, are replaced by the new weighted factors \( w'_1 \) and \( w'_2 \) generated assuming

\[
\sigma = \min \left\{ \sigma_{\max}, \frac{\sigma_o}{|\nu|} \right\} \quad (\sigma_o > 0) \tag{4.31}
\]

where \( \sigma_o > 0 \) is a preset parameter in the order of 1. According to Eqs. (4.16), (4.19), and (4.22), the fact that \( w_1 \rightarrow 1/2 \) and \( w_2 \rightarrow 1/2 \) as \( \nu \rightarrow 0 \) implies that \( \sigma_{\max} \rightarrow \infty \) as \( \nu \rightarrow 0 \). As such Eq. (4.31) implies that \( \sigma \gg 1 \) when \( |\nu| \ll 1 \).

Note that, for any \( N = 2 \) case, one of \( \delta_1 \) and \( \delta_2 \) is \( \delta_{\max} \) while another is \( \delta_{\min} \). As a result, Eqs. (4.18), (4.20), and (4.22) imply that

\[
0 < \delta_{\max} = -\delta_{\min} < 1/2 \quad (\text{some } \delta \neq 0) \tag{4.32}
\]

and

\[
\sigma_{\max} = \frac{1}{2\delta_{\max}} \quad (\text{some } \delta \neq 0) \tag{4.33}
\]

Also for any case with \( N = 2 \), \( \delta_{\max} > 0 \) and \( \sigma = \sigma_{\max} \), Eqs. (4.23), (4.25), (4.32), and (4.33) imply that:

(i) \( w'_1 = 1 \) and \( w'_2 = 0 \) if \( \delta_1 = \delta_{\max} \), and (ii) \( w'_2 = 1 \) and \( w'_1 = 0 \) if \( \delta_2 = \delta_{\max} \).

This completes the description of a new approach by which the weight factors \( w'_1, \ldots, w'_N \), are generated from the given weight factors \( w_1, \ldots, w_N \). In the following, Another approach will be described.

To proceed, the indices of \( s_1, \ldots, s_N \), will be reshuffled such that

\[
s_N \geq s_{N-1} \geq \ldots \geq s_1 > 0 \tag{4.34}
\]

As such, Eqs. (4.12) and (4.13) imply that Eq. (4.14) can be replaced by a set of stronger conditions, i.e.,

\[
\sum_{\ell=1}^{N} w_\ell = 1 \quad \text{and} \quad 1 > w_N \geq w_{N-1} \geq \ldots \geq w_1 > 0 \tag{4.35}
\]

Next let

\[
\eta_\ell \overset{\text{def}}{=} \frac{s_{\ell+1}}{s_\ell} - 1, \quad \ell = 1, \ldots, N-1 \tag{4.36}
\]

Then (i) \( \eta_\ell \geq 0, \quad \ell = 1, \ldots, N-1 \), and (ii)

\[
s_{\ell+1} = \left[ \prod_{\ell'=1}^{\ell} (1 + \eta_{\ell'}) \right] s_1, \quad \ell = 1, \ldots, N-1 \tag{4.37}
\]

Given any adjustable real parameter \( \sigma > 0 \), let (i) \( \hat{s}_1 = s_1 \) and

\[
\hat{s}_{\ell+1} = \left[ \prod_{\ell'=1}^{\ell} (1 + \sigma \eta_{\ell'}) \right] \hat{s}_1, \quad \ell = 1, \ldots, N-1 \tag{4.38}
\]

and (ii)

\[
\hat{w}_\ell = \frac{\hat{s}_\ell}{S}, \quad \ell = 1, 2, \ldots, N \tag{4.39}
\]

NASA/TM—2005-213868
where
\[
\tilde{S} \overset{\text{def}}{=} \left( \sum_{\ell=1}^{N} \tilde{s}_\ell \right) > 0 \tag{4.40}
\]
Because \( \sigma > 0 \) and \( \eta_\ell \geq 0, \ell = 1, \ldots, N-1 \), Eq. (4.38) implies that
\[
\tilde{s}_N \geq \tilde{s}_{N-1} \geq \ldots \geq \tilde{s}_1 > 0 \tag{4.41}
\]
Also, as a result of Eqs. (4.39)–(4.41), one has
\[
\sum_{\ell=1}^{N} \tilde{w}_\ell = 1 \quad \text{and} \quad 1 > \tilde{w}_N \geq \tilde{w}_{N-1} \geq \ldots \geq \tilde{w}_1 > 0 \tag{4.42}
\]
As such, \( \tilde{w}_\ell, \ell = 1, 2, \ldots, N \), form a new set of weight factors and
\[
\tilde{W} \overset{\text{def}}{=} \sum_{\ell=1}^{N} \tilde{w}_\ell x_\ell \tag{4.43}
\]
is an “interpolated” weighted average of the real numbers \( x_\ell \). Note that, for the special case that \( s_N = s_{N-1} = \ldots = s_1 > 0 \), it is easy to see that (i) \( w_\ell = \tilde{w}_\ell = 1/N, \ell = 1, 2, \ldots, N \), and (ii) \( \eta_\ell = 0, \ell = 1, \ldots, N-1 \).

Let \( \ell_1 \) and \( \ell_2 \) be any pair of integers with \( 1 \leq \ell_1 < \ell_2 \leq N \). Then Eqs. (4.12) and (4.37)–(4.39) imply that
\[
\frac{w_{\ell_2}}{w_{\ell_1}} = \prod_{\ell' = \ell_1}^{\ell_2-1} (1 + \eta_{\ell'}) \tag{4.44}
\]
and
\[
\frac{\tilde{w}_{\ell_2}}{\tilde{w}_{\ell_1}} = \prod_{\ell' = \ell_1}^{\ell_2-1} (1 + \sigma \eta_{\ell'}) \tag{4.45}
\]
Because \( \sigma > 0 \) and \( \eta_\ell \geq 0, \ell = 1, \ldots, N-1 \), a comparison of Eqs. (4.44) and (4.45) reveals that \( w_{\ell_2}/w_{\ell_1} = \tilde{w}_{\ell_2}/\tilde{w}_{\ell_1} = 1 \) if \( \eta_\ell = 0 \) for all \( \ell \) with \( \ell_1 \leq \ell \leq (\ell_2 - 1) \). However, in case that \( \eta_\ell \neq 0 \) for at least one \( \ell \) with \( \ell_1 \leq \ell \leq (\ell_2 - 1) \), one has
\[
\begin{cases}
\frac{\tilde{w}_{\ell_2}}{\tilde{w}_{\ell_1}} > \frac{w_{\ell_2}}{w_{\ell_1}} & \text{if } \sigma > 1 \\
\frac{\tilde{w}_{\ell_2}}{\tilde{w}_{\ell_1}} < \frac{w_{\ell_2}}{w_{\ell_1}} & \text{if } \sigma < 1 \\
\frac{\tilde{w}_{\ell_2}}{\tilde{w}_{\ell_1}} = \frac{w_{\ell_2}}{w_{\ell_1}} & \text{if } \sigma = 1
\end{cases} \tag{4.46}
\]
From the above discussions, one concludes that, except for the special case in which \( s_N = s_{N-1} = \ldots = s_1 > 0 \), the disparity of \( \tilde{w}_\ell \) is greater (less) than that of \( w_\ell \) if \( \sigma > 1 \) (\( \sigma < 1 \)). Note that the current approach for amplifying the weight factors has one advantage over the approach described earlier, i.e., in the current approach, there is no upper bound for the value of \( \sigma \) one could use. Thus, in the current approach, Eq. (4.31) can be simplified as
\[
\sigma = \frac{\sigma_o}{|\nu|} \tag{4.47}
\]
where \( \sigma_o > 0 \) again is a preset parameter in the order of 1.

Note that, after sorting through the differences in the notations used in [49] and here, and using the fact that the value of the smaller of the parameters \( (s_-)^n \) and \( (s_+)^n \) defined in Eq. (3.23) of [50] is zero, it can be shown that the weighted-averaging technique introduced in Eqs. (3.23), (3.26), and (3.27) of [50] is equivalent to the special case \( N = 2 \) and \( \sigma_o = 1/2 \) of the second approach just described above.
Consider the $N = 2$ case in which $x \cdot s = 1, 2, a$ are defined by Eqs. (4.9) and (4.11). Let $(w'_j)_n$, and $(w'_{+j})_n$, respectively, be the weight factors associated with $(\tilde{u}_{x-})_j^n$ and $(\tilde{u}_{x+})_j^n$ generated using the first approach described in Sec. 4.3. Then, by definition, Scheme w-3 is formed by Eq. (2.8) and

\begin{equation}
(u_x)_j^n = (w'_j)_n(\tilde{u}_{x-})_j^n + (w'_{+j})_n(\tilde{u}_{x+})_j^n
\end{equation}

(4.48)

On the other hand, let $(\tilde{w}_{-})_j^n$ and $(\tilde{w}_{+})_j^n$, respectively, be the weight factors associated with $(\tilde{u}_{x-})_j^n$ and $(\tilde{u}_{x+})_j^n$ generated using the second approach described in Sec. 4.3. Then, by definition, Scheme w-4 is formed by Eq. (2.8) and

\begin{equation}
(u_x)_j^n = (\tilde{w}_{-})_j^n(\tilde{u}_{x-})_j^n + (\tilde{w}_{+})_j^n(\tilde{u}_{x+})_j^n
\end{equation}

(4.49)

5. Courant number and Mach number insensitive solvers

We consider a dimensionless form of the 1-D unsteady Euler equations of a perfect gas. Let $\rho, v, p, \gamma$ be the mass density, velocity, static pressure, and constant specific heat ratio, respectively. Let

\begin{align*}
\begin{align*}
u_1 &= \rho, & \nu_2 &= \rho v, & \nu_3 &= p/(\gamma - 1) + (1/2)\rho v^2 \\
f_1 &= \nu_2 \\
f_2 &= (\gamma - 1)\nu_3 + (1/2)(3 - \gamma)(\nu_2)^2/\nu_1 \\
&= \nu_3 + (1/2)(3 - \gamma)(\nu_2)^2/\nu_1 \\
f_3 &= \gamma\nu_2\nu_3/\nu_1 - (1/2)(\gamma - 1)(\nu_2)^3/(\nu_1)^2
\end{align*}
\end{align*}

Then the Euler equations can be expressed as

\begin{equation}
\frac{\partial \nu_m}{\partial t} + \frac{\partial f_m}{\partial x} = 0, \quad m = 1, 2, 3
\end{equation}

(5.5)

The integral form of Eq. (5.5) in space-time $E_2$ is

\begin{equation}
\int_{S(V)} \tilde{h}_m \cdot d\tilde{s} = 0, \quad m = 1, 2, 3
\end{equation}

(5.6)

where $\tilde{h}_m = (f_m, u_m), m = 1, 2, 3$, are the space-time mass, momentum, and energy current density vectors, respectively.

As a preliminary, let

\begin{equation}
f_{m,k} \overset{\text{def}}{=} \frac{\partial f_m}{\partial u_k}, \quad m, k = 1, 2, 3
\end{equation}

(5.7)

Let $F$ be the Jacobian matrix formed by $f_{m,k}, m, k = 1, 2, 3$. Then Eqs. (5.2)–(5.4) imply that

\begin{equation}
F = \begin{pmatrix}
0 & 1 & 0 \\
(\gamma - 3/2)\left(\frac{u_2}{u_1}\right)^2 & (3 - \gamma)\frac{u_2}{u_1} & \gamma - 1 \\
(\gamma - 1)\left(\frac{u_2}{u_1}\right)^3 - \gamma\frac{u_2\nu_3}{u_1^2} & \gamma\frac{\nu_3}{u_1} - \frac{3(\gamma - 1)}{2}\left(\frac{u_2}{u_1}\right)^2 & \gamma\frac{u_2}{u_1}
\end{pmatrix}
\end{equation}

(5.8)

Let $c$ be the sonic speed. Then

\begin{equation}
c = \sqrt{\gamma(\gamma - 1)\left[\frac{\nu_3}{u_1} - \frac{1}{2}\left(\frac{u_2}{u_1}\right)^2\right]}
\end{equation}

(5.9)
Let $G$ be the $3 \times 3$ matrix defined by

$$
G \overset{\text{def}}{=} \begin{pmatrix}
1 & \frac{u_1}{\sqrt{2c}} & \frac{u_1}{\sqrt{2c}} \\
\frac{u_2}{u_1} & \frac{u_2}{\sqrt{2c}} - \frac{u_1}{\sqrt{2}} & \frac{u_2}{\sqrt{2c}} + \frac{u_1}{\sqrt{2}} \\
\left(\frac{u_2}{u_1}\right)^2 & \frac{(u_2)^2}{2\sqrt{2cu_1}} - \frac{u_2}{\sqrt{2}} + \frac{u_1c}{\sqrt{2}(\gamma - 1)} & \frac{(u_2)^2}{2\sqrt{2cu_1}} + \frac{u_2}{\sqrt{2}} + \frac{u_1c}{\sqrt{2}(\gamma - 1)}
\end{pmatrix}
$$

Then the inverse of $G$ is given by

$$
G^{-1} = \begin{pmatrix}
1 + \frac{1 - \gamma}{c^2u_1} & \frac{(\gamma - 1)u_2}{c^2} & \frac{1 - \gamma}{c^2} \\
\frac{(\gamma - 1)(u_2)^2}{2\sqrt{2c}(u_1)^3} + \frac{u_2}{\sqrt{2}} + \frac{(\gamma - 1)u_2}{c^2u_1} & \frac{(1 - \gamma)u_2}{\sqrt{2c}(u_1)^2} - \frac{1}{\sqrt{2u_1}} & \gamma - 1 \\
\frac{(\gamma - 1)(u_2)^2}{2\sqrt{2c}(u_1)^3} - \frac{u_2}{\sqrt{2}} + \frac{(\gamma - 1)u_2}{c^2u_1} & \frac{(1 - \gamma)u_2}{\sqrt{2c}(u_1)^2} + \frac{1}{\sqrt{2u_1}} & \gamma - 1
\end{pmatrix}
$$

Moreover, for any numbers $a_1, a_2, \ldots, a_n$, let $\text{diag}(a_1, a_2, \ldots, a_n)$ denote the diagonal matrix with $a_1, a_2, \ldots, a_n$ being the diagonal elements on the first, second, ..., and $n$-th rows, respectively. Then, by using Eqs. (5.8)–(5.11) and $v = u_2/u_1$, one has

$$
G^{-1}F = \text{diag}(v, v - c, v + c)
$$

For any $(j, n) \in \Omega$ and any $(x, t) \in \text{SE}(j, n)$, $u_m(x, t)$, $f_m(x, t)$, and $\tilde{h}_m(x, t)$ are approximated by

$$
u_m^*(x, t; j, n) = (u_m)_j^n + (u_{mx})_j^n(x - x_j) + (u_{mt})_j^n(t - t^n)
$$

where $(u_m)_j^n$, $(u_{mx})_j^n$, and $(u_{mt})_j^n$ are constants in $\text{SE}(j, n)$.

By definition, for each $m = 1, 2, 3$ and each $k = 1, 2, 3$, $f_m$ and $f_{m,k}$ are functions of $u_1, u_2$ and $u_3$. Let $(f_m)_j^n$ and $(f_{m,k})_j^n$ denote the values of $f_m$ and $f_{m,k}$, respectively, when the independent variables $u_1, u_2$, and $u_3$, respectively, assume the values of $(u_1)_j^n$, $(u_2)_j^n$, and $(u_3)_j^n$. Let

$$
(f_m)_j^n \overset{\text{def}}{=} \sum_{k=1}^{3} (f_{m,k})_j^n (u_{kx})_j^n
$$

and

$$
(f_{mt})_j^n \overset{\text{def}}{=} \sum_{k=1}^{3} (f_{m,k})_j^n (u_{kt})_j^n
$$

Because

$$
\frac{\partial f_m}{\partial x} = \sum_{k=1}^{3} f_{m,k} \frac{\partial u_k}{\partial x}
$$

and

$$
\frac{\partial f_m}{\partial t} = \sum_{k=1}^{3} f_{m,k} \frac{\partial u_k}{\partial t}
$$
\((f_{mx})^n_j\) and \((f_{mt})^n_j\) can be considered as the numerical analogues of the values of \(\partial f_m/\partial x\) and \(\partial f_m/\partial t\) at \((x, t^n)\), respectively. As a result, we assume that

\[
f^*_m(x, t; j, n) \equiv (f_m)_j^n + (f_{mx})_j^n(x - x_j) + (f_{mt})_j^n(t - t^n) \tag{5.18}
\]

Because \(\tilde{h}_m = (f_m, u_m)\), we also assume that

\[
\tilde{h}_m^*(x, t; j, n) \equiv (f_m^*(x, t; j, n), u_m^*(x, t; j, n)) \tag{5.19}
\]

Note that, by their definitions, (i) \((f_m)_j^n\) and \((f_{mx})_j^n\), \(m = 1, 2, 3\), are functions of \((u_m)_j^n\), \(m = 1, 2, 3\), (ii) \((f_{mx})_j^n\), \(m = 1, 2, 3\), are functions of \((u_m)_j^n\) and \((u_{mx})_j^n\), \(m = 1, 2, 3\), and (iii) \((f_{mt})_j^n\) are functions of \((u_m)_j^n\) and \((u_{mt})_j^n\), \(m = 1, 2, 3\).

Moreover we assume that, for any \((x, t) \in \text{SE}(j, n)\), \(u_m = u_m^*(x, t; j, n)\) and \(f_m = f_m^*(x, t; j, n)\) satisfy Eq. (5.5), i.e.,

\[
\frac{\partial u_m^*(x, t; j, n)}{\partial t} + \frac{\partial f_m^*(x, t; j, n)}{\partial x} = 0 \tag{5.20}
\]

According to Eqs. (5.13) and (5.18), Eq. (5.20) is equivalent to

\[
(u_{mt})_j^n = -(f_{mx})_j^n \tag{5.21}
\]

Because \((f_{mx})_j^n\) are functions of \((u_m)_j^n\) and \((u_{mx})_j^n\), Eq. (5.21) implies that \((u_{mt})_j^n\) are also functions of \((u_m)_j^n\) and \((u_{mx})_j^n\). From this result and the facts stated following Eq. (5.19), one concludes that the only independent discrete variables needed to be solved in the current marching scheme are \((u_m)_j^n\) and \((u_{mx})_j^n\).

In the current development, the Euler counterpart of Eq. (2.11), i.e.,

\[
\int_{\text{S(\text{CE}(j, n))}} \tilde{h}_m^* \cdot d\vec{s} = 0 \tag{5.22}
\]

is assumed. For any \((j, n) \in \Omega\), let

\[
(u_{m\bar{x}})_j^n \equiv \frac{\Delta x}{4}(u_{mx})_j^n \tag{5.23}
\]

and

\[
(s_m)_j^n \equiv (u_{m\bar{x}})_j^n + \frac{\Delta t}{\Delta x}(f_m)_j^n + \frac{(\Delta t)^2}{4\Delta x}(f_{mt})_j^n \tag{5.24}
\]

Then, with the aid of Eqs. (5.13)–(5.15), (5.18), (5.19), and (5.21), Eq. (5.22) implies that

\[
(u_m)_j^n = \frac{1}{2} \left[ (u_{m\bar{x}})_j^{n-1/2} + (u_{m\bar{x}})_j^{n+1/2} + (s_m)_j^{n-1/2} - (s_m)_j^{n+1/2} \right] \tag{5.25}
\]

Eq. (5.25) forms the first component of each of the Euler schemes to be constructed here. As will be shown, the second component which evaluates \((u_{m\bar{x}})_j^n\) is scheme dependent.

### 5.1. The Euler \(\alpha-\tau\) scheme

To proceed, consider any \((j, n) \in \Omega\). Let \(\vec{u}, \vec{u}_m^n, (\vec{u}_x)_m^n, (\vec{u}_x)_m^n\), and \((\vec{u}_t)_m^n\), respectively, denote the column matrices formed by \((u_m)_j^n\), \((u_{mx})_j^n\), \((u_{m\bar{x}})_j^n\), \((u_{mt})_j^n\), \(m = 1, 2, 3\). Moreover, recall that the fluid velocity \(v\), the sonic speed \(c\) and the matrices \(F, G,\) and \(G^{-1}\) are functions of \(u_m\), \(m = 1, 2, 3\). Thus we will define \(v_m^n, c_m^n, F_m^n, G_m^n,\) and \((G^{-1})_m^n\), respectively, to be the values of \(v\), \(c\), \(F\), \(G\), and \((G^{-1})\) when the independent variables \(u_m\), \(m = 1, 2, 3\), respectively, assume the values of \((u_m)_j^n\), \(m = 1, 2, 3\). Given the above definitions, let

\[
(v_1)_j^n \equiv \frac{v_m^n \Delta t}{\Delta x}, \quad (v_2)_j^n \equiv \frac{(v - c)_m^n \Delta t}{\Delta x}, \quad \text{and} \quad (v_3)_j^n \equiv \frac{(v + c)_m^n \Delta t}{\Delta x} \tag{5.26}
\]
and
\[(\nu_{max})^n_j \overset{\text{def}}{=} (|\nu_1^n_j| + |c_j^n_t|) \frac{\Delta t}{\Delta x}\] (5.27)

Because
\[(\nu_{max})^n_j = \max\{|(\nu_1^n_j)|, |(\nu_2^n_j)|, |(\nu_3^n_j)|\}\] (5.28)

\[(\nu_{max})^n_j\] can be interpreted as the Courant number at the mesh point \((j,n)\).

Next, for each \(m = 1, 2, 3\), let the points \(P^+_m\) and \(P^-_m\), and the parameter \((\tau_m)^n_j\) shown in Fig. 5 be defined in the exact same manner by which the points \(P^+\) and \(P^-\), and the parameter \(\tau\) were defined (see Fig. 3). Moreover, let (i) \([\vec{B}]_m\) denote the \(m\)th component of any column matrix \(\vec{B}\), (ii)
\[
[(G^{-1})^n_j \vec{u}]_m (P^+_m) \overset{\text{def}}{=} [(G^{-1})^n_j \vec{u}^{n-1/2}]_m + \frac{(\Delta t/2)}{\Delta t} [(G^{-1})^n_j (\vec{u}_t)]_m^{n-1/2} - [1 - (\tau_m)]_m^n [(G^{-1})^n_j (\vec{u}_x)]_m^{n-1/2}
\] (5.29)

and (iii)
\[
[(G^{-1})^n_j \vec{u}]_m (P^-_m) \overset{\text{def}}{=} [(G^{-1})^n_j \vec{u}^{n-1/2}]_m + \frac{(\Delta t/2)}{\Delta t} [(G^{-1})^n_j (\vec{u}_t)]_m^{n-1/2} + [1 - (\tau_m)]_m^n [(G^{-1})^n_j (\vec{u}_x)]_m^{n-1/2}
\] (5.30)

Note that, in the current development of the procedures for evaluating \((G^{-1})^n_j\), \((G^{-1})^n_j\) is treated as a fixed constant square matrix for any given fixed \((j,n) \in \Omega\) while \(\vec{u}\) is treated as a variable column matrix (this practice, in spirit, is similar to the definition of \(u^*(x,t;j,n)\) given in Eq. (2.3)) where \(u^n_j\), \((u_x)_j^n\), and \((u_t)_j^n\) are treated as constants while \(x\) and \(t\) are treated as variables. Thus
\[
\frac{\partial [(G^{-1})^n_j \vec{u}]_m}{\partial t} = [(G^{-1})^n_j \vec{u}^{n-1/2}]_m \quad \text{and} \quad \frac{\partial [(G^{-1})^n_j \vec{u}]_m}{\partial x} = [(G^{-1})^n_j \vec{u}^{n-1/2}]_m \] (5.31)

It follows that \(\frac{\partial [(G^{-1})^n_j (\vec{u}_t)]_m^{n-1/2}}{\partial t}\) and \(\frac{\partial [(G^{-1})^n_j (\vec{u}_x)]_m^{n-1/2}}{\partial x}\) at the mesh point \((j \pm 1/2, n - 1/2)\). With the aid of this interpretation, Eqs. (5.23), (5.29), and (5.30) imply that \([(G^{-1})^n_j \vec{u}]_m (P^+_m)\) is a first-order Taylor’s approximation of \([(G^{-1})^n_j \vec{u}]_m\) at point \(P^+_m\) evaluated using the marching variables at the mesh point \((j + 1/2, n - 1/2)\) while \([(G^{-1})^n_j \vec{u}]_m (P^-_m)\) is a first-order Taylor’s approximation of \([(G^{-1})^n_j \vec{u}]_m\) at point \(P^-_m\) evaluated using the marching variables at the mesh point \((j - 1/2, n - 1/2)\). As such, Eqs. (5.29) and (5.30) can be considered as the Euler versions of Eqs. (3.4) and (3.5), respectively. In the following, we will construct the Euler versions of Eqs. (3.6)–(3.9).

By using Eqs. (5.14), (5.21), and (5.23), one has
\[
(\Delta t/2)(G^{-1})^n_j (\vec{u}_t)_j^{n-1/2} = -2(\Delta t/\Delta x)(G^{-1})^n_j F_j^{n-1/2} G_j^n (G^{-1})^n_j (\vec{u}_x)_j^{n-1/2}
\] (5.32)

Let \(G_j^{n-1/2} \approx G_j^n\). Then Eqs. (5.12) and (5.26) imply that
\[
\frac{\Delta t}{\Delta x}(G^{-1})^n_j F_j^{n+1/2} G_j^n \approx \frac{\Delta t}{\Delta x}(G^{-1})^n_j F_j^n G_j^n = \text{diag}(\nu_1^n_j, \nu_2^n_j, \nu_3^n_j)
\] (5.33)

Combining Eqs. (5.32) and (5.33), one has
\[(\Delta t/2) \left[ (G^{-1})^n_j (\vec{u}_t)_j^{n-1/2} \right]_m \approx -2(\nu_m)_j \left[ (G^{-1})^n_j (\vec{u}_x)_j^{n-1/2} \right]_m
\] (5.34)

Substituting Eq. (5.34) into Eqs. (5.29) and (5.30), one arrives at the current Euler versions of Eqs. (3.6) and (3.7), i.e.,
\[
[(G^{-1})^n_j \vec{u}]_m (P^+_m) \approx \left[ (G^{-1})^n_j \vec{u}^{n-1/2} \right]_m - [2(\nu_m)_j + 1 - (\tau_m)]_m^n \left[ (G^{-1})^n_j (\vec{u}_x)_j^{n-1/2} \right]_m
\] (5.35)
and
\[
[(G^{-1})^n_j \bar{u}]_m (P_m) \approx \left[ (G^{-1})^n_j \bar{u} \right]_{j-1/2}^m - 2(\nu_j)^n - 1 + (\tau_j)^n \left[ (G^{-1})^n_j (\bar{u}_x)_{j-1/2} \right]_m
\]
(5.36)

Next we introduce the Euler version of Eq. (3.8), i.e.,
\[
\left[ (G^{-1})^n_j \bar{u} \right]_m (j, n) \overset{\text{def}}{=} \frac{\Delta x}{4} \left[ (G^{-1})^n_j \bar{u} \right]_{m-1} - \frac{(G^{-1})^n_j \bar{u}}{1 + (\tau_j)^n \Delta x/2} P_m^- \quad ((\tau_j)^n \neq -1), \ m = 1, 2, 3
\]
(5.37)
where \( \left[ (G^{-1})^n_j \bar{u} \right]_m (P_m^+) \) and \( \left[ (G^{-1})^n_j \bar{u} \right]_m (P_m^-) \), respectively, are to be evaluated using Eqs. (5.29) and (5.30) instead of the approximated formulae Eqs. (5.35) and (5.36). With the aid of Fig. 5, Eq. (5.37) implies that \( \left[ (G^{-1})^n_j \bar{u} \right]_m (j, n) \) is a central-difference approximation of \( \frac{\partial}{\partial x} \left[ (G^{-1})^n_j \bar{u} \right]_m / \partial x \) at the mesh point \((j, n)\).

To proceed, note that
\[
\frac{\partial}{\partial x} \left[ (G^{-1})^n_j \bar{u} \right]_m (j, n) = (G^{-1})^n_j \frac{\partial \bar{u}}{\partial x}
\]
(5.38)
Thus
\[
\frac{\partial \bar{u}}{\partial x} = G^n_j \frac{\partial \left[ (G^{-1})^n_j \bar{u} \right]}{\partial x}
\]
(5.39)
Let \( \left[ (G^{-1})^n_j \bar{u} \right]_m (j, n) \) be the column matrix formed by \( \left[ (G^{-1})^n_j \bar{u} \right]_m (j, n), m = 1, 2, 3 \) (which are defined in Eq. (5.37)). Then, with the aid of Eq. (5.39), one concludes that
\[
\left[ \bar{u} \left( \bar{u}_x \right)^n \right]_{j} = G^n_j \left\{ \left[ (G^{-1})^n_j \bar{u} \right]_m (j, n) \right\}
\]
(5.40)
represents a central difference approximation of \( \frac{\partial \bar{u}}{\partial x} / \partial x \) at the mesh point \((j, n)\). Thus
\[
(\bar{u}_x)^n_j = (\bar{u}_x)^n_j
\]
(5.41)
is an Euler version of Eq. (3.9). The Euler c-\( \tau \) scheme is defined by Eqs. (5.25), (5.29), (5.30), (5.37), (5.40) and (5.41). It has been shown by numerical experiments that stability of this scheme generally requires that
\[
(\nu_{\text{max}})^n_j < 1; \quad \text{and} \quad (\nu_j)^n < \tau_o \left( (\nu_j)^n_j \right)^2 \quad ((j, n) \in \Omega), \ m = 1, 2, 3
\]
(5.42)
Obviously, the form of Eq. (5.42) is very similar to that of Eq. (3.12).

Consider the special case in which \((\tau_j)^n_j = (\tau_j)^n_2 = (\tau_j)^n_3 \neq \tau^n_j\). For this case, (i) points \(P_1^+, P_2^+, P_3^+\) coincide (the resulting common point will be denoted by \(P^+\)); and (ii) points \(P_1^-, P_2^-, P_3^-\) also coincide (the resulting common point will be denoted by \(P^-\)). As such it can be shown easily that Eqs. (5.29) and (5.30) reduce to
\[
\bar{u}(P^+) = \left[ \bar{u} + (\Delta t / 2) \bar{u}_t - (1 - \tau^n_j) \bar{u}_x \right]_{j+1/2}^{n-1/2}
\]
(5.43)
and
\[
\bar{u}(P^-) = \left[ \bar{u} + (\Delta t / 2) \bar{u}_t + (1 - \tau^n_j) \bar{u}_x \right]_{j-1/2}^{n-1/2}
\]
(5.44)
respectively. Also Eqs. (5.37) and (5.40) can be used to conclude that
\[
(\bar{u}_x)^n_j \overset{\text{def}}{=} \frac{\bar{u}(P^+) - \bar{u}(P^-)}{2(1 + \tau^n_j)} \quad (\tau^n_j \neq -1)
\]
(5.45)
Note that: (i) with the aid of Eq. (5.28) and the fact that \(\tau_o(s)\) is strictly monotonically increasing in the interval \(0 < s < 1\), one concludes that Eq. (5.42) reduces to
\[
(\nu_{\text{max}})^n_j < 1; \quad \text{and} \quad \tau^n_j \geq \tau_o \left( (\nu_{\text{max}})^n_j \right)^2 \quad ((j, n) \in \Omega)
\]
(5.46)
for this special case; and (ii) Eqs. (3.4), (3.5), and (3.8), respectively, are very similar to their Euler versions Eqs. (5.43)–(5.45).

The above simplified scheme has the advantage in its structural simplicity. However, it suffers from the loss of the capability to adjust the value of individual \((\tau_m)_j^n\). This is a serious disadvantage because the theory presented in Sec. 3 along with the fact that Eqs. (3.6) and (3.7), respectively, are very much similar to Eqs. (5.35) and (5.36) in algebraic form strongly suggests that the Euler c-\(\tau\) scheme will perform better if, for each \(m\), the value of \((\tau_m)_j^n\) can be adjusted to match the value of \(\tau_o\left((\nu_m)_j^n\right)^2\). This is particularly true if, for some \((j, n) \in \Omega\), there is a large disparity among the values of \(|(\nu_m)_j^n|\), \(m = 1, 2, 3\), i.e.,

\[
(\nu_{max})_j^n \gg \min\{|(\nu_1)_j^n|, |(\nu_2)_j^n|, |(\nu_3)_j^n|\}
\]  

(5.47)

As an example, consider an Euler flow solution with an extremely small Mach number everywhere (i.e., \(|v_j^n| \ll |c_j^n|\), \((j, n) \in \Omega\)). For such a case (see Eqs. (5.26)–(5.28)),

\[
|\nu_1)_j^n| \ll (\nu_{max})_j^n \approx |(\nu_2)_j^n| \approx |(\nu_3)_j^n| \quad ((j, n) \in \Omega)
\]  

(5.48)

As such, Eqs. (3.13) and (5.46) can be used to show that

\[
\tau_o\left((\nu_j)_j^n\right)^2 \ll \tau_j^n
\]  

(5.49)

Because the c-\(\tau\) scheme tends to become more dissipative as the value of \(\tau\) increases from \(\tau_o(\nu^2)\) (see comment (b) given following Eq. (3.14)), the fact that Eqs. (5.35) and (5.36), respectively, are very much similar to Eqs. (3.6) and (3.7) in algebraic form strongly suggests that the component \([\left[(G^{-1})_j^n \bar{u}\right]]\) will become highly dissipative under the condition Eq. (5.49). As such, one expects that a solution to the simplified Euler c-\(\tau\) scheme would become highly dissipative at a region with a small Mach number.

5.2. The Euler c-\(\tau^*\) schemes

Let \(h_m(s)\) \((0 \leq s < 1), m = 1, 2, 3\), be strictly monotonically increasing smooth functions which satisfy the current version of Eq. (3.15), i.e.,

\[
h_m(0) = 0; \lim_{s \rightarrow 1^{-}} h_m(s) = 1; \text{ and } h_m(s) \geq \tau_o(s) \text{ if } 0 < s < 1, \quad m = 1, 2, 3
\]  

(5.50)

Then, based on the similarity in form that existed between Eqs. (3.6)–(3.8) and Eqs. (5.35)–(5.37), an ideal Euler c-\(\tau^*\) scheme can be formed as a special Euler c-\(\tau\) scheme in which

\[
(\tau_m)_j^n = h_m\left((\nu_m)_j^n\right)^2 \quad (|(\nu_m)_j^n| < 1), \quad m = 1, 2, 3
\]  

(5.51)

Obviously, Eq. (5.51) is the Euler version of Eq. (3.16).

For the same reason that justifies the use of the relation Eq. (3.22), a special Euler c-\(\tau^*\) scheme can be defined as a special Euler c-\(\tau\) scheme in which

\[
(\tau_m)_j^n = \beta_m^n |(\nu_m)_j^n| \quad ((\beta_m)_j^n \geq 1; |(\nu_m)_j^n| < 1), \quad m = 1, 2, 3
\]  

(5.52)

Here \((\beta_m)_j^n \geq 1, m = 1, 2, 3\), are adjustable parameters which may vary from one mesh point to another.

Corresponding to the simplified Euler c-\(\tau\) scheme defined by Eqs. (5.25), (5.41), and (5.43)–(5.45), one can construct an Euler c-\(\tau^*\) scheme in which

\[
\tau_j^n = h\left((\nu_{max})_j^n\right)^2 \quad (|(\nu_{max})_j^n| < 1)
\]  

(5.53)

where \(h(s)\) \((0 \leq s < 1)\) is any strictly monotonically increasing smooth function which satisfies Eq. (3.15). Obviously, we can also construct another scheme in which

\[
\tau_j^n = \beta_j^n |(\nu_{max})_j^n| \quad (\beta_j^n \geq 1; |(\nu_{max})_j^n| < 1)
\]  

(5.54)
Here $\beta_j^n \geq 1$ is an adjustable parameter which may vary from one mesh point to another.

### 5.3. Other Euler extensions

Let
\[
[(G^{-1})^n_j \bar{u}]_{m \bar{x}^-} (j, n) \overset{\text{def}}{=} \frac{\Delta x}{4} \left[ (G^{-1})^n_j \bar{u}]_{m} - [(G^{-1})^n_j \bar{u}]_{m} (P^-) \right]
\]
and
\[
[(G^{-1})^n_j \bar{u}]_{m \bar{x}^+} (j, n) \overset{\text{def}}{=} \frac{\Delta x}{4} \left[ (G^{-1})^n_j \bar{u}]_{m} (P^+) - [(G^{-1})^n_j \bar{u}]_{m} \right]
\]

By definition, $[(G^{-1})^n_j \bar{u}]_{m \bar{x}^-} (j, n)$ and $[(G^{-1})^n_j \bar{u}]_{m \bar{x}^+} (j, n)$ are two one-sided difference approximations of $\partial [(G^{-1})^n_j \bar{u}]_{m \bar{x}} / \partial \bar{t}$ at the mesh point $(j, n)$ with one being evaluated from the left and another from the right. Let $(\tau_m)_j^n$ be defined using either Eq. (5.51) or Eq. (5.52). Then, for each $m$, one can define $[(G^{-1})^n_j \bar{u}]_{m \bar{x}}^w (j, n)$ to be an weighted average of $[(G^{-1})^n_j \bar{u}]_{m \bar{x}^-} (j, n)$ and $[(G^{-1})^n_j \bar{u}]_{m \bar{x}^+} (j, n)$ using any weighted-averaging technique described in Sec. 4. As an example, an weighted average constructed using the second approach described in sec. 4.3 with $N = 2$ is given by

\[
[(G^{-1})^n_j \bar{u}]_{m \bar{x}}^w (j, n) \overset{\text{def}}{=} \frac{[1 + \sigma_m \eta_{m-}]_j^n [(G^{-1})^n_j \bar{u}]_{m \bar{x}^-} (j, n) + [1 + \sigma_m \eta_{m+}]_j^n [(G^{-1})^n_j \bar{u}]_{m \bar{x}^+} (j, n)}{2 + \sigma_m (\eta_{m-} + \eta_{m+})}_j^n (5.57)
\]

Here
\[
(\eta_{m \pm})_j^n \overset{\text{def}}{=} \frac{\min \left\{ \left|[G^{-1})^n_j \bar{u}]_{m \bar{x}^-} (j, n) \right|, \left|[G^{-1})^n_j \bar{u}]_{m \bar{x}^+} (j, n) \right| \right\}}{\left|[G^{-1})^n_j \bar{u}]_{m \bar{x}^-} (j, n) \right|} - 1 \geq 0
\]

and
\[
(\sigma_m)_j^n \overset{\text{def}}{=} \frac{\sigma_o}{|\nu_m|}_j^n (5.59)
\]

with $\sigma_o > 0$ being a preset number in the order of 1. Note that: (i) for each $(j, n) \in \Omega$, the value of the smaller of $(\eta_{m+})_j^n$ and $(\eta_{m-})_j^n$ is zero; and (ii) to avoid dividing by zero, in practice, a small positive number such that $10^{-60}$ should be added to each of the denominators that appear in Eqs. (5.58) and (5.59).

Let $[(G^{-1})^n_j \bar{u}]_{m \bar{x}}^w (j, n)$ be the column matrix formed by $[(G^{-1})^n_j \bar{u}]_{m \bar{x}}^w (j, n)$, $m = 1, 2, 3$ (which are defined in Eq. (5.57)). Then, with the aid of Eq. (5.39), one concludes that

\[
[(G^{-1})^n_j \bar{u}]_{m \bar{x}}^w (j, n) \overset{\text{def}}{=} G_j^n \left\{ [(G^{-1})^n_j \bar{u}]_{m \bar{x}}^w (j, n) \right\}
\]

represents an weighted-averaging approximation of $\partial \bar{u} / \partial \bar{x}$ at the mesh point $(j, n)$. Thus an Euler weighted-averaging $c-\tau^*$ scheme can be formed by Eq. (5.25) and

\[
[(\bar{u})_{m \bar{x}}^w]_j^n = (\bar{u})_{m \bar{x}}^w
\]

For the simplified case in which $(\tau_1)_j^n = (\tau_2)_j^n = (\tau_3)_j^n = (\tau_3)_j^n$, Eqs. (5.55) and (5.56) are replace by

\[
(\bar{u})_{m \bar{x}^-} \overset{\text{def}}{=} \frac{\bar{u}_{j-1} - \bar{u}(P^-)}{1 + \tau_j^n}
\]

and

\[
(\bar{u})_{m \bar{x}^+} \overset{\text{def}}{=} \frac{\bar{u}(P^+) - \bar{u}_j}{1 + \tau_j^n}
\]
Moreover, for a reason given immediately following Eq. (5.49), one would expect that a solution to such a
second approach described in Sec. 4.3 is given by
\[ (u_{m\bar{x}}^w)^n_j \overset{\text{def}}{=} \frac{\left[ 1 + \sigma^n_j (\eta_{m-})^n_j \right] (u_{m\bar{x}+})^n_j + \left[ 1 + \sigma^n_j (\eta_{m+})^n_j \right] (u_{m\bar{x}-})^n_j}{\left[ 2 + \sigma (\eta_{m-} + \eta_{m+}) \right]^n_j} \] (5.64)

Here
\[ (\eta_{m\pm})^n_j \overset{\text{def}}{=} \frac{|(u_{m\bar{x}\pm})^n_j|}{\min\{|(u_{m\bar{x}+})^n_j|, |(u_{m\bar{x}-})^n_j|\}} - 1 \geq 0 \] (5.65)

and
\[ \sigma^n_j \overset{\text{def}}{=} \frac{\sigma_o}{(\nu_{\text{max}})^n_j} \] (5.66)

with \( \sigma_o \) being a preset number in the order of 1. Obviously a simplified Euler weighted-averaging \( c-\tau^* \) scheme can again be formed using Eqs. (5.25) and (5.61) if \((u_{m\bar{x}}^w)^n_j\) denotes the column matrix formed by \((u_{m\bar{x}}^w)^n_j, m = 1, 2, 3.\)

Accuracy of two special Euler \( c-\tau^* \) schemes will be evaluated in Sec. 6. The first is a simplified scheme in
which we assume that
\[ |(\nu_{\text{max}})^n_j| < 1; \quad \tau^n_j = \beta |\nu_{\text{max}}|; \quad \text{and} \quad \sigma^n_j = \frac{\sigma_o}{(\nu_{\text{max}})^n_j} \] \( (j, n) \in \Omega \) (5.67)

Note that: (i) \( \beta \geq 1 \) and \( \sigma_o > 0 \) are preset numbers in the order of 1; and (ii) the mesh point dependent
parameter \( \beta^n_j \) which appears in Eq. (5.54) is replaced by the mesh point independent parameter \( \beta \) here.
Moreover, for a reason given immediately following Eq. (5.49), one would expect that a solution to such a
simplified scheme becomes highly dissipative at a region with a small Mach number, i.e., \( \text{the scheme is Mach number sensitive}. \) Therefore, the first scheme will be referred to as the “Mach number sensitive scheme” in
Sec. 6. Nevertheless this scheme generally is still Courant number insensitive. In fact the so called “new”
Courant number insensitive solutions presented in Figs. 4–7 of [50] and Figs. 9 and 10 of [52] are generated
using the current simplified scheme with \( \beta = 1.0 \) and \( \sigma_o = 0.5. \)

In the second scheme to be evaluated in Sec. 6, we assume that
\[ |(\nu_{\text{max}})^n_j| < 1; \quad (\tau_m)^n_j = \beta_m |(\nu_m)|^n_j; \quad \text{and} \quad (\sigma_m)^n_j \overset{\text{def}}{=} \frac{\sigma_o}{|(\nu_m)|^n_j} \] \( (j, n) \in \Omega, \quad m = 1, 2, 3 \) (5.68)

Note that: (i) \( \beta_m \geq 1, m = 1, 2, 3, \) and \( \sigma_o > 0 \) are preset numbers in the order of 1; and (ii) the mesh point dependent parameter \( (\beta_m)^n_j \) which appears in Eq. (5.52) is replaced by the mesh point independent parameter \( \beta_m \) here. As will be shown in Sec. 6, not only is it Courant number insensitive, the second scheme is also Mach number insensitive. As such it will be referred to as the Mach number insensitive scheme in
Sec. 6.

6. Numerical results

In this section, accuracy of the Mach number sensitive and insensitive schemes defined at the end
of Sec. 5 will be evaluated by comparing their numerical solutions with the known analytical solutions of
several shock tube problems. Without exception, (i) the spatial computational domain which is defined by
\(-0.505 \leq x \leq 0.505, \) is divided into 101 uniform intervals with \( \Delta x = 0.01; \) and (ii) the specific heat ratio
\( \gamma = 1.4. \)

At any time \( t \geq 0, \) the exact solutions of a set of shock tube problems considered here are given by
\[ (\rho, p, v) = \begin{cases} (0.125, 1.0, \sqrt{0.14} \xi) & \text{if} \ x < \sqrt{0.14} \xi t \\ (10.0, 1.0, \sqrt{0.14} \xi) & \text{if} \ x > \sqrt{0.14} \xi t \end{cases} \] (6.1)
Here, for each problem in the set, $\xi$ is a defining constant parameter. As such, for each problem, (i) $p$ and $v$ do not vary with $x$ and $t$; and (ii) there is a contact (density) discontinuity which moves with the velocity $= v$. Obviously the discontinuity occurs at $x = 0$ when $t = 0$. Moreover, because $\gamma = 1.4$, Eq. (6.1) implies that

$$c = \sqrt{\frac{\gamma p}{\rho}} = \begin{cases} \sqrt{11.2} \doteq 3.3466 & \text{if } x < \sqrt{0.14} \xi t \\ 0.14 \doteq 0.3742 & \text{if } x > \sqrt{0.14} \xi t \end{cases}$$ (6.2)

and

$$M \doteq \frac{v}{c} = \begin{cases} \sqrt{0.0125} \xi \doteq 0.1118 \xi & \text{if } x < \sqrt{0.14} \xi t \\ \xi & \text{if } x > \sqrt{0.14} \xi t \end{cases}$$ (6.3)

First consider the case with $\xi = 0.01$. According to Eqs. (6.1) and (6.2), the flow field is characterized by extremely small values of $M$ ($0.001118 \leq M \leq 0.01$) and a contact discontinuity moving with an extremely small velocity ($\doteq 0.00374$). This problem, designated as Problem no. 1, is solved by the Mach number sensitive scheme assuming $\Delta t = 0.0024$, $\sigma_\rho = 2.0$, and $\beta = 1.0$. It is also solved by the Mach number insensitive scheme assuming $\Delta t = 0.0024$ and $\sigma_\rho = \beta_1 = \beta_2 = \beta_3 = 2.0$. Based on Eqs. (6.1) and (6.2), and the given values of $\xi$, $\Delta x$, and $\Delta t$, it is estimated that the maximum local Courant number encountered in each simulation is 0.804. At $t = 60.0 = 25000 \Delta t$ (i.e., $\sqrt{0.14} \xi t = 0.2245$), numerical values of pressure and velocity obtained from both simulations match the constant exact solution values to at least seven significant digits. As such no graphical comparisons of these numerical variables with their exact solution values are given. On the other hand, numerical values of density and Mach number at $t = 60.0$ are compared with the exact solution values in Fig. 6. It is seen that, for this problem characterized by extremely small values of $M$, the contact discontinuity is resolved much more crisply by the numerical values generated using the Mach number insensitive scheme than those generated using the Mach number sensitive scheme. Note that this difference in the schemes' capability to resolve the contact discontinuity could become more pronounced if the chosen value of $\beta$ is raised from 1.0 to 2.0, i.e., the value shared by $\beta_1$, $\beta_2$, and $\beta_3$. However, for the current case with very small values of $(1/V_2)$, reducing each value of $\sigma_\rho$ and $\beta_1$ from 2.0 to 1.0 will result in computational instability—obviously, at some $(j,n)$, the assigned values of $(1/V_2)$ and $(1/\rho)$ become too small to sustain stability.

Next consider the case with $\xi = 10.0$. For this case, the flow field is characterized by relatively large values of $M$ ($1.118 \leq M \leq 10.0$) and a contact discontinuity moving with a relatively large velocity ($\doteq 3.74$). This problem, designated as Problem no. 2, is solved by the Mach number sensitive scheme assuming $\Delta t = 0.0012$, $\sigma_\rho = 2.0$, and $\beta = 1.0$. It is also solved by the Mach number insensitive scheme assuming $\Delta t = 0.0012$ and $\sigma_\rho = \beta_1 = \beta_2 = \beta_3 = 2.0$. It is estimated that the maximum local Courant number encountered in each simulation is 0.851. At $t = 0.06 = 50 \Delta t$ (i.e., $\sqrt{0.14} \xi t = 0.2245$), numerical values of pressure and velocity obtained from both simulations again match the constant exact solution values to at least seven significant digits. Moreover, as shown in Fig. 7, for this problem with relatively large values of $M$, the contact discontinuity is resolved crisply by both schemes. A comparison of these results and those shown in Fig. 6 reveals that the Mach number sensitive scheme is indeed Mach number sensitive while the Mach number insensitive scheme is indeed Mach number insensitive.

The last shock tube problem to be considered is Sod's problem [61]. For this problem, (i) at $t = 0$,

$$\begin{cases} (1.0, 1.0, 0.0) & \text{if } x < 0 \\ (0.125, 0.1, 0.0) & \text{if } x > 0 \end{cases}$$ (6.4)

and (ii) $0.0 \leq M \leq 0.929$ for all $x$ and $t \geq 0$. This problem, designated as Problem no. 3, is solved by the Mach number sensitive scheme assuming $\Delta t = 4 \times 10^{-6}$ and $\sigma_\rho = \beta = 1.0$. It is also solved by the Mach number insensitive scheme assuming $\Delta t = 4 \times 10^{-6}$ and $\sigma_\rho = \beta_1 = \beta_2 = \beta_3 = 1.0$. The estimated maximal local Courant number encountered in each simulation is 0.00088. At $t = 0.2 = 50000 \Delta t$, the computed solutions are compared with the exact solution in Fig. 8. In spite of the extremely small maximal local Courant number
encountered, it is seen that the numerical results generated by both schemes match very well with the exact solution.

Problem no. 3 is also solved by (i) the Mach number sensitive scheme assuming $\Delta t = 4 \times 10^{-3}$ and $\sigma_\beta = \beta = 1.0$; and (ii) the Mach number insensitive scheme assuming $\Delta t = 4 \times 10^{-3}$ and $\sigma_\beta = \beta_1 = \beta_2 = \beta_3 = 1.0$. The estimated maximal local Courant number encountered for each simulation is 0.88. At $t = 0.2 = 50\Delta t$, the computed solutions are compared with the exact solution in Fig. 9. It is seen that the numerical solutions shown in Fig. 8 do not deteriorate much from the current results generated with a much larger maximal local Courant number. As such, both schemes are indeed Courant number insensitive.

7. Conclusions and discussions

Generally speaking, a stable numerical marching for a non-linear problem requires the presence of a sufficient amount of numerical dissipation. However, accuracy of the numerical results, especially for an unsteady problem, will suffer if too much numerical dissipation is present. As such, a careful control of numerical dissipation is a must for an accurate and stable non-linear unsteady numerical simulation. However, a proper control of numerical dissipation is a very difficult task. Although one can increase the numerical dissipation rather easily, it is much harder to reduce it when accuracy consideration requires it.

The CE/SE method is developed from a set of non-dissipative solvers. As such each CE/SE solver is an extension of a core non-dissipative scheme. It is this unique feature that make it much easier to reduce numerical dissipation in a CE/SE simulation. It is also the key reason behind the successful construction of the Courant number and Mach number insensitive Euler solvers described in this paper.

For the 2D and 3D unsteady Euler equations, there are two and three associated Jacobian matrices, respectively. In general, it is impossible to diagonalize these associated Jacobian matrices simultaneously using the same diagonalization matrix. Thus extension of the current work to a space of higher dimension is by no means trivial.

Courant Number and Mach Number Insensitive CE/SE Euler Solvers

Sin-Chung Chang

National Aeronautics and Space Administration
John H. Glenn Research Center at Lewis Field
Cleveland, Ohio 44135–3191

It has been known that the space-time CE/SE method can be used to obtain 1D, 2D, and 3D steady and unsteady flow solutions with Mach numbers ranging from 0.0028 to 10. However, it is also known that a CE/SE solution may become overly dissipative when the Mach number is very small. As an initial attempt to remedy this weakness, new 1D Courant number and Mach number insensitive CE/SE Euler solvers are developed using several key concepts underlying the recent successful development of Courant number insensitive CE/SE schemes. Numerical results indicate that the new solvers are capable of resolving crisply a contact discontinuity embedded in a flow with the maximum Mach number = 0.01.
